Before taking off from the Newark airport, the pilot refers to previous weather reports received over the radio and notes especially any orders from the operations manager concerning the scheduled trip. After taking-off, the pilot receives hourly reports on landing conditions and Weather Bureau forecasts. If landing at the terminal field becomes impossible, reports on intermediate fields along the route and alternate terminal fields permits the pilot to land safely and await more favorable weather. The operations manager has the privilege of following weather conditions closely, advising the pilot enroute regarding his judgment of conditions and transmitting such orders as are found necessary for the proper protection of the interests of the transport company. Arrangements made for motor or rail transportation of passengers and mail, if landing is ordered at a field other than the terminal, can be communicated to the pilot so as to provide for the comfort and safety of the passengers and expediting the mail. Circumstances may require flying at high altitude over ground fog on radio-range signals over the airway, or flying blind by instrument through thick weather and this may be done with safety as long as the pilot is kept advised that landing conditions are safe at the terminal field; or at some other specific landing place. Many trips now lost will be completed with safety as soon as a comprehensive weather communication service is established.

CHAIRMAN MOFFETT: We would like some discussion on this paper.

W. R. GREGG (U. S. Weather Bureau, Washington, D. C.): As one who is connected with the service, I am, of course, vitally concerned with the subject which has been under discussion this afternoon, that is, communications. In fact, for a long time it has been generally recognized that the key to the situation so far as the weather hazard is concerned, is largely communications. Probably in the future, after the experimental stage is over, no one method will be used to the exclusion of others, but perhaps one will be the principal method and others auxiliary. Certain it is that radio must be one of those because it is essential, it seems to me, and I think it is generally recognized that the pilot in the air be constantly informed of the conditions ahead of him.

In this connection perhaps I would take the only exception that I would be inclined to take to anything Dr. Hunsaker said. He made the statement in general, "perhaps we can say the weather we have now will be the same two hours from now." I wish it were true. It is, of course, often true and particularly at the time when we are least interested in it, that is during the spells of good weather. However, during much of the time in the winter, particularly in unfavorable weather conditions, it is constantly changing and it is very essential that the pilot be informed of that.

Short range forecasts will provide remedies to a certain extent, but it will be a long time before we have data sufficiently comprehensive and complete, and meteorologists sufficiently capable to interpret those data to give a forecast that is perfect 100 per cent of the time.

One matter that Dr. Hunsaker brought up and asked me to comment on is the weather conditions at sea. It is true, as he said, that the occasions are extremely rare when even moderately favorable conditions could be experienced all the way across the Atlantic. The Atlantic, of course, is notoriously stormy and the distance is great. In an analysis of daily weather maps for a period, of ten years, we found, to be perfectly frank, that there were no occasions when we could call conditions really favorable all the way. Something like 10 per cent was moderately favorable—all the more reason, therefore, why we must have a dependable and up-to-the-minute system of communications over the sea as well as over the land. That would have to be by radio telegraph.

Having the information, the commander or captain of the airship, or the pilot of the airplane, could take advantage of it and go around the stormy areas, those of the greatest disturbance, providing he had sufficient cruising radius.

CHAIRMAN MOFFETT: Is there any further discussion of this paper?

LIEUT. C. R. BROWN (Bureau of Aeronautics, Washington, D. C.): There is one point that Dr. Hunsaker brought up that I thought ought to be discussed a little. That is the question of local communication around a crowded airport where air traffic conditions are very complicated. He suggested the radio instead of ground signals. My personal reaction to it is that the simpler you have it the better. The less complication, perhaps the more efficient the apparatus will be. With the simple system of control from visual signals on the ground panels, and so on, there is not anything which can disturb it very much except, of course, fog. In that connection, of course, the aircraft carriers are of a good deal of interest. We have about as crowded an airdrome there as you can imagine, particularly when you are trying to put off a large number of planes and get others back at the same time. We have found it entirely feasible and most efficient to use hand signals.

DR. HUNSAKER: Only in daylight operation.

LIEUT. BROWN: Yes, that is what I understood. Of course, in night operation you have your lights. When the fog comes in you have to bring them in and land them by radio.

DR. HUNSAKER: There wouldn't be very many up at night.

COL. H. E. HARTLEY (New York): Under this subject of Communications as an Aid to Safe Flying, I think I ran across a situation that I really believe the National Safety Council could perform a service in which would make flying more safe in the country, and I will have to ask Mr. Gregg about that situation. It is simply this: We are not getting enough information from the ships at sea, because the Weather Bureau hasn't the money for sufficient messages from over the ocean to enable them to predict with certainty the way they do over the land.

If I am not mistaken, before the war there was a movement on foot to obtain communications from a larger number of ships. Two years ago when we got after that first trans-Atlantic flight I discovered that the British Air Ministry was getting and buying a lot of information from a lot of American ships that were not transmitting (because they were not paid) to our own Weather Bureau. We in turn got hearsay evidence from the British Air Ministry. If that is a situation that exists, surely the National Safety Council could in some way get behind the Weather Bureau, who, while extremely efficient are often not too zealous about asking for more money. We might start in here a resolution to the effect that the National Safety Council should post the Weather Bureau in its desire to strengthen the premise upon which it bases its forecast. In that way we will be rendering one of the greatest services conducive to safe flying that I can think of at the moment.

I don't know whether it is within the range of our meetings here to put forth such a resolution, but I think something should be done on it, and communications are certainly the aid to safe flying. If we haven't the money, what is the use of having them? If it is within the range of possibility, I would be glad to frame a resolution, and pass it through you, Mr. Chairman.

CHAIRMAN MOFFETT: I think it would be a very good thing to do.

DR. HUNSAKER: I will second the motion.

CHAIRMAN MOFFETT: You frame it and we will pass it to the Safety Council.

COL. H. E. HARTNEY (New York): I suppose the sense of the meeting is that way here, is it not? Probably Mr. Gregg might have a few suggestions.

W. R. GREGG (U. S. Weather Bureau, Washington, D. C.): Along that subject, the question of more reports at sea was under discussion last May and June in Paris by an international congress on safety at sea, and preliminary measures, at least, were taken at that conference by the meteorological offices of France, Great Britain, Canada and the United States to that end. I am not prepared to say whether a resolution by this body will assist or not, but I thought you would be interested in knowing the matter is under advisement and we hope to get results in the comparatively near future. I won't say the immediate future. As to the advisability of a resolution here, I think I would rather not express an opinion.

DR. HUNSAKER: Being free and a Bolshevik, I will say something Professor Gregg will neither confirm nor deny. I think this matter of getting from the American side reports from ships at sea will depend entirely on whether the budget will permit the Weather Bureau to do it. To that end, any resolution does no harm. It might do some good. It is purely a matter of appropriation of the budget officer. The thing as proposed is going to be up in Congress this winter. It is more important to the Europeans because the weather that may be over the Atlantic is going to be over them tomorrow. It is not so important to our general public. We have had our weather. It is going to sea and we are glad to be done with it.

H. W. FORSTER (Philadelphia, Pa.): I speak not as an aviation man, because I am sorry to say I am not that, but for many years I sat on the Executive Board of the National Safety Council. I thought I might tell you how this perhaps might best be phrased. We should be delighted to have a resolution to set forth what is needed and might be had. If you could give the Executive Com-

mittee a little background of the why and the importance, they will be in an excellent position to pass on it, because they don't have the background that this group has. Be sure to have the formal resolution that this group may endorse carry with it an explanation of the why of it.

CHAIRMAN MOFFETT: Is there any further discussion on Dr. Hunsaker's paper or Dr. Hingsburg's?

CAPTAIN HINGSBURG: I would like to hear from Dr. Hunsaker his reaction to the proposed plan, slightly different than was referred to in his paper.

DR. HUNSAKER: I think it is grand. More strength to you. It is in line with getting an adequate communication service going. It is very hopeful and forward looking. It seems designed on a basis which will serve an increasing number of airplanes. The thing to avoid always is to get the communication service that will break down the traffic situation. I think your system is free from that possible danger.

CHAIRMAN MOFFETT: Is there any further discussion?

C. G. ANDRUS (U. S. Weather Bureau, Hadley Airport, New Brunswick, N. J.): One feature of the two-way communication, I hope, that will be very helpful to us in the Weather Bureau at the terminal airports, will be our ability to then get in touch with what the aviator is meeting up aloft. Whatever system we now have in its completeness is after all but more or less on the ground contour. We cover the ground pretty well; by means of small balloons we covered a certain amount of conditions aloft.

Frequently the pilot is in conditions, the worst of which are ice forming, upon which we would like to get some information. At the present time we do not get it until he is down. Pilots may take off in the meantime and run into that condition. We have no way whatever at the present time except by theoretical measurements of determining what the conditions are. We look forward to a chance to tap not only the ground, but conditions aloft along the line of flight.

Another feature is while all directive means of guiding airplanes across airways are 97 per cent (at times) effective, and a matter of great safety, there is at least one weather condition which is not a matter of navigational obstruction, but is rather a matter of flight obstruction. Of course, it vitiates any directive guidance or any other means of directing the pilot along the line of flight. That condition is a formation of ice barnacles on ships. We face during the next six months at Hadley Field the biggest program we have the whole year of getting ships through ice. Ice has no effect, whatever, upon the directing of the aircraft. It does, however, frequently stop flight in a short time; oftentimes it is as little as ten minutes, and we are anxious to get some means to determine what those conditions which make ice are, when they exist, where they are, so that we may avoid them, and by all means have the most complete information about them.

JOHN STOCKMAN (Philadelphia, Pa.): I would like to ask, what is the present radio range, that is, the meter range for aircraft?

DR. HINGSBURG: Between 900 and 1,050 meters.

MR. STOCKMAN: Is it the same range as projected into other work of Dr. Hunsaker?

DR. HINGSBURG: Let Dr. Hunsaker answer that.

MR. STOCKMAN: I wanted to find out what the present meter range of the radio is that you expect to use, the radio wave length.

DR. HINGSBURG: I think the international congress has fixed 850 and 1,050 for both beacon and broadcast service and my idea is, looking at the future two-way communication will probably be on an entirely different frequency band, shorter down below the broadcasting range, and not to interfere with the public service given by the government to all users of the airway.

MR. STOCKMAN: Is there any way that can be changed without going into a lot of international complications for inter-country use here in the United States so they can use a different wave length for aircraft?

DR. HUNSAKER: Different from what?

MR. STOCKMAN: From the 800 to 1,000.

DR. HUNSAKER: The international congress agreed on all of the frequencies assigned to mobile operation, meaning ships also, a whole string of frequencies we would share with ships.

MR. STOCKMAN: Would it get down to less than the 100 meter class?

DR. HUNSAKER: Yes. I think Mr. Hooper has published a warning against going down much below 100 meters for radio service that is designed with an element of safety in it, that you may communicate or may not, especially for these fellows crossing the Atlantic. If they communicate on short wave, no ships will be able to talk to them.

MR. STOCKMAN: I asked for a projected system.

DR. HUNSAKER: Of course, you are concerned with the skip system. If you are trying to communicate with a specific point near you, you may miss it and get something you have no interest in.

Discussion of Dr. Hunsaker's Paper

By CAPTAIN S. C. HOOPER

Director of Naval Communications, U. S. Navy, Washington, D. C.

In connection with "Long Flights," consider international flights. The Government, it is believed, should provide all possible practical aids for international flights, as is now provided for international shipping. For long flights within the United States, the corporations interested in aviation, it is believed should provide all possible practical aids along their routes, although the Government should encourage such commercial enterprises by permitting use of such facilities as the Government possesses due to its own aviation establishments, including facilities, wherever practicable, of the Army, Navy and Marine corps, Postoffice and Commerce Departments, especially radio weather report facilities. The railroads provide necessary aids for safety's sake along their own lines, and similarly commercial aircraft corporations should provide most of the necessary aids along their own routes.

Long flights, whether international or national in character, should not be permitted, without efficient two-way radio communication facilities. It is presumed that there will be international agreements in this matter. The International Radio Telegraph Convention, Washington, 1927, states in part (Art. 18) "2. Every station installed on board a vessel or an aircraft following a maritime route, such vessel or aircraft being compulsorily equipped with radio apparatus in accordance with an international agreement, must be able to send and receive on a wave of 500 kcs. (600 m.) Type A2 or B. Aircraft stations must be able to send and receive the wave of 333 kcs. (900 m.) Types A2 or A3 (or B subject to the provisions of paragraph 1 above)." It is believed that this provision should be applicable to all aircraft operating over 100 miles off the coast, and that radio telegraph should be used rather than radio telephone for reasons which will be mentioned later herein.

In connection with "Short Range Forecasts," it might be mentioned that the Navy already cooperates with the Weather Bureau both in reporting data to the Bureau and in disseminating weather forecasts and warnings by radio. It is known that such weather forecasts and warnings are copied and used by many commercial activities besides various Government establishments.

Under "Point-to-Point Service" the telephone or printer service would no doubt be an ideal system, for reasons indicated in Doctor Hunsaker's paper, to tie in the various fields along a given airway.

In connection with "Radio Service," it should be kept in mind that the use of radio telephone and radio telegraph will be steadily increasing with increased interference resulting. To keep the air comparatively free of interference, maximum use should be made of landline and wire telephone services in the exchange of weather information and for aircraft movement reports.

I concur in the opinion that telephone broadcast from airdromes should be used in supplying information to small commercial and private aircraft. Radio telegraphy should, however, be used by large commercial planes. The mechanic attached to such a plane might well be required to be a qualified radio telegrapher and have sufficient knowledge of flying to relieve the pilot occasionally at the controls, when not engaged in radio or engine duties. It is believed that a great many mechanics and pilots could be qualified as radio operators with training during spare time during a comparatively short period.

While radio telephony appears in some ways to be superior to radio telegraphy for two-way communication between planes and ground, there are excellent reasons for more general use of radio telegraphy. Radio channels in the air are limited in number and the demand for the available channels is great. Radio telegraphy permits more channels to be used and is subject to less interference than radio telephony. Considering the distance to be covered, the radio telegraph set weighs less than the radio telephone set, a vital consideration in many types of planes.

While considering the matter of radio channels, it might be well for those concerned to study the situation, in order to determine the number of radio channels which will be required by aircraft operations. It is believed that action might well be inaugurated now to have a sufficient number of frequencies reserved for commercial aircraft use.

Considering "Goniometry," if planes are equipped to receive intermediate frequency radiotelegraph, they should likewise have a compass coil, if practicable for use as a homing device (direction finder). This equipment makes available to aircraft all existing nondirective radio beacons and radio transmitters, including broadcasting stations.

Radio beacons are considered satisfactory for a given airway but are unsuitable in case aircraft is forced off course by bad weather. In such a case radio compasses on ground or plane will be essential. And if the radiocompass is on ground two-way communication is necessary.

Despite the use of very sensitive altimeters, radiocompasses, neon boundary lights, etc., it is believed that the only safe method of landing aircraft when fog prevails is to avoid the fog. This may be accomplished by having a number of terminal fields. The pilot may then, after fixing his position with the aid of radiocompass bearings, be directed to proceed to one of the other terminal fields where impenetrable fog is known not to exist. For example, if fog is prevalent at all of the fields on Long Island, the pilot could be ordered into a field on Staten Island, upper New Jersey, or lower New Jersey (assuming he has sufficient fuel) whichever field had been reported by landline or telephone as "clear."

CHAIRMAN MOFFETT: I know I express the feeling of every one here present, in saying we are grateful to Dr. Hunsaker, Captain Hingsburg, Professor Gregg and others. We are very much pleased to know what the Weather Bureau is doing. I myself didn't know what the extent of it was for communication and, therefore, for safety. I quite agree with Mr. Andrus that in all we do we want to be very careful that the man in the air is completely and thoroughly consulted because he is the one who can tell us where it will work practically. My own

experience is that it is extremely important to have the operating personnel, the aviators, completely intermingled with the material part, not only information bearing on safety. I think with so many more people on the ground it is very important for us all to keep in mind that the aviator is the man we all are working to make safe.

The next paper for consideration is "Instrument Navigation and Fog Flying," by a distinguished officer of the Army Air Corps. I have a great deal of pleasure in introducing him. I don't think he needs an introduction from me. We all know the great work he has accomplished and the credit he brought to the country. I have great honor in introducing to you Lieut. A. F. Hegenberger, of the Army Air Corps.

Navigation Instruments and Fog Flying

By **ALBERT F. HEGENBERGER**

First Lieutenant, U. S. Army Air Corps, Wright Field, Dayton, Ohio

One of the most pertinent factors affecting the progress in commercial aviation is fog.

Fog, even though conditional on a relatively quiet state of the atmosphere, causes interruptions and at times complete stoppage of transportation just as effectively as the most violent storm. Even a light fog slows up railroad traffic and other public carriers, while a really heavy fog plays havoc with shipping and is capable of bringing it to a complete standstill.

This latter condition applies to road traffic as well.

The hazard of fog lies in the reduced visibility it creates. Since visibility plays a far more important role in aviation than in any other mode of transportation, it is in this field that its greatest menace lies. Trains and shipping can stop when low visibility reaches the danger point—the airplane cannot. The stability and control of the steamship or train depend in no way on vision. In the case of the airplane, however, the maintenance of straight and level flight normally depends on using the horizon, ground, sky or sun as reference. Without one of these visible references and since the pilot's flying sense is inadequate, recourse must be had to appropriate mechanical senses in the form of instruments. And without these artificial aids no one can fly efficiently in total darkness for any length of time. Moreover, until a pilot can fly in a blank void for hours looking at his instruments and nothing else, he is not a safe pilot to trust passengers or mail to.

Last but not least a pilot flying blind must have immense faith in his instruments and this he attains only by long, arduous training. An airplane with perfect inherent stability would, of course, require additional control only to the extent of maintaining a given course and altitude. The numerous requirements which must be provided for in the design of airplanes preclude, however, the possibility of providing perfect inherent stability. Particularly is this so in regard to the change in longitudinal stability with power on and power off. Yet another detrimental factor to control is that a bank caused by a "bump" commonly introduces yaw and vice versa. As a result of all of this we have created the "Blind" Flying Problem.

Blind flying is a comparatively new angle to the flying game and was principally developed and brought to its present stage of perfection in our country. Incidentally I may say that ignorance of this phase of flying was probably the predominant cause of the many sad failures during the past year or two.

The operation of an airway on schedule when fog prevails along the route produces a condition for the pilot equivalent to flying blindfolded. A pilot as a rule makes every effort to avoid fog and to maintain visual contact with the ground.

Over flat country devoid of high obstacles the practice is often followed of flying very low and in sight of visible landmarks.

Experience has taught us that this practice is not safe in hilly or mountainous country and here a pilot generally flies through the fog at a height sufficient to clear any obstacle, trusting that a break will occur before reaching his destination. It is under these conditions that the pilot's remaining senses must be supplemented by mechanical senses in the form of instruments that will make it possible for him to create a mental image of his position with respect to the ground.

Still, at times, the question is asked "Why isn't the pilot's flying sense sufficient for holding a straight and level course?" And reference is made to numerous

Figure 1.

instances during the war and before instrument aides were perfected when pilots flew through clouds. The answer to this question is that use was made of such inherent stability and excess power as the airplane possessed. In short the airplane flew the pilot rather than the reverse. Then, too, the period of "blind" flying was generally a matter of but a few minutes although to the pilot under tension it undoubtedly seemed much longer. It should also be recalled that at that time there were many disasters due to cloud and fog flying.

Although it is beyond the scope of this paper to enter into a detailed discussion of the physiological aspects of "blind" piloting, some reference must be made to the more important physical factors which give rise to problem in order to better understand it.

Flying sense is essentially an acquired coordination of the senses of sight, muscle, and inner ear. The predominant part played by sight is well known. It is evident that an airplane can be kept correctly orientated by visual reference to the sky, horizon or ground. Further, one's position can be located and direction determined by the identification of distinctive landmarks on the map. The installation of beacons and the marking of towns and airdromes carry this system further.

Figure 2.

The judging of height for landing is accomplished by the powers of depth perception of the eye. In fact with unimpeded sight the other senses are not a necessity but merely assist in the quality of the flying.

The muscle or sixth sense is defined as that sense by which we perform coordinated acts, unconsciously and automatically. Through its aid one assumes the correct posture. It is the "seat" sense of the air man.

The inner ear sense is stimulated into action by body motion. This sense in conjunction with the muscle sense is adequate for maintaining equilibrium in the usual motions performed in contact with the earth, where gravity is the sole or predominant force to which our bodies are responsive.

The ordinary vibrations and stress in flight greatly impair the efficiency of these two senses. Centrifugal and other large accelerating forces which cannot be distinguished from the force of gravity produce false re-actions, as to exactly what is taking place. Much valuable data concerning the foregoing phenomena have been secured by Capt. David A. Myers, Flight Surgeon, Crissy Field, San Francisco, and published in a recent issue of the Air Corps News Letter.

It is evident, therefore, that some means must be provided that will correctly

Figure 3.

indicate to the eye the attitude of the airplane with respect to the ground. While the brain can interpret, by experience, any arbitrary method of indication, it is nevertheless desirable that the method be as natural as possible in order that the position of the airplane with respect to the earth can be readily visualized. Such a device, it will be seen, must indicate motion about all three axes of the airplane.

Flight Indicator

During the summer of 1918 the Army Air Service embarked on the development of the gyroscopic turn indicator which is part of the present 3 component Flight Indicator. The turn indicator used for indicating turning about the vertical axis, makes use of the well known gyroscopic principle of precession viz. if a force is applied to change the plane of rotation of the spinning wheel it will tend to move

Figure 4.

in a direction at right angles to the applied force. As this instrument is now well known it will be dismissed with a reference to the diagram in *Figure 1* with the brief description.

Bank Indicators

Any device, such as a pendulum or spirit level, actuated by gravity will, of course, respond likewise to any other force as for example the centrifugal force. When two or more forces are acting such a device will indicate the direction of the resultant of these forces. *Figures 2* and *3* illustrate how a pendulum would remain perpendicular to the plane of the wings indicating a properly banked turn. In order to be applicable for maintaining level flight it must be used in conjunction with the turn indicator. In practice after straightening out the turn with the rudder, the pendulum assumes the direction of gravity permitting the airplane to be leveled laterally. The standard flight indicator actually utilizes a bank indicator shown in *Figure 4* which is simpler and more compact than a pendulum and indicates more naturally than the air bubble spirit level.

The airspeed indicator has been rather generally used as a longitudinal inclinometer. When such characteristics of the airplane as the best cruising speed, best climbing speed, and best gliding speed are known, the air speed indicator is usually very useful. There is some objection to it because of the slight lag which tends

to produce a little over-control. A greater objection, however, to the use of the air speed indicator as a fore-and-aft inclinometer, arises from the liability of the air speed head to become clogged with moisture, snow or ice at a critical time.

The indication of a gravity actuated device e.g. a pendulum, cannot correctly indicate the pitching of the airplane. The forces to which the pendulum would respond to are shown diagrammatically in *Figure 5*. A properly damped short period pendulum might be useful under certain conditions in that it would not keep in step with a slow undulating pitch. Since an airplane in flight is subject to oscillations over a wide range of frequency such a simple device would be unreliable. The operation of the gyro-controlled pendulum used in the standard flight indicator is shown diagrammatically and described in *Figure 6*.

While the information furnished by the flight indicator is adequate for main-

Figure 5.

taining straight and level flight, the indications are somewhat arbitrary and possibly not as natural as an accurate artificial horizon or vertical keeper. Efforts are being made to develop means for accomplishing the latter purpose.

Maintaining Direction

The pilot plunging through fog must not only maintain control of his airplane but must hold it on its course to its destination. The recently developed radio beacon offers the best solution for this problem. A compass alone would not, of course, be adequate for this purpose on account of the drift. As yet no device has been developed for measuring drift when out of sight of the ground. The compass is a valuable adjunct to flying along a radio beacon as it provides means for keeping a certain heading that will preclude frequent excursions out of the equi-signal zone. While static is rare in fog, nevertheless there have been conditions of static encountered which would render the oral beacon useless. (See Proceedings of the Institute of Radio Engineers, Vol. 16, No. 9, Sept., 1928, for description.) In this case an approximation of the drift based on previous meteorological data coupled with the use of the compass offers the best solution.

It is expected that the vibrating reed indicator of the Bureau of Standards two-frequency beacon will not respond to static impulses. (See Bureau of Standards

report "Aircraft Radio Beacon Development" by the Bureau of Standards, April 15, 1928.)

Localization of Airdrome

Assuming the pilot is approaching the airport in fog along the radio beacon and at a safe altitude. Now the position of the airdrome with respect to his own is his first concern. At a short distance out the marker beacon indicates that he is, say about three miles from the field. What happens from this point on is a matter of conjecture, for our practical experience has not been extensive enough to lay

Figure 6.

down a hard and fast rule. Let us analyze the problem in the light of our experience to date until further flight tests have given us more definite knowledge.

The degree of visibility will determine the kind of equipment and methods necessary. There are few fogs with a ground visibility of less than half a mile, but to the pilot at 200 to 500 feet coming in to land it is almost zero. With such low visibility it seems as if the speed of rushing through the fog gives it an enhanced opaqueness. The flash of the small patch of ground beneath is hardly discernible but will aid the pilot in landing when the airdrome is reached. His immediate concern, however, is, whether or not his path is free from obstacles and whether or not he really is heading for the airport. If he can identify something definite in the fleeting ground pattern below him, his problem is practically solved. Successful landings under conditions as described have been made by skilful pilots, although it never will be considered good policy to subject air passengers to the hazards of a situation where some unforeseen factor or some slight error in judgment on the part of the pilot might invite disaster.

Theoretically the radio beacon will guide the airplane exactly to the antennae mast, adjacent to the airport. Due to the extreme narrowness of the equi-signal and adjacent zones in the immediate vicinity of the antennae it may be easy under conditions of extremely low visibility to deviate and fly through a number of zones thus producing a confusion of sounds.

Under such conditions, it is expected, that the leader cable will prove useful, figuratively speaking, it will take the pilot by the hand and lead him through the gate.

Altitude Determination

Before the pilot has descended sufficiently to see the ground he must know his actual distance or "tape line altitude" above the ground. This is necessary first for the purpose of clearing obstacles during level flight and second when the airplane is at a definite distance from the landing field it is essential that the actual altitude be known in order that the proper angle of glide will bring the airplane to the landing spot. Excess altitude would result in either excess speed or overshooting the field.

Definite distances from the airdrome can be indicated by marked cables at right angles to the main leader cable. The latter may consist of either a large and small loop as in the English system or of a number of lines radiating from the airdrome in the different directions.

By means of a characteristic signal the pilot will know the proper altitude over each point.

The present service altimeter because of its lag and other errors and cramped scale can be considered undependable for altitudes lower than several hundred feet. A sensitive open-scale precision altimeter equipped with an auxiliary barometric scale offers a decided improvement. In practice the barometric reading at the airdrome would be received by radio and the auxiliary scale set accordingly. In event that communication is interrupted a very close approximation could be made from previous study of the weather map.

To date the dependable range of the capacity altimeter has not exceeded 50 or 100 feet, a range so short that its usefulness at present is quite limited.

Tests to date indicate that there are possibilities in the altitude determination by the reflection of short radio waves e.g. around 10 meters. This method depends on the fact that when the airplane's height is an exact multiple of the wave length, the energy of the reflected wave is added to that of the projected wave. When a half wave-length out of phase a minimum would be indicated. The plate millimeter of the oscillatory circuit of a tuned receiver will show these oscillations for every half wave length change of height and the amplitude of the swing of the needle will be proportional to the height. An improved method of indicating which is easily calibrated is desirable.

Fog Penetration

It is of utmost importance that the pilot have the use of his eyes to as great an extent as possible rather than interpret the indication of some translating device. Given sufficient degree of direct vision the pilot will not need the aid of other devices. Assuming the existence of suitable lights capable of penetrating the fog sufficiently the problem of localizing the field and landing would be practically eliminated.

Of the entire range of the electro-magnetic spectrum the radio waves have the greatest penetration. On the other end of the spectrum the X-rays do not penetrate but a few inches beyond the vacuum tube. Fog scatters and absorbs very effectively all wave-lengths within the visible spectrum as is evidenced by the masking of the sun during fog. The greatest transmission obtained to date within the visible band is around 0.53 to 0.59, that is in the yellow.

The transmission decreases more rapidly toward the red than toward the ultra-violet. This is rather unusual as one would expect less scattering of the longer wave-lengths. The water particles in a dense fog are generally of the order of 10μ diameter which explains the absorption of wave lengths from the short infra-red down through the visible spectrum. The band of wave-lengths, between the long infra-red and the ultra-short radio waves appears as worth investigating. In fact the importance of the problem warrants a thorough analysis of a wide range of wave-lengths in search of a band to which fog is transparent. Two outstanding difficulties present themselves in connection with frequencies outside the visible spectrum viz. that of obtaining a sufficiently powerful source for the emission of the wave and second a type of receiver that is selectively sensitive and rugged enough for airplane use. This would, of course, eliminate such detectors as bolometers, thermo-couples, and the radio-micrometer. The ultra-violet waves possess the advantage that an intensive source such as the mercury arc and a suitable receiver such as the fluorescent screen already exist. It is suggested that depth perception might be obtained by the use of quartz binoculars. Further work needs to be done on the measurement of the penetration of ultra-violet waves.

The development of a sufficiently powerful source of ultra-short radio waves, 10 cm. or below, would open up a promising field of endeavor.

The suggestion has been made that advantage could be taken of a receiving reflector for their reception because of their directional property. High powered flood lights are, of course, scattered so that illuminated fog appears as an impenetrable wall before the pilot's eyes.

The possibility of filtering flood lights to produce monochromatic light for purpose of penetration remains to be investigated.

In fogs that are predominantly of smoke origin, the neon light appears to have greater penetration than white light. The long red wave-length are less scattered by the smoke particles, which average in diameter of $.5\mu$, than are the shorter visible wave-lengths.

Neon apparently does not excel white light in the penetration of water fog but is of advantage due to its distinctive color.

Conclusions on Fog Landing

The difficulties of fog landing vary through a wide range from the light fog with several miles of visibility, which is not serious, to dense fog with less than 200 yards. The latter case occurring at night would represent the worst extreme. At this stage of development it is impossible to define what part each of the suggested means will play in final practice. Until the limitations and degree of usefulness of each means are determined, it will be impossible to know where the function of each overlaps and possibly which can be eliminated. It is hoped that the final solution for the worst conditions must be simpler, than at present appears possible, or else the operation of the airplane may have to be divided between two pilots much the same as a dirigible.

Fog Dispersion

Fog dispersion does not appear capable of an early solution. The electrical method consisting of shooting charged particles (either hygroscopic or water) into the air has failed to date because of the small volume affected.

From calculations, the method of drawing cold dry air from above the fog, appears too costly.

Artificial warming has cleared areas up to 200 yards diameter but it remains to be seen if the scale effect will not defeat this procedure also. Sir Napier Shaw has calculated theoretically that 13 tons of coal per hour would be required to raise the temperature over an area 400 yards square with a fog 50 feet thick

drifting 2 miles per hour. In practice probably four or five times as much would be required due to dissipation in all directions.

Radio communication is essential for the interchange of vital information between the ground and the airplane.

Loss of Control Prevention

Such aerodynamical devices as slotted wings are steps toward eliminating some of the greatest hazards, as for example, loss of control at stalling speeds. Automatic control, full or partial, by relieving the pilot of part of his numerous duties should add materially to the solution of the fog landing problem.

Experimental Fog Flying Airplane

Early experiments in fog landing should be conducted under as safe conditions as can be anticipated. The following requirements for an experimental fog flying airplane are suggested:

1. Slow landing (about 25 or 30 mph.).
2. Stable at stalling speeds.
3. Controllable at stalling speeds.
4. Safe in a crash (special padding, bracing, etc.).

A step toward obtaining suitable airplanes for fog landing, as well as for general service, has been taken in the form of a Safe Airplane Competition inaugurated by the Guggenheim Foundation for the advancement of Aeronautics.

CHAIRMAN MOFFETT: Gentlemen, I know you have heard Lieut. Hegenberger with a deep interest and appreciation of what he said. He is one of the greatest authorities on flying, not alone in this country, but the entire world. We can feel that what we have heard from him is about the last word on the subject from a practical standpoint of the man of the air, as well as the man on the ground. I will be very glad now to hear some discussion or questions on the subject.

LIEUT. C. R. BROWN (Bureau of Aeronautics, Washington, D. C.): Mr. Chairman, I have been asked to read this paper prepared by Lieut. Lonnquest of the Navy Department. It was just handed to me.

Instrument Navigation and Fog Flying

By **LIEUTENANT T. C. LONNQUEST**
United States Navy

Aircraft navigation, having passed through a phase in which the airworthiness of the plane was the principal consideration, is now entering a phase in which the ability to make use of this airworthiness under all conditions of weather, in daylight and darkness, is of paramount importance. Aircraft cannot aspire to a position of permanent importance in the world of transportation unless they can present some reasonable guarantee of reaching their destinations, independent of weather. A corresponding responsibility rests with military and naval aircraft. Aircraft cannot properly assume an increasingly important role in national defense unless they can demonstrate that the weather causes no greater reduction in their effectiveness, than the corresponding handicap which bad weather imposes upon other arms. Aviation, both commercial and military, must display the "Business-as-usual" pennant, 24 hours a day, every day. Instrument aids will be of primary assistance toward this end.

Just as commercial and military aviation are partners in the problem of operating during conditions of fog, storm and darkness, so, too, in the development of instrument aids, their problems are practically identical. This is in considerable

contrast to some other contacts between commercial and military aviation; notably, in the design of the airplane itself, where the difference in employment has led to the development of totally dissimilar types. In the solution of the problems associated with the instrument equipment of service type airplanes, practically every instrument perfected through the assistance of the Army and Navy is directly useful to commercial flying, and likewise every instrument developed through commercial operations may constitute a contribution to national defense. In this connection, it is not without significance, that the rather elaborate instrument equipment of military and naval aircraft has successfully withstood the searching scrutiny which service planes must undergo for the purpose of eliminating every unnecessary item. Instrument equipment may be considered to have justified itself in the eyes of service personnel, even in high performance planes, where weight and space are at a premium.

There are available today modern aircraft instruments of domestic design and manufacture of such excellence from the viewpoint of accuracy, reliability, ruggedness, and precision of workmanship as to constitute triumphs of the instrument maker's art. Tremendous progress has been made in instrument engineering during the last decade. However, the fact that the difficulties of blind flying and blind position finding are so great as to prevent, frequently, the utilization of the full capabilities of modern airplanes under all conditions, except by acceptance of prohibitive risks, suggests that the development of additional instrument aids is urgently needed.

Among these new devices the need for at least three instruments stands out rather conspicuously. First, possibly, is the ground speed and drift indicator—a device which would at all times indicate the true ground speed and track of the plane without the necessity of seeing the ground. Another instrument which suggests itself is a non-barometric altimeter of sufficient accuracy, reliability and openness of scale to permit a safe landing to be effected by its use. And finally, the development of a non-magnetic compass, operative under the severe vibrations and accelerations characteristic of aircraft, and uninfluenced by the presence of magnetic material, would be a valuable contribution to blind flying.

The subject of safe flying in foul weather can hardly be dismissed without mention of one element somewhat remote from the subject of instruments, and that is, the degree of stability of the aircraft itself. The problem of making a safe passage through fog is greatly simplified by the employment of an airplane with a high degree of inherent stability. If I may be pardoned a personal anecdote, this subject was very impressively demonstrated to me a considerable time ago.

In connection with some experimental work I had occasion to make a flight in a commercial cabin plane—my first experience in a totally enclosed airplane. From the start, nothing seemed exactly right. The pilot, wearing a straw hat and smoking a cigar, flew along, comfortably at ease. Four passengers and fuel for three hours constituted the additional load for the 220 H.P. engine. There was no turn and bank indicator and the air speed indicator, when it indicated anything, persisted in sweeping around through a full circle, backwards. When we started up through a heavy cloud ceiling my feelings were those of deepest dismay, to express it mildly. Visions of a spin, followed by an immediate excursion of all the passengers from their un-safety-belted chairs into the pilot's lap, predominated in my thoughts.

Eventually we staggered through two or three thousand feet of clouds and out into the sunshine. When we returned to the field and I had worked the cramps

out of my fingers, I ventured to remark to the pilot that he had done a nice piece of work in getting through the heavy cloud layer without instruments.

"Oh," he replied, "in the clouds. I just turn everything loose and give her a little more gun and let her fly herself through!"

While this scheme can hardly be recommended as standard procedure for all cases, the degree of stability of the plane is undoubtedly an element of high importance in fog flying.

LIEUT. O. P. ECHOLS (Wright Field, Dayton, Ohio): I was asked to read a short memorandum written by Captain Ocker of the Army Air Corps, which I think is of interest in connection with fog flying. It is a comment on a paper on this subject.

Memorandum

By CAPTAIN OCHER

Army Air Corps, Crissy Field, San Francisco

I do not believe that any one thing will enable us to fly safely in fog, but that it will be a combination of things. The first necessity is a course in blind flying before a pilot is given his license. This course should consist of two phases; first demonstrations in my device together with explanations concerning our reactions. Then when the pilot understands this, practice in blind flying in a dual control machine having one covered cockpit. Then, and not until then, will a stable machine be of any use for, assuming we have an inherently stable machine that will fly if let alone, or if we have an automatic stabilizer to control a machine, how many pilots without the knowledge that my device gives will let these machines alone? I have come to the opinion that possibly one in ten will do so. The others will presume that their machine and instruments have suddenly failed to function properly and will themselves force the plane from its proper attitude into one of danger, not realizing that the instruments which are not functioning properly are the ones in their own head. The delusion of which you speak in your article, has happened to me also. Had the fog extended to within one hundred feet of the water in your case the result of the delusion would probably have been a fatal accident as it has been in many other cases.

General Discussion

LIEUT. ECHOLS: This device is simply a combination of the flag indicator which Lieut. Hegenberger was describing, and the flying chair with which pilots are familiar. He simply takes a pilot, puts him in the chair, puts a hood over his face, turns it to the left and then decelerates still turning to the left, and asks the pilot which way he is turning. Every time the pilot will say he is turning to the right. He mistakes the deceleration for a change in direction. Then he puts the flight indicator under the hood and lets him see by means of the instrument. Most of them, the first time, feel that the instrument is wrong and they are right.

R. P. SMALL (Aviation Financing & Trading Company, Chicago, Ill.): I would like to ask Lieut. Hegenberger if there is at the present time any ground speed indicator if you are in a fog.

LIEUT. HEGENBERGER: There is none. In the several devices that have been made such as the accelerometer, accelerating forces are greater than the force you are trying to measure. As yet there is none.

MR. SMALL: Is there a need for that?

LIEUT. HEGENBERGER: It is one of the outstanding needs.

C. G. ANDRUS (U. S. Weather Bureau, Hadley Airport, New Brunswick, N. J.): May I ask Lieut. Hegenberger whether the hardest time to get down in a fog is the time betwixt dark and daylight? It is our experience that flyers can get down at night pretty nearly without a great deal of difficulty, and often in broad daylight, but there is a period when both types of visual indicator fail. We are badly in need of something like that.

LIEUT. HEGENBERGER: I think that is experienced in both clear weather and fog in landing at twilight, the period between daylight and darkness. That is the hardest time to see.

Comment on the Climb Indicator

CHARLES H. COLVIN (Pioneer Instrument Company, Brooklyn, N. Y.): I would like to compliment Lieut. Hegenberger on the completeness of this statement of the use of instruments in fog flying. He said he got it up in a hurry. I think there is one thing he left out altogether. That is the climb indicator now being used quite extensively for longitudinal control. That is an instrument showing the rate of change of elevation, and while it is being used to some extent as the sole indicator longitudinally, it is also being used for supplementing the flight indicator he has described.

He mentioned also in the air speed indicator, and quite correctly, the fact that it was sometimes unreliable because of the pitot freezing up. I think it would be interesting to add to what he has said that to a limited extent during last winter and much larger extent this winter, the pitot tubes in transport service will be electrically heated so they do not freeze up, and that maintains the air speed indicator in continuous service.

I have one other note, and that is on the altimeter which he mentioned, that its accuracy in the service altimeter is only within several hundred feet. The commercial altimeters which are of lower range than the service altimeters are accurate within very much closer limits. The standard commercial altimeters of 10,000 or 15,000 feet range have a return to zero accuracy of about 25 feet. The altimeters that are made for service up to 30,000 and 40,000 feet necessarily have a more cramped scale and they do have much greater errors, but in commercial flying the low ranges can be used. It is now quite possible to get down with an accuracy within 25 or 50 feet, using a barometer.

Characteristics of the Altimeter

LIEUT. HEGENBERGER: It was an oversight leaving that out. We have been using that in conjunction with the flight indicator and find it very useful. They supplement each other very nicely.

Regarding the error of the altimeter, service type, I had more in mind the overall accuracy that is found in practice in the usual installation, for example, the question of vibration. It is very difficult to eliminate it all. For that reason it is hard to read the scale. Then over a period of years in use you get a falling off in the axis of the altimeter due sometimes to slight corrosion in the mechanism; sometimes the oil becomes gummy up and dust affects it. So, in speaking of the errors in the service altimeter, I had more in mind in service the overall action.

H. J. E. REID (Langley Field, Hampton, Va.): I would like to ask Mr. Colvin whether this electrically heated pitot tube will prevent the clogging of the pitot lines by heavy rain.

MR. COLVIN: The usual pitot installation on transport ships is arranged so the rain can't get up into the lines. Of course, there is the problem of condensation of water in the lines to be overcome, but that is relatively slow; if strained regularly they are kept clear. With a pitot tube installed with sufficient drop from the pitot tube to the line through your connection, you don't get water into the lines.

When the "Los Angeles" Was in Great Peril

LIEUT. C. R. BROWN (Bureau of Aeronautics, Washington, D. C.): Mr. Chairman, there is one thing that doesn't come right in step with this discussion that I was asked to bring up at this meeting, and this is about the most feasible time to bring it up. It is the question of lighting of aircraft, the navigation lights to be carried by aircraft. I might as well bring up the particular point which happened to bring this to a head.

The Navy's rigid ship, the Los Angeles, was traveling over the airways a short time ago and very nearly had a collision with one of the airmail planes. The Los Angeles was well over to the right of her course along the airways, and had all her navigation lights lit. She was therefore conforming to all the rules of the road. That wouldn't have helped her any if that airplane had piled into that big gas bag. There would have been very few people who would have gotten out, probably.

The matter was brought up at that time that we followed surface vessels too closely in navigation lights afforded to aircraft. You have your exhaust flames extending out six inches or more from each exhaust port. You have a lighted instrument panel. You have your metal propellers giving your reflection disc in front of you. You have your goggles with their glasses in them to give a glint. In that way the pilot does not have the visibility at night that a man on a regular surface vessel has. As a person who has gone to sea, I can say it is almost a court martial offense on a bridge for a ship to allow exposed lights to be shown at night. It absolutely blinds you for vision ahead.

At the same time we usually only require aircraft to have two lights. They are going much faster and come together much quicker. Not only that, but the pilot has to watch the mechanics controlling the aircraft at the same time he is doing everything else. On the other side of the question you have the fact that if you increase the lights on the aircraft, you add weight; you are making more light to be reflected against the propeller and you will be blinding the pilot that way. It seems that nobody has worked out a scheme yet. The Department of Commerce requires one thing and the Army another, the Navy another, and international rules require a fourth. It is a problem that ought to be settled with increasing flying at night, and quickly, before some very serious accident results.

Resolution Regarding Budget for the Weather Bureau

CHAIRMAN MOFFETT: If there is no further discussion, I think the only other business before the meeting was Colonel Hartley's proposed resolution. I will read the resolution if it meets with your approval. It is this:

"RESOLVED, That the National Safety Council communicate with the Director of the Bureau of the Budget to the effect that any increase in appropriation for the U. S. Weather Bureau, which will enable that Bureau to obtain more data

from more ships at sea, will be in the interest of greater safety in flying and thereby conducive to the furtherance of America in the air."

(Upon motion regularly made and seconded, it was voted that the resolution be proposed.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Medical Aspects

First National Aeronautical Safety Conference

Under Joint Auspices of

*The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council*

October 4 and 5, 1928

PORTER ADAMS, Chairman

President, National Aeronautical Association, Washington, D. C.

The session on Medical Aspects of Aviation, at the Seventeenth Annual Safety Congress, was called to order at 10:10 o'clock by the Chairman, Porter Adams, President, National Aeronautical Association, Washington, D. C.

CHAIRMAN ADAMS: Gentlemen, we all know one of the newest and most important developments in aviation has been the attitude of aviation companies, particularly commercial companies, on the medical aspects of flying. It is a very great privilege to present to you today Dr. L. H. Bauer, Chief Medical Director of the Aeronautics Branch of the Department of Commerce.

Medical Aspects of Safe Flying

By L. H. BAUER, A.B., M.D.

Medical Director of Aeronautics, U. S. Department of Commerce,
Washington, D. C.

The privilege of addressing this Congress is an honor I greatly appreciate, for the medical aspect of flying is a topic that is too apt to be confined to the discussions of purely medical meetings. Yet it is a subject which should be familiar to the general public and especially everyone closely concerned with flying, and I know of no better place to emphasize its importance than before this Congress.

"Aviation Medicine," as it has come to be universally called, had its origin in the World War. It was found that the ordinary physical examination required for other branches of the Army and Navy did not suffice for those in the flying arm of the service. It has been said numerous times that the British found 60 per cent of their air casualties were due to physical defects of their pilots as against only 2 per cent due to the enemy. The adoption of a more rigid physical selection and constant medical supervision resulted in this figure being reduced in two years from 60 to 12 per cent. It has also been stated that during the war a flyer (if not killed first) was good for only 150 hours over the lines before he became totally "washed out" physically.

During the past ten years a great amount of experience has been added to the war experience and much research has been accomplished. Mistakes have been made and perhaps are still being made, but I think it is no exaggeration to say that accidents from physical causes are a rarity in both our Army and Navy, and are becoming more and more rare in civilian flying.

During the war a foreign flyer went up to try out a new plane against the earnest solicitation of a flight surgeon. The doctor knew he was convalescent from influenza and in a state where his judgment was unreliable, his attention easily distracted, and carelessness prone to develop. He disregarded the advice, however, and was killed. This could hardly happen now. The cases of service flyers with demonstrable serious eye defects who crashed in exactly the same way that the flight surgeons predicted they would crash if allowed to continue flying, could hardly be repeated today. When the physical examination of civilian students became necessary, air accidents caused by students subject to fainting attacks or epileptic convulsions were obviated. In 1927, of civilian air accidents, 75 per cent were in the case of unlicensed pilots and 41 per cent had never been physically examined.

Man has become adapted over centuries of existence to a terrestrial environment. As a result of modern aviation he is subjected to a new and rapidly changing environment and one calling for quick decisions. He calls into play physical factors he did not know he possessed. He travels at terrific speeds and he has to compensate to the diminished oxygen of high altitudes, to intense cold, violent winds, intense glare, and marked disturbances of his equilibrium. He is subjected to conditions which are markedly fatiguing from both physical and nervous standpoints.

Physical standards for pilots are becoming standardized the world over. While methods of testing these differ, the requirements vary but little.

The physical examination of pilots may be divided into four parts each of which we will consider briefly. First let us give attention to the eyes.

Good vision is essential, because the pilot must constantly watch the sky for other planes. He must see the ground and obstructions clearly. Poor vision interferes with his ability to judge distance. When two planes are traveling towards each other at over 100 miles per hour, it does not take long from the time they are first in view of each other, for them to meet. Hence it is essential that the eye pick them up as early as possible. In military flying the eye is even more important. Certain famous war flyers made the following remarks: One said, "Men with poor vision do not come back." Richtofen said, "Only a wonderfully trained, practiced and observant eye can see anything definite when one is traveling at a great height and at a terrific speed. I have good eyes." Another stated, "If you can't see what you are expected to, your vision is of no use; if you don't see clearly, your information is of little value."

The pilot is constantly called on to judge distance, in landing, taking off, and in formation flying. He has to judge his distance from the ground, buildings, trees, telegraph and light poles, and other planes.

Good eye muscle balance is essential because, it, also, is involved in the judgment of distance. Imbalance likewise produces a vicious circle of fatigue, headaches, inattention and carelessness, and the ever present danger of double vision.

Normal visual fields are important because the flyer not only must see straight ahead, but must be able to pick up objects out of the tail of his eye. This is especially important in the combat flyer. Constructed visual fields are also associated with difficulty in night vision.

Color vision is important because the flyer must detect navigating lights on other ships, colored lights on the airdromes, colored signal panels and lights, his map is often printed in colors, and most important of all, the different shades of green and brown indicate to him the character of the terrain and aid him in picking out an emergency landing field. Recently the question has been raised as to whether or

not color vision is an aid in judging distance. In Connecticut two partially color-blind students were said by their instructor to be helpless so far as landing the plane was concerned. Whether or not their color-blindness was the important factor can only be guessed at, but it raises an interesting question for future study.

A certain amount of accommodation is desirable—that is the power to focus from far to near and back again—else the flyer can read neither his map nor instrument board.

The question is frequently asked why, if a pilot's vision is fully corrected with glasses, we reject him if his uncorrected vision falls below a certain standard? The answer is, in a trained, experienced pilot we do not but almost invariably grant him a waiver. In a student we require to begin with, only a little less than half normal vision, which we wish corrected approximately to normal. The wearing of glasses under goggles is not approved for the following reasons. The flyer has to look through two panes of glass. Furthermore, the lenses of glasses are small in comparison with lenses of goggles. So long as he looks straight ahead he has good vision, but if he turns his eyes to one side he has blurred and distorted vision. The grinding of corrections in goggle lenses has been done satisfactorily in a number of cases, but often the results are not satisfactory, particularly with large corrections. Granted that the correction is satisfactory, there are many times when goggles become misted or smeared with oil. If the pilot is about to make a landing and this happens, he tears off his goggles. We feel that the pilot should have enough vision to get his ship back on the ground without his correcting goggles. A man whose vision is so poor that he cannot even see the ground is certainly helpless.

We now come to the ear, nose, and throat. We find that diseased conditions of the nose and throat light up in acute infections under exposure and fatigue. Obstructive conditions interfere with free breathing and also are apt to hasten infections. Hearing is not particularly important but the pilot should be able to hear his mechanic say "contact" and "switch off" or other directions.

Equilibrium may be considered here though it is properly considered under several headings. The eyes, ear, deep muscle and visceral sensations and effects of gravity all play a part in maintaining our equilibrium. Abnormalities of equilibrium, particularly a hypersensitiveness to motion are a hazard to the pilot and such conditions should be eliminated. Sensitivity to motion has a relation to safety other than that pertaining to defects of equilibrium. The work of Ocker and Meyers has proven conclusively that instrument flying under blind conditions of darkness or fog is more reliable than flying according to one's sensations. The reason for this is, that our brain gives us faulty information. For example, after being turned to the right and the turning stopped, one has the sensation (if he cannot see the horizon) of turning to the left. If, therefore, a flyer goes into a spin in a fog and comes out of it, he has the sensation of spinning in the opposite direction. He manipulates the controls to come out of his supposed second spin and, of course, goes into another. He becomes hopelessly confused and crashes. This, probably, accounts for some of the fatalities to the ocean flyers.

The next part of the examination is a general physical examination. This includes looking for structural defects such as would interfere with the handling of the controls of a plane, organic diseases of the heart, lungs, circulation, kidneys, and other viscera. These diseases lower resistance, increase susceptibility to fatigue and render the flyer unreliable from a physical standpoint. It has been found that the flyer who is suffering from any organic disease or convalescent from the same is a danger to himself and others when in the air.

Finally, we come to the nervous system. This is the system of the body subject to the greatest wear and tear. All organic diseases disqualify, such as mental disease, paralysis and epilepsy. Also functional diseases of any consequence should disqualify. The neurotic type of individual does not last long. He also is the type that "freezes onto the stick." Hence, effort is made to eliminate all those whose

past history shows they do not react well to stress of any kind either physical or emotional. The Army has found that a large percentage of the men it has had to ground after selection are so grounded because of defects of the nervous system. When the nervous system is upset, the whole physical mechanism is apt to go wrong.

The standards to be adopted will naturally vary with the types of work to be done. The Army and Navy will have the highest standard because they require their pilots to be fit for any military duty and this causes rejections for defects that have nothing to do with flying. Then, too, they take their pilots more or less for life. Next highest will be the standard for passenger carrying commercial pilots. Then comes the industrial pilot, and finally the private pilot.

It should be clearly understood that when an applicant is physically disqualified, we do not mean to say that he could not learn or continue to fly. We do say, however, that the hazards in his particular case are increased over and above a reasonable amount.

Before taking up the physical requirements of more special situations, let us consider the necessity of periodic physical examinations and the importance of the flight surgeon. Woolford has said, "periodic physical examinations of the nervous system are imperative to detect early evidences of undue strain in order that an interval of rest may be taken and thus permit the nervous system to recover its normal tone. Failure to take this precaution simply means that disaster is courted as the nervous state goes from bad to worse and the pilot's judgment becomes so impaired that eventually he is involved in a serious crash. Periodic physical examination of flyers presents unusual opportunities for the conservation of health and it has been shown that there is a direct relationship between physical fitness and flying.

A pilot would hardly fail to give his ship periodic inspections. The human element in flight is quite as subject to deterioration as the mechanical. Periodic physical examinations are becoming recognized as life-prolonging. Life insurance companies are offering free physical examinations to their policy-holders because they have found that the early detection of defects leads to better chances of cure and a longer life. The same applies to aviation.

Already in the Department of Commerce we have found a number of cases in which the physical condition of the pilots had fallen off considerably in six months. In a few cases the change was so marked as to cause a new flight test to be required. One large transport company has already instituted the procedure of having its pilots checked once a month by a flight surgeon. This does not mean a complete physical examination but a check for "staleness." The results obtained in the Army and Navy from the constant medical supervision of pilots has been so satisfactory and the spirit of coöperation between the pilots and flight surgeons so excellent that I predict the day will come when all large transport companies will have their own flight surgeons to supervise the health of their flyers. One crash prevented will save lives, and also thousands of dollars worth of equipment. It will be a worth-while investment.

Not only can flight surgeons be trained to make the physical examinations of pilots, but their further knowledge of aviation medicine and flying itself can keep flyers fit to fly and reduce the number of accidents.

Flying is attended by a severe stress and strain on the physical and nervous mechanism. Too much flying day after day, too much dissipation, lack of physical exercise all contribute to produce a condition known as "air-staleness," or "aero-neurosis." This condition is evidenced by irritability, loss of interest, occupational dreams, insomnia, fear of the air, a falling off in flying ability, and certain physical symptoms. If this condition be detected in its incipency, the case can be cured. If it is let go till it is severe, recovery is slow and frequently impossible. Here is where the trained flight surgeon is invaluable.

The Army has found that the incidence of so-called "staleness" is approximately 33 times as great among Air Corps Officers as among officers of the rest of the Army. This certainly shows the flying personnel is subject to a stress that does not affect those in non-flying occupations. Transport companies must realize that too much flying decreases the efficiency and lasting abilities of the pilot. Pilots must realize this and also realize the importance of rest and exercise if they expect to keep in flying trim. The pilot must realize that because he receives a physical certificate today is no guarantee that he will be physically fit to fly every day for the next six months. He must learn that minor ailments may be serious in the air, that consulting a flight surgeon is only good insurance and that minor things taken care of now may prevent serious conditions developing later. In the civilian field the efficiency of medical supervision after the original selection depends largely on the cooperation of the industry and the pilots themselves. Sound physical condition is more important in flying than in any other occupation.

We now come to some of the more special features of flying in which the medical service may be of help. High altitude flying concerns civilian pilots but little as a rule. It is of deep concern to war-time pilots for combat work is carried out at very high altitudes. It has been found that not all individuals react equally well to high altitude. If the day ever comes when we have a 100 per cent efficient oxygen apparatus this fact will be of less significance. At present, however, high flying should be done by those best fitted to withstand it. A classification of pilots should be made and they should be restricted to the altitudes at which they are most efficient. Here again, the classification is only in the interest of efficiency. I have heard more than one pilot boast as follows: "I took the altitude test and they limited me to 15,000 feet. I went out, got a ship, and climbed to 18,000 feet without difficulty." Naturally, he could. He misunderstood the purpose of the test. The classification means, not that the restricted pilot will drop dead if he crosses the line, but only that he will not do efficient work and that his physical makeup will be under too severe a strain at high altitudes to warrant his flying repeatedly over the limit set for him.

There is one other feature of altitude that should interest those who contemplate trying to break the altitude record. The ordinary person believes that if he takes oxygen the effects of altitude are nullified, and that is true *up to a certain point*. However, beyond that point, no person may go and still live even though he is breathing pure oxygen. The reason for this is that man depends for life on a certain pressure of oxygen in his lungs and a certain pressure of carbon dioxide in his blood. When these are absent he dies. Somewhere between 40,000 and 45,000 feet is this critical line. Here the pressure is so low, that even though man is breathing pure oxygen, the pressure of that oxygen is too low to sustain life, and in addition the pressure of carbon dioxide in his blood has been diminished to such an extent that his blood cannot let go of the little oxygen present to his tissues. The effects of oxygen want come on insidiously. The individual is unaware of his flagging efficiency. Unconsciousness supervenes before he is able to do anything about it. Continued high altitude flying is fatiguing. The use of oxygen even at moderate altitudes helps ward off fatigue and above 20,000 feet it is a necessity.

There is one more danger to the flyer and that is high speed. We know too little about it but we do know that flyers have complained of dizziness and faintness on sharp turns at high speed. We know of one instance, where the flyer had hemorrhages into his retinae and probable slight brain injury. Experimental work has shown that speed may cause brain injury sufficient to kill. Straight ahead flying is far less dangerous to the body than making turns at high speed. What the limits will be, I do not believe anyone can say, though I doubt if turns can be made at much greater speeds than 300 miles an hour.

When opportunity permits we shall have valuable statistics to work up at the Department of Commerce with over 14,000 original examinations and over 2,000

re-examinations to draw from. We may as a result find we should revise our standards. We have tried making them more lenient than has ever been done elsewhere. Whether or not this has been wise time will tell. There are many points that need further investigating. Work on color vision and corrected goggles particularly needs to be done. Improvements could doubtless be made on some of our tests. In general though, I think our physical examination is satisfactory and the results bear this out. We need, particularly, closer cooperation between the civilian flyer and the flight surgeon. We need recognition of the importance of aviation medicine by the transport companies, with closer supervision of the health of flyers. We need a more general appreciation of the effects of altitude and high speed with research work on the latter. We need some means of determining the reaction time of students. Slow reactors do not make good flyers. Certain individuals who can pass a satisfactory physical examination never learn to fly for lack of aptitude. It is not purely a medical proposition. It is a matter for cooperation between the doctor and the instructor. The British believe they have solved it in the Reid control apparatus. The Army has hopes in the Ruggles Orientator. It is a matter of great importance to aviation and it will need the cooperation of all those concerned to solve the problem.

The general medical profession is slowly becoming alive to the importance of this new specialty. Facilities must be provided for the training of the civilian flight surgeon. We are endeavoring to have instruction given in all first-class medical schools. We have already succeeded in some cases. The response of the medical profession to the call for examiners has been very gratifying. We have close to 500 examiners now and more are being appointed daily.

We wish you to look on aviation medicine as a branch of preventive medicine. Its sole purpose is to make aviation safe by weeding out those physically and mentally unfit to fly and keeping those selected in a constant state of physical fitness.

Speaking for the Department of Commerce (and I believe I am safe in saying the medical services of the Army and Navy also) we have but one idea and that is to put everyone possible into the air and keep him there. We have no desire to keep anyone out, but a few must fall by the wayside in order to protect the public and those who are safe flyers and aid the progress of this aviation era.

"Normality" Can Be a Doubtful Point

CHAIRMAN ADAMS: The Chair would be very happy to hear any discussion of Dr. Baur's paper. There is no written discussion, but we want to have, if possible, all the discussion we can from the floor.

DR. W. J. FRANCIS (Medical Examiner, Department of Commerce, New York City): One of the things which rather puzzled me has been this: In making out blanks I have noticed that the candidate likes very much to get hold of the blank and see what is on it, and so it has been my custom to use just a check, and that meant "normal" where he was normal, and the thing that has rather puzzled me is whether a man who had had his appendix removed was still normal or whether the fellow who hadn't had his appendix removed was or wasn't normal. The same thing applies to the tonsils and deflected septum. I would like to ask Dr. Bauer about that being normal or abnormal.

DR. EDW. H. BEDROSSIAN (Medical Examiner, Department of Commerce, Philadelphia, Pa.): There is no question that civilian flying is progressing in leaps and bounds. In Philadelphia and in the neighborhood when this work came up, there were only three flying schools with probably less than 100 students altogether. In the course of a year and a half we have about nine flying schools with nearly 500 students. These are not very accurate figures, but they will illustrate the progress of the work.

It seems to me that the students like a medical examiner who is a little bit easy on them. In my experience, when I went through the family history, many of them would ask me what that had to do with their flying—for example, asking about their father's occupation; if he had ever had a nervous breakdown; or about the mother's, the sister's and the brother's health. So in our form, I believe, if we could put down this question of family history and the nervous makeup in a definite form that we could all follow, more or less, and use the same routine, the students would then feel that no matter where they go, more or less the same questions will be asked in reference to their family history.

Another help that came to me, which might be of great benefit to flight surgeons or medical examiners, was this: If we could have some regional conferences. We have been called to Washington, I think, about once a year, and whenever I have been present there it was very helpful and interesting and very stimulating. If any of us could take the training in one of the Army Aviation centers, it would be a great help, but all of us can't take advantage of that opportunity; I thought if, between New York and Philadelphia, or in this section, we could have about three or four conferences of the medical examiners, we from Philadelphia could come to New York some day and those from New York and vicinity could come to Philadelphia; and we could call some sort of conference to meet probably once every three months, to take up problems that might arise in the course of our work and give our opinion or experience. It would be of great assistance.

Many Cases Are Difficult to Handle

In the course of my hundred examinations during the year I have had several problems that I didn't know just how to handle. One, that I come across quite often, is simply tachycardia; no organic disturbance, but the student and the pilot reports a pulse rate of around 112 to 116, and after some exercise it has gone up to 140 or 160, then returning again to 120. I had one heart specialist who took over a case of that kind and said the boy was all right. I wasn't sure whether it was staleness or whether there was some myocardial disturbance there, or whether it was purely psychic or nervous. However, it was a questionable condition.

Then in several cases I have had albumin. I don't see why a young person, healthy in every way, should show so much albumin. I have asked other medical examiners and they tell me they do not find such a high percentage of albumin. In my cases at least 30 per cent had traces of albumin, but not quite so many cases had casts.

There are quite a few cases that could be brought up if we had regional conferences at which we might take up the experiences that occur every day. There are things coming up every day which require our study and co-operation.

Returning to the co-operation between the schools, the instructors and the medical examiners, my personal opinion is that the school likes the medical examiner who doesn't turn down very many cases, because each time that you disqualify a student it means at least \$300 to the school. How we are going to overcome that is a matter to be studied, without compromising with our professional obligation and without hurting the school's progress. Some way ought to be found so that the schools will not look at the medical examiners in some instances as being too fussy and turning too many cases down, while others are more lenient.

DR. BAUER: I would suggest that any medical examiners present who have any technical questions to ask, save those until after the conference is over and I would be glad to stay and answer them as long as you wish. There are a good many people here who are not physicians and I don't think they would be particularly interested in the technical questions, and I think we should confine our discussions to a more general discussion of the subject.

Discussion of Dr. Bauer's Paper**By LT. COMMANDER J. F. NEWBERGER****U. S. Navy, New York City**

I want to congratulate Dr. Bauer on his excellent paper. Perhaps on this particular subject there is no one in this country who can speak with more authority, and it is pretty difficult for me or a great many others to get up in discussion and throw any doubt upon what he has had to say.

In 1923 and 1924 I was attached to the Aircraft Squadron of the Scouting Fleet and we at that time undertook a trip with one of the largest squadrons of planes that had ever been gathered together in a force; that is, in peace times, and we flew from Philadelphia down to Panama. Of course it wasn't a non-stop flight. We stopped at different places because at that time the planes weren't flying such great distances. In addition to that, these planes that we were flying with were bombers, large planes, and could only fly a certain distance as a consequence.

When we started out on this trip I had just left Pensacola, the Flight Surgeons' School in Mitchell Field, and was assigned to the Air Squadron. There were a great many pilots, and the question came up at that time (it was just about the period that we had introduced the new physical examination; at least new for the Navy, though it was the old Army examination). How can we keep these pilots in the best physical condition? Another question that came up, in particular with me, was: How can we avoid, in the best way, any accidents or any fatalities? We started out in January, 1923, and we had a number of severe accidents in the Squadron. Of course the physical examination for entrance or for qualification of a flyer when he first enters the Service is one of the least important. It is only an indication that the man is in the best possible condition at entrance examination for qualification for flying.

The most serious problem in aviation today, and one which is not only in the Army and Navy but also is more important in commercial flying, is how to keep this pilot, or the man who is directing the plane, in the best possible condition. That is one of the most difficult problems to solve because you cannot have a medical officer with your pilot all the time and you cannot have him under constant observation, and you never know what the pilot is going to do. He may stay out till four or five o'clock in the morning, and then the next morning get up and fly. I have had a great many arguments on this question on board ship. I have had officers, for instance, when I approached one and told him, "You didn't come home until three-thirty this morning," say to me, "Well, doctor, it doesn't make any difference to me because you know I am in the finest physical condition. You know I never smoke or drink, so I don't see how it is going to affect me." I have had the greatest difficulty in these cases to convince the officers that in order to fly, particularly in a military organization where you have to undergo a lot of tactics and you must have navigation and a great many other problems, in the first place a pilot has to keep himself in the best possible physical condition; in order to do that he has to get a certain amount of sleep and has to obey a certain number of rules.

Naturally, the problem came up as to how we were going to check this up. Of course in the Aviation examination we have an index which was got on up by Dr. Snyder, who used to be one of the teachers at the Research Laboratory in the School at Mitchell Field, and I have used this index as an indication of each pilot's standing. I had a big board with each pilot's name on it, and this index goes anywhere from 7 to 16. A good index is from 10 to 16. Below 7 is supposed to be poor. In that way you have something by which you can gauge a man. It wasn't

so much the actual gauging of the man, however. For instance, we took "normal," and I checked each man up for about a week or ten days, and sometimes two or three weeks, in order to get his average index, because he might have 8 one day and 12 the next, and I had to get a fair average. Then I checked him up and put him on the board. So at any time during the week that I suspected anything was wrong I could call this man in and say to him, "I want to check you up and see where you stand."

If I had a normal index of him which was 10 or 12, and then suddenly he went down to 7 or 8, I knew there must be something wrong, whatever the cause might be, such as some illness or disease. In that way I created a certain amount of rivalry among the pilots because I noticed, after we had had this system instituted for a period of two or three months, every morning they used to come up and look at the number on the board to see where they stood and who stood the highest. In that way they watched their own physical condition with great interest. There were about 80 pilots and their records were always posted. One had 15, another 16, and another man had only 5. Naturally, after a while they began to take a personal interest in it themselves.

After all, the law of self-preservation is very strong in human nature and if a man has something wrong with him he wants it to be corrected. Thus we checked up on our men in that manner. Our method showed results. The first year we flew to Panama and the next year we flew to Crata. In 1923 and 1924, during this entire period we never had one single fatality, and one year we flew 225,000 miles in this squadron (1923). Of course, we had one or two minor accidents, such as, for instance, we broke wings on landing or pontoons, and so on, but we never had one single fatality to personnel; and with the amount of flying we did I thought it was quite a remarkable thing. The only thing to which I could attribute it was that we kept pretty close watch on them.

In 1924 we got out a paper on "The Causes of Crashes," and at that time we made an analysis of the crashes not only in the Army but also in the Navy. Of course we found in analyzing these crashes just what Dr. Bauer has told you, what the British flyers found during the war, namely, that 75 per cent of all accidents and crashes and fatalities were due to the human element. The Bureau of Aeronautics has made an analysis of crashes, but handled it from a different point of view. They have made an analysis of the crashes in the Navy, because after all the crashes and the circumstances surrounding the Navy are a little bit different because we do a great deal of flying over the water, and that analysis was made from a different point of view, grouping these crashes according to the days in the week, the unit operating, the type of aircraft, the mission of the flight, the cause of accident and experience of the pilot. These various groups were then subdivided until every single factor which seemed possible to trace had been located, and their conclusions were as follows as to the tabulation of the facts elicited:

"1. The modern type of aircraft with welded-steel construction is 75 per cent safer in an accident than the earlier type where the construction was almost entirely of wood with wire bracing."

I remember six or seven years ago, in 1920 or 1921, when I was with the Aviation Unit, we used to have these old type flying boats, and they were very peculiarly constructed, entirely out of wood, and very easily went into a spin. They used to call them "flying coffins," and that was a very good name, because whenever one of them went into a spin it was very difficult to get it out, and whenever one of them crashed the plane was all smashed to pieces and there was often fatality to personnel. Of course it is an entirely different thing today. A great many planes have forced landings, and if a plane gets into a spin you get it out, and I would venture to say that over 40 per cent of the men who have such accidents today get out of it without a scratch. That didn't happen years ago, however.

"2. Within certain limits the number of crashes, injuries and fatalities are indicative of the state of discipline and efficiency of the various units. Further consideration must, of course, be given to the type of duty performed and other affecting elements.

"3. Eighty per cent of the fatalities which have occurred during the past seven years can be traced directly to personnel. In other words, the human and not the mechanical element is most often subject to failure. This is in general accord with the results of similar analyses made in other services at home and abroad."

In 1924, when we analyzed the crashes in both the Army and Navy, we took it from a different standpoint. For instance, the first classification was "Human error in judgment;" then "Mechanical defects," "Bad weather," and so forth; but this is from a different angle.

"4. When a mission of a flight is such as to require the pilot to exercise caution, such as flights where sick or injured are being transported, where other officers not pilots are being carried as passengers, or in other cases where the other occupants of the aircraft are incapable of looking after their own safety and the responsibility rests solely on the pilot, the records show the pilot can and has risen to the occasion with a record of only a few accidents."

That is a remarkable thing. With all the number of accidents we had in the Army and Navy, compared with civilians where a man is carrying other passengers or even in the Service where a man is carrying passengers, we had very few accidents.

"5. The two leading causes of the failure of the human element are bad judgment and inexperience."

There is no question about that. One sees that particularly when one goes to a training station like, for instance, Pensacola, where a great number of flyers are training, and where of course experience counts. A man who hasn't any experience gets scared, just like a man driving an automobile; if he hasn't had much experience, he loses his head and crashes.

"6. During the seven years mentioned above steady improvement has been made in the safety with which aircraft have been operated, amounting to 340 per cent. It is safe to assume that at least half of this improvement represents improvement on the part of the pilots and is a record in itself which the bureau considers with pride.

"7. Over two-thirds of the crashes resulting from so-called engine failures are not a fundamental fault of the power plant, but in the final analysis can be traced to a faulty operation, maintenance or inspection."

So that is the human element.

"8. The factor that counts most with the efficiency of the individual pilot was determined to be experience. Pilots with an average annual flying time of 400 hours have 40 per cent fewer crashes than those with 100 hours. The fact that the pilots of the first named group flew four times as much, and were, therefore, subject to the hazards of flying four times as long, as those of the latter group makes this 40 per cent reduction no less than astounding. In other words, pilots of the latter group had almost eight times as many crashes in proportion to their flying time. Also, seasoned pilots who had been flying over 1,500 hours showed a 75 per cent reduction in crash probability as compared with the inexperienced pilots."

I am, therefore, of the opinion that these steps and other steps of an intelligent nature which may present themselves from time to time as a result of the studies being conducted will bring about a highly satisfactory reduction in aviation accidents.

I am sorry that time does not permit me to discuss in detail all the different factors brought out in Dr. Bauer's paper. I am particularly interested in vision and in disturbance of equilibrium, because in the last three or four years I have done a great deal of work on this subject, but of course the subject is a big one and time

doesn't permit. We might go ahead and talk for the next two or three hours on that subject alone. However, there is one thing that stands out and is going to stand out until perhaps we get a new "Gyro" airplane (such as the one, for instance, in which a man recently flew from Croyden to Le Bourget Field, in France), where you can, perhaps, with the helicopter type of plane stay in the air, just hang there, and there won't be any crashes. But until that time comes, we still have to rely on the human element and look after the personnel.

CHAIRMAN ADAMS: Is there further discussion?

HON. EDWARD P. WARNER (Asst. Secy. of the Navy for Aeronautics, Navy Dept., Washington, D. C.): I don't know whether the layman, having no connection, direct or indirect, with the medical profession, has any right to intrude in this discussion. I have heard several words that are entirely strange to me, but the relation of the flight surgeon to his subject, especially in the preliminary examinations and in the periodic examinations that determine whether or not fitness for flying continues, is, it seems to me, entirely different from any ordinary relations of a doctor to his patient; and I don't believe that the flight surgeons themselves realize entirely in how rarefied and mysterious an altitude you dwell or how uncomprehending the average layman is when he comes under the flight surgeon's jurisdiction for examination or for check on his flying capacity.

Every one of those who have contributed discussion has made some remark about the curiosity of the candidate, the subject of examination, on what is being done. One of those who spoke remarked on the tendency of the candidate to cross-examine the doctor and to try to find out what it all meant and what significance these questions had. Another speaker mentioned the desire of the examinee to see the record and find out what was being put down against him, and still another remarked on the necessity and the difficulty of convincing the officers that this was all being done for their own good.

I have had occasion to talk about accidents and accident reduction and the relation of physical and psychological examination to accident reduction, to a great many airplane pilots in the last couple of years, and every now and then one runs up against an attitude somewhat like this: A fellow says, "Yes, I go up for an examination and the doctor asks me a lot of questions about my ancestors, and he looks me in the eye, and he measures the time that I take to respond to each of his questions, and he reels off a string of words to which I am supposed to respond with a word that each one suggests to me. I think it's all the bunk and I don't believe it has anything to do with flying."

You can satisfy yourself readily enough, I am sure, that it does. You have evidence that is satisfactory to the members of the medical profession that it does have something to do with flying. But it is absolutely necessary, if you are to get a sympathetic attitude from the pilots, without which flight surgery cannot attain its full value, and still more if you are to get a sympathetic attitude from the schools (the absence of which has once been hinted at), that the individual pilot, the head of the organization, shall also understand what is going on and that it is for his own good.

The reputable school has no desire to take students who are not going to learn to fly and be a credit to the school, but they want to be satisfied that the man really isn't going to be able to fly. The most direct means of getting at that, it seems to me, is to make a study and a presentation available to and comprehensible to the layman, of the accident records of those who have been known to be either below the borderline of what is acceptable to the doctor, or very close to that borderline. It seems to me manifest, again speaking as a layman, that if the fellow who just barely gets by has no more accidents than the man who is as nearly as possible perfect on his medical examination, then the fellow that objects to the examination has a fairly strong case in favor of lowering the line of demarcation and letting in those who are still a little lower down the scale. Fur-

thermore, in order that these tests may be acceptable, I think a little explanation by the doctors would be very helpful, and it is very desirable, it seems to me, that the tests be related, so far as possible, to the operations of aviation in some way that the layman can himself understand.

The Reid control apparatus is a success, it seems to me, very largely because it looks like an airplane; it has an airplane control in it and is simply something that the pilot can accept and understand. The same thing is true with the Ruggles orientator. It is a part of an airplane and it looks natural to the aviator. I don't say that it is necessary to follow the airplane in detail, but Dr. Snow, of Northwestern, made some experiments a few years ago that seem to me to have a decided bearing on the question.

He tested out taxi drivers for the Yellow Taxicab Company, and in citing the results I hope you won't suspect that I am drawing any analogy between pilots and taxi drivers. It was required that the would-be drivers go through various maneuvers with an egg and a little paper bag of sugar and a lighted candle and a dish of gasoline, and so on, and it ruined the morale of the organization because they thought it was a joke. So he exercised his ingenuity and built a complicated machine which looked more like a taxicab than anything else, and that accomplished the results because everybody trusted it, whereas before it would have been difficult to have gotten the candidates to take a sympathetic attitude and to get what information they could.

The flight surgeon has a definite responsibility (as it appears to a layman very much interested in finding methods which will reduce the cost of training and reduce the accidents both in training and afterwards), not only to produce tests which satisfy himself and impose them by fiat from on high (as you can impose a prescription on a patient who already knows that he is ill), but also to devise methods which can be explained to the layman, and to produce statistical records of the effect of physical or psychological or temperamental unfitness which can be presented to the layman in such a way that he can't escape being convinced. When you have done that, I am sure you will have the wholehearted sympathy of 90 per cent of the pilots, of the organizers of civilian schools, and of everybody connected with any Government service.

MAJOR I. B. MARCH (Medical Corps, Flight Surgeon, U. S. A., Mitchel Field, L. I., N. Y.): In making over 1,000 neurological and psychological examinations at Mitchel Field in the last three years, we have brought out some of the very features that were just mentioned—the co-operation between the pilots who are making application for flying training, and the doctor. I think the answer to what he has just suggested is an absolutely frank, honest explanation of the examination to the candidate and to the pilot. We have found with our pilots at Mitchel Field that this has helped us a very great deal in gaining their confidence and in getting their co-operation; and even with the candidates who apply for flying training we see no reason whatever for making a secret or a mystery of the physical examination for flying. There is none. In a candidate who has been disqualified, I take his paper and with a red pencil check every disqualification that he has, and explain it in detail as far as I can do so, and try to make him understand why he is disqualified and why that disqualification makes him unfit to be a candidate for flying training.

I see no reason for any mystery, no reason for concealing from the candidate any of his disqualifications, except perhaps to save his feelings occasionally when you find a psychological trait and you are not able to explain it in a way that will not make him feel that he is inferior mentally. There, a great deal of tact must be used. You cannot tell a patient or an applicant for flying training that he is crazy. You will not gain co-operation from others by doing so. But you can explain to him in a nice, tactful way that he has nervous conditions which make it impossible for him to co-ordinate properly in difficulties of flying, and explain those

difficulties so far as you can do so. We have had no trouble in that way and often get letters from candidates who have been disqualified, thanking us for our explanations, and they are perfectly satisfied. We get excellent co-operation from our flyers at Mitchel Field.

The flight surgeon is not only intimately associated with the flyers, but he is also intimately associated with their families and with their personal affairs in a confidential way, so that he can be of very great help to them in relieving them at a time when both family responsibilities and the responsibilities of the flyer conflict.

I wish to stress one thing that Dr. Bauer brought out in his talk; that is the need of greater research along certain lines. That can only be obtained by a sincere co-operation of the flyers themselves with the men who are interested in aviation medicine.

DR. PAGE NORTHINGTON (Medical Examiner for Dept. of Commerce, Bellevue Hosp., New York City): I am sorry to see the opinion expressed by Dr. Bauer, that he viewed the question of the internal ear rather sketchily. After all is said and done in the discussion of the aviation examination, of maintaining the flyer, it is the proposition of the individual being able to maintain a correct position in space and an appreciation of the variations therefrom, and in aviation a man must maintain his position with reference to the odds of gravitational force. It is a prime essential thing. Dr. Bauer submitted that in maintaining equilibrium there are three prime functions of the organs of the body which must be working; that is, of the eyes, the ears and the deep muscle sense. He submitted that with obstruction of any one of those, we can learn to maintain a fair equilibrium sense. It is not a question of the comparative values of vision and the labyrinth. It is as well admitted that acuity of vision is the greatest aid toward one being able to recognize his position in space and maintaining it as he chooses, but in conditions, as in aviation, where the proposition of equilibrium is a prime essential, it would appear that it would be necessary to have the three functions that maintain them without impairment.

It is true that in such conditions as he spoke of, when the reactions were hypersensitive, that was somewhat of a bar. We have found in examinations for the last two years of the graduating class at the Naval Academy, that it is very obvious that the vertical canal, as is recognized, is more sensitive and you get a more pronounced reaction from its stimulation than from the horizontal, which is undoubtedly true due to the fact that we are accustomed to maintain in ordinary life a position horizontal to the surface and we have merely acquired an increased tolerance for the horizontal canal, which is also comparable with that of the vertical canal.

The question has come up with reference to the matter of training. As a rule we accept about 50 per cent of the applicants for aviation. Only about 50 per cent of those people qualify, and in the case of most of the people that I have seen that did not qualify, it was because they got their wind up, they were willing to give up in the vast majority of cases. The pertinent point to me is, why did those individuals give up? Why did they get disheartened or get discouraged or get the sense of fright during their ten hours of instruction? I believe that you could take any student up, when he first enters a class for aviation, and stunt that individual sufficiently so that he will come down and never get into an airplane again. I believe that during his preliminary few hours in the air, that probably through a bump of air, probably through certain maneuvers that the instructor took him through, he became apprehensive and didn't recognize whether he was flying on an even keel or whether the plane was banked, and thus he felt that he would never make an aviator. I feel that it is lack of tolerance from the stimulation of the canal which frequently causes those individuals to give up.

Working on that basis, we devised a plan which provided in the usual gymnasium in addition to the exercises which we give them what was brought out by the Army during the war regarding reverse movements. The idea was to revolve the students by a turning movement forward, flips forward or backward on cart wheels, to see whether they had hypersensitive canals. It would be only a relatively few of them who did have them, but those who did have them, if they were sufficiently interested in aviation and wanted to go into it subsequently, would stand a far better chance, we explained to them, if they continued with these exercises. The burden was upon them to do that if they were sufficiently interested, and I believe in that way the number of successful applicants that go into aviation will be increased.

Speaking of a man turning in a plane, say, in a spin and coming out, if his labyrinth were impaired or dead it would not be as confusing, for the simple reason that he hasn't any vertigo. I don't concur in that. The man has a nystagmus following his turning and his nystagmus is usually longer than his vertigo, and I believe a nystagmus with the objects which you are seeing oscillating, would be more confusing than would be his vertigo; at any rate, his vertigo is absolutely a physiological response and I don't see how we can say that by destroying his vertigo or taking that away from a man and putting him on a pathological basis, that this is going to give him a keener sense of equilibrium. The labyrinth is the main organ of equilibrium. You can remove an eye, or both eyes, and ordinarily you won't get any impairment in the sense of equilibrium. If you removed an ear, you would get a disturbance in the sense of equilibrium; decidedly so. So in the tests we recognize the fact that there are certain conditions, such as, for instance, mumps, where the vestibular portion of the eighth nerve was entirely disturbed, as in a recent case which I saw. The man had had mumps years before and his vision functioned quite normally. The only complaint he had was that he noticed he had bad legs while walking in the dark. That was brought out merely after I had examined the individual. There was another case following encephalitis, in which there was the same thing.

In flying also he spoke of the fact that a person can get along, (I wouldn't say normally), but a man is not greatly disturbed if one of these functions is impaired or lost; but in flying a plane in direct maneuvers, that is, in a loop or a spin, if the maneuver is made directly, a man's deep muscle sense is the same whether he is in a loop or whether he is flying in horizontal. The centrifugal force of his doing a loop, if it is executed properly, the pressure on his deep muscle sense is absolutely at a minimum—a minimum in the sense that whatever maneuver you are in, if it is done correctly, you should not appreciate the change of position. Then you would have to rely mostly on your ears and your vision, your vision being the most important. In night flying, and so forth, Dr. Bauer mentioned about the lights on the dashboard. That is very true, but the lights do not function absolutely 100 per cent. A man has got to rely on his ear in many instances in order, I think, to enable him to come down and land safely.

LT. C. R. BROWN (U. S. Navy, 485-B Middle Neck Rd., Great Neck, L. I.): I have heard with a great deal of interest the various discussions by the doctors here on how to select aviators; and I am from a layman's standpoint rather familiar with it, since I have been in aviation for some time and have been under rather close observation of flight surgeons, having been psychoanalyzed and psychopsychiatrized, and all the other things; and I have from my angle developed some ideas on the other side of the question. I think—and I am very glad to say that the point I bring up is quite exceptional—that it is entirely possible to select the wrong flight surgeons. You can select a good surgeon, but it doesn't necessarily hold that he is going to be a good flight surgeon, any more than you can take a good English student and feed him mathematics and make a great mathematician out of him. I am happy to say that the Navy now is giving flight training of a certain

degree to flight surgeons, and therefore weeding them out in their ability to fly.

I know of one individual that none of us felt could ever fly an airplane, no matter how much training he was given. Not only that, but we didn't have any faith in his psychological gifts. As a matter of fact, after having known us for a very long time and being shipmate with us in the same mess and hearing us in the morning when we were feeling bad and at night when we were feeling good, he still had to resort to catch questions to get slants on us. The result was inevitable. We turned on him and fed him every kind of misinformation we could, and when the annual physical reports came out there wasn't a man on there fit to fly; as a matter of fact, most of them ought to have been in the penitentiary.

I just wanted to bring out the point that in anything which has such a close personal relationship between the doctor and his patient as flight surgery, you must have a man who is clever at that kind of work, who is a natural born judge of men.

CHAIRMAN ADAMS: Is there any further discussion? If not, Dr. Bauer will respond to the discussion.

DR. L. H. BAUER (Medical Director, Air Regulations Div., Dept. of Commerce, Washington, D. C.): Dr. Francis' question I am going to take up with him personally later. It is a technical point which I think most of you will not be interested in. The same is true of Dr. Bedrossian's question. One point he brought out was the question of having certain standard sets of questions to ask candidates. I, personally, am against that for the reason that we do not want what will be a stereotyped examination. We would rather leave it to the examiner to devise his own questions for the particular candidate; that is, each man to be considered as an individual. I know there is a tendency in examinations of the nervous system to use a stock form of examination and personally I am not at all in sympathy with it.

I was in the Army a good many years and I shouldn't make any uncomplimentary remarks, but I am not at all in sympathy with the recent Army examination in which they are laying so much stress on the nervous system. I believe it can be overdone just as any part of the medical examination can be overdone. I grant you that it is important. I believe the eyes and the nervous system are the two most important factors in the examination of flyers, but I think it can be overdone, and I believe the method of having stereotyped sets of questions to ask each candidate is in the line of overdoing the examination and not getting what you really want.

He also mentioned the question of regional conferences among medical examiners. I think that would be an excellent idea, and personally I would be glad to do anything possible to foster it.

As to the question brought up by Secretary Warner about the significance of the examination and explaining to the candidate what it means, I think that the days of mystery in medicine belong to the Dark Ages and there certainly is nothing mysterious about our examination, nor should anyone be led to think that there is. If it is mysterious and can't be explained, then it should be discarded. Examiners are busy and they don't always feel like taking the time to explain to the applicant what each point does mean, but where it is possible or where the candidate shows interest in what it is all about, I think it is well worth while from the standpoint of furthering aviation and cooperation between the examiner and the candidate for him to explain what the different tests are for. Let them understand that they are there for a real purpose; that they have some connection with aviation and are not simply there for the purpose of mystifying him.

The cooperation of the schools was mentioned. I think that the schools that

are really trying to play the game are cooperating. There are some perhaps that are not, but it is like everything else; it is a new industry as yet, and the whole idea of regulation is new and some do not take kindly to it, but I think when it is understood thoroughly what we are trying to do, that there will be no lack of cooperation. There again I think the examiners can help out a great deal by keeping in touch with those who are in charge of the schools and trying to impress upon them that they are there to help and not to deter; that our idea is not to keep them from getting students, but to keep them from getting students who are going to cause them trouble and loss of property, as well as give them a black eye because of unnecessary accidents.

Dr. Northington said he regretted to see the internal ear mentioned sketchily. I didn't intend to mention it sketchily. I said that the ear, nose and throat were formerly considered highly important, as we now went over them rather sketchily. I don't include equilibrium under the ear. I know that the ear has an important part to play in equilibrium, but I don't believe that it is the only thing in equilibrium, and I believe that this was where mistakes were made during the war. I mentioned a minute ago the danger of overemphasizing the nervous system. During the war the thing that was overemphasized was the internal ear. Equilibrium is an important factor. I mentioned that, and I mentioned particularly the question of hypersensitive canals as being a dangerous factor in a flyer, but I think equilibrium has got to be considered as an integrative whole of various factors, and not just the internal ear. While it is true that a man with a dead labyrinth will have trouble in maintaining his equilibrium, nevertheless a man with a normal labyrinth can't maintain his equilibrium when he can't see the horizon, so his eyes are also an important factor so far as the flyer is concerned. I think there has been a tendency to overemphasize the internal ear to the exclusion of other factors in equilibrium. I don't mean by any means to neglect equilibrium as being an important factor in a flyer; I think it is, but I think we have got to consider it as a whole and give the other factors a part as well as the internal ear.

I, too, agree with Dr. Northington that a man with a dead labyrinth has no place in the air, but I do believe that a man whose labyrinth is perhaps hyposensitive has less difficulty than the man who is hypersensitive.

The point brought out by Lt. Brown on the question of the personal factor in the flight student is an excellent one. I agree very heartily that it is quite possible to select the wrong man for a flight surgeon, and the wrong man can do a great deal of harm, and I think that the wrong man is more apt to go wrong with this stereotyped set of questions, which I mentioned a moment ago, than the right man is. That is another reason why I am against it. I think that each case should be handled individually. No two people are exactly alike and you can't treat them exactly alike.

I think that covers the points that were brought out.

The department is endeavoring to make a statistical study. Secretary Warner spoke of the importance of that. We are endeavoring to do that, and we hope eventually to have some worth while statistics on the results of our examinations, particularly on disqualifications and particularly on accidents. We want to find out whether accidents are happening more frequently among people to whom we have given a certain sort of waiver for physical defect. If they are, that means we are wrong in granting waivers for that defect. If they are not, it means that we are right in granting them and that we can become even more liberal than we have been in the past.

On the question of waivers, there seems to be some fear among old flyers that have certain physical defects, that they will be disqualified if they take a physical examination. There is very little ground for their fear as to that. We consider

that flying experience is an important factor in assessing any man's physical ability. In other words, we take a beginner and he shows certain defects which we know by experience are apt to increase the hazard. In his case, he is not going to get a waiver. But the man who has a history of several hundred or two or three thousand hours of flying, and his history shows that he has been free from air accidents, he has conclusively proved that whatever defect he may have has been nullified by his experience, and his experience is going to be taken into consideration. That is the attitude we take in the department in the case of all experienced flyers, and I think it is only just.

Unquestionably the most hazardous time in a pilot's life is during his training period or perhaps shortly after he has got his early training and thinks that he knows it all, before he really becomes experienced; and the man who is experienced has passed those most dangerous stages and therefore there is less hazard for him because of his defect; and also he has become compensated to it, he has learned to fly with that defect or else it has come on him gradually after he has learned to fly and he has gradually become compensated to it. So that the experienced flyer is an entirely different question from the beginner. We are very liberal in the case of trained flyers. In the case of our students we insist that they pass the private pilot's examination. Whether or not we have been too liberal I don't know. So far I am not inclined to think that we have been. It is possible that we may become more liberal, but that can only be told after we have had a chance to study statistics from these 19,000 examinations which we have had so far, and I might say that our examination is as liberal as any in the world.

LT. COMMANDER J. F. NEUBERGER (U. S. Navy, New York City): You say you want to get these statistics about these people that are granted waivers and are going to have crashes. In the Department of Commerce most of these pilots are civilian pilots. If one of those pilots flies to Boston and has an accident, how do you classify that and how do you keep track of it?

DR. BAUER: All civilian aircraft accidents must be reported. Those in charge of all transport companies, the managers of all airports, or pilots themselves, on all that is concerned with an accident must make a report to the Department of Commerce and each accident is investigated by a department inspector and an accident report is sent in to the department with as full information as can be obtained. When that comes in, a man's history is immediately consulted. If he is a pilot who is carrying a waiver, then we try to find out whether or not the accident had any possible relation to his waiver. If a man started out, got into a storm, had no place to land and smashed up the landing, even though he may have no waiver for physical defect, we can hardly call that an accident due to his physical defect. If, on the other hand, the accident very evidently was due to some defect which we have waived, then that is chalked down as an accident that is due to a physical cause. The National Advisory Committee for Aeronautics has investigated recently the aircraft accidents and has tried to devise a standard system for investigating all accidents and assessing them on the basis of their cause, and the physical end of it was not considered in that so much at first but later it was decided to consider physical defects as a basic cause. For example, each accident is assessed according to personnel, material, miscellaneous conditions such as a weather, and undetermined. Physical cause would come under personnel. The personnel is broken down into poor judgment, disobedience of orders, carelessness and negligence, poor technique and miscellaneous or undetermined. Then that may be further broken down as to the primary cause for that poor technique. Maybe it was a physical cause; it may have been lack of training or lack of experience. Eventually I think we are going to have some worth while statistics on the primary causes of aviation accidents and I hope that we are going to find that the physical end of it is almost nil; that if our standards are

at all what they should be, it is going to be almost nil. If they are not, then we are going to find some accidents due to physical causes.

CHAIRMAN ADAMS: Is there further discussion?

I know as a layman that I am very grateful for the opportunity that I have had of sitting here and finding out what a sympathetic attitude, not only the Department of Commerce, but the medical examiners and everybody, has on this question of physical examination, and I think the National Aeronautical Association can do a very real service—and I am going to ask them to do it—by making these applicants and these people who want to learn to fly understand that this is something to help them, not to keep them from flying but as far as possible to make them better pilots.

I thank you very much.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Safety of Airship Operation

First National Aeronautical Safety Conference

Under Joint Auspices of

*The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council*

October 4 and 5, 1928

COMMANDER GARLAND FULTON, Chairman

(C. C.), Bureau of Aeronautics, Navy Department, Washington, D. C.

The session on Safety of Airship Operation at the Seventeenth Annual Safety Congress was called to order at two-thirty o'clock by the chairman, Commander Garland Fulton (C.C.) U. S. N., Bureau of Aeronautics, Navy Dept., Washington, D. C.

CHAIRMAN FULTON: With your permission we are going to make a change in the order of presentation of the papers and will hear, as the first paper, from Secretary Warner on "The Safety of the Airship and the Airplane for Trans Oceanic Operation."

Safety of the Airship and the Airplane for Trans-Oceanic Operation

By HON. EDWARD P. WARNER

Assistant Secretary of the Navy for Aeronautics, Navy Department,
Washington, D. C.

The first requisite for the author of any paper dealing with a comparison of the airplane and the airship is a firm resolve to suppress any personal prejudices. His quest must be for a purely objective analysis. There is no room for conflict between the supporters of the two types of aircraft. Their relations should be mutually supplementary, not competitive. They should support, not destroy, each other. Both the airplane and the airship have work to do, work for which they are ideally fitted. It would be a very poor friend to either type of craft who would set it to a task for which it is fundamentally unsuited. When that is done the resultant failure sheds discredit upon operations soundly and logically based and intelligently and carefully conducted, as well as upon others which may deserve all the unfavorable comment that they can possibly receive.

Safety is an important factor in any commercial or industrial enterprise. The holding of these annual safety congresses, in which aviation now finds a place

for the first time, testifies to a general recognition of that fact. It is especially vital in passenger transportation, for any hazards existing there affect the innocent traveling public. Whatever economy, speed and other advantages may be offered, a reasonable degree of safety is indispensable to the success of a passenger-transport enterprise. It is indispensable, indeed, as a moral justification for offering any such enterprise for public patronage. Many properly managed airplane lines operating over land or across stretches of water not exceeding a few hundred miles have attained that reasonable degree of safety, fully justifying the public favor that they are gaining. The problem of trans-oceanic air transportation, whether by heavier-than-air or lighter-than-air craft, is largely one of ability to duplicate there the record of freedom from accident that is already being made upon numerous air routes in the continental United States and in European countries.

In comparing two things so different as airplane and airship operation, and especially in speculating upon future possibilities, it is necessary to depend to some extent upon theory to reduce the objects of comparison to strictly similar conditions. Lest theory leads us too far afield, however, it should be shackled firmly to the practical record of past experience. Experience furnishes the definite evidence in the case. It constitutes the most effective basis for any discussion.

In selecting historic data bearing upon the present safety of trans-oceanic aircraft operation it is perhaps well, first of all, to define what "trans-oceanic" means. The title was assigned to me. I did not choose it myself, and I have had to interpret it. I take "ocean" in a literal sense as applying to the Atlantic or the Pacific, not to any island sea. "Trans-oceanic" means "across an ocean," not merely above a short stretch of it, as in the flight from the United States to Bermuda or from Scotland to Iceland. Taking that as the definition and concentrating attention upon the North Atlantic, the body of water of most interest to Americans, a scanning of the record reveals approximately thirty attempts to make the crossing by airplane in the last ten years. Prior to 1927 there had been eight attempts, of which four succeeded, and in three cases the airplanes were brought exactly to the point intended and in an undamaged condition. None of the eight had fatal results. Both in 1927 and in 1928, on the other hand, approximately two-thirds of all the trials across the North Atlantic have been unsuccessful, and a majority of those which failed had a fatal termination. In only two or three cases at most has it been possible to make a start without protracted waiting upon the weather. In only two instances, out of a total of approximately a score, has the flight terminated at the point designated in advance, and in only three or four has the ultimate landing been made without damage to the airplane.

There is no desire here to be pessimistic. No one can possibly be a greater believer in the potentialities of the airplane than the author of this paper, but the facts are there and it is well to face them. The facts are that all experience indicates trans-Atlantic travel by airplane to be a slow, doubtful and an ultra-hazardous business; over the past few years the hazard has not appeared to diminish with the passage of time. The proportion of failures has in fact shown a tendency to rise steadily, but that is partially because attention has recently been concentrated upon the more difficult western passage.

Against that dismal record stands contrasted the performance of the rigid airship. Three trans-Atlantic flights have been attempted; three have succeeded. In every case the flight has been terminated at a point previously selected, and in no instance has damage been done to the ship during flight or in the process of landing. When the *Los Angeles* came to America four years ago the ship was insured against accident at a premium of only 5 per cent, in spite of the experimental nature of the undertaking from the point of view of the insurance company, unable to distribute their risk over a number of similar ventures. The

confidence which we all more or less instinctively feel in the ability of rigid airships to carry on such flights as a matter of course is evident in the elaborate plans which are now being made for the reception and entertainment of the crews of the German and British airships which are expected shortly to visit the United States. Their safe arrival not only upon a first crossing, but upon subsequent voyages, is being taken for granted.

It may be hoped that the difficulties and dangers of trans-Atlantic operation with heavier-than-air craft will ultimately be overcome. We may hope that in course of a sufficient length of time airplanes of the flying boat type, staunch and seaworthy, will be able to ply regularly back and forth across the North Atlantic on a fixed schedule with negligible chance of mishap. As yet, however, we are far from that happy condition. For the present, practical experience and an analysis of the fundamental factors involved agree in indicating that the danger of such operation is great and inevitable. It is too great for a commercial service, even with mail, to say nothing of passengers, until vast technical improvements shall have been made. Minor ameliorations will not suffice. In the meantime there are other services which the airplane can perform economically, efficiently and safely, and which are of far more practical present importance than any attempt at regular crossing of the Atlantic or Pacific.

For those oversea operations the airship is available as an alternative, and its record up to the present time has been as good as that of the airplane has been disheartening.

Of course it is not to be hoped for that absolute freedom from accident will indefinitely continue. That would be too much to expect from any new type of transport. Mishaps will occur, especially if operating personnel ever grow careless. No effort must be spared to reduce their number. Certainly the possibility of their occurrence or the accidents themselves, if or when they come, should not be treated lightly, but they should be interpreted in accordance with the experience represented by the operation involved and with the precautions used. It is clear that airships can be operated over stretches of water of several thousand miles without serious hazard and without the necessity of appreciable waiting upon the weather, provided that the ships represent the best available in design and construction and are manned by skillful personnel by whom no precaution is overlooked. To go further than that general statement it is necessary to classify and examine the individual sources of possible trouble in trans-oceanic operation either of airplane or airship.

Such a classification includes seven factors of possible hazard:

1. Exhaustion of fuel.
2. Engine failure.
3. Structural failure.
4. Accumulation of ice.
5. Navigational error.
6. Fire.
7. Crash resulting from loss of control.

Some of these points apply preeminently to the airplane, some to the airship and some with approximately equal force to the two. They may be treated separately.

1. For an airplane engaged in over-water flights of 1,500 miles or more the exhaustion of fuel and the consequent necessity of a forced landing at sea constitutes a serious hazard. While adverse wind of an average strength of 30 miles or more over a considerable period are not common, they must be reckoned with if regular scheduled service is to be maintained over the North Atlantic for even a part of the year. Their possible occurrence requires a reserve fuel capacity of more than a third, and for real safety, taking into account the possibility of having to dodge around storms and make other deviations from the course, that margin

should be increased to 50 per cent or better. The fuel load thus necessary is so great, even on a short route via the Azores and Bermuda or from Ireland to Newfoundland, that almost nothing would be left for a commercial load on a present-day airplane. Certainly to make the venture a commercially practicable one and yet provide the minimum margin of radius compatible with safety, the useful load carried should be at least 15 pounds per horsepower.

The airship, on the other hand, puts a much smaller proportion of its total load-carrying capacity into fuel, and yet has a much longer radius. It is perfectly practicable at the present time to design a ship to carry a pay load of 10 pounds per horsepower and still have a cruising radius of twice the distance from London to New York at 60 miles an hour. With no necessity of adopting a short route and with so great an excess of radius beyond the necessary minimum, the airship pilot is able to change his course at will to meet weather conditions as he finds them, swinging as he may desire from a southern to a northern passage, and the chance of finding continuously opposing winds is much reduced. Even though it may be necessary to lengthen the course to 4,000 miles or more between our own Atlantic Coast and some European capital, there should still be an ample reserve. Fuel exhaustion, a very serious matter for the airplane, need never cause concern to an airship properly handled.

2. Engine failure is almost certainly fatal to a single-engine airplane. Only a flying boat of large size is likely to be able to land heavily loaded in mid-ocean and survive among the waves for any considerable period, while to take off again in the open sea after having made repairs is beyond the capacity even of flying boats of the present day. No one can say how much of the loss of life in oceanic flying attempts in the past two years has been due to engine trouble, but we do know that several of the pilots who have been fortunate enough to be picked up by ships have had to descend from that cause. Even for the multi-engined machine, heavily loaded as it must be for so long a flight, the complete loss of the power of one unit would be a serious matter, especially if, as is commonly the case at present, it were impossible to make extended engine repairs during the flight and put the failing member again into service.

The airship obviously has nothing to fear from engine stoppage. With several power units and the ability to keep steerage by running on any one of them, with access to all the engine rooms for repairs or adjustment in flight, and with the ability to ride indefinitely as a free balloon with no engine power at all, there need be no fear of any untoward consequences from power plant stoppage.

3. Structural failure is a greater hazard to the airship, because of the great complexity of its structure and the difficulty of making rigorously complete strength analyses, than to the airplane. It should in fact be possible to disregard completely any chance of structural collapse of a heavier-than-air machine in straight over-land or over-water flight. It is equally true, however, that the structural failures of rigid airships have been few, and that of the two notable cases one, the R-38, was a collapse of a ship having many novel features, exceedingly light in structure, and undergoing severe preliminary trials before being finally accepted, while in the other instance, that of the Shenandoah, the collapse occurred in a storm of the type most dangerous to airships, but fortunately very rare at sea.

The high winds of a north Atlantic storm may be so steady as to cause but little stress in an airship structure. Atmospheric conditions of high turbulence, most likely to tear the hull of an airship to pieces, are characteristic rather of a mountainous country than of the air above the sea, and when they exist in mid-ocean they are sufficiently local to permit of detection and avoidance by a skilled captain. Structural failure, while a more serious possibility for the

lighter-than-air than for the heavier-than-air craft, should not be a great danger for either.

4. The accumulation of ice on the wings and body of an airplane or the hull of an airship has been greatly feared, especially since the experience of Lindbergh and others on trans-oceanic flights and of many Air Mail pilots in the United States. How many of the planes that have disappeared into the unknown have been brought down by the gradual amassing of an icy burden too great to carry we cannot guess, but it is a fair speculation that that factor has been present in some of the disappearances.

For some years the collection of ice on a structure seemed a peril for which no cure existed. None of the chemical treatments or local applications of heat that have been attempted have as yet proven themselves fully satisfactory, but it has been discovered quite definitely that ice can form only over a very narrow temperature range within one or two degrees of the freezing point. An airplane, especially in flying over land, may be unable to escape the critical conditions, for the pilot must often stay low enough to keep sight of his landmarks. In trans-oceanic voyages, especially for the airship, of which the normal navigation is quite independent of sight of a horizon, it should always be possible to change the altitude, and so the temperature, sufficiently to escape from the ice-forming regions. Taking that freedom of choice of vertical position on the part of the airship's commander, together with the reserve of radius of action which makes it feasible to seek a southern route when weather conditions on the shortest inter-continental courses seem likely to be bad, the formation of ice should be a very minor, in fact a negligible, hazard to a lighter-than-air machine. For the airplane it constitutes a graver danger, although one which can doubtless be successfully combated in over-seas flying with a plane well enough equipped with instruments so that the pilot may freely go, and remain, either in or above the clouds.

The factors previously mentioned, and those which will follow in the listing, apply with equal force to all over-ocean flying. It goes without saying, however, that ice formation is most important on the North Atlantic or North Pacific, and that on a run between southern California, Hawaii and Australia, or across the Caribbean into South American waters, it should be non-existent for aircraft of any type.

5. To lose the course by imperfect navigation is an awkward matter, but by no means a fatal one in a craft having ample endurance, especially if the ultimate objective is within a continental area. An airplane or airship heading for New York might be so unskillfully guided as to make a land fall at Charleston or Portland, Maine, and it would only be necessary to turn along the coast to the port sought. When the target is an island or group of them a few miles across, as in approaching Hawaii or in the "short course" across the Atlantic via Bermuda and the Azores, or in crossing the South Atlantic by St. Paul's Rocks and Fernando da Noronha, the hazard of an error in position is greater, especially if there is no time to waste before fuel exhaustion forces a descent. For the airplane the risk is a real one, especially if the region covered is one where fog is common. For the airship it is unimportant for many reasons. The reserve of endurance permits in case of need in cruising about for hours or days to get a check on position. It permits, also, direct inter-continental passages without intermediate island stops. Most important of all, the size of the crew and the working space allow of navigation methods equivalent to those employed on naval vessels or liners. Radio and celestial navigation can be used at full efficiency. Not even in the largest flying boats is the navigator in so happy a position, although they, in turn, present an enormous advantage over the landplanes with which most of the over-ocean attempts have so far been made. Like several of its predecessors, the navigational factor stands as one distinctly to be recognized,

likely to cause some concern, in using the airplane over very long stretches of sea, but as quite unimportant for its lighter-than-air sister.

6. There have been a number of instances of fire in the air, both on airships and on airplanes, in the past, and in at least one case fire has broken out on a plane during an attempted crossing of the Atlantic. Careful attention to detail has greatly diminished the hazard, especially on passenger-carrying craft not subject to violent maneuvering and with the power plant units well separated from the remainder of the structure. In the case of the airship the substitution of helium for hydrogen has been a factor of enormous importance in reducing fire hazard, especially in electrical storms, and the substitution of the Diesel engine for the familiar type with electric ignition, making it possible to use a "non-inflammable fuel," will be another. Whatever the prospects may be for the Diesel in airplanes, and the writer believes that they will become bright within the next few months, there is no doubt that its practical installation in airships lies just around the corner. Even at the present time, given decently careful operation, the fire hazard should be small in long distance commercial flying with any type of aircraft. When gasoline has been replaced by fuel oil it should be virtually nil.

Dangers from lightning can be almost as completely disregarded; again, especially if helium is used. Electrical discharges to aircraft structures have repeatedly taken place without fatal damage. Being struck by lightning is, however, not an experience to be courted, and in long over-ocean flights it should be quite unnecessary, violent electrical storms being sufficiently local and apparent at such a distance on the horizon as to permit of their evasion without serious sacrifice of time by a ship engaged in a long over-ocean flight.

7. Last of the hazards, but by no means least in its probable contribution to the past role of fatalities, is loss of control. Obviously, that applies only to the airplane, as there is nothing in the aerodynamic behavior of an airship corresponding to stalling or falling into a spin. Provided the airship pilot does not actually run into the surface of the water, the worst that he can do is to follow a crooked course. For the airplane the danger is very real and can only be overcome by long and special training of the pilots and by the provision of very complete instrumental equipment for blind flying. To fly without sight of a horizon is perfectly possible, as has often been demonstrated, but it is equally true that many pilots who suppose themselves thoroughly competent would be completely at a loss if they were out of touch with all landmarks for more than a few minutes. The characteristics of the control of airplanes and the necessity of keeping attitude and speed within certain limits constitute a real, although a diminishing, hazard in flying under bad weather conditions or at night. For the airship, over the sea or over level country, no such hazard exists.

A review of the conceivable sources of trouble thus separately enumerated makes it possible to appraise the relative safety of various trans-oceanic operations at the present time and in the comparatively near future. In summary, of the seven factors there are two which are of major importance as dangers, and three which are of secondary magnitude, but nevertheless real and serious, for the airplane. At least one, and possibly two, of the secondary points the failures of navigation and the spins or other accidents due to loss of control should be substantially eliminated within the next couple of years. The forced landing at sea due to engine failure, the termination of a flight in mid-ocean because of the exhaustion of fuel, and possibly the accumulation of ice, remain, and to those no full answer is in sight. For the airship three of the seven points disappear completely. Of the remaining four only two, the accumulation of ice and structural failure in storm, should be real hazards. Danger from either or both of those sources is slight compared with that to the airplane from inability to reach the destination and consequent descent in the water. The insurance companies which set so low

a premium on that first experimental voyage of the Los Angeles from Friedrichshafen to Lakehurst four years ago did not err on the side of over-optimism.

We ourselves shall make that error if we consider that our safety record is good enough to be perfectly satisfactory, or that the precautions which we already take are all-sufficient. Our striving for further improvement must be incessant, but in the service of airships over water, as in the over-land flying of airplanes with passengers and mail, we can safely feel assured that we have reached a point justifying continuous commercial service and appeal for public support, while at the same time we strive to pare down to still smaller dimensions such hazards as still survive. In that constant effort the airplane and the airship will re-enforce each other technically as well as supplement each other commercially, for much that is learned about navigation, about insuring power plant reliability, about fire prevention, about structural analysis or storm stress, or about coping with ice accumulation on the one can be applied to the other. Collective progress will be most rapid if the proponents of neither type sacrifice what they can do with certainty and reliability to attempt what can be accomplished only intermittently or not at all. Nor should the advocates of either ever permit themselves the cardinal error of total self-satisfaction with what has already been accomplished. Neither in airships nor in liners nor in airplanes or motor busses nor in subways or ferry-boats will complacency be justified so long as a single potential hazard, minor or major, remains.

CHAIRMAN FULTON: I am sure I am expressing your own sentiments when I thank Mr. Warner for his excellent paper. It has been a very interesting one and I believe a thought-provoking one. In his comparison between airships and airplanes I think he has made a pretty good claim for the airship as a safe means of trans-oceanic transportation. I wonder if there is anyone who would like to discuss any part of the paper.

CAPTAIN EMORY S. LAND ([C.C.] U. S. N., Vice-Pres., Daniel Guggenheim Fund, New York City): Mr. Chairman and Gentlemen, I second the comments of the Chair most heartily. I should like to add my personal thanks to one of the busiest men in the United States for taking the trouble to write such an excellent paper and come here to present it. I think our Assistant Secretary of the Navy may not be overworked in Washington, but he certainly is overworked outside, with meetings, banquets, airport and airway openings, and what not. There is a good deal of food for serious thought in his excellent paper. My only regret is that the paper could not have been published and broadcast throughout the world two or three years ago and again each succeeding year. Then I think we might have had some wonderful pilots still with us who have taken "the last chance."

There is one point of our esteemed secretary's remarks on which I am a little more hopeful, possibly, than his paper indicates, and that is for the future of flying boats. He has just returned from abroad and has given us a wonderful lecture in Washington concerning what is going on in Europe as to the construction of large flying boats. We are behind in commercial flying boats. We might as well recognize the fact and get busy and catch up. There are in process of construction in Europe some very large flying boats that may carry anywhere from forty up to possibly one hundred passengers. Whether they will be successful for trans-oceanic purposes or not I wouldn't care to predict, but there is some great hope amongst those who are interested in flying boat development as to the possibilities of building a flying boat that is capable of being forced down and capable of getting off again under reasonable weather conditions. Whether it would be able to get off in bad weather conditions remains to be seen. But I am optimistic enough to hope that the flying boat will come into its own certainly as a coastal commercial vehicle and possibly as a trans-oceanic means of transportation, even though it may not be able to go directly across.

I should again like to add my general thanks and personal thanks to Secretary Warner.

CHAIRMAN FULTON: May we not hear from Senator Bingham who has recently returned from abroad and will doubtless have some interesting things to tell us concerning the latest development of the dirigible in Great Britain.

HON. HIRAM BINGHAM (U. S. Senator from Connecticut, President of the National Aeronautics Assn., Washington, D. C.): Mr. Chairman, I came to listen, not to talk, but as you were so very kind as to ask me what Great Britain is doing, I feel that I must return the favor by accepting your challenge to say a few words in regard to British progress.

Those of us who have been interested in aviation for a good many years have learned to regard with a good deal of skepticism anything we see in the newspapers. The other day a special dispatch from Paris to one of our metropolitan dailies described the arrival in Paris of that interesting new plane called the Autogyro, sometimes referred to as the "windmill plane," whose monoplane revolves. We know, of course, it is not a helicopter, although frequently referred to as such. But what I was going to say is that this special dispatch in one of the metropolitan dailies, in referring to the arrival of this Autogyro at Le Bourget, said, "And then, unlike the ordinary plane he was able to land with his engine entirely cut off!"

When one reads things of that kind—and one continually does, even in the most reputable newspapers—it is somewhat disturbing. In one of the greatest metropolitan areas a few days ago, in giving the picture of an Autogyro, the statement was made that "It goes straight up and comes straight down." Of course it does not. These papers are, I believe, striving to interest the public who are anxious to get an understanding of aviation but they, at times, greatly distort the facts.

Now as to the progress in Great Britain, having in mind that the British were going to build airships that would carry a great number of passengers, naturally I took that with some skepticism when it appeared in the newspapers. So I took advantage in London of an opportunity to visit the two great airports and see the dirigibles that were under construction. They will of course not be finished as soon as their designers had expected, but there is nothing new in that. Very few large yachts or steamers or anything else, for that matter, are finished on time.

One of them, built under the direction of Commander Burney at a remote spot in the northern part of England not far from the town of York, is expected to be finished this fall, and he hopes to have a trial trip before Christmas. The other one, which is being built just outside of Bedford, not very far from London, by the Air Ministry, is based on a totally different design and constructed of different materials. The Burney dirigible, so far as its framework is concerned, is being built entirely of duralumin, while the Air Ministry's ship is being built largely of steel and will probably be finished next spring. It has been delayed a good many years in construction because of their insistence upon having repeated tests of material and of everything connected with the airship.

I hope that both of these ships will meet with the success which they deserve, because I believe entirely with the last speaker (whose paper I listened to with great interest, regretting only that I was unable to get here in time to hear the whole of it), that the airship is in no way the rival of the airplane but is in every sense its proper complement. Needless to say, I believe in both for their proper uses. Until we get a new form of power plant, I do not believe in trans-oceanic airplane travel. As Secretary Warner has so clearly pointed out, the possibility of useful load for those great flights is so small as to make it commercially practically useless. On the other hand, the airship over land competing with express trains is left in the cold because of the conditions of the weather. The latest airship can cruise at about 70 miles an hour in calm weather. If it has a 20 mile wind then of course that is reduced to 50 miles an hour. Our best express trains can average 50

miles an hour, and they can do it day in and day out, weather permitting or weather not permitting, except in the hardest days of winter.

As Secretary Warner has pointed out, the dangers of the peculiar kind of storm overland which the Shenandoah unfortunately ran into, are very much less at sea.

I wish those of us who are interested in all types of aviation would insist upon the fact, so far as we can, that these two great means of travel in the air might be properly used and properly developed along practicable lines—and when I say that, I have in mind how a few days after I said something in the Congress against the use of airships by the Army and did what I could to prevent an appropriation of a large amount of the people's money for the furtherance of Army dirigibles in Scott Field, Illinois, one or two Army dirigibles mysteriously floated over Washington in an interesting manner and showed off their paces to the populace; and everybody said, "Isn't this lovely, and how nice it is that the Army has dirigibles," and of course that was the sole object of the trip.

So far as I can see, with the progress that is being made by airplanes, there is no sense in having airship travel over the land, but over the ocean the shoe is on the other foot. The larger you build your airplanes, the less useful load you get in proportion to the increased size. The larger you build your airship, the greater useful load you get. As happened only yesterday, in that German airship that started out to fly over Berlin, when the weather conditions were found not to be correct it was decided to go around by way of England and it made the 1,700 mile trip with some 70 people on board in perfect safety—not in perfect comfort according to one of the lady passengers, because they were nearly frozen to death and they hadn't anticipated quite such cold; but of course the later dirigibles will have heating arrangements; in fact, both of the dirigibles that I have referred to have heating arrangements for the comfort of their passengers.

This German flight, to which reference has been made, was not stopped by reason of the fact that there was failure in the power plant. Twice, I believe, one of the engines had difficulty, some connecting feed-pipe was broken and fifteen or twenty minutes were required to repair it, but the safety of the passengers was in no way endangered by reason of the failure of one of the engines, or even of two of them, for that matter. In the event of engine failure in an airship if two of the engines fail, a landing can still be safely made on land, but in the big flying boat, as has been pointed out by Secretary Warner, if it once comes down it will probably float for a time until some ship comes along and picks it up; but it is not able to take off in that rough water and cannot proceed with its passage when once the power plant fails. In the airship it is entirely different and you can make a landing with safety.

I cannot understand why the public is not more enthusiastic about airships and hasn't got more confidence in airships. But I know it is true from the fact that this room is not crowded, whereas other rooms where they are discussing airplanes are crowded. When you realize how long they have been trying to fly from the continent of Europe to the continent of America in airplanes, and when you realize the great ovation that would welcome anybody who might succeed in flying from the continent of Europe to the continent of America, or from the State of Germany or France to the State of New York or New Jersey—a thing which has never yet been done—that somewhat explains that great interest in the airplane.

The East to West flight of course has been made by the world fliers and more recently by the German-Irish fliers, but we must all realize that the only two times that a rigid dirigible undertook that East to West flight, both times it was successful. Not only that, but one of them flew from the interior of Germany to New Jersey without a stop, without a hitch, without any difficulty whatever.

When you take all of those things into consideration, it baffles me to understand why the public is not more interested in the advent of the airship and why they don't put their shoulders to the wheel and make it possible for airships to take

weekly trips across the Atlantic Ocean. Of course that is going to be a weekly occurrence. Apathy will not keep this thing back for long. There are five airships under way today; one of them is finished, two are nearing completion, and two just about being laid out, that can make the trip with perfect ease.

The airships which I saw in England are models of comfort, all things considered. I don't mean to say that the private cabins are as large as this room; in fact, the cabins are very small, but they are more comfortable than those on the steamships on which I traveled when a boy, where all the berths were in one big room and all the effects of seasickness of one passenger were not only in the eyes but also in the ears and nose of every other passenger. There is sufficient room in the cabin of one of these airships for two people, and each airship will carry about one hundred passengers.

Of course the trouble is with the terminal facilities, with the port. There is only one good port in eastern United States for an airship and that is Lakehurst, and it cost a great deal of money. My recollection is that it cost about \$2,500,000 to build it. You can't just come down in an ordinary field with an airship. You have to have the proper facilities. The British believe that the mooring mast is of great importance and is all that is necessary except for repairs. Consequently, they have spent a great deal of time and money and done a great deal of experimental work in developing what they consider to be an ideal mooring mast. They have built one near Bedford, north of London. They have built duplicates of that in South Africa, in Egypt, India and in Australia; and they expect to tie the Empire together in the near future by regular journeys from Bedford to South Africa, and from India to New Zealand, and so forth.

Our Navy has developed a mooring mast which brings the airship down nearer to the earth. At all events, the mooring mast problem has been solved, and so far as making a single stop is concerned, the difficulty is not so great as would seem when one says that a single hangar costs \$2,500,000. But what we must do, it seems to me, is to give every possible encouragement to those few courageous and farsighted citizens, like our presiding officer, who are devoting their lives to promoting a knowledge of the requirements of long distance voyaging by airship.

I do not like to hear people make foolish prophesies; I dislike nothing more, and I think nothing is more harmful, than when some self-seeking person who happens to be a pilot says that in the near future we are going to have airplanes carrying 200 people, going in a few minutes from New York to Chicago, when of course that is not true. I dislike prophesies of an exaggerated kind and over-optimism, but I see no reason why, within the next three or four years, certainly by the end of five years, we should not have regular service across the Atlantic in airships. There are other people who believe the thing. There are also others who believe just as firmly as I do in the safety of airships, and I offer you the proof of that in the fact that more than 200 people, (I am told by the newspapers—with what accuracy I know not) have offered \$2,500 for the privilege of coming across the Atlantic for the first time in a passenger carrying ship from England to America. The thing is undoubtedly going to come about, and what we want to do is to see to it that airships and airplanes complement one another and are developed in their own proper lines.

A bicycle on a broad road was, in the old days before the roads became infested with motor vehicles, a fairly comfortable and safe way of traveling. A rigid bicycle on a taut wire used to go across a chasm; it was something of a stunt because if it stopped, that was the end of the performer. But they never have thought any the less of the bicycle for that reason and we never have thought it was necessary to develop bicycles that would go across a chasm on a taut wire without causing the loss of a life if they stopped. On the same principle, why is it necessary for us to think it essential for a land plane to go across the ocean when, if an engine stops, a catastrophe would happen? And by the same token

should we not do everything we can to develop the airship in which, if the engine stops, it can be repaired and the airship proceed on its way?

I haven't meant to talk so long, but unfortunately the commander has caught me on a pet hobby. I have for some years tried to make some of my fellowmen in Congress realize that the airship is not a dangerous thing. Several Senators have said to me that they have determined that there shall be no airships in the United States and they are going to do all possible to see to it that no more money is going to be thrown away on this "foolish balloon stuff." They represent their constituents who have been taught to believe that way by thoughtless people, either talking or writing that way, concerning what has happened in the case of certain great disasters; but I wish that you would talk to your Congressmen and to your Senators, and if you can't think of anything else to say, remind them of this: That of all the pilots who have tried to cross the Atlantic in airplanes of a land design, less than one-half have reached their destination and many have been lost at sea. Of all the airplanes of boat design or seaplanes that have tried to cross the Atlantic, a good many have reached their destination and no lives have been lost, but not more than fifty per cent have reached their destination. But of all the airships that have tried to cross the Atlantic, all the rigid dirigibles that have tried to cross the Atlantic in either direction or to make a round trip, the performance has been this: Lives lost—none. Failures—none. Success—100 per cent.

CHAIRMAN FULTON: Thank you, Senator Bingham.

Is there anyone else who would like to discuss this paper?

DR. FREDERICK L. HOFFMAN (Prudential Insurance Company of America, New York City): I think the reason why so little is said about the airship and so much about the airplane is because the airplane industry is represented by about one hundred concerns all of whom foster its publicity. The airship is not represented by an industrial concern but by the Army and Navy.

The second point of Senator Bingham concerns mooring masts. The newspapers themselves don't realize the supreme significance of the fact that there can be no airship development without mooring masts and that all over the country these should be established.

The third point is the one of safety. Secretary Warner quoted the figures of the Army and the figures of the Navy which show unmistakably that lighter-than-air craft operate more safely per million miles run than heavier-than-air craft. Those facts have not been published because the writers on aviation subjects, as a rule, carry the plea to establish the aircraft industry. I think it is a most important thing that we should arouse a profound interest in the safety of lighter-than-air machines. The Zeppelin Company of Germany has had a most excellent record with this type of craft and it should be shouted from the housetops, but it is not known.

Finally, there is one advantage of the airship over the airplane, an enormous advantage, and that is comfort. It is ten times more comfortable in the airship than in the airplane. You can move about; you have room; you can sleep, and you can eat. You can do all kinds of things. It is far better to build airships than to build airplanes.

As to land travel and sea travel, I am not so sure that the time will not come when land travel, even in this country, between Panama and the West Indies by the airship, may be perfectly feasible; but what we lack in this country above everything else at the present time is a virile imagination to deal with these airships. We must realize the fact that we not only can ride in motor cars and railroad trains, but in airships as well as in airplanes. Too much stunt performance has frightened the public. We need to have a real interest created in normal flying. We shall never develop the aviation industry on an enormous scale until that is done, and it is bound to come, once the public realizes the difference between stunt flying or sightseeing flying and normal, rational passenger

flying, with established airports, and airships flown by licensed pilots. We have plenty of good landing fields but no airports with all the necessary facilities. In Buffalo there is one very good airport, but as a rule what we call an airport is nothing but a landing field, and we are just beginning to realize that fact. An airport is a very different thing from even a first-class landing field, and that is what we have to point out to people.

CAPTAIN HUGH L. WILLOUGHBY (Licensed F. A. I. pilot, New York Yacht Club, New York City): I had intended to make a few remarks on the safety, or immunity from terrible accidents that we have from fire on our airplanes; but there seems to be quite a little discussion about the dirigible brought out this afternoon, and I would like to answer the question which Mr. Warner asked, as to why the public didn't seem to take so much interest in building these huge dirigibles in this country.

Let us go back to the history of the dirigible. Count von Zeppelin built seven of those dirigibles, one after another. They were all wrecked, but no passengers were lost. Some of them came down in trees and the people climbed down from the trees, thus saving themselves; but the difficulty was that if they had to make a forced landing and they were away from their shed, they were sure to be wrecked. The German government, after that series of experiments by Count von Zeppelin, built a lot more dirigibles. The German people gave Count von Zeppelin lots of money to build more of them, preparing for a war. They built a good many of them during the war, but what did the airship do as a military unit?

In the flights that it made over London there was nothing that it destroyed from a military standpoint that was at all commensurate with the enormous outlay of money, first in building those airships and then in maintaining them. All sorts of stunts were tried on those dirigibles. One of the experiments tried was to drop a cage with an observer in it, with about 3,000 feet of wire attached to the cage. They suddenly discovered the fact that they might just as well have had an anchor on the ground. They couldn't do anything, and they were at the mercy of the airplane, so they gave that up.

We always thought during the war that there was a gun mounted on the top of the gas-bag. I think everybody thought so at that time. Naturally, through any fabric (it never can be made perfectly gas-tight), there is always a little ooze of the hydrogen from the top of the gas-bag. That gun was only about a foot and a half from the top of the gas-bag. They fired the gun, yes, but they also fired the balloon. That was the end of that balloon.

Now as to the question of the dirigible as a trans-Atlantic ship carrying passengers, they could do it all right, but if any adverse weather that cannot be predicted by the Bureau comes on before they make their landing, they are very apt to make a crash landing before they can get to their port.

The objection that I think the public makes to building any more dirigibles is not the enormous expense involved, but the danger of those dirigibles even in trans-oceanic work, in perhaps not being able to make a safe landing in their sheds or the wind being adverse so that they cannot put them into their sheds, as was witnessed in the loss of the Dixmude and the Roma and other ships, and that big ship that we contracted for, that broke up before she could be delivered on this side. That would naturally give the public a dread of building these dirigibles.

On the question of helium, I don't think helium could ever be made of a sufficiently low price to make it of commercial value so as to render the dirigible perhaps immune from that serious accident of fire.

I happened to be in Newport when the first experiments were made on the Patoka with the mooring mast. The Shenandoah was expected there at Narragansett Bay and I went up in the admiral's barge to see the Shenandoah make

fast to this new mooring mast that was on the Patoka. The Patoka first anchored down in the lower bay and then they found that the wind was across the current that was running out in Narragansett Bay pretty strongly and it wouldn't do to anchor the Patoka there and then anchor the airship to the mooring mast on the Patoka because it would upset the Patoka; so they moved the Patoka 14 miles up to Bristol and conducted their experiments. They had hard work to make fast to the mooring mast; there was a man on the dirigible who was trying to make fast, and it took two hours to get a line on the mooring mast to make fast to it. I said, jokingly, to the admiral, "We have got to have a new petty officer appointed here as chief lassoer to the United States Navy." They finally made fast to it and it was all right.

To my mind, the mooring mast is not a success. Take the mooring mast that the Shenandoah made fast to previous to her accident; they made fast to that mast and the wind kept blowing harder and harder. Finally, the wind blew so hard that it smashed the nose entirely off the dirigible, and it cost the Navy \$100,000 to put on a new nose; she finally broke loose and drifted in the storm, but after the wind died down she managed with the broken nose to limp back to her shed at Lakehurst.

CHAIRMAN FULTON: Perhaps the next speaker will be able to tell us some more about the things that Captain Willoughby has mentioned, but before closing the discussion Mr. Warner perhaps would like to reply to these various comments made on his paper.

HON. EDWARD P. WARNER (Assistant Secy. of the Navy for Aeronautics, Navy Department, Washington, D. C.): Of the contributions to the discussion, it would be impossible for me to offer any reply to Senator Bingham's except in the form of applause. I heartily agree with all that he has said. I, too, have had a chance of seeing something of the developments in Europe to which he alluded, as has Commander Fulton, and I hope you will all—and many who are not here—be favorably influenced by his strong recommendation for each type of aircraft in its proper place.

Captain Willoughby's criticisms seemed to be to allude to a number of points of detail which it is hardly possible to discuss in detail without the consumption of more time than I want to use now.

I do desire, however, to turn back to what Captain Land said about the flying boat. His multitudinous official duties have taken him elsewhere for the moment, I am sorry to say, but I heartily agree with him about the possibilities of the flying boat. I am enthusiastic about that, too. As at least one member of the audience knows, the last previous public appearance that I made was to talk about "Flying Boats and Their Merits," but the trans-Atlantic flight is as yet too long. They have great possibilities, and it was specifically because of what I consider to be the flying boat's prospects that I gave that definition of the trans-oceanic flights and included the Hawaiian flight and the trans-Atlantic flights of the NC boats in 1919. The time may come for trans-Atlantic operations on some routes, but for the present I consider that I am justified in clinging to the indictment that I made against the commercial feasibility of any heavier-than-air operation on the broad oceans during this year, or probably for several years to come.

CHAIRMAN FULTON: There has been a change in the authorship of the next paper which is entitled "Outstanding Requirements for Safety in Airships." Instead of being prepared by Lieut. Commander Rosendahl it has been prepared by Lieut. Commander H. V. Wiley, of "the Los Angeles," and will be presented by him. Commander Wiley is a rare bird. He is one of the very few men in this country who is really experienced as a pilot on large rigid airships. We need and must have more like him, if airships are to progress and become the safe means of trans-oceanic travel that we hope they will be. Commander Wiley.

Outstanding Requirements for Safety in Airships

By **LIEUTENANT COMMANDER HERBERT V. WILEY**

U. S. Navy, U. S. S. Los Angeles, Lakehurst, New Jersey

Since structural integrity of modern airships has been adequately provided, especially in present designs now under construction, it is proposed to limit this discussion to the *operation* of modern large airships, assuming them to operate on a regular schedule over a fairly long route. The long distance, regularly scheduled route is undoubtedly the field in which the commercial use of large airships will be developed, for their reliability, safety, comfort, habitability, accurate navigation, long cruising radii, speed, weight carrying capacity, relative independence of visibility conditions, etc., combine the desirable and necessary factors for air transportation in a manner superior to any other means of transport.

Terminal Facilities

In the discussion of terminal facilities it will be noted that the requirements are, in general, somewhat similar to those that should be available for heavier-than-aircraft. There is no reason why an airport could not combine the airship and airplane facilities, and development of them will advance side by side. Also this will be seen to be more practical when it is realized that the airplane will cover the shorter air lines and act as feeder for the long airship routes, and it will expedite passenger transfers, etc., to use the same airport.

(a) *Location Meteorologically:*

Of course, the location of centers of population and transport will govern the location of terminals to a large extent, but in locating an airship terminal the atmospheric conditions should be carefully considered, and it is possible that one site within a reasonable distance may be selected that will offer decidedly better general meteorological conditions than prevail at another. After the general area has been chosen, the local conditions should be closely studied, as local fog and even thunderstorm conditions, particularly near bodies of water, often vary remarkably within a few miles. Therefore the situation should be chosen which is favorably located in regard to the general path of meteorological disturbances, and selected locally for freedom from minor meteorological hindrances to aviation.

(b) *Necessity for More Than One Terminal:*

Since we will admit that an airship should not try to land at a terminal during a severe storm any more than a large steamship would try to enter a narrow channel or dock under similar conditions, it is foreseen that for any long distance route there should be an alternative terminal which might be used in case the usual terminal has very stormy conditions which are liable to continue for 24 hours or longer. This secondary terminal can probably be within 200 or 300 miles of the main airport. It gives the airship a haven to enter instead of "heaving to" at the edge of the storm area, and in addition to safety would probably provide a means to keep closely to schedule. For instance, if the main terminal were New York and a general snow storm or blizzard covered that vicinity, the transatlantic passengers and the airship could be shifted to some other place, such as Norfolk or Boston, and the return trip begun on schedule. In any case of fuel shortage caused by long delay in landing at one port there should be an alternative port capable of servicing the airship. It is not likely that conditions would be totally unsuitable simultaneously at two ports separated by 200 or 300 miles.

(c) *Equipment of Airport:*

The equipment of the airport for a long distance airship line does not necessarily include a hangar. Mooring and "riding out" facilities are now sufficiently devel-

oped that a hangar is necessary only for major repairs. However, necessary mast facilities must be provided. For efficient and regular handling and servicing of airships a terminal should have the following additional equipment:

A radio beacon at the port.

Availability of radio compass stations, for cross bearings. These stations are already provided along the coast.

A light beacon.

A radio station.

A fog gun or siren.

A meteorological office and staff.

Service facilities for lifting-gas, fuel, oil, food, water ballast, etc.

The radio equipment, including the radio beacon and radio compasses, enables the airship to find the station and land in dense fog. Airships have frequently landed in fog, and in the last two months the "U. S. S. Los Angeles" has landed once in a light fog when the ground crew could not be seen until 20 seconds before the landing ropes were dropped, and another time in a driving rain when the clouds were down to 400 feet. The ability of the airship to "hover" gives plenty of time to obtain location and then land when the proper place is located.

It may be noted that large landing lights or special illumination of the landing field are not necessary for airships.

Navigation Facilities

Very little has been said in the press of the navigation of airships, as they have been uniformly successful and are approximately as accurately navigated as surface ships. Their superior advantages in this regard over other aircraft are: room for charts, instruments, etc., comfort of navigator, small deviation of compasses, more accurate steering, steady platform from which to take ground or celestial observations, better radio facilities, etc. A seagoing navigator with a little aircraft experience becomes an excellent airship navigator. We may then put down as one of the requirements of airship navigation that the pilot be an experienced navigator.

Ordinary surface ship methods are not adequate for aircraft navigation on account of the much greater speed, the great and frequent changes in wind force—hence greater deviation from the course steered and the introduction of the vertical dimension, with its variable factors, to the medium being traversed. Therefore, the latest design of drift instruments and instruments for celestial observation and calculation will be demanded and can be used efficiently. Long range radio compass bearings can be used when approaching a coast if the navigator knows how to apply them to the chart in use.

Ordinary magnetic compasses are sufficiently accurate with present airship construction of nonmagnetic material. An earth inductor compass could be easily carried and would provide more accurate steering—hence less deviation from the set course—which would amount to several miles distance saved in a transoceanic flight.

It must be understood that in transoceanic navigation the choice of routes depends upon the circulation of the winds, the navigator always trying to take advantage of favorable ones. To do this he must know the general distribution of the barometric pressure areas, and in this connection a nonbarometric altimeter in addition to the barometric altimeter would be a great advantage. It not only enables the pilot to know his correct altitude above the surface but it also provides a method of determining the barometric pressure at the site in question.

Knowing the barometer at his own location, the pilot is better enabled to determine the wind changes to be expected, especially if this can be coordinated with radio reports from other stations.

Communications.

In regard to communications considerable mention has already been made of radio facilities in connection with terminals and navigation. The modern airship has weight and space available for efficient communication equipment. It should therefore have a long range receiving and transmitting installation and if possible a ship's radio compass. "Blind" flying is perfectly safe and practicable in airships, but depends of course on radio facilities for accuracy of navigation. Fog, rain and snow do not keep the dirigible from flying a straight course at undiminished speed as long as an occasional check of the position may be made. The radio set must be capable of quick reception of weather schedules, or perhaps television pictures of weather maps, and it may be desirable to transmit and receive at the same time, as the present weather schedules consume about three and one-half hours a day for complete reception.

Fire Prevention

Danger of fire from hydrogen is not feared by officers experienced in airships. Of course, all practicable precautions are taken, but hydrogen airships have even been struck by lightning several times without damage, because of the dissipation of the charge through the metal frame. This danger is eliminated in the use of helium, and it is considered mandatory to inflate with helium military airships liable to attack by incendiary bombs or bullets. Also dirigibles inflated with helium can valve gas freely during an electrical storm, which would be most inadvisable with hydrogen.

The danger of a gasoline fire is always remotely present, but general safety precautions and constant inspection for leaks, etc., minimizes the possibility of occurrence of this casualty. Heavy oil engines as a substitute for gasoline engines may become an actuality in ships now under construction, and this will reduce the fire hazard somewhat.

Parachutes

With a helium ship it is difficult to visualize a casualty which will bring the ship down more rapidly than a parachute descends, and opinion in general is against the equipment of airship personnel with parachutes. The present type of parachute is not adapted to airship use, as personnel have to move about and do certain work which would be much hampered by a heavy and bulky parachute. However, it would be practicable to develop a type of chute which could be stored at certain places in the dirigible and to which a person might attach his harness and escape in time of need.

Ballast and Fuel Reserves

All dirigibles carry water as ballast, and the amount required depends upon several considerations. However, water carried as ballast is not available for any extensive use for other purposes. Past practice for the provision of excess ballast was met in detachable fuel tanks which were dropped overboard intact. This has been improved upon recently by the installation of "dump" valves in certain fuel tanks, the valve being operated from the ballast board in the control car. With this equipment in operating condition it is possible to start a flight with

much less water ballast than formerly, as any emergency ballast necessary during the take-off is available in the form of fuel. If this emergency ballast is not needed during the take-off, it is then available as fuel and extends the cruising radius by that amount.

The question of fuel reserve has developed one prudential rule in general use in airships, which is: always have from 25 to 33 per cent reserve fuel for any trip. An accurate account of ground speeds in relation to air speeds kept on the "Shenandoah" showed that about 33 per cent reserve was necessary, although there was not that great difference between ground and air speeds. On the "Los Angeles," a faster ship, the difference between ground and air speeds for 60,000 miles has been only about 10 per cent, and a 25 per cent reserve is considered sufficient for an ordinary long flight.

International Standard for Mooring Masts

We in this country are already confronted with the arrival of foreign airships which desire to use our mooring masts and other terminal facilities. The U. S. Army is constructing masts, the Navy has five, municipalities and private airports are erecting them, the British are building them in Canada, Egypt and India. Argentina and Spain are planning an airship line. Our future commercial airships will want to use foreign masts. So far little has been done regarding the standardization of dimensions of equipment for mooring airships. Not only must the physical connection of the mooring mast and airship be of perfect fit, but the connections for fuel, water ballast, electric leads, mooring wires, etc., should be of the same type and size. This is urgently needed. The ships will be in operation before the terminals are available if action is not taken at once, and if the masts are not standardized international intercourse through airship transport will be delayed.

Meteorological Information

On any long distance route suitable weather information should be available so that the pilot may utilize favorable winds and avoid unfavorable ones. Also although modern airships are considered amply strong to withstand in the air almost any atmospheric disturbance, no prudent pilot would deliberately put his ship into a storm when he could easily avoid it if he were forewarned of its existence and location.

The United States Government issues very valuable weather maps twice each day from observations reported at 8:00 a. m. and 8:00 p. m., Eastern standard time, all over the United States. However, in some localities there are very few observing stations, and more reports are desirable. Any person can, after a little study, read the general signs from the U. S. Weather Map, but it takes long study and much experience to be able to forecast more accurately and discern from the lesser details the features not apparent to the untrained and inexperienced. There is an axiom among airship pilots that the pilot who is most successful in operating his ship is also the most weather wise, for he can take greater advantage of favorable conditions and avoid unfavorable ones. Therefore he must be thoroughly conversant with forecasting from weather maps and an expert at foretelling conditions from visible signs. He must also have a thorough understanding of the structure of storms and the variations in atmospheric conditions that they cause. Anything that can be done to improve the knowledge of meteorology will be welcomed by the airship officer.

Several improvements are at present desired. It has already been mentioned that it is necessary to have more reporting stations. The more reports there are

on the map the more the details of weather existing in any locality can be studied; hence the forecast can be made more accurately. At present the Weather Bureau receives reports from a few ships at sea, but these are meager, and for efficient transoceanic flying the Weather Bureau should have facilities for greatly expanding this service. Great improvement has been made in this regard in the last two years, but even now there is not sufficient information to draw any but the scantiest map of conditions over the oceans. Stations also have been established in Canada, Greenland and Alaska the information from which is most valuable in judging the extent and severity of storm areas. Further extension of this phase is desirable.

In England four synoptic maps are available daily and this augments the information for forecasting, for naturally with more frequent observations available unexpected developments can be discerned sooner, with consequent advantage to aviation. There are several reasons why the four map system has not been adopted in the United States, but they are generally included in the lack of funds to pay observers and the difficulty of engaging commercial wire lines for the prompt communication of reports. Both of these items are a question of Government appropriations, and the growth of aviation will undoubtedly develop a popular demand for financial means to establish this facility.

Another phase of weather observation which has been neglected until recently is the observation of the upper air. Within the last two years about a dozen stations in the United States have been equipped with upper air "sounding" facilities, but this service has only begun to furnish data which can be coordinated with surface observation and forecasting rules. Every aviator of any extensive experience knows that there are disturbances and storms in the upper air which are not indicated upon a weather map made from surface observations. The writer knows personally of several instances of these disturbances and of one case where, when the surface barometer record showed a slight "kink," an upper air sounding indicated a wind of over 100 miles per hour at 5,000 feet. No other indications of such conditions were apparent on the surface. As yet we have not obtained sufficient experience to combine the upper air observations accurately with the surface indications, but their use so far indicates that this data is of the utmost value in forecasting and there is a great demand among meteorologists for the expansion of this agency.

When it is realized that even the best forecasters consider that their average accuracy is seldom higher than 75 per cent, it can be seen how great the demand is for more information and observations. Weather is studied mainly by empirical methods—that is—observation has shown that a certain set of conditions usually develops into a subsequent set of conditions, and it is mainly by past performances that forecasts are made. It is admitted that we should know more of the physical reasons for changes rather than base our forecasts on past performance, but governments and scientific institutions have not in the past supported scientific research along these lines to a sufficient extent to develop the science as it should be developed. The scientist cannot bring to light and test new theories without data such as temperature and humidity of the upper air, and more data is the crying need of the meteorologist.

Another need that will become apparent with the growth of long distance aerial transportation is the necessity for international standardization of units used in observation of conditions. In the United States the barometric pressure is measured in inches, in England in millibars (an arbitrary unit) and in Europe in millimeters. For wind velocity we use statute miles per hour, the seaman sea miles per hour and the European meters per second. Temperatures are also

recorded by different types of thermometers using different scales. The international flyer will be at considerable disadvantage in assembling his data for formulating forecasts until one standard is used.

Airship flights are not impeded by rain, fog, snow, and even thunderstorms if they are local and not widespread. No aircraft of any description is safe in a thunderstorm and all aviators will pass around them. As a rule they may be safely approached within five miles, and as long as one can see and avoid them and does not get surrounded so there is no choice but to go through one there is no danger. However, a type of disturbance of great danger is a low barometric area of V shape which sometimes traverses the United States. These are called line squalls, because the main disturbance forms a long line of clouds along the center of the V, and these are sometimes several hundred miles long. In the United States these move in general from east to west, the wind on the east side being from the south and warm and moist, while the wind on the following side is from the west or northwest and cold and dry. Where these two air currents meet is a long line of atmospheric turmoil, the actual cloud itself having a rapid rising current on its front and a following descending current of great force. The meeting of air currents generally forms a roll cloud. This type of storm would keep an airship from making an airport and in some cases would cause a long detour to avoid its effects. Such storms force the establishment of more than one terminal for refuge in case one should be encountered just as a dirigible were arriving from a long flight perhaps faced with fuel shortage. We know enough about such storms to fly through them with comparative safety, but at the very least they are unpleasant.

Qualifications and Licensing of Aviators

Finally it may be stated that it is not too early to decide upon certain physical and professional qualifications for pilots and the form governmental supervision will take in licensing them. There must be some sort of governmental regulation, for the public already realizes that certain adventurous spirits have embarked on perilous flights which should never have been permitted. Regulations will therefore prescribe certain minimum equipment for aircraft as well as physical and mental equipment of the pilot.

Summarizing briefly, we may then say that the outstanding requirements for safety in airships are:

- (a) Proper terminal facilities.
- (b) Proper navigation equipment both on the ground and in the air.
- (c) Efficient means of communication.
- (d) Supervision to prevent casualties, especially fire.
- (e) Vastly expanded meteorological service.

The only further comment is that regarding the necessity for speed in adopting these suggestions. It is not too early *now* to begin international conferences and national preparation for their adoption. Five large transoceanic airships will be completed within two or three years! Aviation is developing faster than even the most enthusiastic ever dreamed it could. It is time for action!

CHAIRMAN FULTON: We are very much obliged to Commander Wiley for his very informative discussion of the operational requirements for safety in airships. Is there anyone who wants to discuss this paper?

S. TRUSCOTT (National Advisory Committee for Aeronautics, Washington, D. C.): Commander Wiley's paper is in a sense a progress report. In listening to it I found myself involuntarily harking back to the time when our interest in airships in this country first began to crystallize. Commander Hunsaker and Commander Fulton were first beginning the work on the construction of our first

rigid airship and were promoting the training of the first airship pilots. It is a long way back, even if the years are not so many, and while Commander Wiley has chosen to outline many things which he thought could be improved, it is the modesty of the man who has accomplished something which leads to that phrasing of his paper; because the people who are now operating our airships—particularly the Los Angeles—have come a long, long way in the past ten years.

I don't want to bore you with all the reminiscences which might come up as the result of listening to what Commander Wiley has just been describing; but I would like to call to your attention the fact that this necessity for improved facilities in connection with weather has been appreciated for a long while and that appreciation has recently crystallized in the formation of a special committee under the National Advisory Committee for Aeronautics, which is to devote its entire attention to the problems of aerial navigation. Subcommittees are to do cooperative work with the government departments and private organizations on the development of improved facilities and a study of the problems, of course, in navigation itself, in the instruments required, the weather problems, and in communication. That committee includes representatives of practically all of the interests which should be represented on such a committee and is just beginning to get under way.

It is true, as Commander Wiley states, that if airships should suddenly blossom, as it appears possible they may, the amount of facilities available appears at first to be rather limited. My own opinion is that our knowledge of what the facilities should be is rather more complete than the impression which he has given you, and that when they are really needed they can be provided in a very short time.

CHAIRMAN FULTON: Is there anyone else?

Lieut. Emerson, would you like to say something on the operation of airships? You have had a good deal of experience along that line.

LIEUT. R. EMERSON (Ex-Lieut. U. S. NRF, Strauss & Emerson, 307 N. Michigan Ave., Chicago, Ill.): Possibly as an older pilot and commander I am not today as proficient as I was in former days, so I hesitate to add anything to his remarks, with which I must agree completely.

I would like to add this one word as to the safety of airships as passenger carriers. It is not commonly known that in history there have been launched and employed in paying passenger service 14 large airships, either rigid or semi-rigid, and that in more than six separate years of commercial operation not a single passenger has been injured in these ships, and that the total passenger mileage exceeds 3,500,000. I am just contributing that small "statistic," as a Britisher would say, to the safety question as to airships. I don't happen to know of any airplane passenger carrying application that has quite that passenger mileage safety record; and I am not saying that as an airship proponent and an airplane opponent because my original interest in aviation was exclusively with airplanes. That is where I spent and lost most of my money, and it is still very vitally connected with the use and employment of airplanes.

CHAIRMAN FULTON: Is there anyone else?

LIEUT. COMMANDER WILEY: I might say, somebody remarked a few minutes ago about the time it took to moor an airship in a certain case as being two hours or more. The last time the Los Angeles was moored at Lakehurst, seventeen minutes was occupied in tying to the mast.

STANLEY Y. BEACH (Beach Engineering Co., New York City): Could Commander Wiley tell us something about the improvements that have been made with stub mooring masts, and so forth.

LIEUT. COMMANDER WILEY: We have been working for some time to simplify the terminal facilities for airships because the great criticism has always been

the matter of getting in and out of the hangar and the delays that occur, and so forth. Also commercial companies are not going to take up airships until some inexpensive and reliable terminal facilities can be provided. The high mast, which in complete operating condition costs about \$100,000, is more or less satisfactory, but we have recently experimented with and worked with and improved a short mast that keeps the airship only two or three feet above the ground. The mast holds up the forward end of the ship and the after end is held up on a wheel which runs around a path. That is the first installation, I may add; and the installation we have now is a little carriage that runs on a railroad track. In the case of the wheel, additional weights were tied to the ship so that the ship could not rise. In the case of the railroad track, the rollers are put under the rail so that the car to which it was attached could not rise. In either case the ship lies close to the ground, where it does not suffer to any comparative extent from the gusts and velocities that it does at the high mast. The stern is also unable to rise in case of sudden change in the loading of the ship or the lift of the ship, or from wind coming from the opposite direction.

With the installation which we now have, which has been worked out there with no money and not much time to experiment, I should say it could be duplicated for a very small sum of money, and it seems perfectly safe. In the last three months we have stayed on that mast nearly 200 hours and we have taken off and gone to it 20 or 30 times. We are improving it all the time. To my mind, if we work on all the faults that we find from time to time, it will be perfectly feasible to establish an airship terminal where the airship can land and remain, and can take off in a comparatively small space of ground.

A. W. FRENCH (Pan-American Airways, New York City): How small an amount of money is that as compared with the thousands of the other?

LIEUT. COMMANDER WILEY: I think you could put the total installation in complete, where you had nothing to start on; that is, where you had no path prepared nor any gasoline tanks nor anything of that sort, for \$50,000. If you had some of that equipment already, I think you could put it in for about \$10,000 or \$15,000.

Measures Adopted in Italian Civil Aviation for General Safety

By Dr. MANLIO MOLFESE

Director, Civil Aviation Italy, Rome Italy

Organization of Airports

A) Legal Provisions—

1. The legal control of airports is effected by Italian aeronautics legislation in such a manner as to reconcile the needs of commercial aerial navigation with the safety requirements over which the State has absolute control, and with the protection of fiscal laws.

The fundamental Italian law (Royal Decree-Law of August 20, 1913, no. 2207, converted into the law of January, 1926, no. 753) and the associated regulation (Jan. 11, 1925, no. 356) both define the idea of *airport* with the manifest purpose of establishing the scope of the application of the legal measures therein that relate to airports.

The Italian law is as follows: "by *airport* shall be meant any locality, on land or water, designed to be a place of departure, a landing-place, or a depot for aircraft, even if only temporarily. When it is designed only to permit the landing and taking-off of aircraft obliged to make a forced landing during flight, it shall

be called "*Campo di Fortuna*" (Art. 4 of the law; Art. 5 of the regulation.) And since other terms than that of airport are widely used in Italian, such as, for example, *aeroscalo* (aero-platform) and *idroscalo* (hydro-platform), the regulation adds that, for legal purposes, aero-platforms (fields for the landing of dirigibles) and hydro-platforms (for the landing [on the water] of hydro-aircraft) shall be considered as airports.

The immediate result of this precision in definition is that no ambiguity can occur concerning the application of implied legal standards to airports, since, as has been seen, this term comprehends any aeronautical establishment whatsoever that serves as a landing or taking-off place or as a way-station for aircraft, not excluding the "*campi di fortuna*," (emergency landing field) in which any aircraft traffic is quite accidental.

Principal Rules Concerning Service in Airports

The more important rules with respect to service in airports, and which have direct or indirect bearing on safety in flight, may be summarized as follows:

Public utility character of airports.

All State airports, and not merely all the establishments necessary for aerial navigation, are *works of public utility*, with all the legal consequences involved. Also, the private airports, under certain conditions, may be declared works of public utility.

Restriction in the matter of distance.

It is forbidden to build walls, houses, shelters, sheds, electric transmission lines, or any building or obstacle whatsoever, to build and maintain constructions, at a distance from the external limits of the airport, of less than fifteen times the height of the obstacle.

Construction of airports.

The construction of State airports and of all State establishments devoted to the use of aerial navigation, is entrusted to the Ministry for Aeronautics, which will take anticipatory measures, to serve as a basis for related projects, in collaboration with the Ministries of Public Labor, of War, of the Marine, or Finance, and with any other parties who may be concerned.

No private airport or other private establishment devoted to the use of aerial navigation may be constructed, except under conditions fixed by the Ministry for Aeronautics, the aforesaid Ministers being agreed as to the suitability of these conditions.

Admission of aircraft to the airports.

The airports open to civil aerial traffic are accessible to all national aircraft.

Foreign aircraft, to obtain the privilege of landing, are required to satisfy the following conditions:

- a) They must be duly registered in one of the countries with which Italy has made aviation agreements.
- b) They must operate in conformity with the standards established in the international agreements, in relation to all the laws and regulations in force in Italy.

Special temporary permits to land in Italian airports may be granted by the Minister for Aeronautics to aircraft belonging to countries which have not yet signed aviation agreements with Italy.

Safety standards for airports.

Airports open to traffic, and devoted in any manner whatsoever to public service, must be in perfect functioning condition at all hours of the day and night.

All airports must be equipped with all the instruments and arrangements necessary for the correction of compasses.

In every airport open for public service a sanitary first-aid service must be permanently established in places exclusively devoted to this purpose and provided with the necessary personnel and materials.

Access to State airport is by rule forbidden to all not attached to its services, or not possessing special authorization, or not present in the exercise of testing or inspection duties.

Supervision in the Airports.

Supervision over the aerial activities which take place in a State airport and in territory under the jurisdiction of the same, is exercised exclusively by the Commander of the Airport. The limits of the zone of jurisdiction of any airport are determined by the Minister for Aeronautics.

The duties of the Commander of the Airport are as follows:

- a) To exercise supervision over aerial navigation for the purpose of ascertaining that all aircraft, departing, arriving, and in transit, shall observe the regulations in force.
- b) To be informed regarding the various essential papers and documents.
- c) To examine the various flying papers of the aircraft, in departing, in arriving, and in transit.
- d) To exercise care that, in the limits of his own territorial zone, each aircraft owner shall observe the regulations in force. In this connection he should keep in touch with the proper local authorities.
- e) To report to the proper judicial authority, in due legal form, all infractions of the laws in force on aerial navigation, sending copies of such reports to the higher aviation authorities.
- f) To exercise care that all operating aircraft shall observe the prescribed standards for aerial traffic.
- g) To regulate departures and landings in the airport under his jurisdiction, and collect the taxes on landings, departures, sojourns, and shelter accommodations, and oversee the payment of rentals.
- h) To provide supplies of fuel and lubricants to aircraft in aerial traffic, and to receive payments made, issuing receipts therefor in due form.

Movement of aircraft in the airports.

Departures and voluntary landings must take place in the *State airports*, or in those built and maintained under its authorization (*private airports*).

Every user of a State airport must rigorously observe the requirements in force and conform strictly to all the rules of flying, and to the regular orders of responsible agents.

All aircraft, immediately upon landing in an airport and in a proper manner, shall be brought to the place designated for an inspection.

No aircraft may leave an airport before the Commander of the Airport or his delegate shall have made the prescribed visit of inspection and consented to the departure.

All aircraft upon being presented for inspection before departure, must be in perfect flying condition.

No additional cargo may be put aboard after the visit of inspection has been completed.

Landings and sojourns in the airports of the State are free for all State aircraft.

Taxes for landing, departure, and shelter accommodations, payable alike by national and foreign aircraft, are fixed for all private aircraft.

Furnishing supplies.

Aircraft landing in a State airport are permitted to obtain from the stores of the same, fuel and lubricants only in quantities strictly necessary for the completion of their flight.

Such withdrawals, made always with reference to the quantity of materials

stored, are made, in any case, upon direct and immediate payment therefor, and at prices fixed in the proper price-list which must be posted in every airport competent to supply the materials in question.

Shelter accommodations for aircraft.

In the State airports, whenever it is possible, special locations are set apart for hangars to afford shelter for private aircraft for a minimum period of three months.

The proper rental payable by every aircraft is fixed by the Minister for Aeronautics, and is based on the space it occupies in cubic meters. This is computed by measuring the maximum dimension of the aircraft (in length, height, and width) and taking the cube of the said dimensions.

The rental is reduced by one-third when the aircraft is sheltered in a canvas hangar.

For aircraft having wings that may be bent or folded back, the rental is calculated from their dimensions when the wings are so folded back.

Moreover, private companies engaging in aerial navigation may request from the Administration of the State the concession of a part of the grounds of State airports for the construction of hangars or other buildings of their own, which shall be devoted to aeronautic purposes. Responsibility for the care of aircraft in shelter always rests upon the owner of the aircraft or his representative.

The State does not assume any responsibility for damages sustained by aircraft in storage, or from faulty or defective care.

Likewise, the State assumes no responsibility for payment for personal services for any work done on aircraft for individual owners and agents.

The owner of the aircraft assumes full and entire responsibility for any damage whatsoever, proceeding from any cause whatsoever, that may be sustained by personnel and materials of the State through service to or sheltering of the aircraft.

Aid for aircraft.

On his own initiative, or in accordance with the request of interested persons, the Commander of an airport may make arrangements for sending aid to aircraft that have been compelled to make a forced landing away from the field. In such cases the owners of the aircraft are obliged to pay the costs according to current rates, and thirty per cent of the receipts from labor charges go to the workmen who have taken part in the rescue work.

Private airport establishments.

Any person intending to engage in any aeronautic activity on fields or plots of water of his own, should obtain permission from the Ministry for Aeronautics.

In the request for such permission there should be specified clearly, the given name, surname, and address of the applicant, the purposes to which it is intended to devote the field or plot of water, and if these are not in a condition for immediate use, a description of the work to be completed. To every such request should be attached a topographic map, on the scale of 1: 100,000, of the locality in which the field or plot of water is situated, and a ground-plan, on the scale of 1: 5,000, of the field or plot of water, with an indication of all construction work to be done.

The Ministry for Aeronautics takes the necessary steps to ascertain that the field or plot of water meets the required specifications, and issues permits for the functioning of the airport, the other Ministries concerned, agreeing hereto.

This duty, as a rule, devolves upon the Commander of the Airport in whose jurisdiction the new airport is located.

Except in cases of necessity, aircraft may not land in private airports without consent of their owners, unless these airports are operated for commercial purposes.

Free access to the private airports must be given at any time to persons authorized to inspect and supervise functions in connection with aerial navigation.

Customs Airports

The aviation laws of all countries, and, consequently, those of Italy, require that all aircraft from a foreign country or going to a foreign country, shall either land in or depart from airports in which a customs inspection service is operating.

This formality is necessitated by the fact that each country imposes customs duties on everything imported into and exported from its territory by air. Yet the same formality places evident obstacles in the way of free development of commercial air traffic, if the customs airports are few or not conveniently located with respect to the main currents of the above-mentioned traffic.

With such difficulties in mind, the Italian Government has established a very close network of customs airports made up as follows:

- 1) *Airports for the landing of airplanes.*
 1. Mirafiori (Turin) Customs collection district of Turin.
 2. Cinisello (Milan) Customs collection district of Milan.
 3. Boscomantico (Verona) Customs collection district of Trento.
 4. Campoformido (Udine) Customs collection district of Udine.
 5. San Nicolo di Lido (Venice) Customs collection district of Venice.
 6. Zaule (Trieste) Customs collection district of Trieste.
 7. Loreto (Ancona) Customs collection district of Ancona.
 8. Brindise (Lecce) Customs collection district of Bari.
 9. Capodichino (Naples) Customs collection district of Naples.
 10. Centocelle (Rome) Customs collection district of Rome.
 11. San. Giusto (Pisa) Customs collection district of Leghorn.
 12. Catania (Catania) Customs collection district of Catania.
 13. Cagliari (Cagliari) Customs collection district Cagliari.
- 2) *Airports for the landing of dirigibles.*
 1. Cinisello (Milan) Customs collection district of Milan.
 2. Ferrara (Ferrara) Customs collection district of Venice.
 3. Ciampino (Rome) Customs collection district of Rome.
 4. Augusta (Syracuse) Customs collection district of Catania.
- 3) *Airports for the landing (on water) of hydroplanes.*
 1. Genoa (Genoa) Customs collection district of Genoa.
 2. Marina di Pisa (Pisa) Customs collection district of Leghorn.
 3. Leghorn (Leghorn) Customs collection district of Leghorn.
 4. Orbetello (Grosseto) Customs collection district of Leghorn.
 5. Ostia (Rome) Customs collection district of Rome.
 6. Naples (Naples) Customs collection district of Naples.
 7. Brindisi (Lecce) Customs collection district of Bari.
 8. Ancona (Ancona) Customs collection district of Ancona.
 9. Venice (Venice) Customs collection district of Venice.
 10. Portorose (Trieste) Customs collection district of Trieste.
 11. Fiume (Fiume) Customs collection district of Fiume.
 12. Zara (Zara) Customs collection district of Ancona.
 13. Palermo (Palermo) Customs collection district of Palermo.
 14. Syracuse (Syracuse) Customs collection district of Catania.
 15. Marsala (Trapani) Customs collection district of Palermo.
 16. Cagliari (Cagliari) Customs collection district of Cagliari.

Thus there is a total of 33 customs airports, to which others situated in the territory of the Italian colonies (Tripoli, Cyrenaica, Erytria, and Somaliland) will soon be added.

Competition Among Local Bodies in the Establishment and Maintenance of Emergency Landing Fields

In connection with securing safety in flight a recent law (June 23, 1927, no. 1630) is very important. This law makes it obligatory for the Provinces to provide for the acquisition of land for the establishment, possible development, maintenance and control of emergency landing fields, those already in existence and operation being included.

In order that they may make headway in fulfilling the obligations imposed upon them by this law, the Provinces, in the event of their not having sufficient means, may be authorized to increase the land-tax beyond the normal limits.

As may be seen, the State by this provision calls upon local public bodies to help in the gradual development of an organic network of emergency landing fields which is absolutely necessary for safety in flight and not to hesitate to raise taxes in order to accomplish a purpose of such great common benefit.

B. Technical Conditions for safety in flight.

The technical conditions for safety in flight such as are in force in the Italian airports, are contained in the cited Regulation for Aerial Navigation, January, 1925, no. 356. These conditions are to a very large degree those of the international aeronautic convention of October 13, 1919. Some of the more important of these are as follows:

It is forbidden to do any stunt flying, such as involves dangerous evolutions not necessary for the proper operation of the machine, over airports open to civil traffic, in inhabited centers, and in other localities where people are gathered together in numbers.

In any airport, any aircraft forced to make a turn or a partial turn either in departing or in arriving, must, except in case of danger, turn to the left, that is, in a counter-clockwise direction.

An aircraft departing from an airport should not begin to make the turn before reaching a distance 500 meters from the nearest point in the boundary line of the airport, and the turn must then conform to the safety rules given in the preceding paragraph.

All aircraft flying at a distance of from 500 to 1,000 meters from the nearest point of an airport, must conform to the aforesaid rule, except when it is flying at an altitude greater than 2,000 meters.

Stunt landings are forbidden in airports open to civil traffic.

It is forbidden for any aircraft to perform stunts at a distance of less than 2,000 meters from the nearest point of said airports.

In every airport the normal direction of landing is indicated by a letter T and wind direction by means of one or more known methods.

Every aircraft in departing from or in landing at an airport should do so according to the direction indicated above, except in cases of necessity.

If two aircraft are approaching an airport at the same time for the purpose of landing, the larger aircraft must manoeuvre to avoid the smaller and in landing, should observe the rule in article 85.

The way must be left clear for any aircraft in the act of landing in an airport.

No aircraft may begin to rise before any aircraft which may have ascended before it, has completely left the airport.

The foregoing rules apply equally to night-landings in the airports. At night lights are placed on the field, as follows:

The airport is marked out with the greatest possible exactness by means of red lights placed on its boundary lines and on obstacles. The direction of landing, insofar as possible, is indicated by a luminous letter T, or lacking this, by means of three lights placed in the zone set apart for landing, in the form of an isosceles

triangle, whose base is about 200 meters long and whose height is at least double this length. The lights are so placed that the airplane shall land proceeding from the middle of the base toward the light in the opposite vertex; the base marks the position at which the flying machine should begin to touch the ground, and the vertex, the spot beyond which it is not wise to pass.

No captive balloon, kite, or anchored dirigible may be kept in the vicinity of any airport within a distance from the boundary line of less than ten times its maximum altitude, without special permission from the Commission for Aeronautics or from an official named by it.

All obstacles existing in the airports and, insofar as possible, all fixed obstacles dangerous to flying (such as towers, chimneys, radio antennas, etc.) within a radius of 500 meters from all airports, are so marked, both by day (when needed) and by night, as to be readily visible. Particular forms for these marks are to be determined by the Ministry for Aeronautics.

All aircraft manoeuvring in water under their own power, must conform, as far as possible, with the laws regulating navigation on the sea, rivers, and lakes, in order to avoid collisions, and for this purpose, they are considered as steam vessels but carry only the signal lights required in the regulations and not those specified in the maritime regulations for steam vessels. Also, they do not, except in special cases, use the sound signals indicated in the said regulations, nor can they be held liable for not receiving them.

C. Contributions by Italian Aviation on the problem of commercial airports.

Due to the shape of the Italian peninsula, and its geographical position in relation to the general configuration of the Mediterranean basin, it follows that commercial aviation in Italy has been developed and must in the future, continue to develop largely on the sea.

The problem of landing-places for hydroplanes is therefore more important for Italian aviation than that of terrestrial airports. It may even be said, as regards the latter, that no great difficulty has been encountered, and that the three military airports (Venice, Trento, and Milan) together with the imposing new airport, del Littorio, in Rome, which is, however, a private airport and was not built for the exclusive use of aerial lines,—are well suited to meet the needs of Italian commercial aerial traffic.

This cannot be said for the hydroplane lines which, for the reasons given, have a preponderant importance in the general picture of our civil aviation.

How shall we solve the problem of giving adequate hydro-airports to the aerial navigation lines touching such important mercantile ports as Genoa, Naples, and Palermo?

It is evident that a large outlay of funds would have been needed to reserve, in the aforesaid ports, zones set apart exclusively for commercial hydro-navigation. However, this would have been absolutely necessary as long as the old notion persisted that the coexistence of hydro-aviation services and maritime services, in ports subject to heavy traffic, is impossible.

The new idea introduced by Italian civil aviation, and the experience offered by it to the entire aeronautic world for the first time, have counteracted this old idea. The Italian hydro-aviation services have been in regular operation, for almost two and a half years, between the same ports, Genoa, Naples, and Palermo. It is hardly necessary to call attention to the fact that this demands strict and cordial cooperation between the port authorities and the aeronautic authorities, for the purpose of conveniently regulating the movement of water traffic during the hours in which the movement of aircraft is going on.

Another important experiment made by Italian civil aviation, and which has no precedents, consists in the use of mouths of rivers for purposes of hydro-aviation. The Genoa-Palermo line, which serves the Capital also, has a regular stop at the

mouth of the Tiber, near Ostia. Here, the difficulties in manœuvring aircraft and their safe sheltering caused by the changeable conditions of the water and the current of the river, were overcome by building suitable shelter-gates (wet docks) along its banks. In these, aircraft find shelter and complete protection from the violence of the current. Besides, this makes it possible to perform all the operations connected with departure while the hydroplane is still in the said wet-docks, until the time when, with its motors operating at the proper speed, it can move into the river and take off from it. The utilization of commercial ports and the adaptation of rivers for commercial hydro-aviation, as has been accomplished in Italy, constitutes an innovation which, evidently, has important results not only from the technical point of view but from the economic point of view as well,—that is to say, in connection with the determination of costs in the hydro-aviation services. The innovations made in Italy, which are followed closely abroad, show, indeed, that in many cases it is possible to eliminate from the economic picture, in connection with these services, the enormous sums expended in the construction of proper hydro-airports and their amortization.

Organization of Services

A) *Meteorological service.*

1) *Sending out forecasts.* The Ministry for Aeronautics has a meteorological department called the Forecast Department, to which are sent all the weather observations made in the civil meteorological observatories and the military aerological stations established in the various airports. The Forecast Department publishes a daily bulletin containing all the meteorological and aerological observations made at 7 A. M. (I. M. G.) and 18 hrs. (6 P. M.) of the preceding day, upon the basis of which the weather prevailing for the succeeding 24 hours is forecast. This is sent by the R. T. at 13 hrs. 35 min. (1:35 P. M.) and transmitted by telegraph to all Italian telegraph offices at 15 hrs. (3 P. M.).

At 24 hrs. the Forecast Department sends by the R. T. a second forecast of the weather prevailing for the following morning and at 11 hrs. (11 A. M.) a third forecast for the *Rotte Aeree* (Aerial Routes) service.

The Forecast Department is in a position to answer all requests for meteorological information and to issue special forecasts at various hours of the day by telephone, telegraph, or radio.

2) *Studies and researches.*

The Forecast Department with the aid of its experts makes theoretical studies on observation data gathered daily and performs experimental researches in the aeronautic station at Vigna di Valle, on lake Bracciano, making captive-balloon flights every day in order to explore the atmosphere.

3) *Meteorological signal services furnished by the telegraph offices.* Besides the meteorological service conducted by the Forecast Department, there is a special weather-signal service in connection with the telegraph offices conveniently situated along the various routes.

B) *Radio service.*

Closely connected with the meteorological services are the radio services which are required to perform a double function:

1. *Sending out notices.* Gathering and broadcasting all information regarding aerological conditions along the routes the aircraft must follow; and keeping in close touch with aircraft in flight, in such a manner as to be able to supply them with the aerological information they require, and receiving all requests for the interpretation of this information.

To collect and distribute the aerological bulletins compiled in the various aerological stations, a network of radio stations, made up of a number of "Meshes," is provided. Each of these "Meshes" embraces a fixed area.

The radio stations in each "mesh" send the aerological bulletins to a central radio station of suitable power, which gathers, coordinates, and broadcasts (by C. Q.) the material in such a manner that all aerological stations interested can receive it.

The broadcasts (by C. Q.) made by the central station of each "mesh" are received by a central radio station which checks, with the various means in its possession, all bulletins received. It also completes and corrects the bulletins, if necessary, by rapid wire communication, and then broadcasts a general bulletin covering the aerological situation of the country as a whole at a given hour.

2. *Inspection of the service.* The radio stations constituting the various "meshes" mentioned above, are carefully inspected in order to assure their regular and continuous functioning, and rapid telephonic communication is provided to replace the service of a radio station of the "mesh," when such station is not operating properly.

Special modifications in the work of the radio stations in a "mesh" are provided when the central station of the latter is not operating properly, so that the information is sent to the central station of a bordering "mesh."

3. *Communication with aircraft.* Besides the above function, each radio station of the network provides for:

a) Keeping in continuous communication with each other for sending signals in connection with the departure, passage, and arrival of aircraft.

b) Keeping in touch with the aircraft for the purpose of communicating important aerological information or other general notices regarding their safe flight.

4. *Radio compass stations.* Radio compass stations will be established very soon as a part of the general radio net-work. These will serve to give directions to aircraft traversing wide stretches of sea or having to cross difficult and rugged mountain ranges, such conditions, for example, as are encountered on the Genoa-Barcelona, Rome-Venice-Vienna, and Milan-Monaco aerial navigation lines. These stations thus function in an effective manner in order to aid aircraft in their flight.

5. *Further provisions.* Many other provisions are to be adopted in order to accomplish the aforesaid purpose with safety and continuous functioning. Among these the following are important:

a) The network of fixed radio stations devoted to the distribution of aerological bulletins will be constituted in such a manner as to permit the transmission of aerological bulletins every hour, to the great benefit of aircraft traffic.

b) Each of the important fixed radio stations devoted to the interchange of messages concerning the movement of aircraft shall have multiple aerials to enable it to listen in on various wave lengths and receive messages from various localities.

c) The fixed radio stations located on the routes of the various aerial navigation lines shall have a special aerial to enable them to be in constant communication with aircraft in flight.

d) The radio plants on the aircraft shall have the aerial so disposed that it will always be in operation, even when the aircraft shall be forced to descend to the ground or upon the sea.

In addition:

a) The aircraft belonging to the important navigation lines must have two radio sets, one having a normal aerial fixed to the plane, the other operating by means of a frame-aerial placed in the cabin of the aircraft. All air-craft must have two separate and suitably designed radio sets.

b) The radio sets on board the aircraft must use, to as large extent as possible, mechanical devices that will permit them to call the fixed stations automatically or to send short phrases. This in itself will insure the sending of a message, when,

by reason of possible physical disability on the part of the radio operator, transmission by hand cannot be done.

c) Radio sets on aircraft must use a special code for communicating with the fixed stations or with other aircraft. The code must consist of set phrases which will become perfectly fixed through practice.

d) Radio sets on aircraft that make long trips, must be equipped with radio compass equipment which will enable them to take their own bearings from the fixed and continuous signals sent out by the fixed radio stations. Such a result can be obtained by suitable construction of the apparatus.

c) *Optical service.*

Various optical devices are being adopted and developed to serve aircraft traffic in the best manner. These may be summarized as follows:

a) *Luminous signals.*

1) Luminous signaling devices of variable power are supplied to regular and emergency landing fields. These are so made as to be well adapted to aircraft in flight.

2) Special flares and luminous rockets for special purposes are given to aircraft, to be used in case of need.

The provisions indicated above meet satisfactorily the needs of commercial aircraft and make it possible for them to operate in a satisfactory manner.

As regards signaling with optical devices, it may be said that orographical conditions in Italy will not permit the adoption on a large scale of the high-powered luminous beacons used on some American and French aerial navigation lines.

b) *New luminous devices operated with neon gas.*

The use of optical characters for aiding the movement of air traffic, which is now being worked out, will be rendered effective:

1. By adopting neon gas illuminating devices generally for use on the ground. These devices will make the illuminated areas easily visible to aircraft.

2. By using in the aircraft optical signaling devices composed of neon tubes, so formed as to represent conventional signals.

Measures for Safety in Flight

A) *Instruments on aircraft, subsidiary routes, and various precautions.*

1) *Flying in fog.* All of the Italian lines do not encounter the same difficulties in meteorological conditions. The Genoa-Palermo, Rome-Cagliari, and Brindisi-Athens-Constantinople lines generally enjoy the best conditions of visibility; others such as the Milan-Monaco, Turin-Trieste, and Rome-Vienna lines may encounter dense fogs in the Valley of the Po and unfavorable atmospheric conditions over the Appennines and the Alps.

The companies are not yet able to make trips in a continuous fog, much less to make landings in areas covered with fog. But they are able to cross fog banks of limited extent with the aid of their navigating instruments and with information supplied by radio compasses on the earth. For this purpose pilots are taught to fly with the cabin closed.

2) *Instruments on the aircraft.* Instruments of this class which have been adopted, are: a flight indicator of the Pioneer type (manufactured by Bodin), a longitudinal inclinometer, and a Smith compass (Aperiodic).

When the routes and terminal airports are covered by fogs, the safety measure adopted is that of suspending flights. This is precisely the case with the Turin-Trieste line, crossing the valley of the Po, which, in winter, may be covered over its entire length and breadth by very dense fog.

3) *Secondary routes.* Some lines, as a safety measure, may use different routes. The Rome-Venice line, when atmospheric conditions do not permit the

use of the direct route, may choose between two secondary routes, one traversing the Tyrrhenian, and the other, the Adriatic Sea.

Machines leaving the airports at the same hour, like those of the Venice-Vienna line are kept constantly informed of the meteorological conditions along the way by the R. T., so that they may change to another route if necessary.

4) *Various precautions.* Engineer pilots are required by the companies to make frequent test flights on their own lines.

The pilots of the land-lines are required, during their flights, to observe ground areas in order to determine whether these are suitable for landing, and to keep the company informed concerning their observations. These areas after being inspected and approved by an engineer, are made known to all the pilots. This provision is particularly useful, as the network of emergency landing fields in Italy is not yet completed.

B.) *The testing and inspection of aircraft and engines.*

1) *Testing standards.* Standards for the testing of civil aircraft do not yet exist in Italy, but for the time being, the standards fixed in 1924 for military aircraft are followed. However, the matter of compiling standards for civil aircraft and motors is now being studied by a committee of which the following men are members:

General Crocco, Prof. Anastasio, Colonel Fiore, Engineer Caproni, Commander Magaldi, Prof. Panetti.

2) *Italian Registry Office.* Testing, inspection, and the granting of certificates of fitness (aircraft) for flying, which until a short time ago were duties of the Aeronautic Engineering Corps, are now exercised by the Italian Registry Office. From the first of July, the aeronautic division of the Italian Registry Office has been in charge of these matters and has taken the name *Registro Italiano Navale ed Aeronautico* (Italian Naval and Aeronautic Registry Office.).

Some of General Nobile's Ideas About Non-Rigids, Semi-Rigids and Rigids

Semi-rigid versus non-rigid:

As regards the non-rigid which has been adopted in some countries for many purposes, it has fully lost the advantage of being the most suitable type of airship for small sizes after Nobile's construction of the NR in the year 1924; in fact, the semi-rigid MR reached the same capacity of the smallest non-rigids, that is, 33,885 cubic feet, with the advantage of the semi-rigid type as regards the maintenance of the form of the hull and having consequently a higher degree of safety. But the MR had not only the smallest volume of all the present non-rigid airships but also a higher useful lift, that is, 990 pounds. Its maximum speed was 114 miles per hour, its length 105 feet, and its diameter 25 feet. During its flights the MR stopped its engine, landed in order to take on or to leave one of its passengers moored; inflated and deflated in the open country as the non-rigids. Sometimes the MR continued its flight with a very low gas pressure. Therefore Nobile says that there is no necessity to be preoccupied with the gas pressure in the hull. Its crew was composed of three men, but the airship could be maneuvered by only one man. Consequently, after this proof by a semi-rigid type, the non-rigids are considered quite useless.

Semi-rigid versus rigid:

As regards the rigid, General Nobile thinks that theoretically the semi-rigid may reach the same great capacity as the former. The great advantage of the semi-rigid is in local resistance, which the rigid lacks. The semi-rigid is an elastic, also a safe airship. The rigid, on the contrary, is a frail airship. A character-

istic comparison of Nobile's: The rigid is like an egg; the semi-rigid is like a rubber ball. If the precipitous fall which recently took place in the polar regions, instead of happening with a semi-rigid had happened with a rigid, General Nobile says we would all have been instantly killed, the airship would have been shattered in small pieces and sparks would have set on fire the whole mass.

If the rigid is lacking in local resistance and consequently is frail, one must nevertheless recognize that this disadvantage will diminish with the increasing of the dimensions, as the area increases with less rapidity than does the volume, and also because the lift is very high they can use heavier and stronger materials in its frame. Consequently, increasing in size the superiority of the semi-rigid over the rigid regarding local resistance is less evident. But with increasing size the rigid has another advantage and this is that even for the greatest sizes the same construction remains. On the contrary, with the semi-rigid, on passing from the present size to another much larger, it is necessary to change the frame construction. So General Crocco in designing some years ago a 4,300,000 cubic feet semi-rigid designed a new type of keel, and for even larger realizations he foresaw also a new type of the hull internally containing a metallic net.

In each case for the construction of semi-rigids of very large size, one must resolve at each following stage of size increase that new problems will be encountered and it is not possible to foresee to what extent and with what convenience these problems may be solved.

Concluding, the semi-rigid is in every respect preferable for the average sizes to the rigid. On increasing the size, only experience will teach us to what point its superiority over the rigid may arise.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Operation of Aircraft in Air Transport

First National Aeronautical Safety Conference

Under Joint Auspices of

*The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council*

October 4 and 5, 1928

HON. WILLIAM P. MacCRACKEN, JR., Chairman

Assistant Secretary of Commerce for Aeronautics, Washington, D. C.

The session on Operation of Aircraft in Air Transport at the Seventeenth Annual Safety Congress was called to order at ten-ten o'clock by the chairman, Hon. William P. MacCracken, Jr., Assistant Secretary of Commerce for Aeronautics, Washington, D. C.

CHAIRMAN MACCRACKEN: We are a few minutes behind our schedule this morning, but I think we shall be able to make it up and finish on time.

The first paper under the heading of "Operation of Aircraft in Air Transport" will be one on "Control of Operations in Air Transport." This paper was to have been presented by Colonel Paul Henderson, vice-president of the National Air Transport. Due to the fact that he is unable to be present he has sent his assistant, Mr. Lester D. Seymour, who will present the paper for him.

Control of Aircraft in Air Transport Service

By PAUL HENDERSON

Vice-President, National Air Transport, Inc., Chicago

The control of aircraft in scheduled air transport services presents one outstanding requirement. That requirement may be translated into two words—"hard work."

This hard work is made up of a multiple of details. Some few of those details are interesting and obvious to the layman. The greater number, however, are uninteresting and may be catalogued as drudgery.

Surface vehicles—horse drawn, motor propelled, or those which run on rails,—will operate, perhaps not 100 per cent of their efficiency, but at least with some certain degree of success, with many minor things the matter with them. A leaky packing-box will not, unless it becomes very bad, stop a locomotive. One missing cylinder will not, of necessity, cause a motor truck to fail. One shoe off a truck

horse or a broken harness will not result in a horse-drawn vehicle being completely out of business.

Minor difficulties with aircraft and particularly with aircraft engines may result in 100 per cent failures. There are only two kinds of airplanes: Those in first class condition and those in bad condition. There are no airplanes in fairly good condition. Those that might be classed as fairly good must, from the point of view of Air Transport, be catalogued as unserviceable.

As a consequence, every little adjustment, every bolt and nut, every piece of fabric, every valve, valve spring, every bearing, every turnbuckle on an airplane must be exactly right before a scheduled trip is undertaken.

Because of the importance of small things the control of aircraft in air transport, if it is properly organized, becomes an intensive effort all directed at the job of making certain by frequent inspections and re-inspections, that every part of the ship is as it should be. These inspections must be carried on by men who know what they are about. Inspection by an uninformed inspector would be as bad as no inspection at all.

When the work of these inspectors indicates that repair work, adjustments or replacements are necessary, these must be done by mechanics of experience.

After every trip, no matter how short or how long that particular trip may be, each N.A.T. airplane is inspected in scores of essential details. These inspections are made by two men, each working independent of the other and each in a measure checked by the other. Inspection cards, listing the inspection and adjustments necessary, are used and when the job of inspection is completed, each of the inspectors signs the card and becomes responsible for the thoroughness with which the work has been done. It would be a mistake, I am sure, to attempt, in a paper like this, to try to cover the character of these inspection items. They cover the airplane from nose to tail.

Repairs on aircraft fall into two very definite groups. The first group might best be described as service repairs. The second group might be labeled overhaul repairs or periodical repairs.

Service repairs are those repairs which, because of minor accidents, general wear and tear, etc., are necessary from day to day to keep the airplanes in flying condition. The replacement of a broken or weak valve spring; the replacement of parts of the distributor head; the patching of a small piece of fabric on either wing or fuselage; the tightening up of a turnbuckle or the replacement of wires or struts all fall in the group properly labeled service repairs. The necessity for these repairs is brought about by the organized inspection previously discussed. Such repairs as these are made between runs. They are generally made in the hangars which are used for storage purposes between runs. They are made by mechanics who have a general knowledge not only of engines, but also of airplane construction. The prompt making of these service repairs postpones the necessity of making the more elaborate overhaul which, theoretically at least, occur at intervals of 150 to 300 hours, in the case of engines and in the case of aircraft themselves, at intervals varying upward from 500 hours. In the case of engine repairs, these periodical repair jobs or overhaul jobs, as they may be termed, consist of the complete disassembling of the unit, the accurate measuring of all of its component parts, the rejection of those which are worn beyond certain tolerances, a searching inspection for evidence of corrosion or change in the character of the metals and then a reassembling of these components with new parts to replace those rejected, which assembling really amounts to a job of motor building.

Two years ago it was thought that if Liberty motors could be torn down and rebuilt with sufficient thoroughness to insure their running from 25,000 to 35,000 miles without difficulty, that a good job had been accomplished. Today, due to the extreme accuracy of inspection and workmanship in the job of reassembling, and due to the substitution of a few parts, these same Liberty motors are serving

N.A.T. for an average of 75,000 miles between failures. (These figures are not to be confused with the time between overhauls which is from 150 to 200 hours.)

After aircraft engines have been used several hundred hours and have gone through one or more of these overhaul periods, it may be almost truthfully said that they lose their original identity. Cylinders from one engine may find themselves placed on another engine after the reassembling is completed. This practice requires absolute interchangeability of all aircraft engine parts. The fact that in N.A.T. we are able to do this work today on engines which were built over ten years ago, is certainly a tribute to the care and skill which was put into the building of these engines by the several manufacturers during the war, because, as is generally known, all Liberty engines are surplus war material. Each make of engine presents a different problem in the matter of tools for its disassembling and re-assembling. With this difference, the job of rebuilding one engine is much like the job of rebuilding another. In each case of engine rebuilding, inspection for worn parts, damaged parts, corroded parts, and chrystalized parts must be made with painstaking accuracy. Of course, after each engine is reassembled it is run for a few hours on a block. Accurate records are kept of the temperature of the motor, the speed of the engine, etc., in order to make certain that it has been reassembled properly. The continued doing and re-doing of this work of course develops little short-cuts and little tricks in both disassembly and reassembly, as well as in cleaning, which are short-cuts towards the end, which is, after all, the best engine possible with the least cost of labor and new materials.

The work of rebuilding or overhauling an airplane fuselage and the wings of an airplane may vary upward from the simple removal of the covering of the fuselage and wings, so that they may be thoroughly inspected, to the more complicated job of replacements of certain steel tubes in the fuselage and sometimes even ribs or spars in the wings. While the covers are off in this work, thorough inspection is made of all instrument control lines, wires, and small relatively unimportant "gadgets." Here again the mechanic doing the work must know his business. He must be able by visual inspection to determine whether deterioration has started in the tubes of the fuselage; whether or not the wooden ribs of the wings are good for another period of use or whether they should be replaced. The whole success or failure of the work depends upon the intelligence with which this man does his job.

Somebody has been quoted as saying that "There is a good deal more to aviation than flying." An hour or two spent around the repair base of the National Air Transport would convince anyone of the truth of this statement.

The actual flying of the airplanes, their dispatching, etc., is a relatively simple matter except for that part of the task entrusted to the pilot and no statement of mine can exaggerate the skill and intelligence necessary on the part of the pilots. They are sent off on their scheduled time except when the weather conditions make that impossible. They arrive on time or ahead of time or behind time, depending largely on the weather encountered enroute. Tail winds make for arrivals ahead of schedule. Head winds make for late arrivals. Fogs, snow storms and heavy rains result in delays and call upon every ounce of skill, courage and ability which the pilot has. The aim of every transport operator is to keep his flying equipment in such condition as will insure on time arrivals except for the unknown influence of the weather. In August just passed, in the flying of over 225,000 miles, N.A.T. ships adhered to the schedules set down for them with practically 100 per cent efficiency except where their flight was interfered with by wind or fog. In other words, we appear to have licked the mechanical job of schedule flying. We have gone a long way toward licking the weather, but still have an equally long or longer road to travel from that particular angle. A year from now I hope at a meeting of this chracter much progress may be reported in the matter of overcoming the obstacles brought about by rain, fog and snow.

This meeting is a "Safety" meeting. Every act of everybody seriously engaged in air transport is promoted by two things: (1) safety, (2) efficiency. How well we have been able to watch out for the safety of N.A.T. operations may be evidence by the statement that since May 12, 1926, N.A.T. airplanes have flown a total mileage approximating three million, and that we have had but two fatalities. Each of these fatal accidents was brought about by weather. Every indication is that in one instance either the pilot or the airplane was struck by lightning and the other—a very severe and unexpected late fall thunderstorm so confused one of our pilots as to result in his flying into the ground with his ship wide open. In each case the fatality was brought about by something over which neither the pilot or any of the personnel of the National Air Transport had any control whatever. Better weather reports might have prevented one of these accidents. I feel that nothing in the world could have prevented the other. However, 3,000,000 miles of scheduled flying, the greater part of it at night, with two fatalities is, I am sure at this stage of the development of this art, a commendable record from the point of view of safety.

CHAIRMAN MACCRACKEN: I am sure that the conference is very much indebted to Colonel Henderson and to Mr. Seymour.

We will now be very glad to have the paper discussed by any of you who are interested in doing so. May I suggest that the discussions confine themselves very much to the safety point of view in the operation and maintenance of aircraft in transport? That is the general heading of this subject and the thing that the discussion should point toward.

H. W. HEINRICH (Travelers Insurance Company, Hartford, Conn.): Mr. Seymour in his most interesting remarks refers to crystallization as a factor that enters into the inspection and the overhaul of the aircraft engines. I would be very much pleased to have him amplify, if he will, in regard to two phases of that particular point. One is whether or not crystallization has (I am referring to crystallization here as it relates to engine parts, all other incidentals of the engines are included) really been a factor of major importance in engine break-down. Second, whether the determination of crystallization in engine parts is still a matter of judgment and observation or whether some progress or development has been made in the way of a test to determine crystallization.

MR. SEYMOUR: The truth of the matter is that we have never had a failure that we could attribute to crystallization or metal fatigue. So far as I know, we have no way of mechanically determining when crystallization appears. What Colonel Henderson referred to was careful inspection rather than actual determination of crystallization. We have no record of it ever having occurred.

CHAIRMAN MACCRACKEN: Are there any other questions that you would like to ask of Mr. Seymour? Any discussion of the paper?

QUESTION: This question of weather control that he speaks of—

CHAIRMAN MACCRACKEN: Was there some particular question in connection with it?

QUESTION: Yes, the improvements they could suggest with reference to weather control.

MR. SEYMOUR: I don't know how successful anybody will be in controlling the weather. I think as time goes on, it will perhaps afford us an opportunity to make more use of the information that can be collected on the ground, because with the radio we can get the information to the pilot in the air, where it is most needed.

CHAIRMAN MACCRACKEN: I am sure that those who are interested in the insurance side of air transport are vitally interested in this particular subject. Perhaps we could get some comment from Mr. Brooks Parker.

MR. PARKER: Thank you for giving me the opportunity of saying that the experience of the National Air Transport and the Western Air Express and the work they have done toward safety, toward good housekeeping, toward the proper

operation and running of their air line, reflects itself steadily in the insurance rates, not only that they enjoy, but that all the operators enjoy. I congratulate them for the work they are doing, which is thoroughly constructive.

CHAIRMAN MACCRACKEN: While the conference, of course, is primarily interested in safety for the sake of safety itself, it doesn't hurt to stress sometimes a little more the economic advantages of safety. I wonder if Mr. Parker would enlarge upon that phase of it in connection with the insurance costs?

MR. PARKER: As applied to air transport particularly?

CHAIRMAN MACCRACKEN: Yes.

MR. PARKER: I will be glad to do that.

I was thinking over what would be of most interest to you people. Let us take the different forms of coverage—fire insurance. Your fire rate is governed largely by three things; your type of construction, which includes the hangar layout, the plan of it, which includes also the provisions which may be made for heating; the operation feature, which has to do with the fueling of the planes, the housekeeping and so forth; and the construction of the planes themselves. The position of a heating unit in relation to the hangar and the rest of the equipment has a very marked bearing.

Mr. Seymour is smiling, because he and I have had long and very painful sessions on the subject of what is the best way of heating a new hangar. We have come to agreement on everything and the effect is that the rates have come down very markedly.

In those hangars which are not properly heated, where an open stove or something like that is used, you can see yourself that there is constant danger of fire from gasoline fumes. A similar point is the tendency to heat hangars in any way they can. That is very important.

There are difficulties in starting, particularly air-cooled engines. They must be practically ready to go when the mail comes in. There have been ways worked out of heating airplane motors in hangars without increasing the rate. I would be glad to go into the detail of that, but I think it would take too much time. I will answer any questions that you have either inside or outside on that point. The fire insurance rates are entirely dependent upon the way in which a man runs his air line and the other factors that I mentioned.

In the operation of it, the fueling inside the hangar is extremely important. The larger the hangar the more concentration of airplanes, the more hazard. If there is a fueling arrangement inside, the underwriter immediately resists instead of trying to help you get the rate that you and your insured desire.

The fire insurance on the planes themselves: I have in mind one particular plane that had a 50 per cent decrease in its rates.

Tornado insurance: The operator should have his weather reports so that he can fly away from any tornados that seem to be coming along. Any attempts he makes in those directions will have a direct bearing on the insurance.

Public liability: If an operator is known to be a conservative, careful, business-like man, his rates will be reduced very markedly over the operator who is not so. On passenger lines, the safety factors that the operator works into his organization have a tremendous bearing. I can't stress that too much, because that liability is a very difficult form of insurance at the present time. Let us take the Western Air Express as an example. I was out there in August. I took a flight from Los Angeles to San Francisco and return. On one of those trips they had a full load. They took the precaution to ask one or two of the men in the ship to walk forward just a little bit so that the plane might be better balanced for the take-off.

In general, the use of safety belts has a bearing. If the men or passengers in the ship can be strapped in at the time of landing or taking-off, it reduces your rate. One underwriter told me the other day that he would make a big differential in the rate if they would do that. It does not cause resistance in the minds of

the passengers. He had seen that plan used in one line, which incidentally was the Western Air Express, and they all seemed to like it. The passengers felt that it was being done for their safety. It is things of that sort that help the insurance people. All the safety factors that you put around the operation of your airways are going to be reflected to you in your rates. If I can answer any questions, as I said before, either now or later, I will be happy to do so.

MR. SEYMOUR: I would like to ask Mr. Parker, if it is true that the Western Air Express uses safety belts in its passenger ships?

MR. PARKER: They are now using safety belts. They weren't being used when I rode in their planes. When this other man rode in one of their planes they were being used. That may be just the individual and the assistant pilot's way of running the ship. That may have been something that has been put in since this Puget Sound accident, because that happened after I was out there. The Puget Sound accident occurred in a plane of the British Columbia Airways.

CAPTAIN WILLOUGHBY: I had intended to say a few words about this terrible hazard that we have had for so many years past, that of fire. The machine would either get on fire in the air or in making a crashed landing, the gasoline would get loose on the top of the hot cylinder and the men would lose their lives.

In my nineteen years of building and flying airplanes (I am building my last one now near Philadelphia and hope to have her ready and in the air in two weeks) a good many of my friends have been killed, notably my dear old chum Steve MacGordon, who was stationed at Norfolk, Virginia. He was in the cockpit. He was making a crashed landing, at least the student behind him was making a landing. Immediately the gasoline was fired. In those generators, the gasoline tanks are only four inches from the hot cylinders. He breathed the flame and died in four hours. I have known of a great many accidents of that sort, notably in Europe and in this country.

From the very start, when I first began building airplanes in 1909—I assisted Wright in his first flight, and the next year I got all my patents out and got my first machine off the ground, the "War Hawk." Ever since then, I have always been particular about my gasoline tanks and their connection with the hot cylinders. I made up my mind from the start that gasoline should not be used under pressure. I believed from the very start in the gravity tanks, and invented my patent on safety gasoline tanks which I have put in all my machines ever since. I use two tanks, one on each side, well-distanced, so that I can reach that valve from my seat. There is very little head resistance. It is a narrow keel that goes right down. That keel answers besides carrying the gasoline to the carburetor in another way also. There is a certain amount of keel surface that is necessary. Years ago we used to put them out on the wings, as you know. That keel answers as a keel surface, which is necessary. The reason I object to gasoline under pressure is that you can't depend on a little fan, a little windmill to pump the gasoline up into your carburetor or into a small gravity tank. That little windmill may become clogged with ice or snow or something and it ceases to function. The pump at the dash is not always absolutely reliable. For these reasons I have always objected to using anything but the gravity tank.

A gentleman touched a few moments ago on the question of the safety belt. I was just going to say something about that myself, but the gentleman anticipated me and put the matter very forcibly before the meeting. The Navy safety belt is the best belt I have used. I believe in the use of the parachute with the land plane but not with the seaplane. With a seaplane, if you are landing in water, if you haven't a belt on, you are thrown out of the machine and invariably you will be drowned. But, if you have a belt on and you are at all a good swimmer and you have nothing around your body to catch in the wires—I have known several men that were drowned in seaplanes simply because they had a lot of life preserver stuff around them and they got tangled up in the wires and couldn't clear them-

performance. However, when these higher-performance airplanes were put into actual service in the field, the operators found additional weight was required to obtain economical operation. As a consequence, these models gradually became heavier until at the present time most of them do not equal and none exceeds the performance of the practical airplane originally referred to. Apparently, the lesson to be learned from this is that the lightest airplane with the best performance is not always best. On the contrary, additional weight in an airplane is desirable provided it is placed there for maintenance purposes and not as a result of poor design.

Presuming that the proper airplane and engine have been selected, it now becomes necessary to use equally as much care in the selection of personnel. From our limited experience it appears that proper inspection and maintenance can only be rendered by capable, experienced men. Since commercial air transport operation can only be carried on economically with the minimum of personnel, and since experienced men are rapidly becoming scarce with the sudden growth of commercial aviation, the commercial operator is at present faced with a serious problem. The greatest care must therefore be exercised in choosing men for the ground force charged with inspection and maintenance. Systematic methods and training must be developed by the commercial operator. A sense of responsibility in inspection and maintenance of equipment must be firmly implanted in each individual since the safety in flying rests largely on the shoulders of the ground force. Experience has proven that this same responsibility can be developed and maintained by requiring all personnel to take frequent flights, thus bringing them face to face with the entire problem. A few experienced, efficient employees have been found to be more desirable than cheaper ones in larger numbers.

The good results obtained in maintenance and inspection are in equal proportion to the conditions under which the personnel work. Even the most conscientious and thorough workman cannot deliver 100 per cent efficiency under bad working conditions. Proper facilities must be available for the work in hand. Convenient stockrooms, tool rooms, light, water, etc., must be provided. In cold climate, heated, well-ventilated hangars have been proven an absolute necessity. For hot weather conditions, fresh air and light are equally essential. Good sanitary facilities with adequate lockers and showers have proven an excellent investment. Cleanliness of equipment and hangars and shops is conducive to careful inspection and pride in workmanship.

After the proper airplane and engine have been selected, experienced personnel of the right type chosen, personnel organized with a definite responsibility from top to bottom of the organization, proper working conditions provided, our experience indicates that a carefully-prepared, written inspection form should be developed. The greatest care should be taken in the preparation of these inspection forms to cover all vital points of the airplane and engine. When a proper form has been decided upon, the inspectors must be impressed with the importance of adhering strictly to the form. It is believed highly desirable to have each point on the written form initialed by the man doing the work. In this way, should any trouble develop, responsibility can be quickly placed and if found the result of carelessness, severely dealt with. On the more important and vital parts of the airplane and engine it is believed desirable to exercise a double check. Since all inspection forms in use by our company are actually rechecked by the chief mechanic or crew chief, a triple check is therefore obtained of the more vital points. A completely detailed, written inspection form requires a longer period of time for inspection, and will therefore increase considerably the cost of inspection and maintenance, but our experience has certainly proved it to be worth while. Space on the inspection form for troubles that develop above and beyond the ordinary routine is necessary so that all work can be properly taken care of.

Careful, painstaking inspection and maintenance produces the reliability and safety that are demanded by the public. It is believed that accidents and losses are practically always the result of lack of care. Proper inspection and maintenance require a given amount of time. To reduce this time required reduces the safety and reliability which in the end will increase the cost.

It is well, therefore, to keep in mind the fact that enough airplanes and engines should be provided initially to insure sufficient time for proper maintenance and inspection. To give an example of this, in originally equipping our line, we purchased seven airplanes and three engines per ship, or a total of twenty-one engines. Daily two airplanes flew, two other airplanes were on the ground, completely checked and serviced, ready to go, and held in reserve, two other airplanes were arbitrarily marked "Out of Commission" and were undergoing inspection and repair. The seventh airplane was held out of the daily operation as an emergency measure, so that in the event of any major trouble developing in any of the six airplanes actually in operation, the system of one ship in the air and two on the ground would never be interfered with. The twenty-one engines were divided as follows: Seven in airplanes, seven completely overhauled and in reserve, ready to go, and seven in the shop, undergoing overhaul. Under this plan each airplane flew approximately only six hours out of each seventy-two and underwent inspection, repair and overhaul during the remainder of the time. Every effort was made to permit no airplane to leave the ground unless it was in first-class condition. This operation schedule produced very good results and proved economical in spite of the large initial investment, and in spite of the fact that the ships only flew six hours out of the seventy-two.

The equipment above referred to was the Douglass M-1 mail plane which was really the U. S. Army O-2 Observation plane converted into a mail plane. The engines referred to were the old reliable water-cooled Liberties. But with the advent of a commercial airplane designed specifically for commercial purposes and a reliable air-cooled engine, inspection and maintenance have been more than cut in half, thus reducing materially the number of reserve airplanes and engines required for a given operation.

It is believed very desirable for all operators to exchange information as to habitual and major inspection and maintenance difficulties. It is equally desirable that the operators work closely with the airplane designers and manufacturers in developing airplanes with good inspection and maintenance features. The same holds true between the operator and the airplane engine designers and manufacturers. From an inspection and maintenance point of view, the addition of extra weight in vital points of an airplane and engine is considered highly advisable in spite of the subsequent slight loss in performance.

The development of a closer relationship between operators, and between operators, designers, and manufacturers, combined with the development of an inspection and maintenance system that permits of no possible chance of human error, should make the airplane the finest and most reliable form of transportation ever developed.

CHAIRMAN MACCRACKEN: I think perhaps it might be courteous at least if we gave Colonel Hartney the first opportunity to comment upon this paper. He said he would like to do it from the floor instead of up here.

COLONEL HARTNEY: In the first place, that was an old trick of Moseley's, giving the sense of responsibility to the mechanic who made the inspection and looked after the maintenance. The mechanic likes to have that responsibility. If you will just give him the job with these forms that are not going over his head and see that he carries them out, he will really carry them out properly.

I want to tell you about the time out at Mitchel Field when Moseley was in

the Pulitzer race. He discovered that the mechanic had put the oil lead in the main bearing. He, however, won the Pulitzer race. When he was going after the mile record, evidently the oil wasn't going through, there was a suck instead of a pressure. The engine let go with a bang, but Moseley succeeded, as he always did; he was a lucky bird.

He stresses in his paper maintenance and inspection. He is absolutely right when he says that maintenance and inspection are very fundamental to safe operation. When he says that most accidents in the air can be traced to a lack of that, he knows what he is talking about.

MR. HUBBELL: I have been impressed with what has been said on the record of the National Air Transport Company in flying 3,000 miles with two fatalities. If that statement could be brought home to the American people with unmistakable emphasis, a great point would be gained in encouraging commercial aviation.

When we started flying two hundred and three hundred thousand miles, it was looked upon as a pretty fair record. The Army makes about five or six hundred thousand miles at the present time. The average of the whole country is near to a million miles. The Imperial Airways in three years has run nearly three million miles without a single fatality.

Something was said a while ago about crystallization. I have been in two forced landings, one in Vancouver Bay, when a bearing broke, due unquestionably to crystallization. The bearing caused a fire, which was quickly extinguished by a fire extinguisher while we were still in the air. The other was caused by a broken axle at Oregon. We hit a rock in landing and the axle was broken.

I have been impressed in my air travels to many airports by the care which is given to the overhaul. Air travel, in my opinion, is as safe as any form of transportation in this country. The accidents are caused in stunt flying and school flying. In the first six months of this year, we have killed four pilots in regular airway flying. We are flying twenty-five thousand miles a day. That is another thing that the public has to keep clearly in mind, that the formal flying, the standard flying, the regular passenger flying over established air routes is as safe a form of flying as any other means of transportation.

We are making wonderful progress in aviation. Every year the records are getting better. If that is the case, we owe it primarily to the Department of Commerce. In the few years you have been in the Department of Commerce, you have established a wonderful Department, charged with delicate tasks, that of harmonizing theoretical considerations of operations with the practical experience of men long in the flying business. There has been no needless red tape, no useless verbiage due to regulations. All the Department has done (so far as I know, and I am pretty well familiar with the facts) has had the endorsement of all those who are primarily responsible for the operation and maintenance of our air lines. What I would like to see is a like development in our State regulations. I wish that every State would adopt a statutory requirement that no pilot shall be allowed to fly a machine who has not a certificate, at least the equivalent of a certificate of authority that he is a pilot from the Department of Commerce, and that no one should be permitted to go up in the air without a certificate of reliability of structural strength and all that goes with it.

European nations are not ahead of us in this method, but behind, and European records carefully studied show no superior achievement in safety than our records show.

Our air transport managers throughout the country have the notion of safety so ground into their nature, so ground into their operations, that they are making creditable sacrifice of money and time and thought to secure the largest amount of flying without fatality, without accident and without injury.

I have been up in the air ninety times. I have had three or four forced landings. I haven't had any results yet. I am more than ever convinced that

flying under normal conditions as practiced in America at the present time, under the control of the Department of Commerce, is as safe a form of transportation to both pilots and passengers as any form of transportation that we carry on.

CHAIRMAN MACCRACKEN: Are there any others who wish to comment upon either of these papers?

MR. SEYMOUR: I would like to refer to a statement made by the gentleman who followed Brooks Parker. There may be too many insurance people here not to go a little farther into the fire problem. Almost all of the fires occur on the ground after crashes. In order to eliminate some of those fires, the Army advocates short exhaust stacks on the engines. Whether or not that is right, I don't know. If Colonel Pratt were here, I would like to hear him discuss that. Anyway, we use long stacks, and we have never had a fire after a crash. Perhaps that is due to our fuel system, which is entirely a mechanical pump pressure. I do want to say that we have never had any fires in the air and we have never had any after a crash on the ground. If I remember the statistics correctly from my Army experience, only one per cent of all the fires experienced with airplanes occurred in the air. I don't know any pilot that has any great fear of fire in the air. We take an extra precaution by packing Pyrene around so that it can be released instantly on pressure. These remarks are directed specifically so that those people who are interested in the room may know exactly what the situation is regarding fires in airplanes in commercial use.

COLONEL HARTNEY: If I might be pardoned for getting up again, I want to say that I absolutely agree with Mr. Seymour. I think that every fire in the air that ever occurred was due to one cause, and that was to a breaking of the fuel line. The last fire that we know of was Captain Courtney's plane coming across the ocean. In one way it was a blessing in disguise because it revealed that the ship can weather the ocean. He did not provide for vibration of his fuel line between those two major engines. You know what they are doing now, they are putting in as many vibrations as they can.

Take the Junker fires, for example. Every one was due to a broken fuel line. I think a reward should be given to anyone who knows of a fire that wasn't due to a fuel line. A fire after a crash is something different.

A. R. SMALL (Underwriters Laboratories, New York City): I am not such an expert in aviation as I might hope to be, but somebody will agree that I know something about the fire conditions. My first experience in the air was on a rebuilt Junker plane that Colonel Hartney just mentioned. I went up to see if it would burn again. I think the fires that occurred in those Junkers were due partly to poor design of the plumbing, too many rubber joints took care of the vibration. One other contributing factor was the poor design of the engine compartment so that gasoline could be retained in close proximity to the hot exhaust equipment.

Getting away from the real technical parts of aviation and aircraft design and getting down to the basic principles of fires, your real trouble in the crashes occur usually by the ignition of the fuel system. You must remember that the lot of aviation fuel is common to most other gasolines, and fuels will not ignite except in the presence of the spark or in being exposed to temperatures in excess of 500 degrees Fahrenheit. If it were possible to provide automatically a cutout at the time of a crash, practically all means of a spark would be eliminated, and I could be reasonably sure that no fire could happen in the case of a crash.

CAPTAIN WILLOUGHBY: The question of vibration has not been carefully attended to. They make a pipe directly connected and solid with the joint so close to the tank, and of course the vibration in time breaks that pipe line loose. The making of a rubber joint does not solve the problem. The rubber is partly soluble in gasoline. It would be ridiculous to put on one of rubber, it seems to me.

The way that I have always attached my pipes is this: Around the center I have always put a coil. That seems to solve the problem, because that coil prevents any undue vibration of the pipe or getting it loose from the solid joint where it attaches itself to the other part or member.

J. S. BRICKNELL: I will accept Colonel Hartney's reward. Five years ago in Army training, I had a fire in the air due to the following causes: I had a leaky carburetor in an A-B type engine. The wind blew a spark on to the hot exhaust manifold and the fire spread back to the carburetor. It was easily extinguished.

JOHN A. FLEMING: Are there any data on the difference between fires in air-cooled engines and fires in water-cooled engines?

CHAIRMAN MACCRACKEN: Can anybody answer that question?

MR. SEYMOUR: I personally was discussing with one of the officials of the company that manufactures air-cooled engines rather extensively last evening that very question. He told me that he didn't know of any fires that had ever occurred even following crashes with air-cooled engines; but unfortunately I was able to tell him of two that I knew of. There may have been others, but I could only think of two off hand.

MR. FLEMING: There has never been any in the air, has there?

CHAIRMAN MACCRACKEN: These have been right after crashes, not in the air.

I notice that one of the pilots of one of our first scheduled air transport routes is in the room and possibly something occurred to Mr. Miller in hearing these papers—he heard one of them, I believe, read—as to the changes that have taken place in maintenance and transport in air transport operations. Perhaps he can tell us of his experience in the early days that will be useful.

MR. MILLER: In the early days it was a one-man battle, you might say, in trying to interest people in aviation. The company that I have reference to is the Albany Airways that started operating out of New York. They had summer operations in New York and operated in the winter in the South. We had two or three bad crashes, and just discontinued operating on account of finances getting low.

As far as maintenance in the early days is concerned, we did not have the personnel that we have today. Also, we didn't take into consideration the factors that enter into the safety of carrying on aviation of the present time.

CHAIRMAN MACCRACKEN: There has been some suggestion that probably we could profit a good deal if we heard from somebody active in the military service at the present time. Is there anybody in the room who will undertake to give the conference the benefit of the experience gained in the military services on this question of maintenance and inspection of aircraft engines?

Apparently our military friends thought this was purely a commercial meeting. I notice that another of our insurance friends, rather a new one in the insurance field, has come in. He probably won't speak so much from his experience in the insurance field perhaps on this point as he will from his experiences as an inspector of aircraft engines. Mr. Jones! (He shakes his head, "no.") I once was able to give him orders.

MR. JONES: I don't know exactly what you want to hear about. I had a little experience with the Department of Commerce on inspection of aircraft engines. I have gone into all angles except the insurance end of it. As Mr. MacCracken just said, I am new in the insurance end of this game. I don't think I have anything to say at this time.

CHAIRMAN MACCRACKEN: Are there any others that would like to ask any questions or contribute something to this discussion? I am sure there isn't a more important subject dealing with safety of aircraft than the inspection and maintenance in our air transport operations. Dr. Hubbell in his remarks pointed out that in the air transport service during the first six months of this year they have made quite a remarkable record. I thought you might be interested to have

his statement supplemented by the fact that I think it was four per cent of the total accidents in aircraft engines occurred in scheduled air transport operations; the remainder was in other types of flying.

JOHN B. KOHLER (Chicago, Ill.): I am a railroad man, not an aviation man. I am just new at this game and I am trying to learn something about it. One thing that Mr. Moseley's paper brought out, I think, shouldn't be overlooked and should be given more emphasis, and that is the value of a complete system of reports with regard to records of inspection and maintenance. Railroad experience can't help but impress that on anyone who is interested in transportation work. There is nothing that can replace a full system of records on the matter of maintaining reliability of service. The point is so important that I think it should have full mention.

Another thing that Mr. Parker brought out—I don't know whether it was inadvertent or not—in his discussion was the fact that the use of safety belts might possibly have been left to the discretion of the pilots. I personally do believe that such matters as that can be left to the discretion of the individual.

BROOKS PARKER: May I say a word? I didn't attempt or didn't intend to create the impression that it was left to the discretion of the pilot. My point was that if they had the orders before that time there were certain pilots following them and others were not. From the experience I have had with the Western Air Express, I don't think that is the case. All their people follow their orders. I think it is probably a new ruling they have put through since I was there, since August.

MR. KOHLER: I thought the point should be cleared up.

MR. PARKER: I think the Western Air Express pilots do follow very carefully their instructions from the several inspections I have made of the line, not known to the pilots.

H. W. HEINRICH (Travelers Insurance Company, Hartford, Conn.): I would like to ask another question. It may not be quite pertinent to the two papers under discussion. I am interested in the use of parachutes, and the specific questions I have in mind are these: Is it the sentiment of the operators and pilots, at least those who are assembled here, that all pilots should be provided with parachutes, should wear them perhaps strapped to their back, and should the passengers be provided with parachutes? My second question is: Is it practicable to instruct passengers in the use of the parachute and to expect favorable results by such use?

CHAIRMAN MACCRACKEN: That is a question that is the subject of a conference that is going on now in another session. I don't think they have concluded that discussion as yet.

JOHN A. FLEMING: There is one note I would like to sound or emphasize that I think has been in the background here but has not been brought to the foreground, and that is the economic importance of what we call business interruptions. It is becoming recognized more and more in the general field of insurance, property insurance particularly. Probably the thing that holds back the completeness of the inspections in a good many cases is the cost of it. I am not speaking from experience. Very often the fact is lost sight of that the cost will usually be made up not only in reduced insurance premiums, as Mr. Parker has brought out, but in the long run by not having the plant out of commission for any length of time by disasters, such as fires or bad crashes or other catastrophes. We must not lose sight of that, I think, in aviation operation as well as in all other operations. We know of cases where they have had catastrophes and because of the keenness of competition in the immediate locality the firm was practically wiped out; although they have been financially sound, have been fully protected by insurance, that is, they have been fully compensated by the loss. But the fact that they do not maintain complete inspection service resulted in this immediate loss and resulted in the eventual wiping out of the company.

CHAIRMAN MACCRACKEN: I see that I was in error on that parachute question. It is going to be this afternoon. Major Hoffman, who is the inventor of the parachute that is used by the Army and the Navy is going to present a paper on that subject. I think it would probably be well if we didn't attempt to cover that in this session this morning.

Mr. Carroll, I wonder if you can't contribute something as a result of your National Advisory Committee work.

MR. CARROLL: I would like to stress one point that I think was finely brought out in Mr. Moseley's paper, and that is, that previous to this conference there has been considerable timidity on the part of the designers and manufacturers. The statement has been made rather fearlessly three times to my knowledge at different sessions of this conference, but Major Moseley's statement in regard to it is worthy of study on account of its source, that the operator prefers additional weight in his airplane providing it is put there not from poor design but to help the maintenance and inspection and repair. I think that that statement, augmented with the statement he makes, that even in view of sacrifice of the performance that they still prefer it is one of those things that many manufacturers should have mimeographed and put on everybody's desk in the factory. I think it is a remarkably good idea and it is particularly well brought out in Moseley's paper.

CHAIRMAN MACCRACKEN: I happened to be out on the field the other day when one of our men was checking up on a plane. I think it was about the eleventh plane that this particular factory had produced, and yet in that brief time, he said that he could inspect that plane in about half the time that it took to inspect plane number five or six, whichever it was.

Here comes Lieutenant Doolittle. We have been looking for you, Jim. You got just too close to the door to escape. This conference, as you probably know, has to do with the subject of the operation of aircraft and its maintenance and inspection therewith. While the papers have been presented by the men who are dealing with that subject in commercial air transport, we all felt that we ought to have some contribution from the Army.

LIEUT. DOOLITTLE: One of the gentlemen said that safety belts should be worn. I thoroughly agree with him on that. The use of parachutes, I don't think is so essential, because it would be very difficult in low altitudes to get all of the passengers out. But in 1921, when several Congressmen and Colonel Miller of the Army were killed, in an Eagle plane, it was caused undoubtedly by the fact that the chairs were loose in the plane and they did not have on safety belts. I think it is very important that the seats in transport planes should be made secure to the floor. The wearing of safety belts is very important in case of a minor crash.

CHAIRMAN MACCRACKEN: Any further discussion or questions?

MR. FLEMING: Do you bring out in the percentages the difference between a ship of a low center of gravity and a ship of a high center of gravity? The various type planes, of course, have various degrees of stability, according to the design. In relation to crashes, I think that there is less liability of crashes in planes of a low center of gravity than planes where the center of gravity is high.

CHAIRMAN MACCRACKEN: That is a question dealing primarily with the matter of design rather than of the operation of the plane. It really does not belong in this morning's discussion. The question you propound is one of design rather than of operation or maintenance.

Are there further questions?

I want to again express our appreciation not only to the National Safety Council for making these conferences possible but also to those who have taken part in the discussion this morning.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Weather Service

First National Aeronautical Safety Conference

Under Joint Auspices of

The Daniel Guggenheim Fund for the Promotion of Aeronautics and the National Safety Council

October 4 and 5, 1928

**PROFESSOR C. F. MARVIN, Chairman
Chief of Weather Bureau, Washington, D. C.**

The meeting of the Weather Service Session, Aviation Division, of the Seventeenth Annual Safety Congress was called to order at ten o'clock by the Chairman, Professor C. F. Marvin, Chief of Weather Bureau, Washington, D. C.

CHAIRMAN MARVIN: This session of safety in aviation in conjunction with the sessions of the National Safety Council marks a very important epoch in aviation. We are particularly concerned in this meeting with the method of meteorology in increasing safety in aviation, and we have two very important papers this morning; one of the objects of the session is to enlist as complete discussion of the papers as possible.

The first paper on the program is one by Dr. Carl Rossby, of the Daniel Guggenheim Fund for the Promotion of Aeronautics, on "Organization of Weather Service for Safe Flying on an Airway." Dr. Rossby has studied his subject very extensively and comes to this country from Sweden with an intimate acquaintance with meteorology as practiced in the Scandinavian countries. We shall be glad to hear what Dr. Rossby has to tell us in regard to his point of view on the organization of the weather service.

Organization of Weather Service for Safe Flying on an Airway

By PROF. CARL GUSTAF ROSSBY

Daniel Guggenheim Fund for the Promotion of Aeronautics, New York City

There are two misconceptions prevailing among a number of pilots and meteorologists which have somewhat retarded the development of an efficient meteorological service for the aid of safe flying.

Many pilots maintain that the weather reporting stations along the commercial airways have been established for their benefit and study, that the reports therefore should be given a character conforming with their own ideas and that the observation hours should be so arranged as to fit their particular flying schedule.

Meteorologists, on the other hand, have occasionally gone to the other extreme and maintained that the weather observations should be turned over to them for digestion and discussion; the finished product of this discussion could then be handed to the pilots in the form of airways weather summaries and forecasts.

At the end of a year devoted almost exclusively to discussions and conferences concerning meteorology and flying I have allowed myself to form certain opinions in this matter, which I, with your permission and patience, will attempt to set forth here.

It seems to me that in this case, as always, the truth is to be found somewhere between the two extreme viewpoints.

It is not difficult to see that the pilots' scheme would not work. Barring very short hops, every flight, to be undertaken with safety, requires a knowledge not only of conditions previous to the start of the flight, but also a guarantee that no radical or harmful changes will take place during the progress of the flight. Such a guarantee, if at all possible, can be furnished only by a trained meteorologist. It is true that a pilot starting out with reports of clear weather throughout his territory has, in most cases, an excellent chance of getting through while the good weather lasts. We must, however, remember that in most parts of the country and for more than half the year, flying has to go on with anything but ideal, clear weather conditions. Weeks at a time current reports will indicate that the ships can get through, but that already a slight change will be sufficient to close the airway. Especially is this true of mountain regions where a little sinking or lifting of an apparently innocent cloudbank is enough to close or open a mountain pass.

It is obvious that if air transportation is ever to be able to compete successfully with other modes of transportation, all these dubious flying days must be saved. No pilot can accomplish this saving without taking chances with his equipment and endangering the life of himself and of his passengers. Increasing competition between the various air transport companies, the necessity to keep, during the bad flying season, customers which have been acquired during the easily flyable summer months, will nevertheless force the pilot to do his utmost to get through. This is exactly where the weather man comes in to the picture: *only the experienced meteorologist knowing the weather conditions and knowing the pilots and planes with which he has to deal can accomplish a saving of flying days without giving up the primary condition of safety.*

It is equally easy to see that the other extreme would be unsatisfactory. We have at present five district forecast centers of the United States Weather Bureau, from which all the airways weather forecasts emanate. We have many thousand miles of commercial airways, touching probably every state in the Union. To give an adequate service, each of the five forecasters on duty a particular day will have to be able to describe accurately, for instance, the location and movement of all the principal cloud or fog banks in his district and to tell if the various mountain passes in his district will be open or closed to flying during the interval of time covered by the forecast. If we keep in mind that each district has an area comparable in size to that of England, France and Germany combined and that the airway work is just a small part of the forecasters' duty, the impossibility of this demand becomes apparent.

We are therefore led to assume that decentralization of the forecast work, detailed consideration of conditions in restricted areas and, whenever possible, personal contact between pilots and meteorologists are necessary features of a successful aeronautical meteorological service.

An acknowledgement of this latter viewpoint, which is by no means new, can be found in the fact that the Federal Government at a number of the more important municipal airports on commercial airways has established regular Weather Bureau Stations for the service of the air transport companies. Along

the more important of these air ways special air way weather reporting stations have been established, from which reports are sent to the Weather Bureau Stations at the terminals. It is this very gratifying development under the auspices of the Weather Bureau, and the Airways Division of the Department of Commerce, which shall here be made the subject of a more detailed discussion.

The airway weather reporting stations established by the Weather Bureau and the Department of Commerce are generally located on the airways themselves, and the report hours have been so arranged as to fit the schedules of the individual operators. In this respect the two government agencies have followed a practice which began with the Post Office Department, while the transcontinental air mail line was still operated by the government. As a result, the number of reports on many airways is very small and the time interval between them quite irregular. Naturally the pilots of the various commercial lines are quite anxious to fit the reports of the actual weather conditions as close as possible to the start of each flight, but this arrangement has several serious disadvantages which should be given full consideration.

Most of the airways are used by a single transport company engaged in regular scheduled flying, while the rest of the traffic over the same airway, by private planes or planes engaged in taxi or sightseeing service, may occur at any time of the day. Infrequent daily reports arranged to fit the few scheduled flights will therefore be of very limited value to this latter traffic. This is especially important to keep in mind in all discussions concerning flying on the Pacific Coast, where the number of privately owned planes is increasing by leaps and bounds, and municipal airports spring up by the dozen.

Even if the number of regular lines over a commercial airway should increase, the reports if arranged according to the present principles, would soon become crowded during certain hours of the day while at other periods no reports at all would be available.

Infrequent reports with irregular intervals are of very little value to the weatherman at the airport, when he sits down to the task of forming a clear picture of the weather changes in his territory. On the other hand, reports at regular, short, intervals, would help him to follow in detail and with great regularity the movements of the various phenomena which may affect flying in his part of the country. The importance of such a close touch with the weather can not be over estimated. I shall later show a few maps to better illustrate what can be gained by such a study. At present it may suffice to say that even if only a single ship flies over the airway every day, an adequate weather service for this ship would require the weather man to be in practically constant touch with the weather all through the day, much in the same way as if the traffic were twenty times as heavy.

The situation is in a way comparable with the one that arises when you want to forecast the weather for, say, the city of Washington, for the next day. To do so you need reports not only from Washington itself, but from a large area surrounding it and extending as far west as to the Mississippi, but once you have these reports you can without any great increase of cost forecast the weather for other adjacent localities like Baltimore, Pittsburgh and New York.

Thus it is almost as costly to organize a satisfactory weather service for one ship as for twenty, and this may explain why a new line, over a seldom flown territory, can not immediately expect a perfect weather service.

It is obvious that between the pilot's demand for weather reports fitting the individual flights and the meteorological demand for equally spaced report hours, there is a conflict which, if precautions are not taken, might even develop into potential source of trouble. It is well then, to see what has been done abroad to overlap this gap between the two viewpoints. In Germany, where the aeronautical meteorological development has reached a height unattained anywhere else, an arrangement has been made which aims to satisfy both parts.

The German meteorological service for airways protection is based upon a network of 65 first class stations, 32 of which are located at the principal flying fields. Each of these stations has at least two trained meteorologists and full instrumental equipment. The majority of stations in this net report at 5 a. m., 7 a. m., 9 a. m., 11 a. m., 2 p. m., 5 p. m., and a few at 2 a. m. The gap between 5 p. m. and 2 a. m. is due to the almost complete absence of night flying on the continent. In addition to the above report hours, the regular international stations, of which there are about 20 in Germany, report at 8 a. m., 2 p. m., and 7 p. m. In discussing these numbers, it should be kept in mind that all these stations are located in a country, about the size of California. The 32 stations at the principal flying fields are connected by a special cable and they are also equipped for regular pilot balloon observations.

The purpose of this net of first class stations is to enable the meteorologist to keep in touch with the weather developments on frequent local synoptic maps. These local maps are drawn at all of the 32 principal flying fields; a uniform set of symbols is used so that the pilots are able to read the maps without difficulty.

In addition to this first class net, there is another net of about 180 stations located along the various flying routes. These stations have only incomplete instrumental equipment and are manned by part time observers. Forty minutes before the scheduled departure of a plane from any terminal flying field, all the stations along the stretch to be flown take such special observations and send them in to the terminal for the benefit of the pilot.

Through this double arrangement an apparently very successful effort has been made to satisfy both pilots and meteorologists.

Turning our attention now to the location of the airway meteorological stations, we will find that the "single-string" type of distribution, although originally introduced to meet the immediate demands on the pilots' part likewise can be made subject to severe criticism. Flying conditions in southern and central California will serve as an excellent illustration.

California is at present far in the lead as far as number of airports is concerned. Even places of a few thousand inhabitants boast of their own municipal airports; these airports are not just open spaces but, on the contrary, often show a remarkable activity. Almost every town has a small flying school and a few privately owned planes. With this rapid growth of the number of plane owners and landing fields flying has necessarily assumed a zig-zag character, so that the actual flights, if projected on a map would form an almost uniform net extending from the high Sierras to the ocean. Many of the more prosperous towns, like San Jose, Monterey, Salinas, San Luis Obispo, and Santa Barbara are located in the coastal valleys and separated from the interior through mountain ranges which deeply affect weather conditions. It stands to reason then, that a single string of stations through the San Joaquin Valley, along the present commercial airway, will serve only a fraction of the traffic.

When we realize that it is the private plane owners and the numerous small flying schools that form the bulk of customers for the aircraft industry, it becomes evident that it is just as vital to the aircraft industry to secure a uniform meteorological protection of all aircraft as it is for the automobile industry to promote good roads.

But even the regular commercial lines are better served by a uniform network of meteorological stations, and this for various reasons. During the summer season the coast and the coastal valleys are frequently covered with high fog or stratus clouds, of oceanic origin. This fog forms or blows in during the afternoon or during the night and usually dissolves during the forenoon. In the winter time one or more of the inland valleys are often covered with a low radiation fog which may last for weeks at a time, virtually making impossible all flying in the particular valley where it occurs. To maintain efficiency in operations it is there-

fore necessary sometimes to fly in one valley, sometimes in another, in other words to maintain *alternative* courses. It is easy to multiply the number of examples of this need.

Southern California is separated from the San Joaquin Valley through the Tehachapi Range, through which there are two main passes. The highway from Bakersfield to Los Angeles goes through the Tejon Pass (through which also the lighted airway leads) and the Southern Pacific Railroad and the Santa Fe go through the Tehachapi pass. During the winter season this range is frequently covered with clouds, sometimes extending 14 to 15 thousand feet high, making

Figure 1.

flying on top impossible. These cloudbanks are usually due to disturbances off the California coast. Sometimes the clouds fill up and close the Tejon pass, but leave the Tehachapi pass open. To take advantage of this possibility to cross the ridge the planes have to leave the established airway and make a detour through the Mojave desert. Occasionally even the summer fog in southern California may extend as far north as to the ridge, completely covering the San Fernando and the Santa Clara River valleys. In those cases, Los Angeles planes bound for Bakersfield and San Francisco have to head southeast from Los Angeles, cross the San Bernardino Mountains at the Cajon Pass and then continue up through the Mojave desert and the Tehachapi pass to Bakersfield.

Finally, if all the mountain passes in southern California are closed by heavy cloud banks there is a possibility, at least for multimotored ships, to get through to San Francisco along the coast, although additional emergency fields would be needed on this route.

The principle of *alternative airways* means of course that the *airway weather* reporting stations should be distributed uniformly over an area rather than just along the main airway itself. In support of this demand we have cited the *net* like character of the actual flying and the necessity of serving all aircraft alike, regardless of whether it is engaged in scheduled flying or not, and finally the need for alternative courses of troublesome weather conditions.

However, even when in a certain territory, flying is confined to a single course, adequate protection is possible only with the aid of a network of weather reporting stations which completely surrounds the airway on all sides. This is easy to see from the fact that all stations on the airway itself may report favorable flying conditions, while fifty or one hundred miles to the side there may be a thunderstorm or a fog bank or a rainbelt which may drift across the course as a complete surprise to pilots who started out with reports of good weather. It is true that the present airway weather forecasts usually take care of the occurrence of such disturbing phenomena, but the observation material available for their preparation is so scanty as to necessarily make them somewhat vague. In the case of ordinary heat thunderstorms of the type that usually occur on summer afternoons, the airway forecast based upon the regular morning weather map will probably say, "thunderstorms in the afternoon and during the night." This may be a very good forecast, but the information contained therein is not detailed enough. Under the circumstances cited, if the airway stations themselves report favorable conditions, a great number of pilots will be inclined to go ahead regardless of the forecast. On the other hand, those heeding the forecast, may miss a perfectly good flying day since the thunderstorms may or may not cross the course. A dense local net with frequent report hours would by and by enable us to keep track of the individual thunderstorms, and thus to take full advantage of the good weather periods.

In order to better illustrate the intimate knowledge of weather conditions possible through dense local observation nets of the type here advocated, I have prepared a few lantern slides, some of which may be old acquaintances to my fellow meteorologists, but should be of a certain interest to the flying public.

Figure 1 and *figure 2* show the movement of a summer squall line of moderate intensity, extending over Denmark from the SE to the NW. This squall line is, as you see, accompanied by a very well defined rainbelt of almost constant width. The two maps, separated by a six hour interval, enable us to obtain a very good value for its velocity. If these two maps had been prepared before the war, before the meteorological stations in Europe were increased to many times their original number, it would have been extremely difficult to detect this squall line. The temperature difference between the air masses on both sides is not very great, and the change in wind direction could easily have been interpreted as a gradual change. It would simply have been speculation to connect the few stations reporting rain. However, the detailed analysis shows that we have a *continuous* narrow belt of rain, low ceiling, and poor visibility.

Exactly the same remarks hold for the next picture which shows the movement of a warm front rain, in other words a rainbelt along a line where cold air is displaced by a warm and moist air current. The detailed analysis has made it possible for us to recognize how distinct and well defined this rainbelt is.

Figure 4 shows a typical fog distribution in central California, a summer morning at 8 a. m. This map was prepared from the weather reporting stations organized by the Weather Bureau and the Daniel Guggenheim Fund in California last spring. Thirty-four stations were used in the preparation of this map, and it was possible to depict in detail the way the fog enters the various valleys.

Now a few words about the organization of this service. The two terminal stations are located at the Oakland Municipal Airport and at Vail Field on the southeast side of Los Angeles. These two stations were established by the Weather

Bureau and are manned by four and three men, respectively. They are fully equipped for pilot balloon work. The two terminals are connected by a telegraph printer line, provided by the Pacific Telephone and Telegraph Company. Two other printer sending and receiving sets are installed on the same line, at Fresno and at Bakersfield, both regular stops on the air mail line along the coast. There is one full time and one part time operator at each of these two places. The four stations Oakland, Fresno, Bakersfield and Los Angeles with the connecting printer line form the backbone of the service. These four stations collect reports from all other points by long distance telephone calls, arranged in sequences. Thus Oakland collects fifteen stations, Fresno three, Bakersfield four, and Los Angeles eight.

Figure 2.

The explanation of this seemingly uneven distribution of substations between the collecting points is trifold. In the first place, to get a clear picture of the fog in the San Francisco Bay District it was necessary to make the station net denser there than anywhere else. In the second place, big population centers like Oakland and Los Angeles necessarily have better telephone communications than the intermediate points. In the interest of efficiency they should therefore handle a larger share of the traffic than the rest of the stations. In the third place, some of the stations off the main airway, for instance San Luis Obispo, although geometrically closer to intermediate points on the airway itself, have direct telephone communications only with the terminal points.

Observations are made with ninety minute intervals six times daily, at 6.30 a. m., 8 a. m., 9.30 a. m., 11 a. m., 12.30 p. m., and 3.30 p. m. One report hour, 2 p. m.,

was for reasons of economy left out until the need for it becomes more apparent.

During the night the government observers on the airway report three times for the benefit of the two transport companies now carrying on regular night operations. There are two planes every night from Los Angeles to Oakland. Although these two companies naturally have to follow the lighted airway closely, it is evident, that their operations would benefit greatly if the whole net of stations were to report also at night, since this would help us to form a much better

Figure 3.

picture of the various slow moving fog belts which form the main obstacle to flying in this territory.

The airport situation in Los Angeles and around the Bay District is, as everybody knows, very complicated. Some transport companies are located at Oakland, others at Mills Field on the west side of the Bay. One or two more fields are in operation or being planned in the East Bay District. The Army uses its own field, Crissy Field, at the Golden Gate. Thus, in order to distribute the weather reports and forecasts as efficiently as possible, it was necessary to install printer receiving sets at Mills Field and at Crissy Field, connecting them with the Los Angeles-Oakland circuit. Another printer, both receiving and sending, has been installed in the San Francisco Weather Bureau office. Similar arrangements have been made in Los Angeles, where the operating companies use fields on different sides of the town. In installing these numerous printers we have attempted to keep down the number of sending and receiving sets and whenever possible use simple receiv-

ing sets. This was done in order to maintain discipline and avoid confusion on the printer line.

In this connection it should be mentioned that we have attempted to handle some of the dispatch messages for the transport companies on our printer line and apparently to their satisfaction. Departure and arrival of planes, number of passengers and express matters, gas and oil consumption, all of these matters are now reported over the printer line. These messages are sent by the Weather Bureau employees and it is understood, that weather reports have precedence over all other messages. Since the communication service is handled by the Weather Bureau itself there is no division of responsibility, and efficiency and discipline are therefore more easily maintained, than if two different departments had been involved.

Figure 4. Shaded section indicates typical distribution of high fog in central California. (Early morning.)

It will not be denied, however, that traffic may ultimately become so heavy, that it will be impossible for the Weather Bureau to handle it. It may then become necessary to make other arrangements, but I think it is safe to say that we have already given proof that an efficient weather service requires that the Weather Bureau should handle its own communications.

The weather reports are plotted on local synoptic charts, a few samples of which I shall circulate among you. As you see, no isobars or lines of equal pressure have been drawn, although they are the most outstanding feature of regular weather maps. The reason for this is that the pressure readings from the various stations are referred to the altitude of the individual stations rather than being reduced to sea level. This was done in order to make the barometer readings more useful to the pilots.

Each pilot in scheduled flying receives, before the take off, a typewritten form containing the flying weather forecast, the last report from the whole net of stations and also the latest upper air data. In addition, he is supposed to visit the Weather Bureau office and look over the local map. Some pilots take great interest

in the maps while others are more lukewarm. However, after one or two troublesome experiences they usually find their way into our office.

In addition to the two government pilot balloon stations at Oakland and Los Angeles, three more such stations have been installed at Hollister, Fresno and Lebec. Each one of these stations is manned by one full time observer, who also has a maximum allowance of \$25 a month to hire local assistance. Thus we believe that economy has been demonstrated.

These additional pilot balloon stations have proved to be very useful, since the ocean fogs often prevent Oakland and Los Angeles from making any upper air observations, while the interior is always clear during the summer season. In view of the fact that the operation of the big transport planes in use between Los Angeles and San Francisco costs between one and two dollars a minute, the time saved by the selection of the correct flying level from their upper air readings actually means hundreds of dollars a month to each company.

The selection of California for this experimental weather service has been criticized, since, as everybody knows, the climate in California is too perfect to demand any weather service at all. In the first place, this is somewhat of an exaggeration. On my first visit to San Francisco from Los Angeles, sometime last February, we had five consecutive days of low ceiling and rain or drizzle. I might add that in spite of this, I still regard San Francisco as the most charming place in the world. In the second place, an experiment of this type, to lead anywhere and to gain the attention and interest of the flying public, should be undertaken in a part of the country where the public is air-minded and the traffic is heavy enough to justify the expense. In the third place, by locating the service in California, we avoided competition with already established airway meteorological services.

I have been asked about the scientific results gained. The service started about the first of May, the first maps were drawn in the beginning of July. Thus, we have only had three months experience and it seems rather inhuman to expect any results after so short a period, falling entirely within the season when California weather is most noticeable by its absence. However, a clear picture of the flow and frequency of the ocean fog, and the slope of its ceiling from one valley to another has been gained. This picture could never have been gained in any other way. I am confident that the young men who now handle the work on the Coast, once having been accustomed to a detailed analysis of weather conditions, would feel very much at a loss, if they had to go back to the old type of service.

The cost of the whole organization is somewhere in the neighborhood of one hundred thousand dollars, which must be regarded as comparatively reasonable taking the amount of traffic into consideration. Then, it should be remembered that the terminal station at Oakland also serves the airways to Seattle and Chicago, while the Los Angeles station serves the Salt Lake City and the San Diego airways.

Sir Napier Shaw, the grand old man of British Meteorology, in the preface to his *Manual of Meteorology*, makes the statement: "The study of meteorology has always been dependent upon the extent to which the community felt itself unprotected against the weather." The world war illustrates this statement vividly, since it led to a multiplication of meteorological stations in central and northern Europe. The immediate scientific result of this increase of the number of stations was the foundation of what may be termed modern synoptic meteorology. Thus, according to Shaw, meteorologists have had to be content with such crops as they could raise in other people's fields. Twenty years from now, flying may be independent of weather. Why should we meteorologists throw away this, perhaps the last chance to raise a bumper crop in the field of aviation?

The viewpoint here argued, namely the need for dense local nets of weather reporting stations with frequent report hours, is by no means new. It was set forth very definitely last year by an informal committee on aeronautical meteorology which included representatives from the most interested government departments and the Daniel Guggenheim Fund. The same type of organization has been advocated by Major Blair of the Signal Corps Meteorological Service for many years as a result of his experiences during the world war. The California experiment, however, is the first attempt to put the theory into practice.

Discussion of Dr. Rossby's Paper

CHAIRMAN MARVIN: Dr. Rossby's interesting and important paper is now before you and I hope we will have some discussion of the points presented. There were several features in his remarks that pleased me, especially where he contrasted the airways of the European governments, the operating, and the flying courses, as compared with the airways over the Atlantic States that we are organizing and supporting in this country. The Weather Bureau, under the present status of the law, furnishes aviation, civil aviation, with meteorological aid and to enlist and insure its safety it has to work over all this area, and we have to spread it out a little to do that at the present time.

Dr. Rossby has given us an ideal picture of the organization of a standard airway and if it could be employed over the entire country it might be all that could be desired. In the mean time, however, any available means to permit such a wide attention and such a close comprehensive net work has the advantages represented in his program. We in the Weather Bureau are building up a system that comes as near this ideal and is as impartial to all the airways as seems practicable.

PROF. A. G. McADIE (Blue Hills Meteorological Observatory): I think Dr. Rossby's ideas are more interesting to me than to any other individual in the United States, because I lived out there for nineteen years, and in my day there was but one plant in California and that was the weather man's and he had the right of way over everything, because human welfare depended upon him. I have a young nephew today, a mere baby to my eyes, and he has been jumping from planes, coming down through the air six or seven thousand feet. He stepped off the plane into space, counted ten, and pulled the string, and the parachute did the rest. Times have changed.

In my day and generation the main thought was to stay in the plane and not step off, and I don't know yet whether I exactly like that idea. I see one good feature to it, and that is if all the old timers, and especially the professor, were to step off a plane, it might deter those who are better saved than we are. This boy is a captain of the Reserve Officers and to me is a mere child. He is only twenty-four, and he told me that the maximum age limit for those fellows in the air course is twenty-two.

Now there is very little to discuss in Dr. Rossby's paper. He has presented it as a very comprehensive view of the situation. I know the folks used to call me the "poet of the fog" and Los Angeles people said I was the only one who could make capital out of the Obispo fog. But those summer fogs are usually about three hundred meters in depth, so if you want you can fly in the north or south, outside the coast, and get over that low fog. These extend about thirty miles and in winter the fogs that come down there are very dense but not higher than ten meters. This sounds like exaggeration, but you can usually get out of those fogs by climbing up about twenty meters, and as Dr. Rossby says, the inability to get

above that low cover of fog is the one difficulty. It can best be done by putting out sounding rooms in stations on the hills. You have to get them out of that low land and put them on the hill tops where you can look down and see the whole thing spreading out.

C. G. ANDRUS (Hadley Airport, New Jersey): The Guggenheim Fund suggested that I comment on Dr. Rossby's paper and I would like to do so, not in a critical way, but in a very complimentary way.

I think the dense local net work is something we can use very well here in the East and the Western district. I think Dr. Rossby said that sometimes there is difficulty in getting the pilots interested in the procedure of getting weather reports, but there is no difficulty in interesting them here. The difficulty is not to fan it to too intense a heat. The local net work would satisfy that demand. This demand in the field falls into two results. One doesn't deal with safety. It deals with the way the mail will fly and whether passengers can be carried. It doesn't deal with safety, but the other feature does.

It is a matter of whether a plane leaving in fair weather will be liable to a successful termination of the trip. A recent example is a hurricane that devastated the greater part of the southeast of America and passed northward along our coast, and contrary to the usual course made a slight turn to the northeast, as it was advancing.

Watching the Progress of the Hurricane

At Hadley Field we watched its progress from the North, South, East and West. The night the airway at New York first began to be closed was the night the turn toward the northwest was first made known to us. It seemed to us during the day, by what we consider our closest net work, the New York to Cleveland part of the line, that the approach would be to the westward and at night we were faced with the question: If a pilot leaves with a tail wind, can he negotiate, with one thousand pounds of mail, a trip to Cleveland, four hundred miles away? He is assured of a successful landing at that point of the airway, or if the same is closed, or bids fair to be closed during the first quarter of the way, he can be notified before proceeding; but the situation was not absolutely certain, as it very seldom is. Well, that put us in a dilemma. The officer said that if I can't get to Cleveland I shall have gas enough to go on to Toledo the next big stop.

The question was one which we would have been able to decide at once had we had a dense local net work between New York and Chicago, but we hadn't, so we discouraged the pilot, in the main moved by questions of safety. It happened that he could have arrived at Toledo safely, but under the conditions, we were forced to discourage him. That is an example where a local net work would have helped us. We are not thinking of current questions. We are thinking of one life. When we get to carrying passengers we shall have to look at it from the standpoint of several lives.

The other point in Dr. Rossby's paper is this: I believe Dr. Rossby is going to find, when he is about fifty years old, that aviation will be just as dependent upon weather conditions as it is now.

CHAIRMAN MARVIN: The time is getting short and there is one more paper; it might be a good plan to reserve discussion until the close of the second paper. At this point I want to introduce Dr. Gregg. He is the man in charge of the Aviation Department of the Weather Bureau in Washington, and he is here this morning to give us his little story of weather and the pilots.

Meteorology as an Aid to Safe Flying

By WILLIS RAY GREGG

Assistant Chief, U. S. Weather Bureau, Department of Agriculture,
Washington, D. C.

The vital importance of an adequate weather service for aeronautics is no longer a subject for debate. It is universally recognized. Striking evidence of this fact comes in daily. Insistent requests—many of them in the form of demands—for more service are received with every mail from all parts of the country,—from the lowly hamlet as well as the mighty metropolis. Caustic are the comments when these truly air-minded people are told—as many of them must, under present conditions, be told—that no funds are available for granting their requests.

A leading air mail contractor is authority for the statement that all of the troubles experienced by his company in the course of a single year were directly or indirectly traceable to weather. And, more recently, the president of the Transcontinental Air Transport Co., has stated that, in the maintenance of schedules in the proposed rail and air service from coast to coast, "everything will depend on the weather."

Other testimony to the universal recognition of the need for weather service is the inauguration during the past two years, by the Government, of such detailed service as funds permit on all of the commercial airways; and, quite recently, the organization by the Guggenheim Fund of an experimental, very detailed and intensive, service between San Francisco and Los Angeles.

The importance of weather service for aeronautics may be considered from two points of view,—that of safety and that of efficiency. The latter will loom larger and larger as time goes on, but this National Congress is devoting its attention to *safety*, and this paper will therefore be confined to that phase of the subject. In it will be discussed briefly the following topics:

1. Present status of airway weather service.
2. Needed researches.
3. How the pilot can cooperate.
4. How the air transport operator can cooperate.

1. *Present Status.* Briefly stated, weather service for aeronautics, as now organized, may be said to be in the pioneer stage. We are trying out many different schemes. We hope and believe that some of them are along the right lines, but only time and experience can tell with certainty as to this.

Since 1926, when the Air Commerce Act was passed, service in greater or less detail, depending upon the amount of air traffic, has been organized along all of the commercial airways that have been established or recognized as such by the Department of Commerce. This new service is of course an extension of that already existing for the general public, which consists of twice-daily reports from all parts of the country and forecasts based thereon, these forecasts covering periods of 12 to 36 hours.

Although this service was very early found to be of a too general character to suit the needs of fliers, it did provide the groundwork or parent organization, and, as such, was capable of expansion at comparatively little additional cost. One of the first acts in making this expansion was to increase the number of what we may call "upper air" stations, that is, those at which observations are made of winds at flying levels. In all, there are now some 50 such stations, well distributed over the country, many of them being located at important points on the airways themselves.

Information regarding upper wind directions and velocities, although helpful in enabling the pilot to select the most favorable flying level, is not *vital* in the same degree as is similar information concerning conditions at the surface. It is this

latter information that determines whether or not any flight at all can be made. Fog, low-lying clouds, excessive rain, sleet or snow, severe thunderstorms and very poor visibility render flying hazardous and impracticable. Not always will this be so, but in the present state of the art it is. Therefore, particular attention is given to these conditions, not only at the upper air stations but also at numerous places where observations are confined to surface weather. In all, there are now approximately 150 stations, most of them on the airways, from which such reports are available, when needed. Naturally, the time when they are needed is just before the pilot begins his flight. Accordingly the reports are in general sent as short a time before the take-off as possible and still insure their receipt in time for use. Of course, the ideal system would be an exchange of reports all along an airway and from points on each side of it at frequent, regular intervals. But, at the present time, available funds do not permit this, and in some cases it is not yet justified, owing to the small amount of traffic that has thus far developed. However, there is now a three-hourly exchange of reports between the principal points on the New York-Chicago Airway, supplemented by special reports to fit the flight schedules from these and intermediate points on this airway. Moreover, as previously stated, an experimental service has been organized by the Guggenheim Fund between San Francisco and Los Angeles, and in this service frequent reports at regular intervals are interchanged between a large number of stations, both on and off the airway.

The reports themselves contain information regarding the general character of the weather, as clear, overcast, rain, snow, etc.; ceiling or height of low clouds; visibility; wind direction and velocity; temperature and pressure; and, when available, upper wind data. These reports go to the meteorologist who in many cases has his offices at the airport. They are used by him not only in giving out information concerning current conditions, but also as a basis for short-range airway forecasts for the following one to five or six hours, depending upon the length of the flight. The utility of these short-range forecasts is becoming increasingly evident. It is no exaggeration to say that, in the early days of flying, pilots in general paid comparatively little attention to forecasts, unless a very long flight was contemplated. For short trips current reports were deemed sufficient. Many experiences, however, some of them involving considerable hazard and a few of them resulting in accidents, have shown very clearly that a condition reported as existing at any given time may, and often does change decidedly in the course of so short a period as an hour or so. Accordingly, on nearly all airways, the current reports are now supplemented by forecasts of probable changes in existing conditions, with particular reference to type of weather, ceiling and visibility.

It should be distinctly understood that neither in the current reports nor in the forecasts does the meteorologist tell the pilots whether or not they should fly. His function is, and must always be, only to describe the weather itself and give his opinion as to what it will be in the next few hours, leaving to the pilot or to others in control of the airways operations the decision as to the favorableness or unfavorableness of that weather for flight. The wisdom of this policy is apparent when one considers that the appraisal of weather conditions in relation to flight is to a considerable extent a relative one, depending on the experience and temperament of the pilots, the type of aircraft and the character of the service. Some pilots do not hesitate to start out in weather that others regard as offering considerable risk. Again, a strong head wind is or is not serious, depending upon the speed and cruising radius of the craft that is to fly against it. Finally, greater caution should be exercised with a passenger-carrying than with a mail or express service. These considerations introduce uncertainties with which the meteorologist, with his usually limited flying experience, is not equipped to deal. He indeed has his own quite sufficient responsibility of saying what the weather *itself* will be.

In addition to the current reports and short range forecasts, the service to civil

aeronautics provides forecasts covering periods of 12 to 24 or more hours. These are the general forecasts, augmented to include upper winds. They are of necessity couched in more general terms than are the short period forecasts. In commercial aeronautics regular schedules must be maintained so far as possible. The operator wants to know today the likelihood of making a scheduled flight tomorrow. Particularly is this true in passenger-carrying service. If the probability is that no flight can be made or that there will be considerable delay, the prospective passenger can be informed and can then, if he so desires, make his trip by train or bus. It seems likely that these longer period forecasts will become more and more important as the service develops.

All of this service—current reports and forecasts alike—is of little use unless it provides up-to-the-minute information to those needing it. This type of service involves two requirements: First, close contact between pilot and meteorologist; second, prompt and dependable means of communication. For the former it has been found by experience that the most satisfactory arrangement is to have the weather service organized and furnished right at the place where the pilot starts on his flight. And that place of course is the airport. Not only does the pilot thus get the reports as soon as they are received but he also is able to discuss them with the meteorologist. This matter of personal contact looms larger day by day as a prerequisite for the best possible service. When the weather outlook is decidedly uncertain (and alas! there are many occasions of the sort to plague the meteorologist) it is tremendously helpful to the pilot just simply to talk the situation over with one who makes a special study of weather and its vagaries. It is now a regular part of the Government's policy to establish service at airports. This has been done in several cases and provides 24-hour service where flying is carried on both day and night. It will be extended to other important airports as the need develops and facilities permit.

But the meteorologist himself is handicapped unless he also receives promptly the reports from points along the airway and elsewhere on which he bases his bulletins and forecasts. And this means a dependable system of communications. Whatever the most satisfactory method may eventually prove to be—radio, telegraph, telephone, typewriter printer, or perhaps something unknown to us now, it will prove its adequacy for the purpose only by showing that it gets the information through more speedily and more dependably than does any other method. Very likely no one method will be used to the exclusion of all others, but one may be the principal, and the others auxiliary, means of communication. All types are at present in more or less general use in the service.

In addition to these ground communication systems there must be means of signalling to aircraft in flight. No matter how detailed a weather service, or how able the meteorologist, there will always be occasions (we hope their number will become progressively smaller) when conditions will unexpectedly change from favorable to unfavorable or vice versa after the flight has started. The pilot must then be warned,—by radio if the aircraft is suitably equipped; otherwise, by visual means. So-called panel signal systems are now being tried out at certain critical points in different parts of the country and much experimental work is also being conducted in developing suitable apparatus for ground to plane communication.

Such in brief is the present status of aeronautical meteorology, so far as its practical application is concerned. Although it is true that only a beginning has been made, it is believed that that beginning is along correct lines. If so, then future developments will be in the nature of marked extension rather than radical change. And that extension will include all sections of this country and its possessions.

2. *Research.* Much has been learned in the course of the past 100 years, concerning the general characteristics of the atmosphere. During the last 30 years our knowledge has been extended very considerably into the regions above the earth's

surface. The general structure of the atmosphere is fairly well known up to 20 miles, well above present-day flying levels. And yet it can truly be said that an almost unlimited field for research lies open before us. The surface has scarcely been scratched. We are not so much concerned with *general* characteristics. What we want to know more in detail are the special occurrences, many of them of small extent but of serious import to the flier.

Meteorological research has suffered greatly from indifference on the part of educational institutions and from the limited field available to those who might take it up as their life work. Happily the situation is materially improving. With the development of aeronautics there is a growing demand for thoroughly trained meteorologists. To meet this demand some of our leading colleges and universities are organizing courses in meteorology which will be of a grade similar to that of courses leading to degrees in other technical and scientific professions. It seems well, therefore, to consider some of the lines in which research is desirable as a means of increasing safety in flying. A few of the more pressing problems will be briefly discussed.

Visibility is the one great concern of the pilot. In proportion as it decreases his troubles increase. It reaches the vanishing point in dense fog. It is not for the meteorologist to try to get rid of fog. But he must study, in a detail that has never yet been attempted, the conditions that produce it and those that dissolve it. True, we have this knowledge in a general way now, but we can't apply it in individual cases. Otherwise, the forecasting of fog would now be a success; instead it is a failure, if we consider forecasting in anything like a specific way with regard to time and place.

Similar study should be made of the occurrence of haze which becomes at times and in some regions so dense as seriously to affect visibility.

Nearly all pilots ask first for information on two elements, visibility and ceiling. Low ceiling simply means that visibility is cut off except at levels which are dangerously low for flying. Studies should be made that will enable the meteorologist to forecast the formation of low clouds with a goodly degree of precision as to time and area. Probably for such forecasts information as to upper air temperature, humidity and wind will be necessary.

This leads to the subject of new and improved methods of procuring upper air data. At present our knowledge of wind conditions is derived for the most part from observations with small balloons, which can be used only in clear weather. There is urgent need of developing instrumental or other means for sounding the upper levels more or less continuously, and certainly at times when conditions are unfavorable or are becoming unfavorable.

This seems to be a requirement particularly in the forecasting of conditions favorable for the formation of ice on aircraft. In this connection it may be stated that a preliminary investigation of this subject will be made during the next few months.

Aside from fog, low ceiling and ice formation there are numerous subjects which are of less importance, but a better knowledge of which would nevertheless contribute very decidedly to greater safety in flying. Among them is the formation of the more or less violent disturbances, such as thunderstorms, line squalls, tornadoes, etc. These are usually not difficult to cope with, providing their occurrence is known, with a reasonable degree of precision, in advance. Much more needs to be known than at present is known concerning gustiness and vertical convection, both near the surface and at considerable heights. In fact, there is very little knowledge of the extent of vertical movements in the upper levels, such as those that were responsible for the destruction of the Shenandoah. Studies of this subject are of special concern in connection with the design and operation of lighter-than-air craft.

Finally, there is much work to be done along statistical lines. We have already gathered together an immense amount of data and we are adding to this supply daily. Most of this has been so compiled as to be quickly and conveniently available for study. There are many lines along which such study would be profitable. For example, an operating company must adopt a schedule that is as fast as possible and one that can be maintained a fairly large percentage of the time. There are two principal factors that determine what that schedule can be. One is the cruising speed of the aircraft employed and the other is the weather. The data concerning frequency of head and cross winds, fog, low clouds, heavy snow and sleet, etc., would determine what schedule could be kept, say 90 per cent of the time. Such studies have been made and published for two of the important airways. Data already available are sufficient for similar studies as to workable schedules for nearly *all* of the airways. Naturally, the results can not be used to predict schedule maintenance for a short period, such as a week or a month. But for periods of a year or longer they would be (and in the cases cited they have been) found to be very nearly accurate.

3. *How the Pilot Can Cooperate.* We have already stressed the value of close contact between pilot and meteorologist. Let it be said at once, and the statement is based upon abundant experience, that the benefit is by no means one-sided. The pilot, in his discussions with the meteorologist, gets help that is immediate and direct. He profits by it that day and is then through with it. But the meteorologist learns from the pilot, if the latter be a good observer, many things that enable him greatly to increase the value of his own service. For one thing he learns the pilot's viewpoint,—comes to know what he is most concerned about. In many cases in which the meteorologist is uncertain as to what the weather will be, the pilot tells him after the flight just what it was. This information often is available in no other way. The meteorologist finds out whether his prediction failed or succeeded, and is better equipped to handle the next similar case.

Oftentimes, moreover, a pilot brings in information which is of great aid to another pilot who is about to start in the opposite direction over the same route. This information supplements, in a most helpful way, the data obtained from other sources.

Accounts of experiences in particularly bad conditions, for example in a squall or while ice is forming, give the meteorologist valuable data not only for the day to day service but also for purposes of research.

In short, it appears that the pilot's contribution toward making the weather service play a dominant part in increasing the safety of flying will be more or less effective in proportion as he and the meteorologist discuss, frankly and sympathetically, their mutual problems. In this way each one profits and, more important, the safety and efficiency of flying are increased.

4. *How the Operator Can Cooperate.* In many respects it is the air transport operator who is most vitally interested in this whole matter of safety. He must be able to guarantee a reasonable degree of it in the service that he operates; otherwise, his ledger will very shortly show a balance on the wrong side. He knows full well that, every time a crash occurs and particularly every time a life is lost, the whole program of the development of commercial aeronautics suffers a setback, entirely out of proportion to the seriousness of that single accident. It is the operator, therefore, from whom we should expect to receive the most effective co-operation in helping to make the weather service do its share in increasing the safety of flying.

He can do this in several ways. For one thing, he can arrange to have the meteorologist accompany the company's pilots on some of their regular trips. Experience shows that in no other way does the meteorologist obtain so clear a grasp of the pilot's problems as through actual flights in the different types of weather in which flights must be made. Poor visibility and low ceiling are terms that

acquire a meaning then that they had not theretofore had. The two men learn, through these flights together, to talk a common language and can thus the more intelligently discuss their mutual problems.

The flights to which we have been referring are those in the operating company's regular schedule. Oftentimes, a pilot will start with less than a full load and it is then that provision might well be made for the meteorologist to go along. But, in addition, it is believed that *special* flights should be provided for during conditions of unusual interest. Such flights would not, as a rule, be cross-country, but would be made right at the airport, up to a certain desired height and down again. For example, suppose that conditions in late afternoon appear favorable for ice formation that night when a regular scheduled flight is to be made, but the meteorologist is uncertain because he doesn't know the temperature and humidity at flying levels. A short, special flight, 20 minutes in length perhaps, would secure these data and enable the meteorologist to tell with more certainty than he otherwise could whether or not a flight should be attempted. Occasional cooperation of this sort from the operator would, it is believed, contribute very decidedly at times to the safety of flying.

Finally, the operator can cooperate very effectively by instructing his pilots to give careful attention to the reports and forecasts that he receives from the meteorologist. He should also at all times be perfectly frank in his criticism of the service. If this service is not dependable, both the operator and the pilot owe it to themselves, to their patrons and to the Government to report that fact to headquarters in order that action can be taken to bring about improvement.

It is proper, and it is also a pleasure, at this point to say that cooperation on the part of the air transport companies' officials, pilots, operators and others, has been and is whole-hearted and most helpful. Probably more appreciative attention is given to the weather service than to any other feature of the aids provided by the Government. And in return the facilities of these companies, almost without exception, have been made available to the meteorologists, many of whom now make occasional flights without cost to themselves or the Government.

Summary and Conclusions. Meteorology can help make flying more safe in the following ways:

1. Through an intensification of the service already organized, so as to provide—
 - a. More frequent reports from a larger number of stations;
 - b. More frequent and accurate airway forecasts;
 - c. A prompt and dependable system of communications, including ground to plane.
2. Through research conducted by properly trained men in—
 - a. The conditions favorable for the formation and for the dissipation of fog, haze and low clouds;
 - b. The development of additional methods for making observations of upper air conditions in all types of weather;
 - c. The conditions favorable for the formation of ice on aircraft;
 - d. The conditions favorable for the development of gustiness, vertical movements and violent disturbances such as thunderstorms and line squalls;
 - e. Statistical data from which can be determined many useful facts, such as the approximate schedules that can be guaranteed for different parts of the country.
3. Through cooperation on the part of the pilot in—
 - a. Discussing frankly with the meteorologist the problems with which he has to deal;
 - b. Telling the meteorologist whether or not his forecasts are correct, and, if not, wherein they failed;
 - c. Describing to the meteorologist the conditions through which he passes that give him most concern.

4. Through cooperation on the part of the operator in—
 - a. Making suitable arrangements for the meteorologist to accompany the pilot in some of his regular flights;
 - b. Providing special flights during particularly interesting conditions;
 - c. Instructing the pilots to pay close attention to the weather reports and forecasts;
 - d. Criticizing frankly the service furnished, in order that it may be developed to the highest possible point of efficiency.

The Future. Those of us who believe thoroughly in the future of aeronautics, and the number is happily growing by leaps and bounds, foresee a development in the not distant future when it will occupy a prominent place in the commercial life of the nation, not supplanting but supplementing in a large way other types of transportation. This development means a similar expansion and intensification of weather service. Such a service is possible, but, to be most effective, it must have the whole-hearted support of pilots and operators, it must be made more nearly perfect through research, and it must be of the up-to-the-minute type through a fast and dependable system of communications. With such a service functioning on all of the airways, the hazards of flight which now unfortunately, and in large measure unjustifiably, loom large in the public consciousness will vanish, and aeronautics will truly "come into its own."

CHAIRMAN MARVIN: This is very comprehensive and this paper of Dr. Gregg's represents the best efforts of the government on meteorology. We should be glad to have the matter discussed. I have some written discussion here that has been sent me by some important persons who did not have the opportunity to attend this meeting, which I will touch on while you are waiting to collect your thoughts. It will not be possible to read the discussion in full as the hour is getting late.

Captain Hingsburg who is the officer of the Department of Commerce responsible for the maintenance of communication and other functions of the civil airways, has written a rather lengthy paper. He says that an adequate weather service and communication system, in addition to aids to navigation along the airway are essential for the full development of a dependable and safe air transportation system. He believes that radio-range beacons are essential to guide airplanes over the lighted route when the lights are not visible one from another. He discusses the present weather communication systems, and another topic is the radio telephone communications.

Also he tells us that an entire new system of weather communications service is under consideration to develop the greatest utility from the new radio telephone facilities now available, and it is proposed to introduce this system on the Transcontinental Airway, using the stations now under construction. This system promises the degree of safety required by air transportation on a basis that permits unlimited traffic. Timely and accurate weather and landing conditions will be made available to any airplane, airport, landing field, or individual, that cares to tune in. The information will be broadcast on hourly schedules. Any airplane equipped with a radio receiver similar to the apparatus installed for the reception of radio-range signals will receive weather information at any point within the sector. This is very desirable.

This development along these lines is going on in the Department of Commerce and the meteorological part in the Weather Bureau and I think we can look forward to some very important improvements.

Now, by way of discussion in writing, Major Blair of the Signal Corps, a prominent meteorologist has submitted quite a paper here. I just want to touch on a few of the things. In this paper he declares that he is afraid that in our zeal for meteorology in the service of aviation, we may perhaps over-emphasize this particular phase of meteorology and so to some extent defeat our purpose. This

is a different side of the picture, but he also believes that it is essential that the entire field of meteorology be developed and extended to include aviation rather than that a special organization for the service of aviation be built up. He says he has tried to give his ideas in a paper which he read before the American Philosophical Society last April, and of which he incloses a copy. This paper is being printed and there will be a limited number of re-prints for distribution some time in the future. What he has indicated as a possibility in the field of meteorology has already taken place in the field of communications. We have legislated and done already many things in radio without reference to communications in general. Radio as a means of communication has its place along with wire and other means of communication and mistakes are likely to be made when we take it out of its place and attempt to give it independent consideration as has been done during the last year or two.

Major Blair says here: "In connection with the paper on the subject of 'Safety of the Airship and the Airplane for Trans-oceanic Operation,' as Army representative on the Policy and other committees preparing for American participation in the 1929 conference on 'Safety of Life at Sea,' I have tried to bring into that conference the consideration of safety of persons in aircraft at sea. The Army Air Corps and the Bureau of Aeronautics of the Department of Commerce are both favorable to having the conference consider safety of aircraft at sea. So far the shipping people have not been favorable to the matter. This seems to me unfortunate because in two of the three sub-committees organized to prepare for the conference, namely, the committees on Navigation and Communication, the problems of aircraft and seacraft are almost identical. The Ship Construction Committee can of course consider only construction of water craft, but a fourth committee on types and construction of aircraft for trans-oceanic flying could easily be organized and would be the only additional committee needed to give the entire subject of safety of crews and passengers of aircraft as well as those of watercraft at sea complete consideration. Separate consideration of air and water craft in this connection has been proposed, and this appears to me a waste of time since there is so much in common in the safety of these craft at sea. The craft are mutually interdependent as far as their safety at sea is concerned and must ultimately have a common organization for this purpose. If you are interested in the subject we might go farther with it by way of securing its consideration at the forthcoming International Conference."

Major Blair has written another comment here on the safety of the balloon. The protection of the balloon in an electric storm is the subject of the comment. These comments all cover a little wider field than the papers presented this morning, but they all relate to great questions of safety in aviation. This memorandum is as follows:—

Protection of Balloon Equipment and Personnel in Electric Storms

1. Without going at length into the underlying theory, I am convinced that the safety of a free balloon in the air during thunder storm conditions would be greatly increased if the entire surface of the balloon were made conductive and this conducting surface bonded with conducting gas in the interior of the balloon as well as with the basket. If a radio set is carried in the basket there should be a flameproof grounding switch so that the antenna may be grounded direct to the conducting system formed by the balloon and the basket. For safety this switch should be closed except when the set is operating. The set should not be operated when the balloon is passing through a thunder storm and if practicable the antenna should be reeled in. Whether the antenna is reeled in or not the grounding switch should be closed during the storm. A loop antenna is more foolproof than a trailing antenna but either type should be safe if properly handled.

2. The above arrangement insures that the entire system is at the same potential except when under the influence of some exterior inducing charge. In order to facilitate the escape of an induced charge, in other words to facilitate the reduction of the potential difference between the balloon and the surrounding air at any time, a great number of points should be distributed over the conducting surface of the balloon and basket. A conducting net with frequent connections from the outside to the inside of the balloon, as well as to the basket, will probably answer the purpose for a conducting balloon surface.

3. In case the balloon and its equipment cannot be properly bonded, or as an additional precaution for the safety of the personnel, the latter should wear electrically conducting outside garments. If the helmet or head cover is not an integral part of the conducting garment, it also should be conducting and be bonded to the garment in such a manner as to provide an electrically conducting protection from head to foot inclusive. This garment furnishes electrical protection to the balloonist in precisely the same way as the bonding described in paragraphs 1 and 2 protects the balloon and its equipment.

(Signed)

WM. R. BLAIR,
Major, Signal Corps.

We are looking forward to trans-oceanic flights. There are three huge ships ready to start in a short time. The United States may be visited in the near future by one at least. I have submitted these papers from the gentlemen who have not been here and they will be incorporated as a part of the record of our discussion. Now let me enlist once more the open discussion of the paper by Dr. Gregg.

Before this, if you will permit me a moment I would like to inject another thought here. You are well aware that thunder storms are one of the menaces that the pilots have to face, and there has just recently appeared in the Monthly Weather Review an article concerning the upper rush of the air. It did not say anything about lightning, but it spoke of hail. We have affidavits in the weather bureau telling where perfectly enormous hail-stones fell this summer and Dr. Humphries of the weather bureau has computed the uprush of the air necessary to sustain these hail-stones. Some were seventeen inches in circumference, I have forgotten the weight. However, the density of the hail-stones was five times that of pure water. This is half the density of the solids. I think it is without saying that we must teach the airships and the airplanes to keep away from any portion of the atmosphere in which that is going on. The safety consists in turning tail and running as fast as possible.

PROFESSOR A. G. McADIE (Blue Hills Meteorological Observatory): That is a very proper attitude. One of the most important things we can do is to get some way of finding out when, and where and how intense these things are, these currents of the storm. I mean the thunder storm. And it is just as Dr. Gregg says. Then I was also glad to get a copy of the Monthly Weather Review with the very interesting article that was just mentioned. It may interest you to know that we have a record on the oscillograph of a lightning wave. The wave electrically induced on the transmission light rose to its maximum in about five micro-seconds. Then gradually it decreased to zero in about forty micro-seconds. This machine and this measure gives the exact time required for a cloud to discharge. The result is zero and the charge is non-oscillatory. I thought that this would be of interest to you.

CHAIRMAN MARVIN: This is very interesting. Is there any other discussion?

DR. GREGG: May I speak for just a moment on the subject of vertical movements. Just before I left Washington a report came in from an airport in Illinois from a pilot who had gone out two or three days previously in the face of a forecast of thunder showers. But since it was day time he thought that he could at

least get around it. Unfortunately the visibility decreased and presently he got with the thunder storm itself. He very soon turned around and headed back to airport for the reason that he found a condition that indicated an upward rush of air, almost of thirty-nine meters. His altimeter showed an altitude change in the course of twenty seconds that indicated that the upper rush of air was at the rate of eighty miles per hour.

Another case, indicating that a tremendous velocity of air that is experienced, or that occurs, in the midst of a thunder storm, was that of a pilot who was in a thunder storm and was unable to control his plane at all. Finally in desperation he turned it straight down with full power, which means that he was going about one hundred and ten miles an hour. Nevertheless, his altimeter showed that he was going up. Those are two authentic cases that have occurred just recently and are on the subject.

CHAIRMAN MARVIN: You know the theory of these hail-stones that are formed in a storm is that the wind and the rain and ice are mixed and carried up where the temperature is low, this makes them move up and down and form into great huge hail-stones. These are supported from falling by the up-rush of air and the currents must be from one to two hundred miles per hour. It is this condition of the upper air which the airships must keep out of, the currents especially. Is there any further discussion?

Well then, I think that this meeting will come to a close, and I think that the records of this meeting are a very important contribution to the work of the whole National Safety Council.

Comments Upon Professor Rossby's Paper

By J. E. WOODMAN
New York University, New York

Professor Rossby's paper presents so many points of importance and interest that it is difficult to resist the temptation to comment upon several. There is one, however, upon which I feel inclined to differ from the author. That is in his optimism regarding the degree in which the aviator of the future will be independent of the weather. If measurable independence is attained, it will result from two causes. One of these will be in aircraft development; the other in such increase in knowledge of the atmosphere as will enable us to draw more general and more accurate conclusions as to the behavior of the air aloft from its characteristics at the land surface. To many of us it seems unlikely that the first will ever become quite independent of the second.

Man's "conquest of Nature" consists in adapting his actions to her laws. We cannot break them with impunity; we seldom dare even to bend them. In transportation, as in other lines of activity, we are still more or less bound by natural conditions in spite of the power of our machinery and the skill of its operators. Our automobiles have attained a high degree of efficiency; but there are road grades still too steep for them, snow drifts that cannot be surmounted, and fogs that headlights cannot penetrate. Our locomotives possess great power; but snow and fog still disrupt train schedules, and floods and landslides bury tracks beyond use. Our steamships usually go where they will on the oceans; but icebergs, fog, gales, typhoons and currents are still determining factors in their movements. The Weather Bureau stations of such ports as New York practically control the local movement of shipping at many critical times each year. Finally, for permanent operations we still use different tracks across the oceans for full-powered and low-powered steamers.

If, in spite of the power and efficiency already attained by the vehicles of transportation on land and sea, we still are circumscribed somewhat by weather and climatic factors, is it not reasonable to believe that aircraft, whether heavier than air or lighter, will at least for a long and indefinite time be influenced in their movements by the exceedingly mobile medium through which they fly?

Looking forward to increased efficiency in aircraft design and operation, and to increased knowledge of atmospheric and greatly enhanced ability in forecasting at long range and aloft, certain trends seem probable. First, aircraft will continue to differ in size and power, just as automobiles and steamers do; and it is highly probable that the small ones will outnumber the large, and that they will be called upon to bear the chief burden of passenger and limited load traffic. This implies continued differences in degree of weather dependence, but not its complete elimination. Second, there will always be portions of the world where stability of atmospheric characteristics will contribute to ease of flying and of planning flights, and where "weather" need be considered but slightly. Conversely, there will always be other and large portions of the world where atmospheric variability will cause diversity of flying problems; and there will always be seasons of greater and of less disturbance of the normal primary circulation of the air, both below and aloft—for considerable distances. A fair illustration is the half-dozen areas of tropical cyclone storms and their seasons.

In other words, in different parts of the world, for different seasons and for different types, sizes and powers of aircraft, different atmospheric problems confront the flier; and it seems unreasonable to expect complete independence of these problems to be attained by any flying devices now known.

All this implies the necessity of increasing our studies and experiments in aeronautical meteorology, not decreasing them in the near or distant future. Granted, if desired, that the time may come when an airship *can* go anywhere at any time; commercial considerations are certain to dictate that the flying will be done along the routes and at the times that will result in greatest efficiency—that is, the greatest productiveness possible with minimum time and cost commensurate with maximum safety and dependability. The meteorologist, whether theoretical or practical, will not be thrown into the discard at any time by those interested in practical and efficient aviation!

Comment Upon Dr. Gregg's Paper

Dr. Gregg, following Professor Rossby's description of the special work in California, not only shows clearly the structure of the daily studies being made by the Weather Bureau in the interests of American aviation, but raises in my own mind a serious question as to the adequacy of those studies for the ends sought. The desirability of an expansion of this work was hinted in the paper, with mention of the need of more attention to the upper air. It is along this line that I should like to add a few words.

With all the aids to weather forecasting now available through the splendid, if undermanned and underpaid, work of the Weather Bureau observers, serious study of upper-air conditions simultaneous and co-extensive with observed and known ground conditions, has lagged behind. In other words, we have quite insufficient knowledge of the real *structure* of atmospheric disturbances. This is due largely to difficulties in securing and using a sufficient number of self-recording instruments attached to balloons and kites, to the scarcity of stations at which such observations can be made, and to the resultant lack of correlation between these and critical or characteristic lower-air phenomena. In considerable measure, however, certain observations have been seriously hampered by loss of visibility above cloud ceilings, or in fog, where movements of a balloon cannot be

traced. With all these handicaps we know far too little about what is taking place at times in the upper air, and we are not likely to increase this knowledge much with the means now at command.

One of the outstanding needs in aeronautical meteorology is a full series of observations, made at regular and frequent intervals above selected Weather Bureau stations, and maintained for a considerable length of time. These are designed to acquaint us with the conditions at different elevations above the ground-station, during the variations of weather marking the passage of alternate high and low pressure areas. The study of such an accumulation of data, from a sufficient number of properly situated stations, will acquaint us better with the atmospheric peculiarities aloft that accompany known variations below. And with the growth of a competent body of upper-air facts studied and plotted in their proper relationship to the daily weather map, we should reach a point where we can forecast to a degree of accuracy not now obtainable, the probable conditions of wind velocity, direction and steadiness, of humidity and precipitation, visibility, etc., likely to accompany any ordinary cyclonic or anticyclonic disturbances in the different seasons. The value of this is self-evident.

Such observations cannot be made by means used heretofore. It will be necessary to employ laboratory planes, capable of attaining considerable altitude rapidly, equipped with the necessary self-recording instruments, and sent up at regular and frequent intervals day after day and week after week from the chosen stations. Such studies are not within the financial possibilities of the Weather Bureau, and must be carried on, if at all, by a privately endowed research. But the results in a few years would be worth the considerable cost, and the value to commercial aviation, in increasing efficiency and safety of flights along fixed routes, would be incalculable.

Comment on Papers of Professor Rossby and Dr. Gregg

By F. W. REICHELDERFER
Lieutenant, U. S. Navy

I am greatly interested in both papers. They reveal a progress in the appreciation of the needs of an aviation weather service which is promising after these many years.

I do not have much comment about Dr. Rossby's paper. The California service represents as close an approximation to the ideal service as we have ever had in the United States. For that reason it is more or less epochal. If it proves its value, as I feel sure it will, it should receive the hearty support of the operators and other "consumers" to the end that Congress will provide funds not only for its continuation but for its duplication over other airways. In addition to its day to day practical value, it represents real possibilities in fog studies which will disclose more about fog formation and persistence and point the way to better fog forecasts.

Dr. Rossby's last paragraph overlooks the weather "nets" which the Army and Navy have operated over the most heavily travelled eastern airways for several years. True, they were *abbreviated* in comparison with the California organization, but they were the same in principle, as distinguished from the old Weather Bureau service organized on the basis of centralized forecasting centers.

Dr. Gregg's paper shows what decided progress the Weather Bureau has made in becoming air-minded. For a long time we have stressed the importance of this. A paper, read before the American Meteorological Society in 1925, emphasized

the necessity for local forecasts in detail, contact with the pilots, and other points as Dr. Gregg has done in this paper. Dr. Gregg states that the decision as to the favorableness or unfavorableness of the weather must be left to the operators. This may be an administrative necessity for civil airways. However, it puts the forecaster at a disadvantage at the same time that it relieves him of some responsibility. Frequently, weather conditions cannot be adequately described without the qualification, "Unfavorable," or "Dangerous," etc. Word description in the abstract often fails to convey to the pilot or operator, the condition in the mind of the aerologist. The latter is, after all, a technical adviser, and as such, should be in position to advise as to what he thinks is the best action under the circumstances.

Personal contact between the weather forecaster and the pilots is vital. Experience is the best proof of this need. The Weather Bureau's experience during the last year or two has convinced that Bureau of this fact. The forecaster must know operating conditions, and the operator must have personal confidence in the forecaster.

Dr. Gregg has mentioned the importance of the longer forecast in the development of passenger traffic. At present, operators are interested largely in the "duration of flight" forecast, as distinguished from the twenty-four to thirty-six hour forecast which may be called the "planning" forecast. The latter will certainly become of great importance as traffic increases. As you know, it is of much importance to the Navy. In order to improve the "planning" forecast, we need more weather maps daily, and especially, an earlier weather map in the morning which will permit the preparation of a fresh thirty-six hour forecast at six or seven in the morning, at the beginning of the working day, instead of at 9:30 or 10:00 a. m. as at present. Europe has these facilities now. We need them.

Dr. Gregg's remarks on cooperation between operators, pilots and aerologists are timely. His outline of needed research shows how much there is to be done to get the weather service in step with what is absolute necessity to successful and widespread commercial flying.

I have found both papers particularly interesting because, as you know, they cover things which we have been "harping on" for years, and many of the points which are emphasized are included in the program, or outline, which we sent to the Fund a year or two ago.

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

The Public and Flying

First National Aeronautical Safety Conference

Under Joint Auspices of

*The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council*

October 4 and 5, 1928

WILLIAM MAYO, Chairman

Chief Engineer, Ford Motor Company, Ford Airport, Dearborn, Mich.

The Public and Flying Session of the Aircraft Division of the Seventeenth Annual Safety Congress was called to order at ten-fifteen o'clock by the Acting Chairman, J. H. Doolittle, Daniel Guggenheim Fund for the Promotion of Aeronautics, New York.

CHAIRMAN DOOLITTLE: Mr. Mayo, Chief Engineer, Ford Motor Company, was to be here this morning, but has not as yet arrived. I think it advisable that we start the meeting and let him take it over when he comes in.

HARRY F. GUGGENHEIM: Can we interrupt you for just a moment, Colonel? Mr. Mayo has just arrived, and I know we will be very interested to have him preside at this meeting. Mr. Mayo, Chief Engineer of the Ford Company, needs no introduction to this audience. This particular subject, "The Public and Flying," is one in which he is admirably capable of presiding over. I think we are all indebted to Mr. Ford for making the public realize that flying is the coming means of transportation.

I take pleasure in introducing Mr. Mayo! (Mr. Mayo took the chair.)

Private Flying and Ownership

By **SHERMAN M. FAIRCHILD**

President, Fairchild Airplane Manufacturing Corporation, New York City

In any discussion of safety in aviation the private owner must be considered also. Opinions regarding the future of private ownership of airplanes have ranged all the way from abject pessimism to unqualified optimism. On one hand we have had those who held that the sale of airplanes to private owners had no future and that the airplane was exclusively a commercial vehicle. On the other hand we have had those who regarded aviation as another automobile business, and who therefore expect the whole development to come from sales to private owners. Most probably the true prediction will be found to be somewhere

between these two extremes, for while the airplane as a whole is *primarily* a vehicle of transportation, certain types fit themselves excellently into the picture of sport.

Interesting the Prospective Private Owner

First interest of the prospective private owner is almost invariably aroused by a flight in some one else's airplane. It may be simply a business trip on one of the air transport routes or it may be a pleasure trip in a "ship" owned by some friend. But, in either case, interest in flying is aroused once the first flight is made. The exhilaration of this trip usually shatters many preconceived notions about flying and stirs the ambition of the passenger to learn more about it. If he is one of the increasing number of those who take a natural interest in this as a sport, he does not rest long without some more flights and in a short time becomes bitten by the "bug." From then on nothing will satisfy him until he has his own "ship."

The Variations in Type and Price

There is no one type or price of airplanes best suited to private use any more than there is any one type of motor boat. Just as with the motor boat, the airplane in private use will vary with the fancy as well as with the pocketbook of its owner. So far as type is concerned the prospective purchaser will have both open and closed landplanes, seaplanes, flying boats and amphibians to choose from. The price range varies greatly, usually according to the comfort and power desired. On one hand we have the market for the low priced airplane of small power and—because of its lower cost—this is the type most likely to have the largest sale to those who fly for pleasure as distinct from business. On the other hand there is a definite market also for the larger types among private owners although their greater cost necessarily limits their sale to the wealthy. It seems most reasonable to draw a parallel with the motor boat market and, indeed, this field really offers a better basis of comparison than the automobile. For the automobile is a utility of a different type, it serves not merely as a pleasure vehicle but even more as a medium of transport over short distances,—to the homes of friends, the theatre, or to the shopping district.

Selecting the Type

The prospective private owner usually starts to make his selection with some fairly definite preferences or perhaps some preconceived notions as regards the price range. The personal activity of one man will make the flying boat or float seaplane the only logical type to consider. In another case the landplane or the amphibian may be the more desirable. So far as this part of the choice is concerned each case must be decided on its own merits. If an excellent flying field exists near his home, the landplane would seem to have a distinct advantage. If suitable water areas are available nearby the float seaplane will make a more direct appeal and, if he already has owned a motor boat, the trim lines of the flying boat may take his fancy. The questions of size, seating capacity, comfort, horsepower and speed are usually dependent more upon the pocketbook than upon other elements although this is not *always* the case. Many wealthy aviation enthusiasts have purchased two seater airplanes of moderate power because their personal preferences lay in that direction rather than towards the larger or the faster types.

The Importance of Factory Organization

The prospective purchaser should make his decision with care, for aviation is not yet in the position of the automobile industry and purchases cannot be made more or less blindly. The first point for investigation is whether or not the manufac-

turer is thoroughly well established, having adequate manufacturing and service facilities. Even a good airplane may be a bad purchase if its manufacturer is not properly equipped to follow up the sale with proper service facilities. Generally, the purchaser will do well to avoid the "fly-by-night" type of airplane builder who can give no assurance that he will be in business in two or three years from now. For an airplane which is well taken care of will last several years but, if its manufacturer has gone out of business in the meantime, its maintenance may become an expensive luxury. Furthermore, the well established factory organization usually has a better inspection system and exerts more care in construction as it has a valuable reputation to maintain, such as the newcomer has not yet achieved. All of these considerations have a very direct bearing on the question of safety.

Judging the "Ship"

Having satisfied himself as regards the particular type which best fits his needs and having reduced his consideration to products of the better established manufacturers, the prospect will find that he still has ample room for choice. If he has properly eliminated the "fly-by-nights," he will find that each of the types of airplane remaining already have been granted what are known as "approved type certificates." These certificates are to be made essential before a license can be obtained and they are granted by the Aeronautics Branch of the Department of Commerce after complete investigation of the structural design and safe performance. Hence the possession of a "type certificate" may be assumed to cover most questions regarding structural design and safety.

Flying Characteristics and Performance

The possession of a type certificate however, carries no assurance that the airplane lives up to the performance claimed by the manufacturer. For assurance on this point the purchaser must either rely upon an independent flight test or upon the good faith and responsibility of the seller. Here the purchaser must exercise caution and should inform himself upon the actual performance as to such outstanding points as landing speed, climb, stalling speed and high speed. If a pilot himself he would do well to make sure that the airplane considered takes off and lands properly and otherwise behaves normally in flight, that it does not "stall" suddenly or tend to fall off into a spin too readily when stalled or indicate other features of performance affecting safety in operation. If not an experienced pilot himself and not already familiar with its flying qualities, he would do well to hire some experienced, trustworthy and open minded pilot to investigate these for him before he makes final his decision to buy any particular airplane.

The Question of Hiring a Pilot

Some private owners prefer to hire a capable pilot rather than to pilot their airplanes themselves. While this is not at all essential, it may be desirable in cases where the owner feels that he is temperamentally or otherwise unsuited to make a good pilot or where the occasions of his own piloting would not be sufficiently frequent to keep him in proper practice. While the amount of flying necessary to keep in "proper practice" depends very greatly upon the individual it might be well to note that the Army and Navy Air Services require pilots to fly at least several short flights per month to draw flying pay and the Department of Commerce requires applicants for private pilots license to have had at least two hours solo flying within the 60 days just prior to date of application. Hence it will be obvious it is by no means necessary for the private owner to fly every day or two to keep in practice.

Selecting a Pilot for the Private Owner

The private owner who elects to hire a pilot instead of flying his own airplanes should carefully investigate the record of his man before taking him on. Just at present most of the experienced pilots are satisfactorily placed and it may be necessary to offer some added inducement to encourage a good man to change. Experience and care are the two essentials of a good pilot for the private owner. While difficult, if not impossible, to reduce these elements to hard and fast figures, the private owner should hesitate to hire a pilot who has not had at least 100 hours solo flying including some reasonable experience on the exact type of airplane which he owns. However, experience is not the sole consideration of safety as not all experienced pilots are as careful as they might be and his record for careful flying is just as important as his experience.

Flight Training for the Private Owner

If, as is usually the case, the private owner of an airplane intends to fly his own "ship" (and is not already an experienced pilot) he must go through a training course in some suitable flying school. There are many such schools now and they are so well distributed that it will usually be possible to take the course at some flying field nearby. On the question of the school, again the usual caution should be exercised. A proper course of training includes "ground school" work as well as the actual flying and this schooling is equally important although it may not always be so interesting. A good ground school course includes both instruction on the theory of flight and some training in maintenance of airplanes and engines. Flight Training may be taken simultaneously with or following the ground work.

The Time Required to Learn

The actual time required for flight training varies greatly with the individual but the student who is *properly and safely instructed* should spend at least 10 hours at "dual" flying,—handling a dual control stick while the instructor coaches him. It is quite possible for a student to be able to fly in less time but this has been found to be bad practice. The most dangerous time for the learner is usually between the completion of his "dual" flying and the completion of his first 60 hours of solo flying. At the end of this period he is usually sufficiently well trained to be considered a safe pilot for average flying. From this period on he will improve until his experience makes him a pilot capable of meeting all emergencies.

The Future of Private Ownership

With aviation undergoing such rapid development as at present, predictions regarding its future are very dangerous. It seems clear, however, that flying is destined to develop along at least three distinct lines: (1) Regular transport services flying on schedule, (2) Commercial flying of other types, (3) Private flying chiefly for sport. Just what will be the relative importance in the future of these three major groups cannot be predicted with any degree of accuracy. It seems probable that the first two will always exceed the third but this does not mean that private flying will be insignificant. Indeed, the probability is that the private owners of airplanes will, at some time in the future, be about as numerous throughout the country as the owners of motor boats now are on the coasts. The growth of transport and other commercial flying operations will undoubtedly develop an increasing interest in private flying and,—through this,—a corresponding increase in the number of private owners of airplanes. With this increase the question of safety must be kept constantly in mind and the manufacturer of air-

planes must continue to exert every effort to construct airplanes that depend less upon the skill of the pilot than upon inherent stability.

MR. PERRY (Somerset Airways, Somerset, N. J.): Mr. Chairman, the present type of airplane, of course, has proved very successful in many respects, but the knowledge of what it will be five years from now is very small. It all depends on future inventions and new wrinkles that come up. Doesn't the gentleman who just read the paper think that as time goes by, there will be some relinquishment of the regulations, or a decrease in the restrictions as has come about in the case of the automobile? Doesn't he think there will be a simplification of operation, and in time the general public will take to it better?

MR. PITLER (Mutual Life Insurance Company, New York): The company I represent is faced every day with problems of insuring people who do more or less flying at different times. Some of them are passengers on regular transport lines, and we occasionally get applications from people who own their private planes. We have been rather timid in insuring the latter group. It has been our impression that their planes are not subjected to the same rigid inspection tests before and after flying as those that are serviced by the regular transport companies. I should like to get some expression from some of the experts here as to whether or not we are on the right track in following through that idea.

COLONEL BAIN (Fairchild Airplane Mfg. Co., N. Y.): In connection with the remarks of the last gentleman, I think he is undoubtedly correct. The average private owner at the present time does not have the facilities for maintaining his airplane in the state that the commercial operator has. There is no use in predicting how that is going to be solved in the future but probably as airports spring up around the country, there will be facilities at these airports where the private owner can keep his airplane and where he can be assured of at least an equal kind of maintenance such as the scheduled operator gets. As long as the operation of privately owned planes is concerned in this interim before those things are established, I think the insurance companies are quite right.

At present, there are two or three airports that I happened to have visited which have facilities now where I am sure that the private owner gets equal attention. Does that help you any?

MR. PERRY: My question was, that the present requirements are very severe. That is quite just and right; but as time goes by, I believe the airplane will be simplified as much as the automobile has been, and the requirements will be lessened. There will be a general evolution in people's knowledge and their airworthiness. I hope that there will be a decrease in the restrictions and requirements for the pilot five years from now.

COLONEL BAIN: I quite agree, except in the decrease in restrictions for the pilot. The improvements in the airplane will make it easier to fly. Certainly, the modern tendency is to make a modern airplane (as we say), "foolproof." Everyone is working in that direction. After that is done, it will be well enough to consider cutting down the requirements for the pilot. At present, I would be in favor of just the opposite.

MR. PERRY: What is your opinion of the future development of the airplane; will it be in the hands of large companies as steamship companies control steamship lines and as railroad companies control transportation on land, or will it be more in line with the paper just read, a "happy medium" between the private owners and corporations?

COLONEL BAIN: You mean the manufacturing end of it?

MR. PERRY: No, the use. Will it tend to be in the hands of a few controlling groups or will it be as the automobile game is?

COLONEL BAIN: I think there will be no question of control involved in flying. I think that the scheduled operated lines will develop the one field, and private own-

ership and operation of airplanes will develop another field. I think it is a little early to predict anything now.

Of course, the airplane can't be compared with the automobile in its development. I think we shouldn't be overenthusiastic and assume that the airplane will follow exactly the expansion of the automobile. The airplane companies maintain their own premises. You see, you must have an airport, and that at once is going to be a feature that will more or less slow down development or large use by a great many people of privately owned aircraft.

MR. PERRY: From your experience at McCook Field and elsewhere, in your opinion, what fields should inventions cover which would tend to make the airplane available and usable in the man's backyard—having his own garage, you might say? Along what lines should the inventors of this country be putting their energy toward producing a machine which will be available to each individual? What would be the form of the machine? Of course, we don't know what gravity is. Is there some physical way of neutralizing the influence of gravitation on an object?

COLONEL BAIN: I am afraid not. I don't know anything about neutralizing gravity. I don't claim to be versatile in the art of predicting and advising the well-established and thoroughly competent engineers of this country in the direction of this development that the airplane should take.

I don't feel that we will ever be in a position to maintain airplanes in our backyards. I don't feel it will ever come in that direction. It will always require a more or less large place to get off and land on. And, in the interest of good maintenance and proper supervision, I think airplanes should perhaps be maintained at some central location where they can have expert attention. An accident in the air is a serious matter, whereas if something breaks on an automobile, they can stop until they get some attention and fix it.

The Commercial Airplane Not to Be "Stunted"

MR. LEMKE (U. S. Naval Academy, Annapolis): I am somewhat of an outsider, but in one of the meetings yesterday, a point was made that struck me very forcibly. This is a point in connection with safety consideration of a commercial airplane. The ordinary commercial airplane that will deal directly with this subject of private flying and ownership is not built to be stunted.

I don't know whether ten out of a hundred people today who are interested in flying know that. I doubt whether many pilots who operate those machines know it. At any rate, I remember this summer going to a commercial airport, and one of the standard commercial airplanes (of a somewhat smaller kind, to be true) was being stunted in a rather violent manner. That is a point that might be stressed. Incidentally, it was only brought out yesterday, and it struck me as being something that might consist very greatly in helping folks to become more air-minded by assisting very directly in the general program of safety.

MR. PERRY: The average airplane when it reaches the pilot's hands, I believe, is considered to be perfectly airworthy, not only for average use in travelling, but sufficiently so to stand overloads and strains in stunting. Stunting is used a good bit to draw trade, and while I am against all reckless driving in the air just the same as you gentlemen are on land, I believe that there should be a resolution drawn up in view of the safety campaign to disapprove of all stunting hereafter.

CHAIRMAN MATO: Are there any others?

MR. BRYNER (Consulting Engineer, Orange, N. J.): The question of what the future may bring in the way of private flying has interested me for quite some time. I have given it a good deal of study for eighteen or twenty months, anyway. I have really tried to reduce a good many of those things down to practice. There is one thing in regard to the public's interest in flying, that has stood out in my

mind very clearly. It is the fact that you will never be able to interest the public extensively or be able to entrust private flying to the general public until you are able to slow the airplane down.

In an article written by Mr. Stout some time ago in the *Saturday Evening Post*, he enunciated the doctrine of safety in flying rather clearly when he said that at present, safety depends upon speed. He said essentially that the airplane plus speed produced a solid on which you could rest the airplane. In all other forms of transportation, whether it be the motorboat, sailing vessel or the steamship, we have always needed to slow the thing down when it came to a matter of safety. In fact, most of our rules even in regard to the automobile, limit speed.

Along the line of what is required, of course, we know about preventing stalling and slowing down the speed, and as Mr. Ford has written, it is necessary to use the power of the engine in landing, which he evidently intends shall slow the speed down in landing. That is one of the critical points. Until that is done, I don't believe that you can entrust the general public with private flying.

Special Study of the Airplane Propeller

One of the things that I have spent considerable time on has been the control of a pitch propeller. At the present time at the take-off (which is a hazardous period) if it is not properly made, the machine might be stalled or it might go into some kind of a sideslip or a spin. At the present time, only about 65 per cent of the power is available on the take-off due to the fact that the propeller has a fixed pitch. It is, therefore, necessary that the propeller should be studied more thoroughly. More attention should be placed upon that part of the work so that the propeller does not have a fixed pitch, but should have a very slight pitch on the take-off.

A good many years ago, as a marine engineer, I found out that propellers which were suitable for towing (which represents a take-off condition where great thrust is demanded) were not speed wheels at all. The fact is, it requires an entirely different kind of a propeller to tow a fleet of barges by a tugboat than it does for a tugboat that can make good speed. In that, the two were not analogous at all.

I leave that as my thought, that more attention *must* be placed upon this point of slowing down the speed. I will give an illustration that was used yesterday. On the route between New York and Atlanta, one of the pilots saw a gray object in front of him. It was dark, but he said he was squarely on the airway. Everything seemed to be going fine when he saw this gray monster ahead of him. He didn't know what it was, and to avoid an unknown danger, he just pulled the stick back and went over it. He was so surprised at that condition that he wanted to know what it was. So he turned around and found out it was the Los Angeles.

So long as you have those conditions, so long as you are not able to slow up, a thing like that may result in a catastrophe, even when ships of that character are handled by the very best of pilots. When it comes to the general public, which means bringing in the layman, safety must depend on being able to slow down, and if necessary, (as in the case of the steamship or launch) in emergency, you ought to be able to reverse and then get out of the stall that might be involved in it. Of course, I know that is a good deal in the imagination at the present time, but that is what the conditions demand, and what we will probably have to meet.

CHAIRMAN MAYO: Mr. Stout is on his way abroad. I don't know whether he wrote a paper for this section or not.

J. F. VICTORY (National Advisory Committee for Aeronautics, Washington, D. C.): Before you came in, Captain Land handed me Mr. Stout's paper and asked me if I would read it:

CHAIRMAN MAYO: Will you come forward and read it, please?

Non-Scheduled Flying

By WILLIAM B. STOUT

President, Stout Metal Airplane Company, Division of Ford Motor Company, Detroit

Safety in non-scheduled flying does not involve perhaps any more problems than in the field of scheduled flying except that the problems go further in the unknown factors before and during the trip.

On a scheduled flight between regular points there is a knowledge of conditions ahead of the pilot that can be rarely had in non-scheduled flying as it runs today and the operation must be more of a hit-and-miss affair than would be considered on regular airline work.

For example a pilot has a commission to fly a load of passengers from his own airport to Anthill, Florida. First he wonders whether there is such a town. Is there a field there? Can he get gas and service? What is the country in between? What fields must he stop at on the way? What of the weather and wind conditions to be met? Are there lights on the field if he should be late in arriving? and so on; a score of questions immediately in his mind, and all of which should be solved in part at least before he takes off.

The list of airports and emergency fields issued by the Department of Commerce may be his first line of defense against dangers. Maps; phone calls; visits with pilots who have flown the route, collection of all the weather reports he can get before he departs, wires to have gas and oil at certain points, and a worry as to what kind of gas he will get, real aviation specification gas or the Sinclair variety so glibly advertised for motor cars under the misleading caption. Here alone is a danger the non-scheduled pilot has to face through misleading merchandising.

If a scheduled plane is leaving over an established airline the pilot has by many previous trips a knowledge of the terrain he is to fly over, he knows the idiosyncracies of the weather, the fields en route, the field equipment at each point, and gas and oil are already arranged for long before his flight is undertaken. All that he has to do is to fly and navigate over a well known route.

If bad weather comes up he still knows all the landmarks and can spot the packinghouse district of Chicago from a thousand feet in the air without even seeing it, so keen has his scent become for locations. The non scheduled flight on a trip to a new destination however is a different problem, and unknown factors multiply.

On the regular air route prepared fields are available so that a plane of fairly high landing speed, and with a sluggish take off can be used if necessary, that greater pay load may be carried, and more speed accomplished.

On the unknown trip however fields of any kind may be encountered and the safest plane is that one that can land in the shortest amount of space, on the roughest possible ground, and take off accordingly. This would specify for the unscheduled trip a different type of equipment, a type toward which all planes are drifting and including many new items unnecessary in military or private flying planes so far. These might be listed as in use so far, as items which this type of problem is bringing into aircraft design.

- (a) Forward placed landing gear
- (b) Stronger fuselages
- (c) Powerful separate brakes
- (d) Wider track wheels
- (e) Multiple engines
- (f) Enclosed cabins
- (g) Added comfort to interiors
- (h) Better vision to
 - (1) pilot; (2) passengers
- (j) Metal construction

Where landings have to be made in strange fields every precaution should be taken to make every stop with nothing sacrificed to safety. If a commercial plane or a private owned plane has not safety it is worthless no matter what its performance, nor what tricks it may be able to perform.

There is no danger in a plane in the air, unless it catch on fire or a piece fly off the engine or prop and hit you. The danger is when you touch the ground. The control of this one thing in the maximum number of emergencies constitutes the safest plane. The items just named have a very definite place in a variety of emergencies in which one might be caught, and any one of them far more important to safety than a parachute, except in military and test work where structural strength may be in question or fire a menace.

One of the greatest sources of danger is nosing over, especially if the gas tank, as in so many pre-war types, is placed directly behind the engine. Many a fire has meant death to pilots in minor crashes which would have meant nothing with the gasoline in the right place. Placing the landing wheels further forward eliminates much of the menace of nosing over, and thus starts a sequence of possible improvements provided the fuselage construction is solid enough to carry the new tail loads. If it is not, then brakes, of course, with any real kick to them cannot be fitted.

In the new Cessna light plane I notice the wheels even forward of the leading edge of the monoplane wing, and a take off that is very sweet in spite of what must be a rather heavy tail load. The test field this company uses is just 19 acres in extent surrounded by trees, so that the landing characteristics must be pretty good. With the gear in such a location I do not see how the plane could nose over with loads that would not wipe the landing gear off.

Once the wheels are placed forward the next thought comes: now we can fit brakes, and brakes are put on that can slide the wheels and still not nose the ship over. Another added safety item.

With the wheels far forward and the heavy tail load, the tail comes off the ground a little slower it is true, but a slight increase in the tail area and its aspect ratio can more than offset this, while if you want to hold the brakes, you can get the tail off the ground before the plane starts to move anyway. The heavy tail weight now causes trouble, digging up the landing field and playing hob with the grass. Add a wheel on the rear and the problem is solved. With brakes why not make a real rolling vehicle of it? There is no more rumble and rattle in taxiing.

With the brakes there is a tendency to ground loop if one takes hold more than another. Why not take advantage of it. Result—a wider landing gear so that ground looping can be done purposely in an emergency without rolling the plane over. Individual brakes now give the plane a control on the ground that a motor car has, and side winds do not swing you around off the runway between the trees that you may have to land in. Nearly all the new commercial planes have followed these new items and are proving their safety in the unscheduled flights of private owners every day, big ships and little ships.

First motor cars were used in summer and the horse brought out in winter. Airplanes have been the same but with closed cabins these craft are now an all year vehicle even for the private owner. There is an especial reason for closed cabins on airlines, for pilots fly with but a small percentage of the fatigue when in out of the weather. In private vehicles they are a sales necessity for the same reason that closed cars sell. Pilots will not agree perhaps but after all the sales of the future are to the public which will hire the pilots. The public wants comfortable travel—not a thrill, and the public, not the engineer or the pilot, will tell us what the eventual plane must be. Safety first, then comfort will be his rule.

Whether multiple engines will be the rule is only a guess. For airline planes it is my opinion that multiple engines will be the rule. For training and the bulk of

privately owned planes the single power plant will presumably dominate, particularly with the newer more reliable engines that are coming on.

Probably the greatest problem of the designer is to get better vision under all conditions. Some of our newer cabined planes are much better in vision in good wather but when rain or snow comes along one must fly with side windows open and the snow and cold coming in, in order to see. Particularly for the non scheduled type of flying over strange country part of the time at least, vision is a predominate necessity.

Not only is this due to the pilot but the passengers as well should be able to clearly see the horizon—if any—ahead as well as at the sides, if only as a preventative of seasickness in bad weather.

Metal construction will come as soon as costs can be brought down. There is the same reason for it that there is for steel rail coaches, and it will come in spite of cost for all of the better makes. As a safety item it is of real importance, and the drawbacks so often cited to metal are mere bogeys visioned from office desks and advertising departments rather than from experience.

But we have not gone far enough yet in the safety plans. The main problem of unscheduled flying will be the owner of the plane himself. This man with a few hours flying will start using the airways, and even before long follow the lighted lanes at night. Radio will be necessary for his steering and to control him as relating to scheduled planes using the route.

Planes chartered to outside parties for cross country work can be airline planes but if equipped as described have a greater chance at safety under the emergency conditions that will arise than if just the old type planes. An overpowered plane is certainly a great advantage for safety in a small field.

Navigation is also a problem to the unscheduled flier going over a, to him, new route. He must spend much of his time watching the ground, following his map, checking his route. New instruments can add to his certainty. An automatic pilot that could even for a few moments take the actual flying off his hands would help his navigation. A map table in front of him. A new type system of mapping that would give a different course in one direction than in the other might help prevent collision possibilities.

There will be a small amount of non scheduled flying by airplane companies. We have flown about 1,300,000 miles on our airline work so far, between Ford Motor and Stout Air Service lines, and have carried 55,000 passengers and six million pounds of freight. In all that time we have as an airline made probably not over 30,000 miles of non scheduled trips nor carried in this work over 500 persons. The real non scheduled operator will be the private owner of small planes, but since he will come in so great numbers to infest our airline routes he is a part of our problem. In fact we expect all of us to be one of the infestors, and to fly our own safe, stable, automatically flown and navigated ships about the sky starting when and why we wish and our destination the same.

The work that is being done by this group, under the inspiration of the Gugenheim fund has undoubtedly more value to the public mind than could be had from any other source. The thoughts in this paper I hope may stimulate some thought for new ideas, though the material be but straight analysis based on our experience of the past few years in airline work.

CHAIRMAN MAYO: Are there any comments on this paper?

J. E. RAGG (Inventor, New York): I have a few general remarks to make concerning both papers. The fundamentals of the airplane are the power plant, the controlling surfaces and the lifting power or lifting capacity, that is, the weight. It is inevitable that each one will examine these fundamentals and find adherence and specialize on one particular phase in the effort to produce safe aircraft. I am one who is stressing the importance of the lift capacity, or rather, the capacity control.

All of the arguments that have been advanced, for instance, for the necessity of high speed, for the variable pitch propellers and for the inherent control of balance are valid, but to my mind, none of them is so important as the one factor of being able to influence the amount of play which the wing gives. If a pilot can increase his lift, he can land slowly. If the motor cuts out, that is most necessary; that being a time when the reversible propeller is out of use. If a pilot under special conditions, such as on a very gusty day, needs to land fast (which is sometimes desirable), with the control of lift in the wing he has this capacity to do so, but if he is very heavily loaded just after the take-off and has to land in a restricted field without any choice of space, by increasing the lift capacity of the wing, he is enabled to do so.

If one thing, or any other thing, is necessary in this matter of speed, a slow machine is very unsafe. A fast machine is very unsafe too, but if you have a machine which can embody these two factors, it is absolutely safe under all conditions of flight, whether the motor is working or not. This feature has been provided, it is a simple lever control which enables the airplane to utilize what is equivalent to a gear box in an automobile. By moving a lever, an auxiliary wing can be adjusted which affects the lift capacity of the whole wing for any attitude of flight. This, I submit, is perhaps the most important feature that produces the safe aircraft necessary for general public operation.

W. C. POND (John Hancock Mutual Life Insurance Company, Boston, Mass.): I am encouraged to say a few words by reason of the fact that we have another life insurance company represented in the room. Whether there is more than one, I do not know. I speak with some timidity, because the profession or the institution of life insurance perhaps is not directly interested in the problems that many of the men here are interested in.

There seems to be an idea among some of the airplane manufacturers, or those who are most interested in it, that the life insurance companies are, in a way, standing against the progress or making it impossible for those who use the airplane to obtain life insurance at a reasonable premium. I am not holding a brief for all of the life insurance companies, in fact, what I say is entirely on behalf of my own company. I can only say and give you every assurance that it is my belief that the life insurance companies are anxious to cooperate to the furthest degree with the general public in offering life insurance at a premium which is relatively safe.

As you can imagine, a life insurance company is limited in many ways, as compared to a liability company. The liability company, when a risk is sought on a plane, can place in its contract all those restrictions which it cares to make at that particular price. In other words, they say, "Yes, we will insure this particular plane, providing it is flown by such-and-such a pilot, and you will keep a monthly record of your air hours and furnish us with that schedule at the end of the month. Your premium will be adjusted accordingly." And if for any reason whatsoever at the end of the month they decide to go off the risk, they are at liberty to do so by reason of their contract.

It must be borne in mind that when a life insurance company accepts a so-called "aviation risk," it is on the risk for life. We cannot and do not propose or have any desire to limit the activities of the person insured relative to his activity with the plane or motorboat, balloon or whatever. They can assume any hazard that they see fit without any restraining measures on behalf of the life insurance company, and for that reason, the life company has to receive adequate information.

I can give assurance now, that if the life companies had only to deal with the problem of those who are flying on schedule, on regularly established lines such as are described in Mr. Stout's paper, the added premium would be little or nothing as compared to a standard premium. The problem that we must face is a big, doubtful class, and when you consider those people in that class who come to us for life insurance, what can we do? Well, I have never been able to figure out

the standing of the reserve officer, the man who still retains his commission in the National Guard. I am not familiar with just what the National Guard requirements are, with reference to the number of hours that they are obliged to fly during a year to maintain their standing as a reserve officer in the Aviation Branch, but there seems to be some regulation. Whether that is lived up to, I don't know.

With such a man, what can a life insurance company know about the equipment that he is offered? He has been in business since the war. He is married, he is active every day in business. He is not supposed to be around the air fields and airports, knowing all the new things with relation to airplanes. He comes to the National Guard field once a year, and here is a plane for him to use. He will drive it. We have paid some losses in that direction.

We have been given here at the few meetings that I have attended, quite positive assurance that the equipment and the quality of the plane, the reliability of it, is a great factor in safety. That must be true. It is only natural that it must be true. I recall one accident, a marine plane, starting from Quantico or the field which is nearby, to fly to Nicaragua, making one stop at Miami. It was flown by a very competent flyer, Colonel Lutz and Lieutenant Busby, with a radio man and a mechanic. It was a three-engine Fokker plane. It was a very splendid and reliable plane so far as anybody could know. We assume that it was inspected most carefully. The take-off was at 1:25 a. m., and the plane was down in forty-five minutes, with an instantaneous loss of life of both Busby and Lutz, the pilots of the plane.

I can recall another instance where two of the most competent men in the Curtiss Field here in New York were sent to Buffalo to bring back Colonel Lindbergh's plane. When I say Colonel Lindbergh's plane, that is all I need to say about the quality of the equipment and the perfection of the plane. We will grant it must have been a hundred per cent plus, as far as that is concerned. Unfortunately, both of those men were killed and the plane destroyed somewhere in Pennsylvania, between Buffalo and New York City.

Now, in considering the thing, the life insurance company points to those. Of course, we can't say that that proves the equipment is the solution of the safety of the proposition. You still have the human factor to deal with. The only thing that we find difficult is to get the information which will enable us to safely authorize or issue life insurance to those who are interested in the planes. Now, that is only a matter of time when the statistics will take care of it. When you can show us a class of a hundred thousand private owners that have used those planes for a period of five years, then the life insurance companies will quote you an adequate premium, and there will be no hesitancy about it.

It isn't a question of how many are killed, so far as the insurance and the premium are concerned. However, at the present time, there are not enough statistics for life insurance companies to establish a definite premium. We are going to go along with you just as far as we can and just as fast as we can. But we are anxious for statistics which will enable the companies to offer the protection. I want to dispel the idea that the life insurance companies are in any way standing in the way or making it difficult to secure that protection. We are going to go along with you. That is why we are here. We are seeking information. We are going to seek it and chase it down as far as we can and offer the protection just as reasonably as we can for the safety of the company. Thank you.

CHAIRMAN MAYO: Any other remarks?

MR. PERRY: I would like to say, Mr. Chairman, on a well-known airplane route, air mail route from New York to Atlanta, one of the pilots took a machine out and for some reason or other, within a very short time after he left the field, he crashed. No one knows what caused it. It was in clear weather, and, of course, it might have been heart failure on the part of the operator. However, those

things from an insurance point of view, are protected by physical examination, are they not?

MR. POND: Yes, but that isn't a sign that they are protected, because a man may be able to pass an insurance examination some time previous to having heart failure in a plane. I think perhaps I would have heart failure in some planes.

MR. RAGG: From the viewpoint of the insurance, I submit this: If the insurance people in general who are investigating the matter of insurance of the plane make particular inquiry as to the maximum speed and minimum flotation speed, and they find the ratio is five, it is a safe risk.

MR. POND: We can make inquiry before we write the policy, but after a policy is written, it is all over. We have no control over the gentleman then. He may fly with a ratio of five, or minus one. We can't control it.

CHAIRMAN MAYO: Anybody else? The question of insurance is quite an important one. If anybody has any ideas, we would like to have them.

MR. PERRY: Can you tell me how Henry Ford and Mr. Stout control their facilities?

CHAIRMAN MAYO: Well, as far as the Ford Company go, they carry their own insurance on the plane with the exception of damage to other people's property. In the Stout Company, they carry full insurance, which covers the passenger from crash.

MR. PERRY: Their own insurance?

CHAIRMAN MAYO: They don't carry their own insurance, they take it.

MR. PERRY: Henry Ford carries insurance?

CHAIRMAN MAYO: Only for the plane itself, but for damage to other people's property, they must take out insurance with an insurance company. I have had quite a good deal to do from time to time with insurance companies. I have always thought that they were very backward in taking on risks for air insurance. Most all other companies, in particular, industrial companies, are always reaching out and taking a great many risks in pioneering different things, and it always seemed to me that insurance companies should do likewise.

However, as I see it, they sit back and want statistics. Of course, those are not obtainable in a new industry. When an industry is young, small, I don't think the old time insurance company (if very large) is taking a great deal of chance when they take a risk, small in volume, that doesn't perhaps appear very sound at the time. The best way to get experience, in my opinion, is to take some risks and get it all first-hand rather than cast around trying to get statistics. It is very easy, it seems to me, for insurance companies, life, accident, liability, or whatever you like, to place around the policy they give, a certain restriction. I think the insurance companies should take some chance to sort of help the game along. It isn't as though it was a flash in the pan. Here is something coming. We all know it has grown to very large proportions, and the only way to safely help it along is to get into it with both feet, and get the experience first-hand.

When the Ford Company went into the manufacture of planes, we wanted to get our experience first-hand, the same kind of thing I have been talking about. So we started freight carrying, a line to Chicago, Cleveland and Buffalo. We felt that if we were going into the building of planes, we didn't want to try out what we built on our customers. We have gotten our own experience and it has been a very profitable one. The result is, we have plenty of recommendation on planes we have handed out to the public. That experience would have come to us a great deal more slowly had we not operated our own lines and found out what a good plane was through experience. We found out the weak points in construction more quickly than we could have in the hands of our customers. We found what made up a good or poor pilot. We found out what kind of weather was suitable to fly in, and what wasn't. We found out what kind of fields we should have. We built our own air ports. It is like any other thing you pioneer, you can't

get a true picture from going out and talking to people, no matter how much experience they may have in the particular thing you are talking about.

I remember distinctly when we built the first planes with closed cockpits. Practically every pilot told me it would be impossible to fly in them, but today, by preference, most every pilot likes enclosed flying.

Mr. ROGERS (American Airports Corp., New York): We have been informed lately on the question of insurance, that some of the accident companies are planning to issue at the airports (like we do at the railroad station) accident policies for one day. One of the big problems we have in putting on air meets, is to get proper insurance to cover all the risks that come up of one kind or another. It takes a great deal of time and correspondence, and the answers you get from different insurance companies or agencies are quite varied. There does not seem to be today, any real definite thing that one can depend upon.

This new thought was brought out lately that many people hesitate to fly because when they are just going to take a taxi or pleasure trip, they are afraid that their insurance policy may not cover them if anything happens to them. Their families may lose out on all the insurance. To obviate that, the insurance companies are going to have the one, two, or three day accident insurance, the same as the accident companies sell at our railroad stations.

As Mr. Mayo said, it is one of the very important questions of this day in aviation because when the novice goes into passenger flying, they must take that into consideration to a great extent. You have to figure, "Suppose there was an accident, what risk am I taking?"

At a very large air meet which we directed at Lowell, Massachusetts, I watched carefully to see what the effect was upon the people who lined up to take the short taxi flights. To protect ourselves and the company for which we were putting on the big air meet, we had everyone sign a release. Whether that release will be of any great value when it comes to court or not, I don't know. However, we took the Government release that they have people sign who ride in Government planes at times, and used the basis of that as ours.

To everyone who lined up to pay their money to take the taxi ride, I had a man say to them, "You are taking this ride entirely at your own risk, and you will have to sign a release." Out of several thousands of people who took the rides not a single person turned away when they were told that. The taxi boys hesitated very much at first. They said, "You will drive away customers, Mr. Rogers, if you ask them that."

I said, "We don't want anybody to ride with the wrong impression of the local airport corporation or the American Airports Corporation (the people who owned the airport), in thinking that they would be in any way responsible."

In our release, we covered not only that, but we covered the taxi company that did the taxiing.

There is a question whether the insurance companies will cover it in that way so that people who are taking trips maybe from here to Chicago, can cover themselves against any accident that may happen so that their families will be protected if their regular insurance policies do not protect them.

Mr. PERRY: Mr. Chairman, can some gentleman who is conversant with the conditions in foreign countries such as Germany, in the insurance line give us some idea of how they handle it over there?

CHAIRMAN MAYO: Do you happen to know how they handle it abroad?

W. C. POND (John Hancock Mutual Life Insurance Co., Boston, Mass.): With reference to Mr. Roger's remarks on the accident problem, he speaks of a man who is going to fly from New York to Chicago. There you have a definite proposition. Your accident company knows the equipment, the quality of the pilots, and you have a definite proposition. It is different with the life insurance company.

Perhaps I left you with the wrong impression, Mr. Chairman, with reference to life insurance companies, I think most all the companies have some aviators' risks. I know my own company has several millions of dollars involved in that type of insurance, and we have paid a very considerable amount in claims. We are going along with you. We want to go along faster, but we want to go along surely.

With reference to the thought that the life insurance companies have a duty to go on and assist and take their load in the pioneering, I should like to say that if the life insurance companies were all stock companies and the losses sustained would be borne by the stock holders and their pocketbooks would be the ones that would be affected, then I agree with you. But the majority of the larger companies today are mutual companies. We are not dealing with our money or with stock holders money. We are dealing with the money of the policy holders, of which we are simply custodians. We are placed in the position of having to answer the question, "What right have you to take chances with our money on an unknown problem?"

Be that as it may, we still say we are anxious to go ahead with you just as fast as we can.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Flying and Ground Personnel

First National Aeronautical Safety Conference

Under Joint Auspices of

The Daniel Guggenheim Fund for the Promotion of Aeronautics and the National Safety Council

October 4 and 5, 1928

HARRY F. GUGGENHEIM, Chairman

**President, The Daniel Guggenheim Fund for the Promotion of
Aeronautics, Inc., New York City**

The Flying and Ground Personnel Session of the Aviation Division of the Seventeenth Annual Safety Congress convened at two-five o'clock, Chairman Harry F. Guggenheim, President, The Daniel Guggenheim Fund for the Promotion of Aeronautics, New York, presiding.

HOMER E. NIESZ (President, National Safety Council; Commonwealth Edison Co., Chicago): Ladies and Gentlemen, it is my very great privilege to introduce the presiding officer of this meeting. But before doing so, I would like to express, on behalf of the officers and members of the National Safety Council, its very great gratification and pleasure to have with us at this Seventeenth Annual Congress such a fine representation of the newest industry connected with the National Safety Council. You have had prepared for you a program of sixteen separate and distinct sessions, covering every branch of aeronautics. The credit for the preparation of this program, the obtaining of the speakers and other work in connection with it, is due to Mr. Harry F. Guggenheim, president of the Daniel Guggenheim Fund for the Promotion of Aeronautics. I have very great pleasure in presenting Mr. Guggenheim!

CHAIRMAN GUGGENHEIM: It is indeed gratifying to find such a splendid attendance at this technical session. If we have the usual percentage of discussion after the papers are read, we will indeed have a great volume on this subject of the Training of the Commercial Pilot.

In the Smithsonian Institute at Washington there is an exact model of the sailing ship "Santa Maria" in which Columbus made his historical voyage of discovery to America. In the same museum is the actual airplane in which Lindbergh made his historic voyage from America to Europe. In different fashion, but with equal daring, both these achievements were adventures in pioneering. The first one discovered a New World; the second united it more firmly with the Old. Each was a herald of a new phase in civilization.

The epoch-making flight of the "Spirit of St. Louis" marked the end of the pioneering period in aviation. The experiences of this period have taught us that the safety of airplane operation has until lately been almost wholly dependent upon the training and skill of the pilot. Those of us who are fortunate enough to be in close touch with the extraordinary developments that are taking place in aerodynamic design, construction, and airplane operation are justified in the belief that the present day great dependence upon the extraordinary abilities of the pilot will gradually disappear. The universal use of the airplane will follow.

Today, under the right conditions and within certain limitations of operation, there is no safer vehicle of transportation than the airplane. Based on the developments taking place, one is further justified in the conviction that the airplane will soon compare favorably with the automobile in ease of operation, and will become, even in common use, the safest vehicle for fast travel. Fundamentally the almost limitless unobstructed air above the treetops, without intersecting highways swarming with traffic, offers the safest travel lanes.

In the meanwhile, the training of a commercial pilot is the most vital factor in safe aircraft operation, and I know of no one in the world who can speak with so much authority and wisdom on this subject as Colonel Lindbergh, whom it is my very great honor and pleasure to introduce to you!

... (The audience arose and applauded.) ...

Requirements and Training for a Commercial Pilot

By COLONEL CHARLES A. LINDBERGH

The commercial flying school is one of the most important problems confronting aviation today. Most of our pilots in the past received at least a major portion of their training in military schools, but with the rapid advance in commercial flying the supply of these men is no longer adequate. Consequently it is becoming necessary to draw from pilots who have not had the opportunity of attending military institutions, but who have received their instruction in commercial schools.

These schools, in the past, have not been particularly well organized. In many instances, the practice has been to advertise flying courses for their low cost rather than their high quality. It has been very difficult for a student to obtain enough instruction and solo flying experience to fit himself for a pilot's position. The number of our flying schools has increased greatly and as a class still leave a great deal to be desired. However, several have organized quite complete courses of flying and ground instruction. It is possible for a student, with sufficient capital, to attend one of the latter and graduate with sufficient training to enable him to become a commercial pilot with a limited flying experience.

Many of our present schools, however, are still advertising on their low cost. Students are graduated from flying courses with ten hours or so in the air. These men can not operate under federal licenses, but in a number of states they can carry on commercial flying with passengers provided they do not cross the state boundary.

A majority of the accidents in flying are due to faulty pilotage. There are two methods of decreasing these accidents. By training and regulation of pilots, and by advance in aerodynamic design of aircraft so that less is required of the operator and more of the airplane.

Accidents due to improper training will continue to an excessive degree as long as federal inspectors have no control over intra-state flying activity.

In so far as the first method is concerned, one of the essential steps is to obtain a standard of flying instruction. Our flying schools should be rated by their stand-

ing and patronized on account of their excellence as are our universities and colleges. State regulation of flying activity is of utmost importance, but not individual state legislation. Individual legislation which would create different regulations in the various states would seriously hamper the growth of an industry whose product cover a number of states in a few hours. Uniform regulations should be obtained throughout the country by the individual state adopting the federal flying regulations of the Department of Commerce.

As the interest increases in aviation, more and more people are wanting to learn to fly. Some desire to enter aviation as a profession. Others wish to use the airplane as transportation in their business. Many are interested in flying merely as a means of pleasure.

The first or professional class can devote a large amount of time to training and fly constantly both during the training period and after entering the profession. The man or woman who uses an airplane at irregular intervals is confronted with an entirely different problem. The professional student enters flying training, completes it as soon as possible and begins commercial work. The other type is often unable to train regularly and frequently long intervals elapse between flights after training. Training and irregular flying require a different type of airplane than that used in commercial service.

We have not developed a satisfactory commercial training plane. The military planes used for this purpose are too costly and overpowered for use in commercial schools if flying training is to be placed within the reach of the average student.

A training plane does not require high performance. It must be rugged and able to withstand the rough usage of an inexperienced flyer. Vision is of paramount importance as there are usually a number of machines in the air around a training field. A great deal of attention should be given to designing the training plane for possible crash. By sacrificing a little performance, a plane can be so constructed and its cockpit so arranged that a crash will result seriously only in extreme cases.

Another problem now confronting us is the location of fields for flying training. Air traffic is already becoming congested at some of our major airports. It certainly is not advisable to have a number of student pilots operating from the same field with passenger transports. A number of flying schools have been located near a small town in order to escape the air traffic of the large city. Others fly their students from the airport to some field several miles away and return after the training period. It is certain that regulations will be enacted against student training at many of our airports in the near future.

It is difficult to state what a flying course should consist of. At present we must base our training largely on the experience of military schools and incorporate changes in order to place training within the financial reach of the average commercial student. As time goes on and our flying schools become better organized, a great deal more efficiency in training will be attained.

The use of light planes with engines of comparatively low horse power for preliminary instructions and the building of aircraft on a production basis will greatly reduce cost of operation and the price of good training.

The Department of Commerce requires a minimum of fifty hours of solo flying for an "Industrial" or "Limited Commercial Pilot" and two hundred hours for a "Transport Pilot." In addition, a general knowledge of many subjects pertaining to aviation is necessary to pass the examinations for these ratings. A pilot's real training begins in flying as in other professions after he has left school.

Ground school training should include such subjects as Aerodynamics, Airplane construction and assembly, Inspection of aircraft, Engines and Accessories, Instruments, Aerial Navigation and Radio.

Flying training should be divided between dual instruction and solo flying. Even after the student has completed a number of hours of solo flying, he should undergo dual instruction in acrobatics, cross country, night and instrument flying.

In summing up, the safety of flying training may be advanced in the following ways:

By a Definite standard of flying instruction, State adoption of Federal flying regulations, Development of commercial training planes, and Suitable location of training field.

CHAIRMAN GUGGENHEIM: You have heard the paper, and like any statement from Colonel Lindbergh, it is straight to the point, and meets the issues with which we are confronted today. We would like to have free discussion of this paper, and I would like to call on anyone who wants to talk on the subject, so please give us the benefit of your experience and views. We would like you to confine yourselves to the subject, which is, "Requirements and Training for a Commercial Pilot." Please remember this is a safety congress, and we are discussing the papers from the point of view of safety.

ALEXANDER McADIE (Blue Hills Meteorological Observatory, Harvard University, Cambridge, Mass.): I only venture to rise because you asked for a volunteer, Mr. President, to start the discussion, and I feel that I have a right in a very small way to talk, because I am the oldest instructor in Meteorology in the country. Some forty-three years ago, I began to work in the Weather Bureau, and that has led up to our study of this subject.

Colonel Lindbergh's paper, of course, was straight to the point as has been said. All I could add to it would be to say that progress goes on very rapidly on the scientific side of our knowledge of the structure of the air. The commercial pilot must know all he possibly can about the conditions of the air, particularly with relation to fog flying, thunder storms, lightning, hail, and that ice coating which perhaps has brought disaster to so many flyers. He must not neglect the scientific side of the problem relating to the structure of the air.

CHAIRMAN GUGGENHEIM: Professor McAdie has brought up a vital point in the requirements for the training of a commercial pilot. Professor McAdie is extremely well qualified to talk on this subject because of his long and honorable career in meteorology. He has devoted much time in recent years to meteorology in aviation, and the discussion that he has initiated should be very valuable.

D. H. LAYTON (New York): I will appreciate an expression from Colonel Lindbergh on his attitude toward teaching the new flyer stunts before turning him loose for solo flying. Of course it is done in military circles, but I am wondering what he thinks of it from a commercial standpoint.

COLONEL LINDBERGH: I don't believe that can be answered without very careful analysis. At the present time, as you know, the practice is to solo at most schools without teaching acrobatics. In some instances, students are taught to come out of spins before they are allowed to solo. I do believe that any student should be able to do acrobatics and that acrobatics should be a part of his training, but how much should be given before solo flights, I am not prepared to say at this time.

CHAIRMAN GUGGENHEIM: One point in Colonel Lindbergh's address impressed itself particularly on me. It was his statement that flying schools should have rating and standing. I believe that it might be advisable to go perhaps farther than that at this time and say that *all* flying schools should be under supervision and not be granted licenses to teach flying until they had come up to certain qualifications. I think that subject is a moot one. I would like very much to have some expression of opinion on that particular phase of the flying school with which we are confronted in this country today.

MR. WILD: Mr. Chairman, I recently took my wife for a flight across the continent to the Los Angeles Air Meet. We stopped at about ten places along the way, gassing up. At some places the students seemed to be well satisfied. In coming back here to New York, down through Ohio and Pennsylvania, how-

ever, you find that in many places the students do not seem to be satisfied. They don't seem to be getting what they think they are paying for.

I am one of the old timers in this air game. Thirteen years ago I flew from the Palisade Park grounds around the Flat Iron Building, and landed out in Central Park. I have done quite a bit of airplane flying, and have watched the growth of student training come up. There have got to be many changes, for example, Mr. Guggenheim's intimation that these schools be placed under Government supervision. Any schools which are going to train pilots or accept applications or take money for payments should be thoroughly looked into. A great many schools are trying to teach students how to fly by mail and one thing or another. A great many good pilots are going to be made if they have the proper schools to go to.

WOODY HOCKADAY (Aeronautics Division, Department of Commerce, Washington, D. C.): I would like to ask Colonel Lindbergh if it would be possible for the Department of Commerce to regulate the airplane schools in the same manner that they license a pilot. You can't go out and fly around without a license. Would it be possible to do something along the same line in having the Department of Commerce regulate these schools?

COLONEL LINDBERGH: That is a question concerning the authority of the Department of Commerce. I think that Secretary MacCracken could give you that information. The Department is only able to regulate pilots engaged in interstate traffic. Pilots operating within their own state, or intrastate flying, are not subject to the Department's regulation unless the individual state they are flying in has adopted the Federal Regulations. The flying school, of course, may operate entirely within a state. I believe that any further information would have to come from the Department.

LIEUT. COMMANDER WICKS (Lakehurst, N. J.): I was very much interested in hearing Colonel Lindbergh's talk on this subject. I think it is a vital one.

I can say that I have been in the Navy going on twenty years now, and I think for nineteen years of that time I have been going to school. Going to school doesn't mean necessarily just sitting behind a desk and reading books or studying them, or making out theoretical answers. Going to school has its practical side as well as the other.

I sincerely hope that Colonel Lindbergh's remarks about schools for transport pilots will be well taken. I hope everybody will bear it to heart and carry it out so that it will be considered more of a university course than something to get through with in a couple of hours in order to earn a precarious living at it.

LIEUTENANT BERTRANDIS (New York): I think the commercial flying school is one of our most serious questions. There are out on the Pacific Coast (as I have seen) a number of schools that we might say, "fly by night." They have no set instructions or program to follow out. You go out and climb into a ship. You don't know who your pilot is or what sort of aircraft you are flying in.

I think commercial flying schools should be recognized in the same way that military schools are recognized, whether they be recognized or registered with the Department of Commerce or some other department. The equipment of these schools should be of the type approved by the Department. The instruction should start out as it does in other schools, with classroom work. That would give the student the foundation of flying; then next would come the air work; and third, the finishing training. That should take in the usual amount of solo work and acrobatics.

The schools that we now have do not come into night flying. They should have further advancement and training by carrying out, maybe, a hundred hours of that. Today, it takes only fifty hours to make a pilot, but it really takes years to make a good pilot.

I can remember a pilot back in the days when I started with Art Smith, in 1915, at the World's Fair. That man is dead today. He was flying between Chicago and Cleveland over the air mail route. He was killed because there was not that control from the two points as to whether he should go through or not. He sacrificed his life for the development of aviation.

I warn everybody that the course you get in commercial flying by correspondence will not fit you as a transport or good commercial pilot. The schools you find out in the country that have a sign, "Learn to Fly with Bob, \$5," are dangerous. I hope that enough pressure is brought to bear to establish some set rules for commercial flying schools. Then, I think we will have some more Lindberghs.

CHAIRMAN GUGGENHEIM: Thank you, Lieutenant Bertrandis. You have spoken right out on this subject.

I think that is the sort of speaking we want to have. He has spoken in no uncertain words about some of the pitfalls that are before us in aviation. I think we should take them to heart. He says that it takes years to make a pilot. I most heartily agree with that. I would like to add that it only takes a short while out of the game to unmake him. I am talking from my own personal experience.

MR. BEARDSLEY (Brooklyn, N. Y.): I would like to ask a question, as a non-flying civilian, in regard to the regulations or safe practices which have been developed in the flying schools concerning the minimum limit above the level of the terrain for flying. The question comes up somewhat on account of my residence in Brooklyn. A great many flyers come over the house, some so low that we feel it is dangerous. The airmail planes maintain a very high elevation. It comes up also in night flying and in fog as to whether these limits are established by practice. Are there any devices being made which will warn a flyer in fog or at night about his getting down to a dangerously low elevation, or the proximity of some projection like mountain ranges, high buildings and so forth?

CHAIRMAN GUGGENHEIM: I must remind you that this discussion must be limited to the subject, The Safety Requirements of Commercial Training. As a matter of fact, the point you bring up in regard to legislation is a very important one, and we are having a session, under the Chairmanship of Assistant Secretary of War Davison, which is going on now in this hotel. The principal speaker is Assistant Secretary MacCracken, of the Department of Commerce. I am sure that any matter pertaining to legislation would be very welcome if brought up for discussion at that session.

MR. BEARDSLEY: In explanation, I didn't bring it up as a matter of legislation, but warning during the training period, as to what a safe level might be, not a legal level.

MR. STOCKMAN (New York): Is it conducive to safety to teach pilots with such safety devices as slotted wings and others which may add to safety?

CHAIRMAN GUGGENHEIM: The question put is whether it is advisable to train with slotted wings and other devices. Will you answer that, Colonel Lindbergh?

COLONEL LINDBERGH: A great many instructors hold that a student should be trained on a machine similar to the OX5-Jenny type. That is a machine which might be called "able to take to the air, but not to do very much more." Others hold that all devices such as slotted wings should be used in training. While there is a great deal of controversy along those lines, I don't believe that any one person is capable of deciding whether such safety devices as slots should be incorporated in the training plane or not. As I stated before, the safety may be increased very greatly in either case by constructing a training plane which is able to go through an ordinary crash without serious injury to its occupants.

MR. RIDGES (New York): I think we are all impressed by the fact that there

is such a thing in industry in general as a character basis of safety and efficiency. I think we are all impressed by the wonderful character of most pilots. I would like to ask Colonel Lindbergh a question having to do with a specific point of requirements in training—whether anything is being done specifically, or can be done further, to get at the development of pilots on the character standpoint purely from the standpoint of safety. Is anything being done along the line of character development?

CHAIRMAN GUGGENHEIM: Colonel Lindbergh feels that is a little bit outside of his province. He would prefer not to answer that as he is confining his remarks purely to the technical subject of training.

MR. CHAPIN (Philadelphia): I am not an airman, I am an engineer, but I have gone to school, and I wonder where we are going to get teachers who will be of the type capable of giving these men the training they should have. If we can find those men, how many schools and what distribution should there be through the country today or ten years hence? I am looking to the development of an educational system which will take care of the problems you have here today. I think now is the time to begin to train the teachers who are going to try to train the flyers in the next generation.

MISS WARNER (Washington): In view of the fact that a great many young pilots now get licenses after ten hours of solo flying and immediately start out in cross country flying, their friends are lucky to be so optimistic as to be willing to fly with them. They should be required to know how to get out of tail spins, and so on. Those things should be part of the examination for private licenses. I have never had a tail spin, and I don't think I want one.

CHAIRMAN GUGGENHEIM: The lady who just addressed us is a pilot, and the sister of the Assistant Secretary of the Navy for Aeronautics. She has made a very valuable contribution to this discussion. She raises an important question.

COLONEL LINDBERGH: The requirement for a private pilot's license at the present time, as most of you know, is that the pilot must have completed ten hours of solo flying in addition to the instruction he has received. Ten hours of solo flying, of course, will not make anyone a pilot. We can not require, however, as much experience on the part of the private pilot as we require on the part of the pilot who carries passengers or property for hire. Personally, I am entirely in favor of more rigid requirements for private pilots than we now have. It was a very short time ago, however, when we had no regulation whatsoever, and it was not advisable to begin with too rigid regulations for our pilots in this country. I believe that in the not distant future, the requirements for this type of pilot will include such things as acrobatics and dead stick landings.

CHAIRMAN GUGGENHEIM: I think that is very clearly answered, Miss Warner.

DR. FRANCIS (New York): One of the gentlemen asked a question a little while ago (I have forgotten just how the question was put) on the moral hazard or something like that. I want to say this, before a person is permitted to even study aviation or to go into any school, it is necessary for him to visit the flight surgeon. That flight surgeon is supposed to sit and talk with him anywhere from one-half to three-quarters of an hour and to try to learn all of his private affairs in order to size up the man and to see whether he is an individual whose nervous system and whose psychic system are such that he can stand up under the stresses of the air. Many of these flight surgeons are Army-trained, and it is the custom in the Army to have the same Army flight surgeon appointed by the Department of Commerce. Regarding schools, I certainly believe that something ought to be done to classify them or to regulate them and see that the students get a fair deal. Most of the students starting in, of course, know nothing about aviation. Many of them have wild ideas about it.

I talked with one student who was supposed to have been studying for a while

who told me that an airplane ran entirely by electricity. If you ask many of the students where they expect to fly, they would say, "Well, within the city limits." If you asked them where the field was, they wouldn't know. If you asked about the people, they would probably tell you they didn't own a plane yet. About all they had gotten was a bunch of promises. Of course, that naturally occurs during the early days of most anything, and I think that many such schools have passed away now.

I might say that I have talked with some six hundred or more, and the students seem to be getting pretty well grounded, so that the matter of education, I think, is getting fairly well settled, but I do think that is a matter for careful consideration.

LIEUTENANT McCAGUE (U. S. N.): The two years of flying which I had during the war will never be forgotten in the sense that the parachute at that time was not used to any extent. Of course, it was the regret of everyone concerned that we weren't using the parachute at that time to save the lives of the student pilots and those who were training them oftentimes, but since this parachute has come into its own and is a very valuable asset in the way of safety, I am wondering, from a point that Colonel Lindbergh brought out this afternoon, whether the parachute could be brought into another use.

He said that a training plane could very well be built strong enough and in such a manner that if the pilot or student while training crashed, he very likely would be nothing more than crippled temporarily at the worst. I would like to ask from the standpoint of safety with the parachute, whether it is the plan to use, along with the student plane of today, the parachute in any form. I think it could be done. We have different sized parachutes and have different capacities. In that way, we can train pilots for both commercial and transport work or anything of that kind with the assurance that if something does get beyond them and crash is inevitable, if they have any altitude at all, they can save themselves by means of the parachute.

CHAIRMAN GUGGENHEIM: That question of parachutes is of such importance that a whole session has been devoted to it. I am afraid if we opened up that subject here, we would probably become involved in the whole parachute discussion. But, it is recorded that you have thought it important in the training of pilots. Any further details will be contained in the parachute session of this conference.

MR. NORBY (New York): I believe schools should have more rigid examination of pilots. Also, in the actual tests, I think the regulations are too lenient. In the Navy regulations at Pensacola, when you get just beyond the boundaries of the field with not sufficient altitude, they will tell you to cut the gun and try to get back into the field. The Department of Commerce inspectors don't have you go into tail spins or any of those things at all.

A great many have airspeed meters, but unless the inspector is a good man, he doesn't know himself unless he is equipped with instruments, so the student is allowed to spin and slide and turn, and nothing is said about it. In making these various tests, I believe the student should be turned down by the Department of Commerce and sent back to school for another ten hours or so of flying if he fails to come up to the proper standards. As far as the theory of flight and all that goes, it is a mighty good thing for the pilot to know, but the air test is the main thing.

MAJOR HARTNEY: On the subject of the requirements for training of a commercial pilot, there is one point I certainly would like to state very definitely. There should not be any stifling of the possible supply of students by stringent regulations on schools.

In other words, there might be some little boy probably away out in the Rockies who has the urge and private initiative and desire to learn to fly, and

he might be our next Lindbergh. If we place regulations on flying schools which are going to stifle the chances of that boy getting in there and learning, we are going to lose another good man, absolutely.

We have certainly done better than other countries did when they established similar regulatory powers. But, we are not always going to have the present Assistant Secretary with us, and we must be very careful when we establish any regulations that limit schools and thereby stifle private initiative. When I speak of that, I mean not only of the student coming in, but also the man who is running the school. It is interesting to note that in the development of the technical side of aviation, the Army, by bringing out motors and planes, has done its part wonderfully. That holds true also in the Navy and other Government departments. But when it comes to operation of the plane, it is always interesting to note that it is the private initiative in competition with individuals not connected with the Government that brings out what the airplane can do.

As an illustration of that, who in this country would not have been called crazy three years ago if he had told you that nine planes loaded like those nine planes were two or three weeks ago, taking off for San Francisco or Los Angeles, could take off in a twenty-five mile an hour side wind? Everybody would have said that person was crazy. It took private initiative to do that. You might say the Department looks askance or overlooks the danger of the thing, the Department of Commerce, which might have stopped that. It took that initiative, and that competition coupled with it, to bring out the fact that you could take off with a heavily loaded ship in a twenty-five mile an hour side wind, as those nine ships did, and get away with it. It was absolutely remarkable. It is true that the equipment developed by the Government did it, but it took private initiative to do it.

That same thing applies in schools. Every school that can buy enough airplanes to attract students surely should be given that responsibility, and surely the regulations applying to them should be placed on the machines and the pilots. That may give a basis for some discussion, but I certainly am for keeping the regulations of the schools to a minimum and not shutting out these young boys who might come in.

CHAIRMAN GUGGENHEIM: That is an interesting point, and it really brings up the fundamental decision that will have to be made within the next few years. We want to get some more light on it. We are all agreed that pilot training should be safe. How are we going to make it safe? Are we going to gradually raise the standards by private initiative (which is one point of view and very ably expressed) or are we going to have some Government regulations? Those are the two important issues, I think, in this whole problem. We are all pretty well agreed on that. Discussion on that particular point by those who have had experience (and there are many of you in this room) will be very heartily welcomed.

COLONEL LINDBERGH: I am speaking now purely from the point of view of the layman. From the discussion I have heard here, it appears to me that the chief difficulty is competition. The schools that are not fully prepared to give the student proper training are running the better schools out of the market. It appears to me that the proper way to carry on the proper training of the pilot would be to organize good schools, set up safety principles, see that the planes and pilots are licensed and that the students have had a medical examination before they enroll, and that their records are kept right from the start by the Department of Commerce. By so doing, I believe that we will control without undue regulation and without interference, the proper training of pilots. If the best schools band themselves together to run the mediocre schools out of the market, the proper standard of safety will be maintained.

Mr. DONALDSON (New York): I would like to know if there is some way

by which a person interested in taking up flying can ascertain where the proper schools are and the merit of those schools. Naturally, if they write into the school they see advertised in different places where they can pick up aviation, they are assuming they are going to get a course in flying. If they ask for the qualifications of that particular school, they are going to send back the best report possible. Is there any possible way in which the younger generation taking up flying can have an assurance when they finish that course that they have taken the best course to fit them for the future in aviation?

I ask this question because, being a flyer myself, I have had a number of inquiries come to me within the past year as to the best place to take up flying, both from the point of paying for the tuition and also in working one's way partly or entirely through. I think it is a very difficult question. I would like to get some more light on the subject. I think it should be handled in some way so that the public would be able to know the answer to those questions as well as the people already in the flying game. Is there any place where that information is available—the list of schools and the method of training courses that they give?

CHAIRMAN GUGGENHEIM: Some of that information is available and some of it is not. Nobody will take the responsibility of branding any school as the best in the country or the worst school in the country for a course in flying. The Department of Commerce will give you a list of all flying schools, and they will give you as much information as is available about them. From that point on, you have to make your own inquiries in the locality in which the school exists. That is something which everyone can probably do better for himself than through some other agency. It is not as satisfactory as we would like to have it. If there was some method of rating these flying schools, it certainly would add to the safety in the training of pilots.

MR. LOENING (New York): There should be a positive rating of the schools by the Department of Commerce on the score of their effectiveness. There is no reason why the Department of Commerce couldn't have a statement, that each school has graduated so many pilots and is graduating so many others. They could then get out a quantitative statement based on the record of the school, which in turn right now would tend to make these schools establish a better record if they knew their record was going to be subjected to considerable scrutiny.

This question is brought up to me many times in New York. It is very difficult to say what are the good and the bad schools. There are lots out West that sound good. We don't know whether they are good or not. There ought to be some authoritative ranking of schools on the basis of past records which would help to make them get good records.

CHAIRMAN GUGGENHEIM: That is a very interesting contribution. Is there any further discussion before we pass on to the next paper?

QUESTION: I would like to know what Colonel Lindbergh's opinion is relative to the advantage or disadvantage of a course in gliders in connection with training a pilot in flying.

COLONEL LINDBERGH: We have no practical experience upon which to base such a comparison in this country. Consequently, I am unable to give any answer.

CHAIRMAN GUGGENHEIM: I might add that gliding has a great historical interest in aviation, because the pioneers learned to fly in gliders. That was all there was available to them. I don't think that in any other country but Germany, has gliding been taking up to a great degree in recent times. I think that the gliding enthusiasm that took place in Germany shortly after the war was brought about, to a large extent, by the restrictions imposed after the Treaty of Versailles.

CHAIRMAN GUGGENHEIM: The next paper has been prepared by Commander E. E. Wilson, U. S. N., who is Chief of Staff, Aircraft Squadrons, U. S. S. Langley. This fleet is now operating in the Pacific, and it is impossible for Commander Wilson to be with us today. Commander Wilson is an aircraft engine specialist, of very great reputation, throughout not only the Navy, but also in the industrial aviation world. He, also during the war, established a system of training for ground personnel, which stands today as an example of what ground training should consist of. We are very fortunate in having this paper, and unfortunate that Commander Wilson is not with us. Lieut. Commander Wicks has kindly consented to read his paper.

LIEUTENANT COMMANDER WICKS (Lakehurst, N. J.): Mr. Chairman, Ladies and Gentlemen, I took this job with considerable misgivings, as I know what Wilson is and what he has done and what he could do. I also have a slight acquaintance with my own ability, so I feel rather reticent to take his place, because I know I can't fulfill it the way he would have done. However, it seems that the airplane can't fly across the continent in a couple of hours yet, so Commander Wilson couldn't get here.

Requirements and Training of Ground Personnel

By COMMANDER E. E. WILSON, U. S. N.
Chief of Staff, Aircraft Squadrons, U. S. S. Langley

A fundamental requirement for safety in aviation is an efficient ground organization. Broadly speaking, the ground organization includes all of the organization except that which actually flies. For the purpose of this discussion, however, the ground personnel will include the technical staff of the ground organization. This technical personnel will fall into three classifications, Operations, Maintenance, and Communications. In the task of insuring dependability and safety the technical staff will find its profession to be what has been termed "Preventive Engineering."

Experience in all transportation has demonstrated the importance of preventive engineering. A defect which can be located and corrected in advance of a journey eliminates a potential accident. The character of the inspections to be made is largely a matter of experience with the type of apparatus employed. The preventive measures taken are likewise matters of experience. In the operation of a Liberty engine, for instance, we know that an examination of the ignition distributors in advance of a flight may prevent ignition trouble during the flight. An operations department must, therefore, establish a routine of inspection and correction calculated to prevent trouble enroute. The efficacy with which this system functions is in turn dependent upon the training of the personnel which operates it. How shall these men be selected, and how shall they be trained?

This question has no doubt been answered by a number of organizations. It will pay us to look into the history of the matter. My personnel experience covers the Navy's solution to the problem, and for that reason I will outline this experience.

At the close of the world war the demobilization of the war-time personnel threatened to leave the Navy without any trained enlisted personnel. Unlike the other branches of the Service, Naval aviation had been almost entirely recruited from civilian life. If operations were to be continued it was necessary to develop a new staff. During the war the Navy Department had called upon Doctor Charles Edward Lucke, head of the Mechanical Engineering Department of the Columbia University, to organize the aviation mechanics training system. Doctor Lucke was peculiarly fitted by virtue of his personality to perform this colossal task.

Bringing all his energy and executive ability to bear, he established a large

number of schools at the different naval air stations and at the factories of certain industrial organizations supplying material to the government. For example, a school for engine mechanics, known as the Liberty Engine School, was established at the plant of the Packard Motor Car Company, which company was then building large quantities of Liberty engines. This aviation mechanics training system developed its own text books, trained its own instructors, purchased and installed its own equipment, and, having educated itself, proceeded to educate its students. Although the schools were widely scattered, they were none-the-less standardized, both in theory and in practice. They were sound in their methods of instruction, and were administered with a vigor which reflected the personality of their leader, Doctor Lucke.

The post-war demobilization might have resulted in the abolition of these courses of instruction, save for the foresight of Captain E. L. Bennet, then head of the Training Division of the Bureau of Navigation. A decision was reached to concentrate at the Naval Training Station, Great Lakes, all of the aviation mechanics training schools then established at the different air stations and industrial plants, and to build them up in such a way as to permit expansion in the case of another emergency. It was decided after having established the schools there to utilize the training of the new recruits as a sort of service test of the new installation. The necessary orders were issued to cover this situation. Doctor Lucke kindly remained in the Service long enough to get the transfer well underway and to turn it over to the author of this paper.

Early in 1919 many carloads of apparatus had been transferred to the Naval Training Station at Great Lakes and had been installed in working order. A number of selected wartime instructors remained in the Service to instruct the new staff. Many of them are still in the Service. As soon as it was apparent that the schools would be ready, an intensive recruiting drive was begun. Men were selected especially from the nearby manufacturing centers, and all recruits were required to meet the standards of entrance to the Navy. Aviation duty, by virtue of its appeal to the youth of the country, attracted a very high class of men. These were, to a large extent, students or graduates of high schools, with or without mechanical training, but in all cases with a fine spirit and attitude toward the Service. After the usual preliminary recruit training period these men were introduced into the schools. Certain outstanding ones were immediately selected as instructors in certain of the periods of the different courses. Before very long the machinery was in operation, and when the school reached its peak it was receiving men at the rate of from 50 to 100 per week, and graduating them in about half these numbers. Nearly 3,500 men completed the course in the two years it operated to capacity. This was an early application of American production procedure to education. The numerous graduates of the schools went out to the different operating stations, where after a reasonable amount of experience and familiarization they replaced the wartime personnel very satisfactorily. Hundreds of these men are now in the Service, occupying the key positions of the Navy's aeronautic organization.

One of the interesting aspects of this training system was the preparation of the text books. Doctor Lucke selected from among the best instructors of the wartime system men who were peculiarly competent to prepare text books. It was his desire that the experience of the war be made a matter of permanent record and not lost with the release of the personnel. There was established at Great Lakes a Text Writing Detail, consisting of from 75 to 100 people. This Detail was under the supervision of an editor-in-chief. It was thoroughly well organized into its writer, editorial, and art departments, with all the other ramifications of the sort. Thirteen courses of instruction were covered, and for each course of instruction there was prepared a book covering the syllabus of the courses, a book covering the details of the courses and the allocation of time, and a text book from which

the instruction could take place. A total of 39 volumes were prepared. After the preparation of the text and the illustrations the volumes were printed by contract with a well-known publisher of technical literature. They constituted the basis of instruction in the schools, as well as at numerous stations throughout the Navy. They were so carefully prepared in the beginning that even though new types of engines and new types of aircraft have come into service the instruction books are still of great value.

The Aviation Mechanic Schools at Great Lakes, applying the systems outlined by Doctor Lucke and utilizing the text books prepared by the wartime personnel, furnished the Navy with a full complement of well trained mechanics. These men, working throughout the aeronautic organization, are now the key men. Among their tasks is that of training the new recruits in the operation and maintenance of naval aircraft. Whether these men be employed as a part of the large number on one of the large operating bases or on a large carrier, or whether they be one of two or three members of an aviation crew of a small vessel, they function under the same method of training and with the same degree of efficiency.

The courses established at Great Lakes fell into three categories; (a) the apprentice courses; (b) the intermediate courses; and (c) the advanced courses. The apprentice courses were intended to take recruits with little or no mechanical training and instruct them in mechanical principles. The intermediate courses were intended to take men of practical training and instruct them in the aviation specialty to such an extent that they might become the rank and file of the operations departments. The advanced courses were intended to take men of operating experience from air stations and train them in the advanced phases of aviation, with a view to qualifying them as leading men and instructors on the stations. In addition to the above classifications, the courses of instruction were divided into; (a) heavier-than-air; and (b) lighter-than-air activities, the one pertaining to airplanes and the other pertaining to airships. In each of these two major classifications four main trades were developed; (1) the aviation machinist's mate, or engine mechanic; (2) the aviation carpenter's mate, or woodworker; (3) the aviation quartermaster, or rigger; and (4) the aviation metalsmith, or metalworker. The latter rating was developed in anticipation of the arrival of metal aircraft.

The principles of wartime training were based on the fact that men from civilian life could be trained in a specialty in a comparatively brief period. They could not be trained to take the place of the regular soldiers and sailors, who by virtue of years of training and experience could be classified as more or less all round men. The sub-division into four specialties outlined above was largely predicated upon this premise. The same principles were employed in training the post-war recruits. As time has passed and the men have remained in the Service for long periods certain changes have taken place. There is no longer a separate rating as quartermaster, or rigger, and all the men so trained have been transferred to other ratings, for which they have first been required to qualify. Metal construction has changed the situation to the extent that carpenters are less necessary and metalsmiths more necessary. The limited number of men available for service and the limited space available aboard ship has brought about the development of the all around mechanic, who, as a leading man, is capable of supervising the operation and maintenance of the whole airplane.

Our engine men fall into three classifications; (1) the Plane Captain, who is responsible for the routine service and inspections; (2) the Leading Chief for top overhaul; and (3) the Shop Chief, for major overhaul. In normal operations the Plane Captain takes care of routine maintenance. When the airplane goes to the hangar for routine inspection, check and minor overhaul, the Leading Chief supervises the work. When the plane or engine has reached the state requiring major overhaul it is transferred to the shop, where the work is done by the shop men.

Sharp lines of demarkation are not drawn, and men exchange duties as the service permits. The shop qualifications, however, require special training in the use of machine tools, jigs, fixtures, etc., so that our aviation mechanics can be said to fall into the three classifications. As it now works out, the newcomers are assigned as plane mechanics, and after experience and training move up to shop men in the hangar. After further experience and training in special schools they find their places in the shops. As a result of the foresight of responsible officers the Navy has never lacked for trained aviation mechanics, and the quality of men now employed is very high. The Navy's experience in this regard may be valuable to commercial aviation.

Commercial aviation is today in the midst of tremendous expansion. Factories for building airplanes, engines and accessories are being rapidly organized. Air lines are being rapidly expanded in numbers and in territory. This tremendous expansion must carry with it the corresponding increase in personnel. If safety is to be obtained the personnel must be adequately trained and highly dependable.

The source of supply of trained personnel is something of a problem. Fortunately, expansion in associated trades has greatly increased the available supply of partly trained men. Ten years ago, when the Naval aviation mechanics' training system was functioning, automotive mechanics were comparatively rare. This situation has changed enormously, and the automotive trade alone is a potential source of supply for aviation mechanics. The metalsmiths' art as applied to the automotive practices, as well as practically every other mechanical line, furnishes a source of supply of metalsmiths. The wide-spread knowledge and application of radio telegraphy and telephony throughout the country should furnish a supply of well trained material for the establishment of proper communication systems. Ten years ago these men had to be trained from recruits. Now numerous skilled men are on call. Woodworkers are available from the numerous woodworking trades. There is no allied art to rigging, and training in this capacity will be necessary. In general, however, it may be said that an adequate supply of men trained in the fundamentals of the art is available. The training in the specialty is the factor which will determine their suitability to aeronautic activities.

Here again we may take a leaf from the booklet of our own experience in the case of engine mechanics. For instance, even highly skilled men experienced in the inspections and maintenance of one type of engine must receive training and experience in new types in order to handle them properly. With the passing of the war-time water-cooled engines and the advent of the modern air-cooled engines this factor was appreciated, and steps were taken to provide for it. The cooperation of the engine builders was immediately forthcoming. It was to the interest both of the purchaser and the engine builder that dependable operation be had. Our engine builders therefore trained in their shops selected Service men of proper personality, who went out to the operating units and instructed the operating personnel in the specialized maintenance and operation of their product. Engine builders likewise rendered this service to commercial purchasers of their engine. As the instruction has been completed, these Service men have taken over the service activities in a manner similar to that of the automobile trade. Thorough training of engine mechanics is largely responsible for the dependable operation of the modern engines.

This same principle has been applied to a certain extent in the Navy in the case of airplanes. Our different manufacturers have assigned service men to the units operating their aircraft, and these service men have lived with the units. In some cases the service men have gone on long cruises with the Fleet to distant places. As a result of their assistance operations have been made more certain, and as a result of their reports manufacturers have been able to incorporate changes and improvements of incalculable value. As production increases, the same procedure may follow commercially.

Over a long period of time the Navy has been making a very careful analysis of accidents of all kinds. Complete information is submitted to the Bureau of Aeronautics in the case of every trouble, no matter how minor. These reports have been analyzed from every point of view. The outstanding conclusion from this analysis is that every accident is preventable. The real problem is to so apply the experience as to preclude the possibility of accident. It can be confidently stated that good aeronautics material today is more dependable than the personnel that operates it. Given adequate inspection, intelligent administration in the correction of faults before they develop, material failure can be prevented. Manifestly, the degree to which it is prevented is a function of the adequacy of the training of the personnel and adequacy of the administration.

For example, a commercial air line operating with modern aircraft equipped with modern engines will or will not give dependable service, depending upon the skill of its operators. This has already been conclusively demonstrated in the operations of existing air lines. Even the briefest analysis will show that certain air lines operating under certain conditions are absolutely free from material failure. Certain other air lines operating under similar conditions are singularly subject to these failures. The difference is entirely in the skill of operations.

The analogy is complete in the case of military units. Our squadrons which have been organized over a period of time, in which the men have been selected with some care and trained with even more care, are singularly free from material casualties. On the recent cruise to Hawaii three squadrons of airplanes, totalling forty-two, operated from the "Langley" out over the Pacific Ocean. They were using Boeing fighters and Vought Corsairs, with Pratt & Whitney Wasp engines. The personnel of these squadrons had been carefully selected, had worked together over a long period of time, and was thoroughly dependable. During this period over six hundred flights were made, for a total distance over the sea of at least 60,000 miles, and not a single forced landing occurred. By contrast, certain new units in process of organization have not such a clear record. It takes experience and training to attain this degree of excellence. The rapidity with which it is attained in any unit is a function of the character of instruction and the quality of administration.

In so far as operations are concerned, the nature of the weather will govern to a large degree. No doubt, numerous aviation accidents result from the failure to properly estimate the situation in advance of a flight. Frequently, weather conditions indicate the hazardous nature of a projected journey. Frequently, the voyage is undertaken in spite of this. In any problem of this kind, it is necessary to make an analysis before the take-off. Rear Admiral Hutch I. Cone, a member of this Fund, many years ago coined a phrase which is of continuing value in all operations. In discussing destroyer maneuvers which were hazardous, he said "While the Department does not desire to discourage the taking of intelligent chances by young destroyer captains, it cannot too strongly condemn foolhardy operations." The expression "Intelligent Chances" can be applied to every airplane flight. Before the flight takes off the question may be asked, is or is this not an "intelligent chance." In other words, is the expected gain commensurate with the risk involved. If the necessity for the flight in spite of the hazards is sufficient, then it should be undertaken of course. If the gain is not sufficient to compensate for the risk, it should not be undertaken. The judgment of the director of the whole ground personnel will govern here.

To summarize: We may say that every aviation accident is preventable. Eliminating the errors of judgment on the part of the pilot and referring to the mechanical troubles, these are certainly preventable. The degree to which dependable operation is had is a function of the skill of the operating personnel. There are three circumstances under which this skill is tested. First of these is in the normal operations on the line, when routine inspections and preventive measures

are taken, not only with regard to the power plant and aircraft installation but with regard to such rudiments as insuring clean fuel, an adequate supply of lubricating oil, etc. The second phase is in the top overhaul and detailed inspection in the hangar. Every airplane and every aircraft engine should be given a thorough routine inspection at the end of an interval determined by the character of the operation. The skill and thoroughness with which this inspection is made will determine the dependability of operations. The third phase is in the major overhaul of the airplane or engine. The degree of skill displayed in the shop and the quality of the inspection therein will again control dependability.

In the rapid expansion that is taking place great care must be devoted to the training and selection of ground personnel. Fortunately, a source of supply of men reasonably well grounded in basic education is available. From these men those of the highest character and educational attainment should be chosen. They should then be properly trained in the basic training of aviation specialty. This may take place in operating units, with the assistance of technical representatives of the producers of the material. It may further take place, and probably will take place, in trade schools, as in the case of other trades. These men must have special training with *special emphasis on dependability*. They must be taught to realize the seriousness of failure and the effectiveness of success. This is a problem for each and every operator of an air line. It should be completely solved before any passenger carrying operations are undertaken. The records of organizations now in operation are a measure of the degree to which these principles are carried out. The rapid expansion of aeronautic operations today makes this one of the most important subjects for consideration. Future development and expansion will depend largely on the degree to which the requirements are met in the immediate future.

CHAIRMAN GUGGENHEIM: Gentlemen, that is an admirable paper, written by a man who knows his subject thoroughly. The airplane's ability to fly in the air is entirely dependent on the ground personnel and their training. The paper is now open for discussion.

WOODY HÖCKADAY (Aeronautic Division, Department of Commerce, Washington, D. C.): I am not versed in this subject, but it is my impression that in a good many cases where accidents occur, they say "it happened on account of a faulty gas line, the gas line was clogged or the oil line was clogged."

Does that happen because the station or airport where they ought to have funnels and chamois skins to drain the gasoline, do not use them? How do they protect their oil in the majority of instances? It seems to me that they certainly could guard against dirt and trash in gasoline and oil, and they could guard against water getting in, too. For instance, I know if just the least bit or drop of water gets into the gasoline in an automobile, sometimes it will stop it instantly. It seems to me they certainly should guard against those things somehow. Do they drain their gasoline and lubricants?

CHAIRMAN GUGGENHEIM: That is involved in the maintenance of aircraft. That gets back to this question of adequate training, proper training. If that is done, those difficulties should not exist, and incidentally, they do not exist on properly organized air routes operated under the right sort of management.

Is there any further discussion of this paper? Gentlemen, we certainly are very grateful, I am sure, to Lieutenant Commander Wicks for his kindness in reading this paper.

ADJOURNMENT.

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Passenger Safety

First National Aeronautical Safety Conference

Under Joint Auspices of

*The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council*

October 4 and 5, 1928

CAPTAIN EMORY S. LAND, Chairman

(C. C.) U. S. Navy, Vice-President, Daniel Guggenheim Fund for the
Promotion of Aeronautics, Inc., New York City

The Passenger Safety Session of the Aviation Division at the Seventeenth Annual Safety Congress, was called to order at two-forty o'clock, by the chairman, Captain Emory S. Land (C.C.), U. S. Navy, Vice-President, Daniel Guggenheim Fund for the Promotion of Aeronautics, Inc., New York City.

CHAIRMAN LAND: The first paper on our program this afternoon was prepared by Major Mayo, who is the British Representative of the Daniel Guggenheim Fund for the Promotion of Aeronautics, and who is an aeronautical engineer of great experience. He is with the Croydon Aerodrome, is on the committee to investigate accidents, and is one of the best rounded men, particularly in connection with passenger traffic that there is in the world today.

He was recently over here in connection with commercial aviation, both engines and aircraft. But unfortunately he was unable to remain for our first National Aeronautical Safety Conference.

During some of his tours around New York, he came in contact with a number of our representative people in aviation, and upon one of those who gave him most able guidance and assistance, we are calling to read Major Mayo's paper.

He has been an aviation enthusiast since he rolled out of the cradle. He took an aviation course in college. He has written a book and done everything there is in aviation. And this summer he learned to fly.

I take great pleasure in introducing, Mr. Grover Loening, who will read Major Mayo's paper.

GROVER LOENING (New York City): I wish before reading the paper, I could describe Major Mayo to you. He is very eager, extremely intelligent, and active minded, very quick (very un-English in that regard) and has every aspect of flying right at his finger tips, as you will readily see, after hearing this paper.

Safety of Passengers**By MAJOR R. H. MAYO****British Representative, Daniel Guggenheim Fund for the Promotion of Aeronautics, London, England**

The subject of safety will be reviewed from so many different angles by the various contributors to this Congress, each a specialist in some particular aspect of air transport or aircraft design, that there must necessarily be some difficulty in dealing with the safety of passengers without encroaching on the ground which is the proper domain of other contributors. No attempt will be made in this paper to review the whole subject of safety in passenger air transport, as it will be assumed that all possible precautions making for safety in the aerodynamic and structural design of the aircraft, in the installation of the power plant, and in the methods of operation have already been taken, and the paper will deal only with certain particular features affecting the personal safety of the passengers carried. Some of these features are so closely interrelated with the design and operation of the aircraft as a whole that a certain amount of overlapping will probably be unavoidable.

It will be necessary to consider the subject from two different points of view. First, there is the question of the safety of passengers under normal conditions of operation on the ground and in the air, and secondly there is the question of the safety of passengers in case of accident. On the one hand there are certain precautions which must be taken to secure the safety of passengers even when the aircraft and its engines are functioning perfectly, and on the other a good deal can be done to minimize the risk of injury to passengers when, as must happen on occasion in all forms of transport, there is failure resulting in accident. Although the requirements for safety of passengers under normal and abnormal conditions may be at variance in certain respects, it will be found in general that there is little divergence between them. The most convenient way of dealing with the subject may therefore be firstly to trace a normal passenger carrying transport flight through from start to finish and secondly, to consider the various forms of failure which may result in interruption of the flight or accident.

Preliminary Stages

It is to be assumed that the aircraft will be taxied to a convenient position, so that it can be approached by the passengers without risk by the passengers. In the case of land airplanes this presents little difficulty, but as air transport develops some care will be necessary to ensure that passengers can reach their particular airplane without having to cross the path of other airplanes which may be moving in the vicinity. Special care will be necessary if the use of taxi airplanes develops considerably. In the case of marine airplanes greater difficulty may be involved. The docking of marine airplanes is by no means so easy as the docking of ships owing to the large wing span, and the embarking of passengers is correspondingly more difficult. One of the chief requirements is that the start must be made from really sheltered water, so that the passenger is not required to perform gymnastic feats in order to get on board.

On reaching the airplane the passenger must be properly protected against certain risks which may be summarized as follows:

1. All risk of walking into a rotating propeller must be eliminated. Airplanes in which the propellers are definitely out of reach have a distinct advantage in this respect. Where propellers are within reach, guards should be provided either as fixtures on the airplane or as part of the field equipment; in the latter case special care is needed when a start is made from an unorganized base.

II. Passengers must not be called upon to pass through the blast from a running propeller in order to get into the airplane. Any engine whose propeller slipstream may interfere with passengers getting into the airplane, should be stopped while the passengers enter, and the means of starting must be such as to ensure a quick and certain start afterwards.

III. Access to the airplane by passengers must be easy and safe. Wide doors properly secured in the open position must be provided, and no climbing on slippery steps or ladders must be involved. Airplanes providing easy access from ground level without the use of auxiliary steps have a distinct advantage, as the auxiliary steps may sometimes not be available. This requirement has often been grossly neglected, especially in the case of taxi and touring airplanes. Passengers have sometimes been required to clamber up into the airplane in a manner which they would not tolerate in any other form of transport; such efforts involve not only inconvenience but also risk to passengers. In the case of marine airplanes easy and safe access is of even greater importance as steps, etc., are more liable to be slippery.

The closing and securing of the door after passengers have been embarked is a matter which presents some difficulty. The door should be positively locked for security, and it is desirable that the locking should be controlled from the inside. In the case of large airplanes carrying a steward in the passengers cabin no difficulty is involved, for the steward can be made responsible for locking the door immediately after embarkation of passengers. If a steward is not carried some other member of the crew must be made responsible; this involves the inconvenience of the pilot or other member of the crew passing through the cabin after the passengers are seated or the complication of remote control. In general it is not feasible to place the cabin door within direct reach of the pilot's cockpit. There is scope for the development of improved types of automatic locks for cabin doors.

Taxying and Taking-Off

Under this heading it is necessary to emphasize the importance of providing against jolting of passengers. The essential requirements are ample provision for shock absorption in the undercarriage and tail-skid system, and a proper fixation of the passengers' chairs. In cases where rough ground surfaces have to be dealt with, belts should be provided for passengers; such belts must be strong but with a certain amount of elasticity. It is, of course, compulsory to provide belts for passengers carried in open cockpits. The seats must be well padded and so placed that the passengers are not liable to injury against sharp or projecting objects while the airplane is taxying. The backs of the seats should be designed with this end in view. Taxying, taking-off and landing are usually the most uncomfortable phases of air transportation from the passengers' point of view, and risk of injury may be involved if proper precautions are not taken. In the case of marine airplanes, where there may be no provision for the absorption of shock except through the elasticity of the hull or floats, it may be necessary to provide shock-absorbing seats; this will obviously depend to a considerable extent on the particular design of hull or floats.

It is important that all passengers should be seated when taxying starts and remain seated til the airplane is well in the air. Two precautions are necessary, viz., (1) every passenger must have this brought to his personal attention by notices or otherwise, and (2) the pilot should if possible be provided with a view of the passengers in the cabin.

One obvious but important precaution affecting both taxying and flying should be mentioned here, namely, that no open windows must be so placed as

to involve risk of any passenger being struck by a propeller if he leans out or puts his hand out. Where any such risk might be involved a guard such as wire netting must be employed.

It will be convenient to deal here with the question of smoking. Provided no part of the fuel system enters or comes into proximity with the cabin, and provided the cabin is of non-inflammable construction there appears to be little risk involved in smoking. The question as to whether it is desirable to permit smoking from the point of view of passengers' comfort is outside the scope of this paper. If smoking is permitted it should take place in a separate compartment, and in any case passengers must be warned to cease smoking and extinguish lights on receiving a signal from the steward or pilot.

Every passenger should have placed immediately in front of him a notice of instructions embodying the obvious precautions mentioned above and others such as the danger of throwing objects out of windows, etc.

Flying

There is little to be said in regard to the safety of passengers under normal flying conditions. Certain general precautions which apply from the time when the passengers enter the airplane have been mentioned above. It is only necessary to add to these certain precautions to cover exceptional weather conditions. In conditions of extreme bumpiness passengers may be thrown out of their seats and this may not only involve some risk of minor injury but it may also in some cases cause shock and strain. Fortunately such conditions rarely occur except in particular regions, but in all regions where they are liable to occur passengers should be provided with strong shock-absorbing belts, and every object in the cabin should be properly secured. It is desirable that the pilot should have some means of communicating with the passengers, so that he can reassure them in case of such conditions of bumpiness, and should he decide to alter course or land at any time he can notify the passengers accordingly. It is reassuring to passengers to be able to see the pilot through a window, but it is not always possible to provide for this.

Under no circumstances should the pilot of a passenger-carrying transport airplane be allowed to indulge in any form of stunting. Some passengers enjoy stunting but others not only dislike it but are scared by it.

Landing and Completion of Flight

Landing under normal conditions and taxiing in present little or no risk to passengers, but the same precautions as indicated in the case of taking-off are of course required. It is important that all passengers should be seated before the landing is made and remain seated until the airplane comes to rest. Instructions to this effect should be communicated to every passenger.

Causes of Accident

It is not possible within the limits of this paper to analyze in detail the possible causes of accident to passenger airplanes but it may be useful to refer briefly to some of them with a view to indicating the precautions which should be taken for the safety of passengers. The following are some of the more important causes of accident:

1. **Structural Failure.** Provided the normal strength requirements are met and proper care is taken in the maintenance of aircraft, structural failure is a remote contingency and it may be ruled out as a serious factor in organized air transport. Major structural failure will in general result in disaster and nothing can be done to mitigate its consequences.

2. Fire in the air. This again is a practically negligible risk, provided all reasonable precautions are taken in the installation of the power plant.

3. Loss of control. Although steady improvement in control-ability of airplanes has been effected during the last few years, loss of control still occurs occasionally and it remains a potential cause of major accident. Fortunately loss of control is less likely to occur as the size of airplanes increases owing to the slower rate of change of attitude in the larger airplanes; it may be said in fact that loss of control such as to cause major accident is an extremely rare occurrence in the case of large passenger-carrying airplanes operated by organized transport companies. In the case of smaller airplanes loss of control is more liable to occur, although there is good reason to hope that this possible cause of accident will be eliminated before very long.

Accident resulting from loss of control is, of course, liable to be serious. The airplane will probably hit the ground nose first, the amount of damage done depending of course on the height at which control was lost. Precautions which can be taken to safeguard passengers will be summarized below after enumerating the causes of accident.

4. Collision in the air. Up to the present time there have not been many collisions in air transport but as traffic develops it will become increasingly important to guard against this risk by providing pilots with unrestricted fields of vision and carefully regulating traffic. The precautions to be taken to avoid collision will no doubt be dealt with by other contributors to the Congress. In the case of head-on collision in the air the results must almost inevitably be disastrous, while in the case of less serious collision there may be complete or partial loss of control resulting in more or less serious crash on reaching the ground. Nothing can be done to mitigate the effects of head-on collision, but the precautions for the safety of passengers referred to under "Loss of Control" are equally applicable in the case of accidents resulting from the less serious forms of collision.

5. Accident arising from forced landing. There are various possible causes of forced landing such as engine failure, fog or other unfavorable weather, the pilot losing his way, etc. With the development of multi-engine airplanes, and with improved meteorological services and navigating instruments, forced landings are becoming comparatively rare and the time has already arrived when they have ceased to be a serious risk in organized passenger air transport. In the case of single-engine airplanes, however, the forced landing still remains a potential cause of accident. The risk involved varies, of course, very widely according to the nature of the country, the weather conditions and the cause of the forced landing, but the precautions which can be taken to safeguard passengers will be found to apply in the case of most accidents of this kind. It may be said in fact that accidents resulting from forced landing are of the same general class as those resulting from loss of control and the risks involved to passengers are similar.

6. Accident arising from bad landing. Bad landings due to error of judgment on the part of the pilot are comparatively rare and they seldom cause risk to passengers. Collision with other airplanes or obstructions after landing, or a bad landing due to exceptional weather conditions may result in damage to the airplane and possible injury to passengers. In all such cases the results so far as passengers are concerned are similar and similar precautions are required.

Precautions for the Safety of Passengers

Before summarizing the safety precautions which may be taken it may be useful to dispose, or attempt to dispose, of a supposed safety measure which

has frequently been proposed, namely, the use of parachutes. There is one important factor which is common to all the classes of accident summarized above, namely that unless there is a complete disaster such as structural failure or head-on collision in the air, neither the pilot nor the passengers know until the last moment whether a crash is inevitable. In the event of disaster parachutes could very rarely be used successfully by passengers, and their use while the issue is still in doubt is undesirable. The pilot's attention should be concentrated on avoiding accident and it may be dangerous to saddle him with the responsibility of instructing passengers to leave the airplane. It would obviously be undesirable for passengers to decide for themselves. The carrying of parachutes would involve a considerable sacrifice of paying load which cannot be afforded, and, even if provided, they would seldom if ever be of any value. This so-called safety measure must therefore be ruled out.

The provision of a parachute to sustain the whole airplane must also be ruled out for similar reasons. After all, the occurrence of major accidents in organized passenger air transport is extremely rare, and safety precautions must be considered in relation to this fact.

Apart from the question of disaster in the air, the risks to passengers involved in the various classes of accident fall into two main categories: (1) shock or injury on crashing and (2) fire arising out of the crash. There is in addition one particular case of forced landing which should be mentioned, namely, the forced landing of a land airplane on water. In all cases where a land airplane has to pass beyond gliding distance from land special precautions must be taken for the safety of passengers. The forced landing of a marine airplane on land is an extremely rare occurrence and the risks involved in such landing are generally similar to those in a minor accident to a land airplane.

Precautions Against Risk of Injury

Risk of direct injury to passengers in a crash may arise from the breaking up of the cabin structure as a whole, local damage to a part or parts of the cabin, or passengers being thrown forward through momentum. The following are some of the precautions which can be taken towards the reduction of such risks:—

The airplane body structure, and particularly the cabin portion of it should be made as robust as possible and with special regard to its ability to maintain its form in a crash. Metal construction of the main structure must be regarded as an almost essential requirement for the large passenger carrying airplane; but there is not much to choose between steel and duralumin construction provided due attention is paid to robustness as apart from strength under flying conditions.

The cabin should be so placed in relation to the airplane as a whole that the risk of damage is a minimum. Passengers placed in the extreme nose of the airplane, although provided with an excellent view, have the minimum of protection in case of a crash. The wings and undercarriage will take up a very large amount of shock, and passengers should be placed behind rather than in front of them.

The cabin structure should be strengthened locally at points where heavy loads are likely to be imposed in a crash, such as points of attachment of undercarriage members. Strong, robust flooring should be provided.

No engine or other concentrated weight should be placed so that it is likely to be thrown forward into the cabin in a crash. A luggage or freight compartment placed behind the cabin must be very robustly constructed. A

freight compartment placed forward may be an advantage as it may act as a buffer in case of crash.

Passengers' chairs must be strongly and robustly built, and must be positively and rigidly attached to the floor. This is a point requiring special attention in view of the fact that chairs are usually made removable for purposes of cleaning, etc.

The backs of chairs should be padded and should have no sharp projections which might cause injury to passengers thrown forward from behind. The backs of chairs must be strong and rigid enough to give support to the passenger behind at the moment of impact in a crash. Alternatively, separate handrails should be provided to enable passengers to take some of the shock.

There should be no hard or sharp cabin fittings which can cause injury to passengers, and all fittings should be firmly secured.

The provision of belts for passengers cannot be considered essential except under abnormal conditions of operation as indicated above.

Precautions Against Fire Risk

Fire risks will no doubt be dealt with fully in the papers bearing on engine installations and it is therefore unnecessary to refer in this paper to the causes and prevention of the outbreak of fire after a crash. The disposition of the fuel tanks is usually included in the term "engine installation," and other contributors will therefore no doubt emphasize the importance of placing the tanks properly, not only in relation to the engines but also in relation to the passengers' cabin. Apart from the question of power plant installation the most important precaution for the safety of passengers is the provision of ample facilities for passengers to get out of the cabin after the crash. Except in the case of a very bad crash the airplane rarely bursts into flames immediately; there may be in fact an appreciable interval before the fire breaks out and a considerable time before any fire reaches the cabin. Reliance should not be placed on the main door alone as this may be blocked or jammed. Two or three emergency exits should be provided in the roof, and every window should be large enough to permit of the exit of passengers in emergency. Cabins should of course be properly equipped with hand-operated fire extinguishers of a kind which does not generate poisonous fumes. Clear instructions in the use of extinguishers should be posted with them. Automatic fire extinguishers of the sprinkler type are of little value as they are not sufficiently directive.

The special precautions referred to above in the case of a land airplane which has to pass over large stretches of water may be summarized as follows:

(1) The cabin should be at least temporarily watertight provided all windows and doors are shut. If a steward is carried he will be responsible for shutting, before the landing is made, any windows or doors which may be open. Otherwise the pilot must instruct the passengers to shut windows and doors themselves.

(2) Several emergency exits of ample size must be provided in the roof of the cabin. These must be so placed in relation to chairs, etc., that passengers can get out without difficulty.

(3) Lifebelts must be provided for every passenger and every member of the crew. Having regard to space available, etc., the pneumatic type of lifebelt is usually preferred; if this type is used the lifebelts must be tested at regular intervals and two or three spare belts should be carried. Lifebelts must be placed in obvious and accessible positions. The carrying of a collapsible lifeboat cannot be considered necessary in organized air transport.

(4) Full and clear instructions as to the procedure and use of lifebelts should be issued to passengers in the form of notices or otherwise.

In reviewing this aspect of safety in passenger air transport it has been necessary to deal at some length with the various forms of accident which may occur from time to time. A few years ago it might have been considered inexpedient to refer publicly even to the possibility of such accidents, but the time has now come when the subject can be freely discussed without any fear of scaring the prospective air traveller. The record of safety which has already been achieved in organized passenger air transport is such that free discussion of possible risks and safety precautions is likely to increase rather than decrease confidence. The passenger on a modern ocean liner is not scared when he sees the array of boats on the boat-deck or the lifebelt in his cabin, and in the same way the modern air passenger will be reassured rather than scared by the observance of safety precautions in air transport.

CHAIRMAN LAND: I think the paper speaks for itself. We are indebted to Major Mayo, and we are indebted to Mr. Loening for the able manner in which he presented it to us.

The paper is open for discussion.

F. C. PERRY (Indemnity Insurance Company of North America, Trenton, N. J.): I don't believe that Major Mayo touched on the subject of air sickness. Was this included?

CHAIRMAN LAND: Well, it is part of the show all right. But I don't know whether it is a question of safety. That is possibly the reason why he didn't mention it in this paper.

MR. PERRY: How about this proposition then: If you took a canvass of every person here physically, do you suppose a group of doctors would pass every one as to strength of heart and for altitude flying of anywhere from 500 to 5,000 feet? Supposing each one were to take an airplane ride. There might be some casualties, maybe two per cent.

CHAIRMAN LAND: I shall ask Mr. Loening to make general reply to the discussion at the end.

MR. LOENING: As far as I can get Major Mayo's general scheme, I don't think the study of that would come in except that he would want the seats separated from the pilot, so the disturbed person can't start doing something funny that would disturb the other passengers. The pilot should be entirely separate from the passengers.

MR. PERRY: My point is, supposing you made a survey of the United States to find out the available number of people who would avail themselves of air transportation. It is not everyone who would want to go up that should go up, because their physical constitution doesn't warrant taking that risk.

MR. LOENING: When we get to that stage, I guess doctors will be available at every air station.

I think Major Mayo brings up one point about which we might differ. He says, "Bad landings due to error of judgment on the part of the pilot are comparatively rare and they seldom cause risk to passengers."

If he limited that to landing in the home aerodrome, that might be true. But we have lots of examples. Only recently an army plane had to make a landing in Newport, in which the pilot used bad judgment. He didn't know the field and made a bad landing, as bad as he ever made in his career. I certainly would want to enter my objections to that statement.

I think that is where Colonel Lindbergh's training comes in for the safety of the pilots.

LT. ALDRIN (26 Broadway, New York City): Mayor Mayo's paper was cer-

tainly very illuminating. There is one point I would like to emphasize, and that is, in regard to parachutes for passengers.

Major Mayo spoke in connection with organized passenger air transport. Sometimes it is necessary to carry passengers in other directions, not on organized routes. That is to say, you want to carry passengers on intermittent flights over very bad territory, probably. Take for example in the Rocky Mountain district, where there is no possibility of landing. Sometimes it might be a question of having your passengers carry parachutes as well as the pilot.

The other question is in regard to fire extinguishers. There was recently a very serious accident down near Cincinnati, in the case of a cabin machine taking fire. They had a pyrene fire extinguisher. Somebody tried to use it around a cabin and asphyxiated them all, including the pilot. Of course, landing was a pretty serious affair.

In regard to communication between the pilot and passengers, I think that is a very important point. I recently made a trip to the Coast in a cabin machine, in which there was full communication. The danger there is where the passengers might get hysterical and might interfere with the full use by the pilot of these facilities and their control.

On the other hand, in separating them, there is a certain lack of moral support; you might say, in the pilot being away from the passengers. There is a happy medium, I think. You may have windows or something of a similar nature separating them. There is a big value right there. I think both sides must be considered very seriously.

MR. LOENING: I think Major Mayo answers some of the points that have just been brought up.

He specifically states, about the fire extinguishers, that they should be of a type that would not cause asphyxiation, and he covers the other points in a way.

The big distinction is the question of parachutes. I think his attitude might be explainable from the standpoint of lack of knowledge of what parachutes do in Europe, compared to the many experiences we have had in this country, and their wide use.

It is only a year or so, I believe, since the British and French air services started to use parachutes at all. I believe Major Mayo feels an encumbrance like that would not be a proper thing to use in air transport. And if flight were made over rocky regions it isn't a fit place for air transport.

DR. FREDERICK HOFFMAN (Newark, N. J.): I feel strongly that it would be ill-advised to use parachutes in passenger service. In an open plane you can jump, but in the passenger plane jumping with the parachute is very difficult, and it is a needless expense for the company and an unnecessary load.

In regard to the contact with the pilot, at times when there seems to be an impending accident, it adds to the courage of the passengers to see the pilot undisturbed by impending risk.

I had an accident one time and there was a forced landing. I heard a ripping noise, the plane caught fire. I looked at the pilot, and he was undisturbed, as much as to say, "I should worry," and I gained moral courage from him.

I think it is a great thing to see a pilot in operation, and it is certainly an inspiring thing. It gives you courage in your lonely cabin. But if you can't see out, if you know there is something wrong, you become easily frightened.

LT. BROWN (Navy Department, Washington, D. C.): It has been my particular job to study accidents for a little over a year, and I certainly want to add my commendation to the way in which the Major has treated this subject.

I am inclined to agree with him on the subject of parachutes in cabin planes. You should make them safe enough so the parachute is not necessary except in the most extreme emergency, and therefore, they should not be carried.

There is something about a parachute that to the uninitiated is very terrifying.

both when it is put on and when they are instructed. I have seen people turn around and back away from a plane after being given a parachute, told to count six and then pull the string after having jumped.

Another thing is, in time of emergency, those people aren't going to jump. We have had enough cases of experienced men who have refused to jump, have become panicky and just frozen in their seats and will not jump.

In regard to bad landings, I disagree with the Major, having gone over the statistics in respect to this, and although we have no fatalities from land planes, we have had eight fatalities in a period of seven years from bad sea-plane landings. The sea-plane is apt to have a tendency to dig in if it is landed improperly, falling over on its back.

So I don't think that can be altogether disregarded, particularly in sea-plane construction.

CHAIRMAN LAND: We don't want to get too far ahead of our program here, as so much of this discussion is running on parachutes. I think unless there is someone else who wishes to discuss this paper, we will go to the next paper, which is on the subject of parachutes.

Our next speaker is again, like Major Mayo, a man who "knows his stuff." There is nobody in the United States, to the best of my knowledge,—I don't think there is anybody in the world, as well qualified to talk on parachutes, who has done as much human service for parachutes, who knows about their use, and who is as vitally interested, as is the next speaker on our program. I take pleasure in presenting to you, Major Hoffman of the Army Air Corps.

The Parachute in Passenger Flying

By E. L. HOFFMAN

Major, A. C., U. S. Army Corps, Wright Field, Dayton, Ohio

By far the greatest adverse factor with which we have to contend in the development of passenger transportation by airplane, is the risk involved. The layman often feels that aviation is not safe enough and the lure of speed and time saved are not sufficient to induce him to use air transportation. The further development and application of the parachute will go far towards meeting the public's requirements regarding safety.

The public will travel by air just as soon as it has definite assurance that air travel is not unduly dangerous.

When the individual parachute was put on the market great difficulty was experienced in getting the pilots to use them. Today there are several thousand in use and records show that over 100 lives have been saved by the parachute. In the development of a parachute suitable for use with passenger craft, support will probably be difficult to obtain and to convince commercial operators of its utility will be another serious problem. It is human nature to absorb new ideas slowly and almost unwillingly.

Surely there is no one who will say that the individual parachute, as we know it, isn't worth while. Its uses are limited, however, and in its present form it is certainly NOT suited for commercial passengers. There are some applications of the "Parachute Principle" which are suitable for this purpose. Part of the problem is to determine which application is most suitable and the other part is to apply it successfully.

Any heavier-than-air craft may fall. Gravity is working all the time and if not opposed will cause falling bodies to acquire high velocities. Man is so constituted that he can with-stand only relatively low accelerations so that if he is suddenly stopped while traveling at a high velocity, the result is fatal. Almost any person

can withstand a free jump from a height of four feet above the ground and many can withstand a jump of ten feet. The problem of relatively safe aviation thus resolves itself into providing equipment which will give assurance that, under all circumstances, man will never strike the ground with a force greater than that caused by a jump from a pedestal four to ten feet high.

There is only one means by which this can be accomplished feasibly with heavier-than-air craft, and that is by use of the parachute mechanism.

Now let us see what form such parachute mechanism should take:

In general, it can either be an individual or collective parachute. In the first arrangement, one individual is launched with one parachute, and in the other arrangement, more than one person is launched with one parachute. The parachute in use by the military forces of all the world is an individual parachute. It is not suitable for commercial use. This parachute generally requires that the release trigger be pulled after the person has left the plane.

It could be arranged so that this releasing was done automatically after leaving the plane. Elderly persons, children, and others will not jump out, no matter what the consequences of their not doing so will be.

So for commercial planes, it is easily seen that the release of the passengers must be in the hands of one person, the pilot. It must be arranged so that no passenger, either carelessly or deliberately, can fail to go with the parachute mechanism when the pilot so wills. Still keeping within these restrictions, the mechanism could be arranged in the following ways:

- a. Individual parachutes concealed in the seats or elsewhere, automatically releaseable when the pilot opens the floor.
- b. Detaching the cabin and carrying it down by parachute or parachutes, either with or without other parts of the plane.
- c. Bringing entire airplane down by one or more parachutes. (The engines and/or gasoline could be detached if necessary.)

The objections to (a) above are these:

- (1) All passengers must be in their seats and securely strapped in, at the moment of opening the floor.
- (2) The airplane might be on its back, so they couldn't fall out.
- (3) It doesn't seem feasible when passengers are in their berths.
- (4) The floor might drop prematurely.

The objections to (b) above are these:

- (1) Structurally, it is an extremely difficult problem, and the additional weight required will be GREATER than that required to bring down the entire airplane. Visualize the additional weight caused by putting a bomb bay in a bomber, and you can begin to see why this weight goes up.
- (2) At moment of launching, the plane could be in a position where all passengers might be thrown on their heads and on top of one another.
- (3) Six years ago an experiment was conducted in which the fuselage was pulled in twain in the air and the after portion with seats descended by parachute. The experiment was successful, but it was thought that any such releasing mechanism would be dangerous and unreliable.

The solution is to bring down THE ENTIRE PLANE by parachute or parachutes.

Hereafter, a parachute mechanism which lowers the entire airplane will be called a "Planechute."

Up to the present time two different airplanes have been landed by the use of a giant parachute. Both tests were held in California and both were very successful, especially in view of the newness of the art.

The following points are to be considered:

- a. Where will the parachute be stowed?
- b. How will the plane be suspended when descending by parachute?
- c. How rapidly can the plane be allowed to fall?
- d. What will be the weight of the entire mechanism? What will be the bulk?
- e. How will the parachute be launched?
- f. Will the parachute be rendered inoperative by breakages, fire, or collision?
- g. How will the added weight affect the balance of the airplane?
- h. Will a device be necessary to release the parachute from the airplane after landing? Or in the air?
- i. How many operating controls will be required for launching, where will they be placed, and of what will they consist?
- j. If releasing devices are necessary, where will they be located, etc?
- k. Will auto rotation occur when plane is suspended. If so, what remedies will be the best?
- l. What effect will rain, snow, mud, heat, etc., have on any part of the parachute mechanism?
- m. Will it be certain to operate, without ever failing, in any position the airplane can ever get itself into?
- n. Can it be positively prevented from premature release?
- o. What is the minimum altitude at which it can be expected to operate?
- p. Is there any limit to the size and weight that can be successfully descended by parachute?
- q. Provide for ease of packing or stowing and inspection.
- r. Will the addition of the planechute cause any resistance while in flight?

Discussions of the Above

a. *Where will the parachute be stowed?*

Consider the conventional airplane; for example, the Bellanca monoplane, Columbia, or the Spirit of St. Louis. These are selected because most passenger airplanes will be of this general type; i. e., top wing monoplane with enclosed cabin.

Assume that it will weigh, fully loaded, carrying six persons, 3,000 pounds. A parachute mechanism to handle this plane can be built to weigh 150 to 200 pounds. These ships carried a ton more weight than this across the Atlantic, so they could surely carry this load without inconvenience. If the added 150 to 200 pounds of parachute is considered bothersome, then just leave out one passenger. In other words, consider the plane as a five-passenger ship with parachute, rather than a six-passenger ship without parachute.

Now 150 pounds of concentrated weight can be carried on an airplane in only certain locations. It can't be carried aft near the tail, nor can it be carried out near the wing tips. It should be carried as close to the center of gravity of the airplane as practicable. This leaves the center section of the wing and the central portion of the fuselage from which to choose. Further discussion will enlarge on this point.

b. *How will the plane be suspended when descending by parachute?*

The plane should be made to meet the earth in the manner in which it can absorb the most shock. Obviously, this is the normal position of landing; i. e., with wheels and tail skid both touching the ground at once. In this position the fuselage makes an angle of about 15 degrees with the horizontal, with the nose uppermost. The parachute attachment must be so arranged that it will cause the plane to ride in this position when descending. A single-line attachment will not answer here, nor will a double one. A three-point suspension is the least number of lines that will do and it may be desirable to have four such lines. The point of lift of the parachute will have to be slightly ahead of the center of gravity of the plane, in order

to keep the nose elevated as much as desired. Since these bridle cables or rods need be quite strong, they will consequently be heavy, and, it is therefore desirable to keep them as short as practicable.

c. How rapidly can the plane be allowed to fall when descending, by parachute?

In considering this point, we will use the same reasoning that was used in designing the military SERVICE parachute. In the military service men are taught to jump with a large chute which will let them down gently, but for emergency jumps a smaller chute is used. This is done because one would be unnecessarily hampered in carrying the large chute all the time, for he might never use it. The small SERVICE chute is made just large enough to let one down without serious injury, although it may under some conditions cause slight injury.

When we design to bring the entire plane down in an emergency, we are justified in bringing it down at such a rate that no one will be seriously injured, although they may be shaken up somewhat. The faster we can let it come down, the smaller and lighter will be our parachute mechanism.

A person sitting in a plane can hit the ground much harder, without injury, than can a person descending in an individual parachute, for the reason that there is more shock absorbing material intervening. In the first case, part of the shock is taken up by the tires; part by the regular shock absorbers; part by the seat cushions; and part by the collapse of the landing gear, if the shock is great enough to cause such collapse.

Experience shows that it is likely that a plane can be allowed to descend as rapidly as 25 feet per second.

In calculating the minimum size of planechute required to bring down the present Army training plane, i. e., the P. T., without regard to the speed of fall, but only insuring that the nose be held up in landing position, it is surprising to find that a chute of about 36 feet diameter will do. The falling speed, however, would be of the order of 30 M.P.H. It's not likely that this speed would kill the occupants. Now, the other odd part of this is that that parachute area is only slightly greater than the area of the two service chutes always carried by the two occupants. Someone suggested that the plane would be ruined if it struck at this speed, but it wouldn't be any worse off than it is now when the two occupants leave it high in the air.

This is the minimum of planechute which could be used. The maximum is only limited by the weight the plane can carry. Just what shall be settled on as the right size for emergency use will have to be determined. An exhibition or demonstrator planechute should be larger than one purely for emergency, for the same reasons that the Army training chute is larger than the service chute.

d. What will be the weight of the entire parachute mechanism?

Without going into details, the statement may be made that the weight of this mechanism for any plane will be of the order of 5 to 7 per cent of the loaded plane.

With regard to bulk, one cubic foot of planechute mechanism for every 700 pounds of gross airplane weight should provide a safe rate of descent.

e. How will the parachute be launched?

First, remember that any relatively light thing such as a parachute, when released from an airplane, does not rise or go up or soar, as has been popularly believed. Rather it goes straight to the rear, parallel to the line of flight at the moment of release. Of course it does not go back, it is the plane that goes forward. What we are visualizing is, the relative motion between the parachute and the plane.

With this in mind, then, it will follow that from the point of release, there must be nothing directly to the rear on which the parachute can catch or foul.

In (a) above we limited the storage location of the main parachute to two places, i. e., the center section of the wing, or the mid portion of the fuselage. To the rear of these positions are the following obstructions to be considered in connec-

tion with fouling: the horizontal stabilizer with elevators; the vertical fin; the rudder; the balance on the rudder; the tail skid; the braces, wires, or struts in the empennage.

In stowing we must consider not only the main chute, but the suspension lines, which may be from 50 to 75 feet long, and may number 50 or more, as well as the suspension bridle mentioned in (b) above. None of these may be allowed to foul anything.

In (b) above we have definitely located our points of attachment for the suspension bridle. They must be on top of the airplane and within a few feet of the center of gravity. This is the region of the center section of the wing.

Now if we should decide to stow the parachute in the fuselage, it will be found that it can not be launched from the bottom or either side without danger of fouling in either a right or left-hand spin. That is, the attaching means will foul or wrap around the fuselage. It does seem feasible to launch it from the top of the fuselage or the center section or perhaps both.

If it is possible to stow in the center section, then the parachute, suspension lines, and attachment bridle are as short as possible; the whole thing is concentrated and can be neatly concealed.

f. Will the parachute be rendered inoperative by breakages, fire, or collision?

The only breakages likely to occur in the air are wing and aileron failures. Since the chute is stowed in the center section, such breakages would not interfere, as any of these breakages would be considerably outboard from this location.

Airplane fires are of two general classes, i. e., fire in the air and fires after crash; or simply air fires and crash fires.

With reference to air fires, when fire does break out, it does so in the engine section. It starts small and gradually grows to greater proportions, fanned by the blast of the propeller. This blows it directly aft, endangering the occupants of the cabin.

With the planechute, the moment fire breaks out, the pilot releases the chute and shuts off the engine. The wind blast on the fire is then upward, removing the flames from the vicinity of the cabin. The blast is also much less than that from the propeller. The pilot then has a chance to fight the fire on the way down with extinguishers. Modern planes will be constructed so that all portions which can become exposed to fire will be of metal.

In the Columbia, and in most conventional planes of this type, the pilot is seated right next to the engine, so that he will discover a fire as soon as it breaks out.

It is proposed to make the suspension lines of the parachute or a part of them of cable, which will not be immediately affected by fire. The suspension lines and attachment bridle being some 75 feet in length, the parachute will be clearly out of the way of the flames.

In considering fires in the air, thoughts sometimes turn to "Flaming coffins." These huge fires were the result of the gas tank being ruptured and ignited by incendiary ammunition. The chances for fires of such huge proportions in commercial aircraft are very remote. Fires from ruptured feed lines only will be the rule. With proper cowling above the motor, metal cabins, wings, etc., such fires can do little if any damage to the inflated parachute. The gas will be shut off immediately.

When collisions occur, the planes usually bump on their extremities, i. e., wing tips or tail; therefore it is advantageous to locate the parachute near the center of the airplane.

g. How will the added weight affect the balance of the airplane?

Not at all, since the principal weight is carried near the center of gravity.

h. Will a device be necessary to release the parachute from the airplane after landing?

The reason for fitting release devices to individual parachutes, when it has been done, was for the purpose of preventing the person from being dragged by the wind after landing. The dragging force of a giant chute is unbelievably great, and a release will be necessary for service use. For testing and demonstrating, such a device should be incorporated, for should anything go wrong when launching high in the air, the pilot might cut away the entire chute and bring down the plane as is usual.

i. How many operating controls will be required for launching; where will they be placed; and of what will they consist?

In general, there will be one control and it must be within easy reach of the pilot. It most likely will take the form of a wire cable, with handle and locking pins. With two distinct motions this should release and launch the entire parachute mechanism.

j. If releasing devices are necessary, where will they be located, etc?

A releasing device will be necessary. This should consist of a handle, placed within easy reach of the pilot and a small cable, perhaps ten feet in length, running to the concentrating point of the supporting bridle.

k. Will auto rotation occur when plane is suspended? If so, what remedies will be best?

One of the marked disadvantages noted in the most recent drop with a parachute at Tracey, California, seemed to be that the plane continued to rotate, tending to wind up the suspension lines. Most planes, if unrestrained, want to take a spinning attitude. This point will have to be studied. It would seem that several remedies are feasible, however.

l. What effect will rain, snow, mud, heat, etc., have on any part of the parachute mechanism?

The parachute must be protected against all these when stowed. After release, they will have no effect on the efficiency of the parachute.

m. Will the parachute be certain to operate, without ever failing, in any position into which the airplane can get itself?

A parachute in use is a very peculiar thing. We are generally satisfied with a thing if it works successfully 99 per cent of the time. Not so with a parachute. It must never fail because human life depends upon it. Most things can be classed generally as good, fair, and poor. A parachute must be good; it can not even be fair. Passenger carrying airplanes are not going to be stunted deliberately but nevertheless, studies have been made of the possibilities of failure to function in the following positions and maneuvers of the airplane: 1. Level flight, 2. Nose Dive, 3. Steep climb, 4. Stall, 5. Side slip, 6. Loop, 7. Tailspin, etc. In analyzing these maneuvers, no condition is found in which a parachute, installed as described above, would fail to function.

n. Can it be positively prevented from premature release?

It can be and must be. In designing the release, at least two distinct movements, easy to make, should be required of the pilot. Both the release handle and all parts of the release mechanism should be designed to prevent accidental release.

Stowage compartments for parachutes in the slipstream must be so constructed that they will resist any tendency of the slipstream to open them.

o. What is the minimum altitude at which the parachute can be expected to operate?

When using the individual parachute, the person usually drops over the side and pulls the release. The parachute thus is not opened until the person is 100 feet or more below the level of the plane. This is termed the dropping method. Another method which is used in practice jumps particularly, consists of crawling out on the wing and pulling the release while still hanging on to the ship. Here the parachute inflates and pulls the person away from the plane. This is termed the lift-off method. With this last method about the only valuable altitude that is lost, is equal to the length of the suspension lines. In other words, with the military para-

chute, whose suspension lines measure 20 feet, an aviator could lift off safely as low as 50 feet above the ground.

The planechute utilizes this lift-off method and so the Columbia could be saved by the parachute when as low as 100 feet above the ground, and a fall from a lower height wouldn't be apt to kill anyone. This considers only the position of level flight. In a dive more altitude would be necessary.

p. Is there any limit to the size and weight that can be successfully descended by parachute?

There seems to be no limit to either. The greater the weight to be supported, the greater must be the strength of the suspension lines. It would seem that the strain on the supporting fabric can be kept constant by increasing the area, until the unit strain is the same. In other words it would seem that if 300 lbs. require 300 square feet in descent, then 3,000 lbs. will require 3,000 square feet. In either case each square foot of cloth is only subjected to a strain of one pound.

This is not strictly true, for the strength of the fabric is governed by the tensile strength of each individual thread and this gives results considerably at variance with the above; but with proper reinforcing, fabrics can be made to withstand a great deal.

q. Ease of stowing, inspection and maintenance.

With the locations as proposed; i. e., the main chute and all lines stowed in the center section or fuselage, it is relatively easy to get at either for the purposes enumerated above.

r. Initial cost, length of life, and repair parts.

For a plane the size of the Columbia (5 passengers), the initial cost may be from \$1,000.00 to \$1,500.00. The military parachutes have given a life well above five years and these should last longer.

No matter what improvements are made in heavier-than-air craft in the way of lighter engines, greater speed range, lower landing speed, stability, better climb, more reliable motive power, or what not, the fact that the machine is still heavier than air makes it imperative that it be parachute equipped, for when it is several hundred feet in the air, something can and may happen to it which only the parachute can remedy.

A parachute which oscillates will never do well for a planechute. There are now non-oscillating parachutes.

It is true that the planechute may land in trees, on the edges of buildings or cliffs, or elsewhere. The present individual chute is apt to also. It can't be helped at present. With the motor running, the planechute will be more steerable.

For the benefit of those who do not know, let me say that parachutes are more readily affected by air currents than planes and that up and down trends always will be troublesome and do the unexpected. Figures for rates of descent only hold in still air and this is seldom experienced. While theoretically the up and down trends usually cancel each other, actually you can always expect a down trend, especially when the wind is high.

With the planechute, wind draft must be considered. There is a parachute now extant which tends to land with a certain side down wind. This will be of value here.

It seems that with the planechute, it will always be best to arrange to land down wind, just the opposite of conventional practice. An arrangement has also been proposed, which consists of a light drag line attached near the tail which will come into play as the plane nears the ground, and by the force exerted will tend to swing the tail into the wind.

No doubt the use of the planechute will call for stronger landing gears and oleos capable of absorbing more shock than are usually fitted now, and it will be necessary to provide anchorages and follow through sufficiently strong to withstand

the shock occurring when the parachute opens. After the parachute is opened and the plane is descending, the strain on these parts will be greatly reduced.

Whether or not the dissipation of the kinetic energy of the plane at high speeds will be a serious problem, will have to be determined. The shock load on an 80-foot diameter parachute, carrying a load of 1600 pounds, traveling 100 MPH. is of the order of 5600 pounds. The particular parachute used in the test by which these figures were obtained took care of this load readily.

If it is found necessary, a Shock Chute or decelerator chute may be used. Such a chute will be so made that it can withstand high shock loads, and will come into play to slow up the plane by pulling up its nose before the other chutes are brought into play.

It is easy, indeed, to visualize the use of a planechute on the smaller planes. It is more difficult to imagine their use on very large planes. The larger the plane, the longer the planechute's suspension and, therefore, the plane has to be higher for it to operate successfully. Perhaps the planechute will have an influence on limiting the size of the planes for passengers.

If it is asking too much to imagine all planes equipped with planechutes, surely it is easy to imagine such planes as small commercial passenger planes, civilian and military training planes, ambulance planes, military transport planes, etc., so equipped.

Designers and operators speak of "Pay loads." They say the planechute will reduce their pay loads. It will from their present figures, but they have no business figuring their pay loads as they do today. The Leviathan could carry many more passengers if all the life boats and life saving apparatus were taken off. I am afraid the present pay load is bound to shrink considerably when safety appliances are demanded.

The Effect on Flying of the Entire Airplane Parachute

When we first started to develop the military parachute, much indifference and opposition was encountered in our service. A few of the war pilots wanted them, particularly those who had seen some Germans use them successfully, but the average peace pilot looked upon them as just one more thing to bother him—and felt sure that nothing was going to happen to HIM, anyway.

After a while some pilots were saved from certain death by the use of this parachute, and one would have thought that certainly, then all fliers would demand them. There still remained some, who in their peculiar way, reasoned that THEY would never need one. Later their use was made compulsory in the Army. At the present, this parachute has saved upward of 100 persons' lives. Colonel Lindbergh is high gun with four jumps to his credit.

The layman, however, does not consider a safety device in this way. When told that it is possible to have a parachute which will take care of him and the plane without any knowledge or precaution on his part, he is at once interested in flying. Such an attitude has been displayed by hundreds of persons who have said that they would not consider going up without such an apparatus.

Flying today, aside from the military, is done without any parachute device—just a blind trust in Providence.

For several years it was difficult to get anyone sufficiently interested to go into the business of manufacturing parachutes. The market for them was obscure. Even those in closest touch with conditions couldn't foresee that soon all civilized countries would be bound to supply parachutes for their military and test pilots. Two manufacturers started in finally to build them. The Army bought all it then needed and there was a lull. One company went out of business, certain in the belief that the saturation point had been reached. The other company stuck and is now sup-

plying these parachutes to our Army, Navy, Post Office Department, Great Britain, Spain, Canada, Australia, Brazil, Japan, Poland, Sweden, and other lands.

Looking backward, it is simple to see that any prime life-saving device is bound to succeed, almost in spite of anything. People think a lot of their lives and are willing and anxious to buy anything that will insure that they continue to live.

This parachute will materially reduce accidents caused by the following:

- a. Fire in the air.
- b. Fire after crash.
- c. Collision.
- d. Motor failures.
- e. Fog or clouds.
- f. Night flying.
- g. Sleet on wings.
- h. Stalls.

When these sorts of accidents are greatly reduced, there are not many causes remaining.

We will now discuss the sub-heads listed just above:

a. Fire in the air.

This has been previously discussed.

b. Fire after crash.

If we have fewer crashes, we will have fewer crash fires.

c. Collisions.

This has previously been discussed. It must be remembered that in any collision there must be more than one plane involved, and even if one plane should fall and yet the others were saved, we have still accomplished something worth while. There may be collisions in which nothing can be of any help.

d. Motor failures.

In many cases, a forced landing in difficult terrain may be fatal. It requires considerable skill and luck to land safely with a dead stick under the best of conditions. Often military pilots have jumped rather than attempt a landing, because they knew that in either case the airplane would be a total loss and if they stayed in the plane, they might get pinned in the wreckage and burned to death.

There are any number of little things that can go wrong with an aviation engine which may require an emergency landing. Often it is something that can be easily fixed, but you have to come down to do it.

e. Fog or clouds.

Fog has baffled man since the beginning of time. It hampers the mariner greatly. When he encounters it, the laws require that speed be reduced and whistles blown at intervals. The aviator has to keep his speed up to be able to stay aloft. He wouldn't dare navigate in areas where other aircraft might be flying. Collision in the air is much more serious than collision at sea. But what worries him most is what to do in case his motor stops—from lack of fuel or any other cause. With the parachute this worry is eliminated.

Pilots hesitate to go through or above clouds with their present flying equipment, especially on cross-country trips. The height of the clouds above the ground is variable and the pilot has no means of telling, except by meteorological reports, whether or not he has a space below the clouds of good enough visibility to permit a safe landing. This condition is the greatest cause of irregularity in flying schedules.

With this parachute device the cloud menace is not nearly as serious. If the motor fails or a landing is required for any other reason, the parachute may be released, allowing the airplane to float down in comparative safety.

f. Night flying.

It is always dangerous to make a forced landing anywhere at night. With this parachute it would be very simple. It is an unusual person who can sleep in an

airplane, but perhaps the use of this device will allay their fears so that sleep will be possible.

g. Sleet on wings.

Under certain atmospheric conditions, sleet forms on the wings, changing their shape and destroying their lift. An airplane in this condition must be landed with more than usual speed. This increases the danger. The remedy is the parachute.

h. Stalls.

This is the condition in which the plane loses flying speed and falls. The plane will usually correct itself after falling a slight distance, say three or four hundred feet. Hence, the stall results in an accident when occurring near the ground. It is usually brought on when taking off, by motor failure combined with turning in an endeavor to get back into the same field.

Since this parachute device will operate at about 200 feet altitude in level flight the pilot may be trained to take off with one hand on the parachute release lever, so that he can immediately release the chute at the first sputter of the motor. This chute will catch him every time when above 100 feet and when at lesser altitudes it will tend to hold up the nose, even if not fully inflated, and in this attitude, no fatalities should occur.

This device has one highly important and very unusual potentiality. Many times when making a forced landing, the pilot still has the use of his motor. With the parachute inflated and the motor usable, the device becomes a SEMI-DIRIGIBLE; and as a result, with a little practice, the pilot should be able to land in an *extremely small space*.

Without doubt, with the constant use of this device many advantages, not now apparent, will come forth, just as was the case with the military parachutes.

As soon as the public is satisfied that it can travel in the air with reasonable safety—and this device is just the one and only thing which will bring this about—the entire aviation industry will spring to life with a rush, the proportions of which are difficult to forecast.

This parachute device should be "The Renaissance of Aviation." It will bring aviation out of the dark, because it will do away with the fears of the public, and make possible normal progress.

CHAIRMAN LAND: Major Hoffman has given us a lot of food for thought. His paper is constructive. It is evolutionary; to some of us it may be revolutionary. Nevertheless the keynote in the paper is in the last paragraph. If you can assure our public that aviation is safe, you have the keystone laid.

The paper is now open for discussion. I want to thank Major Hoffman for the excellent paper.

H. J. STACK (In Charge of Parachute Experiments During the World War in France): I want to say that Major Hoffman's remarkable paper is to me one of the finest things of the whole convention. We have something in his plain truth that if perfected is going to be the finest thing in aviation.

Traditional pilots have always disliked parachutes. For years and years the British, French and American pilots have disliked parachutes. We had parachutes available for them during the last years of the war, but most of them, the British particularly, preferred to take a sporting chance rather than use the Guardian Angel, and our own American pilots didn't want to bother with the things.

I believe, during this period of ten years, in the development of these remarkable parachutes that Major Hoffman has been bringing about in his work, that it is one outstanding thing. It certainly has paralleled the growth of aircraft, and I believe every assistance should be given to these people who are directing the work of the development of the parachute. It certainly sounds like a mighty fine thing.

R. W. GRISWOLD (Formerly with Fairchild Aviation Corporation): After what you said in regard to the advisability of bringing down the whole plane instead of

just the cabin, you gave the reason of impracticability; if you make it a detachable cabin it will run into excess weight.

I have put some thought on this thing. I have been very much interested in your experiments, and it seemed to me that it was too bad to bring down the dead weight of the airplane and motor, gas and oil, when all you want to save is the passengers. I believe it is possible to use a type of construction where the cabin will not contribute anything to the structural strength of the machine. In that case, it would be very simple to build a detachable cabin.

I would like to have you express some thoughts on that, as to whether your parachute can be righted to just bring down the cabin itself. Of course, it may be the wings of the machine may contribute to the lift of the parachute in coming down.

I would like to have your thoughts on that.

MAJOR HOFFMAN: I may not be entirely correct in the analysis of that cabin problem. I have worked on it and decided to abandon it because it appeared as though it were going to add too much weight.

I was thinking of inserting a false cabin within the fuselage. That, of course, does build up the weight. If you know of some way you can hang it onto the structure as false work, you may get away with less weight.

It is a matter of launching, too, that has to be considered; it is a fact that you do get considerable lift from your wings if they are on, and from your fuselage surfaces. So the detachable cabin arrangement may have some uses. For strictly passenger work, I think I prefer the entire airplane.

DR. GEO. F. MYERS (President, Plane Parachute Corporation, Jackson Heights, N. Y.): I think this matter of taking up just the fuselage or the cabin is wrong, because there is a heavy plane dropping down to the earth, and probably killing somebody; if it should drop on a church or schoolhouse, probably eight or ten people would be killed or maimed and the building set on fire. Therefore, I believe the only thing to do would be to take the whole plane.

It is not going to be such a heavy affair or such an expensive one. When you figure it out the way Major Hoffman has, it is going to be a moderately cheap affair, when you come to think of the lives it may save. Even if it would only save one life a week or a month or a year, it would be worth while putting parachutes on all planes.

MR. EMERSON (Chicago): It has been a great privilege and satisfaction to listen today to the authority from the Western Hemisphere and the development of the parachute during the decade since the war. It is also satisfying to note the disagreement with Major Mayo of the British Service, as to the utility of parachutes for passenger service, and also his disagreement with Lt. Brown, who expressed similar doubts.

It was my good fortune to receive my first parachute instruction from Major Hoffman's predecessor, the most practical parachute expert the world has ever known. This was the late Captain Tom Baldwin.

Shortly after my designation as a test pilot in the Navy, eleven years ago, they wished on me the problem of seeing what could be done in providing parachutes for Naval Aircraft. I went to my old friend, Captain Tom, who gave me the lowdown on the whole proposition; and having such a good start, I did what I could in those days on the development of this safety device for our Naval Aircraft.

It is a remarkable thing about that parachute, that it vies with the boy's kite as being the most antique or most anciently known form of aircraft. And up to the present time it, like the kite, has been so little developed. The potentialities of parachutes for various purposes are greater than the layman has any conception of.

The development that the major is now encouraging, in bringing down whole planes, indicates one of those very great potentialities. It is extraordinary that in

the last dozen years there have been, so far as I am aware, only five distinct mechanical advances in parachute types.

They being so few, I will detain you long enough to enumerate them, because they contribute to this discussion of aeronautical safety. I will take them up in chronological order.

The first was the Guardian Angel in its several types. I believe I was the first to try that type on this side of the water, and I will say this for it: It is the only parachute I ever tried that I hadn't seen packed myself.

A second development was carried on simultaneously in France and by the United States Navy. It was analogous to Major Hoffman's problem of bringing down the whole aircraft. The people in the latter part of 1917, who were using parachutes on the Allied side, were not plane pilots. They were the balloon observers who, when their balloon was set on fire by the incendiary bullets of a diving attack plane, were notified up at the telephone cable by the men on the ground that the balloon was on fire and they must jump immediately. They had a leeway of three seconds in which to jump, because if they delayed longer, the burning balloon came down just as fast as the parachute and set it on fire. Their decisions to jump must be of the immediate, military character.

The problem was to save not only the observer but to save the valuable maps which he had made in his artillery spotting. Therefore, the problem was to bring down the whole basket. In the later part of the war, two observers were usually carried up.

It is a curious coincidence that the first of those basket parachutes was tested out by the United States Navy on the same date that Captain Wolf of the French Service tested out the first one for the French Army.

A third development was the automatic or self-opening type of parachute, developed by Coughlin, one of our very old parachute experts, who is the civilian parachute expert for the Navy. It is little known outside of naval circles.

The fourth development was the Irving parachute, which is the parachute you are now familiar with, in which the person jumps free, and after counting three or four or five or six, pulls a release cord and opens the parachute.

The last development is what Mr. Hoffman has stressed.

Those are the only important developments that have taken place in parachutes for a dozen years.

I will mention, not as a development but as a small contribution which I tried to make to the art, a number of years ago, something that may be of use to this overseas flying, particularly for commercial purposes.

I conceived the idea of using one of these pneumatic, rubber, inflated boats to jump into the sea. Being a naval aviator, naturally that problem concerned me, and I believe I was the first to make use of that particular method.

In this instance, I jumped from an airship, not from an airplane, with a fully inflated rubber boat. The parachute was an ordinary man-carrying parachute, and functioned normally. After being dragged under water and half drowned, I managed to scramble aboard the boat, where I had oars that I could connect up, and I would have been able to paddle ashore, but a destroyer picked me up.

I contribute that thought because of its applicability on a larger scale to over-water aircraft, either heavier or lighter than air. There are quite large pneumatic boats, inflated or uninflated which may be carried with little addition to the weight, and the passengers upon their landing in the ocean will be as safe as they are in the modern life boat.

The individual parachute is like the life preserver on a ship. The larger type of parachute may be likened to the life boat.

I may mention that in railroad transportation we have nothing corresponding to either type of salvage. Therefore, we increase the weight of the structure and its

strength to such a point as to reasonably protect the passengers against severe shock.

STARR TRUSCOTT (National Advisory Commission for Aeronautics, Washington, D. C.): I would like to appear in a dual capacity. First I would like to read a short note which has been received from Lt. Harper of the Bureau of Aeronautics, Navy Department, who unfortunately has been prevented from appearing here, but has read Major Hoffman's paper.

When Major Hoffman says, "With the planechute, the moment fire breaks out, the pilot releases the chute and shuts off the engine. The wind blast on the fire is then upward, removing the flames from the vicinity of the cabin." Lt. Harper takes issue with that statement and believes that is questionable. He believes that there is a possibility or probability that the fire will continue going backward and not all up, because the plane will still have some forward motion while the parachute is opening, and during that time the parachute may take fire.

With reference to the point where the major answers the question, as to whether the parachute will be certain to operate without ever failing in any position into which the airplane may get itself, Lt. Harper wishes to call attention to the fact that he has omitted the question of what happens if the airplane is descending on its back. Airplanes have been known to descend in this position, and that would appear to be a question to be seriously considered.

He also believes that the assumption that the planechute, using the liftoff method, would save the airplane from an altitude as low as 100 feet from the ground is somewhat too optimistic, and that the distance will be considerably greater than this.

There is also a question as to the life of the parachute particularly for use in tropical areas. We, apparently, are pretty sure that a parachute used in the tropics will have a considerable reduced life as compared to the life of the same parachute in the temperate zone.

There is also the question of the possibility of using the combined airplane and open parachute in the landing of the airplane. Major Hoffman states that with the parachute inflated and the motor usable the device becomes a semi-dirigible. With this statement, Col. Harper is inclined to differ and believes that the pilot would have very little control if he tried to use the airplane as a semi-dirigible, and that that lack of control would come at the time when he needed the control the most.

Lt. Harper also notes some further points which might be added to the discussion. One of those I believe I am competent to deal with myself, and will pass on to the final point, which is that the Handley-Page Slot properly installed in use will function to a certain extent as a planechute. Of course, the plane with the slot will still have forward velocity, but so will the plane chute in the wind.

With the slot the airplane is still under control and has a speed of vertical descent which is comparable with that of a plane chute.

If you will now visualize me as passing from the mouthpiece of Lt. Harper to my own person, I want to express, as have others, the very great pleasure in hearing from Major Hoffman. For some years I was associated with the Bureau of Construction and Repair and the Bureau of Aeronautics in the Navy Department, and in the office of the chief of those bureaus it was my duty or part of my job to follow the development of parachutes and further it as far as it was possible.

During that period, Major Hoffman was active and the work was done as far as it was possible to do it.

In the Navy Department there were developed certain sources of supply and certain methods of construction, which have in some part been taken over by the Army, and others still remain. In others the Army has remained satisfied with its own practice and quite justifiably so.

But it was a great disappointment, when some years ago Major Hoffman

apparently had to give up activity in parachutes, and this is the first opportunity I have had to see and listen to him since he has returned to that activity. I feel very, very glad to learn of the progress which he has been making in solving this very difficult problem which he has tackled.

May I add a few words which may give you something of a background? This business of fitting parachutes to airplanes began in the minds of inventors many years before the airplane was a practical device. It has been my misfortune in the last few years to have to deal with many new aeronautical inventions.

The number of people who have attempted to combine the airplane and the parachute and the number of different ways that have been attempted is positively astounding, and of course, in discussing these applications with the various inventors, I found that it was very advantageous to be able to refer to the past practices or past attempts to reduce the idea of the practice. But so far no one except Major Hoffman has made a really successful job of the combination.

CHAIRMAN LAND: I will now ask Major Hoffman to reply.

MAJOR HOFFMAN: I want to thank Mr. Truscott for all the nice things he said about me, which were undeserved.

I didn't find anything in Mr. Emerson's discussion with which I didn't agree. To take up Lt. Harper's comments, which are very well taken indeed, the first one is about fire, setting the parachute on fire during the course of launching, as I understand it.

There is a possibility that this will happen with a very great, large fire. But I don't believe it will with the so-called small fires that we can expect. That matter will just have to be proven. That is the only way to find out about that. We will assume when we get our mechanism finished we will actually set a plane on fire and see what happens. I am very confident we can do it and get away with it.

About the plane being on its back sometimes, that is a very good point. I didn't think it was likely that a commercial plane could get around on its back, but it might in some cases. So we will look into it.

He says that my estimate of saving the plane at 100 feet is rather optimistic. I had to make it that way to satisfy everybody. I don't infer that you will save the plane, but I say that no one will be killed at 100 feet. The plane may be smashed considerably. The nose is supposed to be held up, and when the nose is held up you aren't going to get killed.

About the semi-dirigible features—I know why he takes issue with that; but I may say I am confident on that score, because we have already done enough with our model planes and have been dropping them in our wind tunnel work to know that the semi-dirigible idea is all right.

About the Handley-Page Slots—They are of course very valuable as an addition to safety in aviation. But I can't see that they are going to take care of many of these things that we have enumerated here, some of which I can easily recall. In a jam of the controls, your slots wouldn't be much good. If a wing breaks off they wouldn't do you any good. For fire in the air they wouldn't help a great deal. In a collision they certainly would not. Sleet on the wings certainly wouldn't be helped by slots.

CHAIRMAN LAND: I wish to thank Major Hoffman again for his able paper and his discussion. He has aroused some very interesting discussion. I wish we had more time to elaborate on it.

The last paper we have today was to be presented—again going to the superlatives—by the best informed man on all phases of aeronautics in this country or abroad, Dr. Ames of Johns Hopkins University. He has many duties and one of them is Chairman of the National Advisory Committee for Aeronautics.

Those of you who have topside jobs realize the work is delegated down the line, and the preparation of the report which the National Advisory Committee for Aeronautics has permitted to be released today on the subject of "Accident

Analysis," has not only a national but an international importance. Passing down the line, from Dr. Ames to the sub-committees who do the initial work, they naturally associated themselves with the representatives of the services, representatives of civil life taken into their Advisory Councils, aviation attaches in Washington, and so on. The man who has been designated to deliver this paper, as intimated, has done a lot of work. This is Lt. C. R. Brown, Bureau of Aeronautics, Navy Department, Washington, D. C., in charge of the Statistical Section.

He has done a tremendously loyal, faithful amount of work, in an effort to reduce crashes not only in the Navy but also in cooperation with his army brothers and in cooperation with civilians.

I take pleasure in introducing, Lieutenant Brown.

Accident Analysis

By LIEUT. C. R. BROWN

Bureau of Aeronautics, Navy Department, Washington, D. C.

We are here today for the single purpose of reducing accidents and promoting the safety of aviation. The conference I find, from the papers which have been read, has left no stone unturned. The problem has been attacked from every conceivable angle, from the actual mechanism of the machine itself to the supervision of its operation through more efficient weather service and more intelligent ground administration.

The committee whose report I present was organized by the National Advisory Committee for Aeronautics in response to a request from the air coordination committee consisting of the Assistant Secretaries for Aeronautics in the Departments of War, Navy, and Commerce. The work was undertaken in recognition of the difficulty of comparing and drawing correct conclusions from reports of aircraft accidents prepared by different organizations using different classifications and definitions. The air coordination committee's request was made "in order that practices used may henceforth conform to a standard and be universally comparable." The purpose of the special committee therefore was to prepare a basis for the classification and comparison of aircraft accidents, both civil and military.

Prior to the preparation of this analysis form, the different departments of the government and certain industrial concerns had been analyzing accidents using widely varied methods. Further complication arose from similar practices abroad. No two methods were identical. The results though illuminating and in some degree helpful, were difficult if not impossible to compare. If compared they were confusing and in some ways apparently contradictory. To correct this condition was the task of this committee.

The various members brought to the meetings widely divergent opinions, but the report in its final form does not represent a combination of compromises. As our studies progressed, and they were extended over a period of four months, we found that our differences of opinions arose from the fact that none of us had had a complete grasp of the subject and the factors involved. Our apparently divergent views were harmonized by combination, not by compromises. The report as it now stands was unanimously approved.

The report therefore affords a method of correlating these various factors which have here before this conference been given so much painstaking study and of balancing them one against the other in order that we may learn their relative importance. Obviously we must know our weaknesses before we institute corrective measures. Like the doctor, we must diagnose our ills before we may cure them, and we must be certain that our diagnosis is correct, that we know

the true underlying causes. Like our medical friend, we must treat the disease, not the symptoms.

Also, in any science so closely governed by the law of compromise as aeronautics is, it is essential that the relative importance of these various factors be known. We cannot build a landing gear strong enough to withstand any impact. Such a landing gear would be too heavy. We can only give it sufficient strength to withstand what we consider are its normal landing loads with a reasonable margin of safety. Then if our statistical report shows that landing gear failures are prevalent in a particular type of aircraft, or should they show they are prevalent in all types, the gear must be strengthened. Likewise, if no stalls ever occurred, it would be foolish for a designer to fit an anti-stall device which decreased the aerodynamic efficiency of an aircraft.

In short, correct statistical service is vital if we are to devise corrections for the ills we encounter. By checking and rechecking constantly, it keeps the designer and those responsible for the safe operation of aircraft correctly informed. If efficient, nothing can escape. It exposes defects and subjects corrective measures to a critical and dispassionate examination.

The essence of the whole report may be found in the accident analysis form (reproduced as a part of Dr. Ames' paper, which is a part of this record.) The rest of the report is an explanation of that form, with exact and comprehensive definitions of the various sub-divisions represented in the form.

In the upper left-hand corner are the words "Classification of Accident." This provides first for the classification of an accident according to its nature, such as "Tail Spins," "Collisions," "Forced Landings," "Take-off Accidents," etc.

Below the classification, according to nature or type of accident, is the caption "Result." An occurrence, of course, must have certain results before it can be termed an accident and the committee recognized this fact by defining an accident as "an occurrence which takes place while an aircraft is being operated as such and as a result of which a person or persons are injured or killed, or the aircraft receives appreciable or marked damage through the forces of external contact or through fire." But we are also interested in the *degree* of injury received by personnel and the *degree* of damage done to material. Consequently the caption "Results" is introduced and these results are further subdivided under headings of "Personnel" and "Material." Personnel injuries are divided into fatal, serious and minor injuries; material damage into complete washouts, damages requiring a major overhaul of the aircraft, etc.

From this much of the form alone, a clue may be obtained to its possible uses. For example, we may find the percentage of fatal accidents due to tail spins, and, if results warrant, show how necessary the elimination of this type of accident has become. Let us suppose that our diagnosis shows that thirty per cent of all fatal accidents result from tail spins and that experience tells us that these spins can be completely eliminated by the use of a slotted wing. The installation of this gear on all aircraft not required to possess high maneuverability would in all probability become obligatory. If, on the other hand, collisions in the air were found to be the greatest single taker of human lives, it would be just as essential to provide better visibility or in some way correct this condition. The degree of damage resulting from the various types of accidents would also be of great interest to the commercial operator and, for that matter, to all who are responsible for the maintenance of aircraft. This information would be as readily available.

But, as can be seen, the form carries the analytical study much farther than this. Regardless of whether the accidents are classed according to nature, results or as a whole it allows for their analysis according to *causes*. They may be analyzed according to the immediate causes and the underlying causes at the same time and these two methods are dovetailed together by the form.

The committee realized that one accident may be traceable to a number of

causes and allowed for this by considering each accident on a percentage basis. For example, a pilot who finds his engine has failed him may still be in a position to safely land his aircraft. If he fails to do this through some error on his part, a certain percentage of this accident would be charged to "Power Plant Failure" and the remaining percentage to "Errors of Pilots." This "Error of Pilot" may have involved both faulty technique and an error in judgment on the part of the pilot. In such a case, the percentage charged to "Error of Pilot" would be again divided and part of it charged to each one of these sub-heads, the amount under each depending upon the relative importance they bore in the subject case. Thus factors in each crash can be traced down to the last subdivision under any heading and weighed in accordance with their importance.

It may be held that the degree of responsibility and the weight given the various factors is subject to a great deal of difference in opinion. It is a remarkable fact that two commercial aviation accidents, two Army aviation accidents and two Navy aviation accidents, six in all and all of them typical of the operations carried out by these different activities, were analyzed separately by each member of the committee and that the findings were so nearly uniform as to be almost identical.

It may be thought that the information regarding the average accident is too fragmentary to permit analysis by so elaborate a method. On the contrary, it was found that the data available on the vast majority of accidents was entirely sufficient.

Near the end of the Committee's report, as presented by Dr. Ames in this record will be found the "description and typical analysis of an accident." This description illustrates the methods used in analyzing the average accident.

In conclusion the Committee feels that the form already referred to enables the presentation of a composite and comprehensive picture of all accidents which can be easily and readily broken down into their component parts. Power plant failures, for example, can be given a separate study without juggling figures and the various factors entering into them can be easily determined. In fact, regardless of the angle from which it is desired to attack the problem, the form lends itself readily to such use. We recognize that it cannot be considered complete; additions and revisions will inevitably be made, but the construction is flexible and admits of such changes when the occasion does arise.

CHAIRMAN LAND: I take this occasion to congratulate Lt. Brown on the work he has been doing for the last two years and the able manner in which he has presented this subject for our education and consideration.

We are probably not truly appreciative of this work and won't be for several years, but if this accident analysis can be standardized in this country and adopted abroad, we are taking one of the major steps to reduce accidents, and thereby promoting safety, again the keystone of the arch of success of commercial aviation.

We are grateful to the National Advisory Committee for Aeronautics for permission to use this paper and for holding it up so as to be released at this time.

There is one gentleman here who is in a position to tell the aviation public at least, and possibly the general public how much value there is in this paper, not only from a national point of view, but also from an international point of view.

I should be glad to have the paper discussed or to hear any comments on it.

R. B. ANDREWS (Crayman Company): In the analysis of this accident, of course, you have a very obvious initial point: that is the breaking down of the ignition system, and from the fact the pilot was seriously injured and not killed we got some other information.

How are you going to analyze the accident where you say there is only a pilot, no observer, no passenger, no observable or apparent engine trouble. How are you going to analyze that? How are you going to get your causes? In other

words, how are you going to get the averages when you are going to wash out a lot of things you don't know anything about?

LT. BROWN: That point is very well taken. Of course, in any statistical study the unknown is of no use. We feel anyway that if we have got enough of the known that the unknown is going to follow the same law, the same thing by the law of averages.

In this classification you will find, under the immediate causes, "undetermined." That is for an accident of which nothing is known. You may have information which is fragmentary. You may find it is a material failure, that it was a power plant failure. But you may not be able to determine what failed about the power plant. You only know the power plant failed. So under "power plant" you will find "undetermined."

In that way we have followed right through under structural failures and have inserted those for the purpose of record. But when the final analysis comes, of course, the undetermined will have to be struck out and you will have to take the average of those you know for the results obtained.

Does that answer your question?

MR. ANDREWS: In a large part.

Special Investigation of Each Accident

LT. BROWN: The Department of Commerce now has an inspector who goes around to every accident and he reconstructs that accident, whether it was fatal or not, as well as he can, from the information at hand. The Navy Department has what is known as a "Trouble Board," which is separate from our Boards of Investigation and all that. That is made of three members, and they visit the crash. They take the testimony, not under oath of course, and thresh the thing out and submit a report of each accident that way.

I might take occasion to refer to last year's crash analysis that the Bureau of Aeronautics put out to see the percentage of unknown causes. The unknown was 3.6 per cent of the other causes. That is, we divided pilot and material. Other causes, which is material, and everything amounted to 52 per cent. The pilot was responsible for 48 per cent.

So roughly that is 1½ per cent of unknown crashes we had in the Navy. Of course, civilians will be under greater handicap. They haven't quite the imperialistic control we have. But I am happy to say we have reduced to less than two per cent, the unknown accidents.

EARL D. OSBORN (Aviation Publishing Corp., New York): I was wondering whether you are going to be able to tie this in on the mileage basis or classify the types. Is that contemplated at all? This, as I understand it is just based on the number of accidents.

LT. BROWN: The Navy is studying on hours flown, which is a poor basis, because one aircraft may go up and carry eight passengers and another may carry no passengers at all. So it has been worked out on a passenger basis.

But you can do that if you have your number of fatal accidents, serious accidents and minor accidents, up in the left hand corner of this form, on page 9. You also have your reports from all sources of the amount of flying done.

We unfortunately haven't got the reports on the passenger hours flown. I don't believe civil aviation carries that far. We have complete reports for each month.

The main idea here was to get the causes of accidents, not the relative safety. The relative safety is an excellent thing from the point of view of deciding whether the company is efficient or not, and from the point of view of the layman who wants to take a flight in a plane. But from the point of view of the man who is analyzing these accidents and trying to reduce them, he is more interested in what is causing the most accidents to passengers and of passenger legislation according to that.

Aircraft Accidents—Method of Analysis**By DR. J. S. AMES****Chairman, National Advisory Committee for Aeronautics,
Washington, D. C.****A Report Prepared by
Special Committee on the Nomenclature,
Subdivision, and Classification of Aircraft Accidents**

This report on a method of analysis of aircraft accidents has been prepared by a special committee on the nomenclature, subdivision, and classification of aircraft accidents organized by the National Advisory Committee for Aeronautics in response to a request dated February 18, 1928, from the air coordination committee consisting of the Assistant Secretaries for Aeronautics in the Departments of War, Navy, and Commerce. The work was undertaken in recognition of the difficulty of drawing correct conclusions from efforts to analyze and compare reports of aircraft accidents prepared by different organizations using different classifications and definitions. The air coordination committee's request was made "in order that practices used may henceforth conform to a standard and be universally comparable." The purpose of the special committee therefore was to prepare a basis for the classification and comparison of aircraft accidents, both civil and military.

The special committee was organized in pursuance of resolution adopted by the executive committee of the National Advisory Committee for Aeronautics on March 1, 1928, and held its initial meeting on March 19, 1928. Sixteen meetings were held, the last being on July 17, 1928.

Following is the organization of the committee:

Representatives of the National Advisory Committee for Aeronautics:

Dr. George K. Burgess, chairman.

Mr. George W. Lewis.

Representatives of the Army Air Corps:

Lieut. D. B. Phillips, United States Army.

Lieut. J. D. Barker, United States Army.

Representatives of the Bureau of Aeronautics of the Navy:

Lieut. Commander L. C. Stevens, Construction Corps, United States Navy.

Lieut. Charles R. Brown, United States Navy.

Representatives of the Aeronautics Branch of the Department of Commerce:

Mr. Daniel deR. Scarritt (succeeded by Mr. Edward P. Howard).

Mr. Lester T. Bradbury.

Mr. Scarritt, having resigned from the Government service, was succeeded by Mr. Howard as a representative of the Department of Commerce at the ninth meeting of the committee. Most of the meetings were attended also by Mr. E. M. Kintz, of the Department of Commerce, and Mr. Starr Truscott, of the National Advisory Committee for Aeronautics, and they assisted the committee in the preparation of this report. In connection with the preparation of the definitions and explanations involving the physiological aspects of aviation Dr. L. H. Bauer, of the Department of Commerce, and Lieut. Commander John R. Poppen, Medical Corps, United States Navy, were also of assistance.

Foreign Cooperation

The meeting of May 22, 1928, was attended by the following representatives of foreign governments:

Wing Commander T. G. Hetherington, air attaché, British Embassy.

Lieut. Yoshitake Miwa, Imperial Japanese Navy, assistant naval attaché, Japanese Embassy.

Commander Silvio Scaroni, air attaché, Italian Embassy.

Maj. Georges Thenault, assistant military attaché for aeronautics, French Embassy.

At that meeting the proposed method of analyzing aircraft accidents was explained and the value of a uniform system for reporting accidents was discussed. It was suggested that the representatives of the foreign governments consult with the personnel in their governments who were responsible for analyzing and reporting aircraft accidents, regarding the possibility of adopting the proposed method and form.

Great interest was expressed, and it was the opinion of those present that the adoption of a uniform system would be advantageous. The representatives of the foreign governments were invited to submit comments and suggestions regarding changes, but none had been received up to the date of the last meeting of the committee. This was probably due to the necessarily lengthy period of time required for translation, consideration, and approval.

An aircraft accident is an occurrence which takes place while an aircraft is being operated as such and as a result of which a person or persons are injured or killed, or the aircraft receives appreciable or marked damage through the forces of external contact or through fire. A collision of two or more aircraft should be analyzed and reported statistically as one accident.

Immediate Causes of Aircraft Accidents

In the course of its meetings the committee considered various methods of analyzing aircraft accidents. These included studies and classification by (a) the immediate causes, (b) the underlying causes, (c) the nature, and (d) the results of the accidents. Each of these methods was considered in detail, and it was finally found possible to reduce their analysis to the methods described in this report and combine the results in the form of a single chart.

A plan devised by Lieutenant Philips, of the Army, and Lieutenant Brown, of the Navy, for the division of the immediate causes of aircraft accidents into four major classes, and providing for the further subdivision of these major classes as seemed desirable, together with proposed definitions of these classes and subdivisions, was submitted to the committee for consideration.

The outline and definitions of the classification of accidents as presented to the committee were carefully considered by the members of meetings, and modifications were made in the plan as originally drafted so as to provide for every type of aircraft accident in the light of the experience of the members in classifying and analyzing accidents in the Government services.

In working out this outline the committee attempted to provide a plan which would permit of the careful analysis of aircraft accidents by the different organizations from the point of view of both personnel and matériel problems. The plan also permits of the analysis of a given accident into two or more distinct causes and makes possible, by the use of percentages, the indication of the relative weight of each cause in any particular accident.

Cross Analysis

The plan provides for the analysis of crashes according to the nature of the accident (take-off accidents, tail spins following engine failure, etc.), the degree of seriousness of personnel injuries, and the amount of damage occurring to matériel.

Furthermore, the system, through the use of a cross-analysis method, allows for analyzing pilot errors and matériel failures according to the underlying causes of these errors or failures.

The plan also provides for the analysis of aircraft accidents of different organizations on the same basis, so that the records will be comparable and the preparation of a composite report of all aircraft accidents will be possible. It is the belief of the committee that if all aircraft accidents occurring in all agencies are classified in the manner recommended a composite of all the accidents will offer a basis upon which a study may be made and correct conclusions drawn.

Aircraft Analysis Form

In drawing up the aircraft accident analysis form and the accompanying definitions the committee had in mind the frequency rate of accidents from the various causes, the logical lines along which studies should be conducted, and the ease with which these studies can be made from this chart. It is recognized that to make a detailed study of accidents due to any one cause a further subdivision may be necessary. However, if all accidents are classified according to this chart the major causes can be easily determined and further investigation can be readily carried out for the purpose of eliminating these causes.

It was also recognized, in working out this chart, that the division of immediate causes between personnel and matériel as set forth in the chart and definitions was more or less arbitrary, since all defects of aircraft can in the last analysis be attributed to errors of personnel, whether in operation, inspection, maintenance, manufacture, or design. Since the purposes of the accident study seemed to be best served by drawing attention to defects of matériel, even though traceable ultimately to personnel errors, the line between personnel and matériel in the immediate causes was drawn at the operating personnel of the aircraft. In other words, under the main heading "Personnel" there are included only those accidents for which personnel engaged in operating the aircraft are responsible. Accidents due to matériel failure are classified under "Matériel" even though personnel charged with design, construction, or operation may be held responsible for the failure. Errors due to personnel other than those immediately accessory to the operation of the aircraft are shown in the "Underlying causes" or "Cross analysis," as set forth hereinafter, rather than in the main headings of immediate causes.

The plan as drawn up by the committee is not in any sense final or complete, but is presented to provide a working basis for the study of aircraft accidents from all sources.

Weighing of Accidents

Where two or more factors cause an accident, part will be charged to each; for example, in the case of an avoidable accident following an engine failure the responsibility for the accident might be considered to be equally divided between the pilot and the power plant, in which case 50 per cent would be charged to "Personnel" and 50 per cent to "Matériel." If the responsibility for the accident rested largely upon the pilot, "Personnel" would be charged with 60, 70, or 80 per cent of the accident, or even more, depending upon the degree of responsibility decided upon. Conversely in the above cases "Matériel" and "Miscellaneous" would be charged with a total of 40, 30, or 20 per cent of the accident. This same division of responsibility might be carried out under "Personnel" or other subheads. However, in the particular case cited "Errors of pilot" would be the only division of "Personnel" which could be charged with this accident. If 80 per cent of the accident were charged to "Personnel" in the above instance, then 80 per cent of the accident would be charged to "Errors of pilot." Then, assuming that the responsibility for such piloting error rested jointly upon error of judgment and poor technique, a still further subdivision would be made and 40 per cent of an accident would be charged to "Error of judgment" and 40 per cent to "Poor technique." Thus the factors of each crash could be traced down to the last subdivision under any heading and weighted in accordance with their importance.

Classification of Accidents

For the purpose of comparative study aircraft accidents may be divided into groups of accidents of the same general characteristics. Accident prevention must be regarded as the primary purpose of aircraft study. Studies of accident causes point out needed remedies more clearly when they are supplemented by certain studies based upon the nature and results of the accident.

For example, in both bad landings and tail spins the principal cause is usually errors of the pilot. Statistics based upon the study of causes merely show that pilot's errors are responsible for more than half of all accidents, and the formulation of remedies for the situation appears difficult. If, however, the same accidents are classified according to their nature and results, it is found that the tail spin is the kind of accident that is by far the most prevalent among those which produce fatal consequences. It is apparent that new designs which decrease the tendency of airplanes to spin, or new training methods which increase the ability of pilots to avoid falling into spins and to recover from them quickly, will have a marked influence toward the prevention of fatal accidents.

Likewise, the study based upon nature and results indicates, in the case of collisions, that this kind of accident is third in importance among those which produce fatal results, and that these accidents are much more prevalent during winter months than in summer; and while remedies are not so obvious as in the case of tail spins some lines of attack immediately suggest themselves.

The following classifications for study of accidents according to their nature are recommended:

I. Nature of the Accident

This consists of dividing accidents into separate classes according to the type of accident which occurs.

1. *Class A—Collisions in full flight with other aircraft.*—This includes all collisions with airplanes, balloons, or other aircraft while the colliding aircraft is at flying speed or at an altitude which permits free maneuvering. It excludes collisions (1) on the ground while taxiing, taking off, or landing, and (2) in the air immediately before landing or after taking off and while the airplane is at or near its minimum flying speed.
2. *Class B—Collisions in full flight with objects other than aircraft.*—This includes collisions while at flying speed and with power plant functioning normally with trees, poles, houses, mountain sides, or other obstacles. It includes collisions with the earth or water by diving. It excludes collisions (1) on the ground while taxiing, taking off, or landing, and (2) in the air immediately before landing or after taking off and while the airplane is at or near its minimum flying speed.
3. *Class C—Tail spins following engine failure.*—This includes spins, stalls, and all collisions with the earth while the airplane is out of control due to loss of flying speed following engine failure.
4. *Class D—Tail spins without engine failure.*—This includes spins, stalls, and all collisions with the earth while the airplane is out of control following loss of flying speed, with the engine functioning normally. It includes spins due to structural failure or defective handling qualities of the airplane.
5. *Class E—Forced landings.*—This covers accidents while making landings necessitated by conditions which could not be overcome while in flight. Such conditions include engine trouble and other defects of the aircraft, loss of knowledge of the direction to the destination or the location on the map of the aircraft's position, bad weather, darkness, and exhaustion of fuel.
6. *Class F—Landing accidents.*—This includes accidents while the pilot is in the act of executing a voluntary landing. It does not include forced landings

or accidents while examining a field from the air or approaching it for a landing.

7. *Class G—Take-off accidents.*—This includes accidents occurring between the time of starting a take-off to the time when full flying speed is gained, except those covered under other classifications, as, for instance, tail spins or forced landings.
8. *Class H—Taxying accidents.*—This includes all accidents which occur while the aircraft is maneuvering under its own power on land or water. It excludes accidents while the aircraft is still rolling after a landing or while it is getting up speed for a take-off.
9. *Class I—Fires in the air.*—This includes all accidents in which fire breaks out, either as a cause or result of the occurrence, while the aircraft is in flight.
10. *Class J—Carrier, platform, and arresting-gear accidents.*—This includes accidents occurring while the aircraft is landing upon or taking off from (1) the deck of a floating aircraft carrier, or (2) an elevated platform intended for the landing and taking off of aircraft, but excludes launching-gear accidents.
11. *Class K—Launching gear accidents.*—This includes accidents during take-off in which the aircraft is assisted in gaining flying speed by the application of an external force.
12. *Class L—Miscellaneous.*—This includes accidents the nature of which is known but which do not fall into one of the above classifications.
13. *Class M—Indeterminate and doubtful.*—This includes all accidents concerning the nature of which so little is known that any classification can not be intelligently accomplished.

II. Injury to Personnel

This consists of dividing accidents into separate classes according to the injury suffered by personnel in such aircraft.

1. *Class A.*—A "Class A" injury is one resulting in the death of the individual within a period of 90 days.
2. *Class B.*—A "Class B" injury is one resulting in serious injury to the individual. Because of the difficulties of classification, the opinion of a physician should be obtained whenever possible as to whether an injury is severe or minor. When a physician is not available, the following general rules should be followed: Any injury that results in unconsciousness; any fracture of any bone except simple fractures of the fingers and toes; lacerations that involve muscles or cause severe hemorrhage; any injury to any internal organ; or any other injury that it seems probable will incapacitate the individual for more than five days should be classed as a severe injury. All other injuries should be classed as minor.
3. *Class C.*—A "Class C" injury is one resulting in only minor injury to the individual.
4. *Class D.*—Any personnel who experience an aviation accident with no personal injury shall be classified as "Class D."

NOTE.—The classification of an accident according to injury to personnel shall contain a letter for each individual in the aircraft at the time of the accident, the first of these letters representing the pilot of the aircraft. For example, in an accident where the pilot is killed, one passenger seriously injured, and the remaining passenger escapes with only minor injury the accident would be classified as a Class ABC accident. Had the pilot escaped with minor injury and both passengers been killed, it would have been a Class CAA accident.

III. Damage to Matériel

This consists of dividing accidents into separate classes according to the amount of damage which occurs to matériel.

1. *Class A.*—This includes all accidents as a result of which the aircraft is of no further value except for salvage or usable parts.
2. *Class B.*—This includes all accidents as a result of which it is necessary to completely overhaul the aircraft before it would be again airworthy.
3. *Class C.*—This includes all accidents as a result of which it is necessary to replace some major assembly of the aircraft before it would be again airworthy, such as a wing, fuselage, undercarriage, tail, or engine. Accidents in which the damage to the engine or other major assembly was a *cause* and not a *result* are excluded from this category unless the remaining damage warrants such.
4. *Class D.*—This includes all incidents which because of other factors come within the category of an aircraft accident and as a result of which there is only minor and easily repairable damage to the aircraft, such as a broken tail skag, wheel, bent propeller tip, etc.
5. *Class E.*—This includes all incidents similar to Class D accidents above in which there is no damage to matériel.
6. *Class F.*—"Class F" is included in this analysis only because of the interest it may have for the different organizations which may use this method of analyzing. It consists of matériel failures which did not result in an accident, and, strictly speaking, does not actually fit into an accident analysis. However, the methods here used for analyzing matériel failures which did result in accidents can as easily be applied to those which did not, and thus afford a method of studying the potential accidents, which because of other reasons did not occur, such as a successful landing after engine failure, etc.

The following classifications for study of aircraft accidents according to their causes are recommended:

A. Immediate Causes of Aircraft Accidents

The following is a proposed list of immediate standard causes of aircraft accidents, with definitions where considered necessary for clarity.

- I. *Personnel.*—This includes all accidents which can be traced to persons accessory to the operation of the aircraft, either on the ground or in the air. This does not include accidents due to errors or omissions of personnel charged with the design, manufacture, maintenance, or inspection of aircraft.
 1. *ERRORS OF PILOT.*—This includes all accidents the responsibility for which rests upon the pilot. The pilot is the actual manipulator of the controls or the individual responsible for their correct manipulation.
 - (a) *ERROR OF JUDGMENT.*—This includes all accidents resulting from a decision made by the pilot which was not the best possible under existing circumstances.
 - (b) *POOR TECHNIQUE.*—This includes all accidents resulting from lack of skill, dexterity, or coordination of the senses in handling aircraft controls, whether traceable to inherent inability to attain such or to infrequent flying, lack of experience in flying, lack of experience in flying under particular conditions, or in the particular type of aircraft.
 - (c) *DISOBEDIENCE OF ORDERS.*—This includes all accidents resulting from the violation of disobedience of local or general orders or regulations or provisions of law governing the operation

of aircraft, such as low acrobatics, acrobatics in aircraft not to be used for such purposes, or any other type or manner of operation specifically forbidden by orders or regulations issued by competent authorities.

(d) CARELESSNESS OR NEGLIGENCE.—This includes all accidents resulting from the absence of care on the part of the pilot according to circumstances or the failure to use that degree of care which the circumstances justly demand, either on the ground or in the air, such as careless manipulation of the controls of an aircraft, failure to ascertain the amount of gasoline on board before taking off, failure to ascertain the conditions of the instruments, etc.

(e) MISCELLANEOUS.—This includes all accidents resulting from errors of the pilot not accounted for above.

2. ERRORS OF SUPERVISORY PERSONNEL.—This includes all accidents the responsibility for which rests upon individuals other than the pilot who exercise control over the operation of the aircraft, such as navigators, formation section leaders, ground-operations officers, etc.

3. ERRORS OF OTHER PERSONNEL.—This includes all accidents the responsibility for which rests upon other personnel directly concerned with the operation of the aircraft, such as members of the flight and ground crews of the aircraft, aerographers, etc.

II. *Matériel*.—This includes all accidents resulting from failures of the airplane, power plant, accessories, and launching and arresting devices, whether traceable to materials, faulty design, maintenance, or inspection.

1. POWER-PLANT FAILURE.—This includes all accidents resulting from failure or malfunctioning of the propelling system and all auxiliaries essential to its proper functioning, exclusive of instruments.

(a) FUEL SYSTEM.

(b) COOLING SYSTEM.

(c) IGNITION SYSTEM.

(d) LUBRICATION SYSTEM.

(e) ENGINE STRUCTURE.

(f) PROPELLER AND PROPELLER ACCESSORIES.

(g) ENGINE CONTROL SYSTEM (THROTTLE ROD, ETC.).

(h) MISCELLANEOUS.

(i) UNDETERMINED.

2. STRUCTURAL FAILURE.—This includes all accidents resulting from failures of the airplane exclusive of the propelling system and instruments.

(a) FLIGHT CONTROL SYSTEM.

(b) MOVABLE SURFACES.

(c) STABILIZING SURFACES.

(d) WINGS, STRUTS, AND BRACING.

(e) LANDING GEAR.—This includes all accidents resulting from failure of the landing-gear struts and shock-absorbing gear, but does not include accidents resulting from failure of the wheels or floats attached thereto.

(f) WHEELS, TIRES, AND BRAKES.

(g) SEAPLANE FLOAT OR BOAT.

(h) FUSELAGE, ENGINE MOUNT, AND FITTINGS.

(i) TAIL SKID OR WHEEL ASSEMBLY.

(j) ARRESTING APPLIANCES ON AIRCRAFT.

(k) MISCELLANEOUS.

(l) UNDETERMINED.

3. **HANDLING QUALITIES.**—This includes all accidents resulting from those peculiar characteristics of certain types of aircraft affecting their controllability while on the ground or in the air, such as marked tendency to ground loop, inability to recover from a spin, etc.
4. **INSTRUMENTS.**—This includes all accidents resulting from failures of instruments which were essential to operation under the conditions of the flight.
5. **LAUNCHING DEVICES.**—This includes all accidents resulting from failure or malfunctioning of catapults.
6. **ARRESTING DEVICES.**—This includes all accidents resulting from failure or malfunctioning of arresting gear not a part of the aircraft.
- III. **Miscellaneous.**—This includes all accidents not accounted for above.
 1. **WEATHER.**—This includes all accidents resulting from conditions of the weather which could not reasonably have been foreseen and avoided. (Mention may be made on the chart of contributing weather causes, as fog, gale, ice, hail, snow, rain, lightning, etc.).
 2. **DARKNESS.**—This includes all accidents resulting from conditions due to nightfall which could not reasonably have been foreseen and avoided.
 3. **AIRPORT OR TERRAIN.**—This includes all accidents resulting from airports or landing conditions of places which could not reasonably have been detected or avoided. (Forced landings should be charged to power plant, etc., unless report shows that safe landing could have been made, in which case the crash would probably be attributed to error of judgment or poor technique.)
 4. **OTHER.**—This includes all accidents resulting from causes not otherwise accounted for above.

IV. *Undetermined and doubtful.*

B. Underlying Causes of Aircraft Accidents

The following is a list of standard underlying causes of aircraft accidents, with definitions where considered necessary for clarity.

- I. **Errors of pilot.**—Returning to "Errors of pilot," paragraph I, subparagraph 1, above, the subdivisions of this paragraph were made according to the immediate causes of the errors attributed to the pilot, such as an "Error of judgment," "Poor technique," etc. The underlying causes of such errors may frequently be of more interest than the actual causes themselves. These causes may be defined as those elements which contributed to the pilot's mental and physical equipment at the time of the accident or to the deficiencies which existed in such equipment.
 1. **LACK OF EXPERIENCE.**—This includes all accidents resulting from insufficient personal acquaintance with the actual conditions which had to be met under the circumstances.
 - (a) **LACK OF GENERAL EXPERIENCE.**—This includes all accidents resulting from a lack of experience in the general problems of aviation, such as landing, taking off, air work, etc.
 - (1) **LACK OF TOTAL GENERAL EXPERIENCE.**—This includes all accidents resulting from a lack of general experience due to the fact that the individual concerned has never engaged in such work for a sufficient period of time to acquire the necessary experience to have avoided such accidents.
 - (2) **LACK OF RECENT GENERAL EXPERIENCE.**—This includes all accidents resulting from a lack of general ability due to the fact that the individual concerned has

too infrequently engaged in general flying activities prior to the accident, and consequently lost the ability he had originally acquired.

(b) **LACK OF SPECIAL EXPERIENCE.**—This includes all accidents resulting from a lack of experience in special problems of aviation, such as certain features of cross-country flying (which might, for example, require an intimate knowledge of the terrain of a certain section), carrier operations, night flying, blind flying, etc.

(1) **LACK OF TOTAL SPECIAL EXPERIENCE.**—This includes all accidents resulting from a lack of special experience due to the fact that the individual had never engaged in such special problems for a sufficient period of time to acquire the necessary experience to have avoided such accidents.

1. **LACK OF EXPERIENCE.**—Continued.

(b) **LACK OF SPECIAL EXPERIENCE.**—Continued.

(2) **LACK OF RECENT SPECIAL EXPERIENCE.**—This includes all accidents resulting from a lack of ability in the special problems due to the fact that the individual concerned has too infrequently engaged in special flying activities prior to the accident, and consequently lost the ability he had originally acquired.

2. **PHYSICAL AND PSYCHOLOGICAL CAUSES.**—This includes all accidents resulting from a demonstrable disease or defect or poor reaction.

(a) **DISEASE OR DEFECT.**—This includes all accidents resulting from a disease or defect, demonstrable by physical (including nervous system) examination.

(1) **INHERENT DISEASE OR DEFECT.**—This includes all accidents resulting from a disease or defect which is not susceptible to remedy within a reasonable period of time, such as overshooting a field, faulty landings or collision because of defective vision or judgment of distance; unconsciousness; hysterical or epileptic tendency; chronic air sickness; inability to withstand altitude, etc. The history of an individual may often be necessary to determine if a disease or defect is inherent.

(2) **TEMPORARY DISEASE OR DEFECT.**—This includes all accidents resulting from a disease or defect which is remediable and one which may not be expected to repeat itself with undue frequency in the individual concerned, such as fatigue, either mental or muscular, staleness, temporary illness, incomplete convalescence, etc.

(b) **POOR REACTION.**—This includes all accidents which result from no demonstrable disease or defect but from psychological causes, making the individual react either erroneously or slowly to a situation, such as selecting what is manifestly the poorer of two fields for an emergency landing, persisting on a course when better judgment would indicate that he should land or turn back, indulging in acrobatics over prohibited areas or at too low altitude, etc.

- (1) **POOR REACTION, INHERENT.**—This includes all accidents resulting from psychological causes which apparently are not susceptible to correction within a reasonable period of time. The history of the individual would be a very important adjunct in determining if such poor reaction were inherent and its repetition to be frequently expected.
- (2) **POOR REACTION, TEMPORARY.**—This includes all accidents resulting from psychological causes which apparently are subject to correction, disciplinary or otherwise, within a reasonable period of time.

II. Matériel failures.—The underlying causes of "matériel failures" should also prove of considerable interest in analyzing accidents.

1. FAULTY INSTRUCTIONS.—This includes all accidents resulting from matériel failures which were traceable to errors or omissions in the standard instructions covering the use of such matériel.

(a) **FAULTY OPERATING INSTRUCTIONS.**—This includes all accidents resulting from matériel failures which were traceable to the operation of such matériel in accordance with standard instructions which prove to be incorrect or incomplete, such as instructions governing the use of the mixture control which when carried out are found to damage the engine, instructions governing the proper engine operating temperature which when carried out are found to damage the engine, etc.

(b) **FAULTY MAINTENANCE INSTRUCTIONS.**—This includes all accidents resulting from matériel failures which were traceable to the maintenance of such matériel in accordance with standard instructions which prove to be incorrect or incomplete, such as instructions governing the type of protective coating to cover duralumin parts when operating as a sea-plane, etc.

2. FAULTY INSPECTION.—This includes all accidents resulting from matériel failures which were traceable to errors or omissions in the inspection of such matériel.

(a) **FAULTY MANUFACTURING INSPECTION.**—This includes all accidents traceable to faulty inspection of matériel where such errors or omissions occurred prior to the receipt of this matériel by the consumer.

(b) **FAULTY OVERHAUL INSPECTION.**—This includes all accidents traceable to faulty inspection of matériel where such errors or omissions occurred during overhaul or storage of the matériel.

(c) **FAULTY MAINTENANCE INSPECTION.**—This includes all accidents traceable to faulty inspection of matériel where such errors or omissions in inspection occurred after the final delivery of this matériel to the operating unit.

(d) **FAULTY INSPECTION, INDETERMINATE.**—This includes all accidents traceable to faulty inspection of matériel where actual responsibility for the errors or omissions in inspection can not be definitely placed.

3. FAULTY MATERIALS.—This includes all accidents resulting from matériel failures which were traceable to defective materials when such defects in materials could not reasonably have been detected and eliminated by a proper system of inspection.

- (a) **ORIGINALLY DEFECTIVE MATERIALS.**—This includes all accidents traceable to faulty materials where the materials contained such defects when originally delivered.
- (b) **DETERIORATED MATERIALS.**—This includes all accidents traceable to faulty materials where the defects of such materials occurred through deterioration after delivery.
- (c) **FAULTY MATERIALS, INDETERMINATE.**—This includes all accidents traceable to faulty materials where it is not possible to determine the actual time or place when such defects first appeared.
- 4. **FAULTY DESIGN.**—This includes all accidents resulting from matériel failures which were traceable to errors or omissions in the original design of such matériel.
 - (a) **FAULTY DESIGN, ORIGINAL.**—This includes all accidents traceable to faulty design where such errors or omissions in design occurred in the original design of such matériel, or in the course of changes initiated or directed by persons having recognized authority regarding design or construction.
 - (1) **FAULTY ORIGINAL DESIGN, STRUCTURAL STRENGTH.**
 - (2) **FAULTY ORIGINAL DESIGN, ARRANGEMENT.**
 - (3) **FAULTY ORIGINAL DESIGN, AERODYNAMIC.**
 - (4) **FAULTY ORIGINAL DESIGN, INDETERMINATE.**
 - (b) **FAULTY DESIGN, MODIFICATION.**—This includes all accidents traceable to faulty design where such errors or omissions in design occurred in modifications to the original design of such matériel initiated or directed by persons not having recognized authority regarding design or construction (such as jury rigs, emergency repairs, etc.).
- 5. **INDETERMINATE MATÉRIEL FAILURE.**—This includes all accidents from matériel failures the exact source of which can not be determined.

Description and Typical Analysis of an Accident

Pilot John Doe was flying in a seaplane at 200 feet altitude over a point of land between a bay and the open sea when the engine stopped. Pilot Doe had an opportunity to land either directly into the wind in the open sea or cross wind in the bay. He started to land in the ocean, but at 100 feet altitude he changed his mind and attempted to turn so as to land in the bay. In turning, Doe held the nose of the seaplane up, stalled it, and spun into the land. The airplane was demolished, the pilot was seriously injured, and the passenger was killed.

Doe, according to his record, was an experienced aviator with 30 hours' flying during the preceding month and with recent experience in stunting airplanes.

Examination of the engine showed that one of the teeth in the magneto timing gear had stripped, the broken tooth having been drawn into the other teeth, causing the eventual stripping of all teeth. The original break was determined to be a visible hardening crack.

The NATURE of this accident is Class C—Tail spin following engine failure. The classification according to RESULTS is Personnel, Class BA; Matériel, Class A.

In analyzing this accident the IMMEDIATE CAUSE is charged, as indicated on the analysis chart, as 75 per cent "Personnel" and 25 per cent "Matériel," for the reason that the account of the accident shows that the pilot had two chances to make a safe landing and took advantage of neither of them. Considering the 75 per cent which is charged to "Personnel," it is obvious that this is chargeable neither to "Errors of supervisory personnel" nor to "Errors of other personnel,"

PREPARED AND RECOMMENDED BY
SPECIAL COMMITTEE ON THE NOMENCLATURE, SUBDIVISION
AND CLASSIFICATION OF AIRCRAFT ACCIDENTS
NATIONAL ADVISORY COMMITTEE
FOR AERONAUTICS
JULY 17, 1928

so that the whole weight, 75 per cent, must be placed under "Errors of pilot." It appears further that the errors of the pilot involved errors of judgment in that he lost altitude while wavering indecisively between landing in the ocean and attempting to land in the bay. It appears that poor technique was the most important single factor in that he continued to pull the nose up, still further stalling the seaplane, when he should have sensed the approaching stall. It is considered that

a charge of 35 per cent to "Error of judgment" and 40 per cent to "Poor technique" represents as near an approximation as can be arrived at in this case.

On analysis of UNDERLYING CAUSES it would appear that the "Error of judgment" and "Poor technique" were both due to a "Temporary poor reaction" with a strong possibility of such "Poor reaction" being "Inherent" rather than "Temporary." However, in the absence of a history of the individual this would have to be classified as "Temporary."

Considering the 25 per cent charged to "II. Matériel," the entire 25 per cent obviously should be assigned to "1. Power plant failure," in the second order of subdivision, and again in the third order of subdivision the entire 25 per cent should be charged to "(c) Ignition system."

The underlying cause of this matériel failure is unquestionably faulty manufacturing and accordingly on the cross analysis it would be placed under the head of "Manufacturing inspection."

Conclusion and Recommendations

The special committee on the nomenclature, subdivision, and classification of aircraft accidents, having studied in considerable detail the problem of classifying and analyzing the causes of aircraft accidents, at its final meeting held on July 17, 1928, unanimously adopted a resolution approving this report and recommending that it be published by the National Advisory Committee for Aeronautics and that copies be transmitted to the War, Navy, and Commerce Departments with a recommendation that the proposed method of analysis of aircraft accidents outlined in the report be adopted for use in their respective services. The special committee recommends further that copies of the report be transmitted also to the appropriate representatives of the various interested foreign governments with a request that they cooperate by contributing information from time to time in relation to aircraft accidents.

With the submission of this report the work of the special committee is concluded and it should be discharged. It is probable, however, that the introduction of the proposed chart for the analysis of accidents will result in questions as to interpretation and suggestions for changes, many of which, it is believed, have been considered during the meetings of the committee. It is also probable that study of the information obtained from the application of the method of analysis will indicate that certain features in aircraft construction or operation should be given more detailed study or consideration. The committee therefore at its final meeting adopted a resolution recommending that its present personnel be reorganized into a standing committee on aircraft accidents of the National Advisory Committee for Aeronautics for the purpose of considering from time to time such new matter regarding aircraft accidents as may appear desirable or as may be brought before it.

Respectfully submitted.

SPECIAL COMMITTEE ON THE NOMENCLATURE, SUBDIVISION,
AND CLASSIFICATION OF AIRCRAFT ACCIDENTS.

GEORGE K. BURGESS, *Chairman*.

WASHINGTON, D. C., August 15, 1928.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Legislation

First National Aeronautical Safety Conference

Under Joint Auspices of

The Daniel Guggenheim Fund for the Promotion of Aeronautics and the National Safety Council

October 4 and 5, 1928

HON. F. TRUBEE DAVISON, Chairman

Assistant Secretary of War, War Department, Washington, D. C.

The session on Legislation of the Aviation Division at the Seventeenth Annual Safety Congress was called to order at two forty-five o'clock by the chairman, Hon. F. Trubee Davison, Assistant Secretary of War, War Department, Washington, D. C.

CHAIRMAN DAVISON: Gentlemen, as you know, the subject is "Legislation" and the first paper will be read by Mr. MacCracken, the Assistant Secretary of Commerce in charge of Aeronautics. Of course, Mr. MacCracken knows more about this legislative question than anybody else; he has been operating under the Air Commerce Act that was passed in 1926; and as a result of that experience and the experience he has had in several of the states as well as in local legislation, he is particularly well qualified to present a paper on this topic.

HON. WILLIAM P. MACCRACKEN, JR.: Mr. Chairman and Members of the Congress: Before undertaking to read the paper itself, I want to express my personal appreciation of the work of the National Safety Council in getting up this aeronautics program. I think that they have been most generous and most successful in what they have undertaken.

Federal Legislation Relative to Safety

By HON. WILLIAM P. MACCRACKEN, JR.

**Assistant Secretary of Commerce for Aeronautics, Department of Commerce,
Washington, D. C.**

Federal policies pertaining to the subject of the safe operation of civilian aircraft are defined by the Air Commerce Act of 1926. The purpose of this Act was declared to be "the encouragement and regulation of the use of aircraft in commerce." Its administration is vested in the Secretary of Commerce, who, by its terms, is clothed with broad powers to promulgate regulations; impose, mitigate and remit penalties, and to issue and revoke licenses for aircraft and airmen.

There are four essentials in the Federal Government's policy relating to the safety of civilian aircraft: (1) Airworthiness of the craft; (2) Competent personnel; (3) Uniform Air Traffic Rules; (4) Adequately equipped airways.

In determining what regulations should govern the first three of these factors essential to safe operation, the Department of Commerce endeavored to secure the advice of all those in any manner engaged in, or connected with, the manufacture or operation of aircraft and engines. Whatever merit there may be in the present Air Commerce Regulations is, in a large measure, due to the response of the industry to the Department's expressed desire for cooperation, coupled with the fact that the administration of the regulations has been almost wholly in the hands of experienced flying personnel.

Under the terms of the Air Commerce Act the owners of aircraft engaged in interstate or foreign commerce by air are required to secure a federal license for such aircraft. The first prerequisite is that the owner shall be an American citizen. Such owners, though their craft do not engage in interstate or foreign commerce by air, may secure a federal license if they so desire.

At the time of the passage of the Act very few of the states had any laws relating to the licensing of aircraft. During the past two years several such laws have been enacted. These have not been uniform, but there has been a marked tendency towards requiring a federal license for all aircraft operating within the state.

In some instances the state legislation has in effect made the federal license a prerequisite for the issuance of a local license, with the result that at the present time of the 8,177 civilian-owned planes appearing upon the records of the Department of Commerce 4,488 are operating as licensed aircraft, or upon letters of authority pending action upon their applications for license.

When the Air Commerce Act was pending before Congress there was considerable sentiment in favor of requiring all aircraft to conform to the federal licensing provisions. Those who advocated such action did so upon the theory that in order to adequately protect interstate and foreign commerce by air, it was necessary that only airworthy craft in the hands of competent pilots should be permitted to use the air space of the United States and its territorial waters.

Those opposed to this view argued that such a requirement would constitute an infringement upon the rights or the responsibilities of the several states. The latter view prevailed insofar as the licensing provisions of the Act are concerned.

It is unfortunate that some state authorities in administering their licensing laws have shown a tendency to establish standards at variance with those of the Federal Government. This is bound to cause confusion, as well as to increase the burdens of aircraft operators and the possibilities of accident. If this practice continues the Federal Government will ultimately be forced to assume a broader jurisdiction. The states, through legislation and their administrative officers, can cooperate in such manner as to avoid the necessity of extending the licensing jurisdiction of the Air Commerce Act. What the processes will be I cannot forecast, but there can be no doubt that in the best interests of aircraft development and safety there should be but a single standard for licensing equipment and personnel.

In determining the question of airworthiness the Department has fixed certain minimum safety factors, and has also provided the industry with a handbook of approved practices. It is not the intention of the Department to in the least stifle the originality or the initiative of the aeronautical engineer. To do so would not only retard economic progress, but also militate against advance in the safety of the air.

When an airplane is designed, the stress analysis is submitted to the Engineering Section of the Air Regulations Division. When this is approved by that Section the application for an Approved Type Certificate is then referred to the field service. An inspector examines the shop facilities and practices of the manufac-

turer, and the plane is given a thorough flight test. If the reports are all favorable the Approved Type Certificate is issued, and the manufacturer can produce duplicate plans according to this design, with the assurance that they will be licensed by the Federal Government. From time to time inspectors visit the factories where planes are being manufactured under Approved Type Certificates, to check up on the workmanship, and materials, as well as to ascertain that the manufacturer is not deviating from the approved design.

Due to the unusually heavy demands for this type of service, some delays and difficulties have been experienced. On the whole, it has demonstrated that, for the present at least, this method will probably prove satisfactory from the point of view of the manufacturer and the operator, as well as the Federal Government.

Once the aircraft is licensed, it is then subject to the regulations of the Department relative to maintenance and inspection. The responsibility for this rests almost entirely upon licensed mechanics employed by the operators, subject to periodic checks by the Department's inspector. Daily and other periodic inspections are prescribed by Regulation to be carried out by those licensed to make them.

In the licensing of personnel the pilot presents a much more difficult problem than the mechanic. At the present time the Regulations require that all pilots take an annual physical examination, and that pilots carrying passengers for hire or reward shall also take a semi-annual check-up.

In addition to the physical examination, the applicants are required to pass theoretical written examinations, and a practical flying examination. Renewals of licenses are issued upon the passing of the physical examination, accompanied by an affidavit that the pilot has had the minimum amount of flying time required during the preceding period.

In order to secure a mechanic's license, it is only necessary to pass the written examination, and to submit evidence of prior experience in airplane rigging or internal combustion engines, according to the type of license desired.

The Air Commerce Act requires that all planes, civilian, and military, commercial and non-commercial, shall conform to the Air Traffic Rules promulgated by the Department of Commerce. In this respect, Congress recognized the need for uniformity in order to adequately protect interstate and foreign commerce by air.

The fact that the Federal Government has undertaken to prescribe Air Traffic Rules applicable to all aircraft obviates the necessity for any state or local legislation on this subject, and in all probability the courts will hold that any such legislation is unconstitutional. However, the successful enforcement of these regulations will, to a great degree, depend upon the measure of cooperation that exists between state and local authorities on the one hand, and the Federal authorities on the other. Thus far there has not been any evidence of a lack of cooperation on the part of either group in this regard, although there is evidence that the law and regulations have not been brought to the attention of a great many of the local and state authorities.

For violations of the Air Traffic Rules, as well as for other regulatory provisions of the Air Commerce Act, civil penalties are prescribed. These are assessed by the Secretary of Commerce upon complaint. The party penalized may submit evidence to controvert the charge or in mitigation of the penalty. The matter is then investigated by the Air Regulations Division, and a recommendation is sent to the Secretary, who either remits the penalty or mitigates it to such sum as he deems reasonable. To date this method has proven very satisfactory. It has avoided increasing the burdens of our Federal Courts, and has assured the aircraft operators that their transgressions would be dealt with by those having a real knowledge of aeronautics.

The Air Commerce Act places upon the Department of Commerce the responsibility for investigating and determining the causes of all accidents involving civil aircraft. This has already reached considerable proportions, and has necessitated

the creation of an Accident Board. At the present time this Board consists of two pilots, the medical director, a statistician and a lawyer.

In analyzing the report of each accident the following factors are taken into consideration:

Many accidents involve several factors, and it is the function of the Board not only to determine what factors are involved, but also to assign a relative weight which should be given to each factor. This is done in terms of percentages, and reports are to be issued quarterly showing the results of the findings of this Board in a consolidated form.

It is the hope of the Department that this report will not only prove of benefit by pointing out the weaknesses to the Department and to the industry, in order that they may be corrected, but will also be of assistance to the insurance companies who are covering the risks, as well as the means of stimulating confidence in the minds of the public.

So far this paper has dealt entirely with the regulation of aeronautics by the Federal Government as a means of increased safety in operation. By far the greater part of the expenditure of Federal appropriations made to carry out the purposes of the Air Commerce Act has been spent in providing and maintaining airway aids. The subject of lighting, directional radio, communications, airway selection and marking, and weather service are subjects of other papers which have been presented to the conference. It is not my purpose to even attempt a summary of these papers, but merely to point out that while the public in general is inclined to lay emphasis upon the Department's regulations and their enforcement in promoting safety in aeronautics, by far the greater part of the funds expended are used in providing safer airways for the pilots.

During the current fiscal year the Department will spend approximately twenty dollars for air navigation facilities to promote safety in aeronautics for every dollar it spends toward accomplishing the same result through regulation. The total appropriation for carrying out the provisions of the Air Commerce Act is in excess of five millions of dollars. While this sum is not large as Federal appropriations are judged, it must be borne in mind that the original appropriation for the fiscal year nineteen twenty-seven was but five hundred thousand dollars.

While there is much room for improvement, it is gratifying to note that this program of the Federal Government which, as a whole, has been in effect for less than two years, has done much to increase public confidence, as well as to reduce the dangers in air operation. Perfection is impossible of attainment, but sufficient experience has been gained to indicate that air transportation will not only be relatively as safe as any other means of transportation, but eventually will probably be the safest means of transportation.

In order to bring this about, however, it requires the continued cooperation of all Governmental authorities, Federal, state and local, not only among themselves but with the manufacturers and users of aircraft.

There is still need of further legislation, particularly on the part of the states, and there will always be an ever increasing need for substantial Federal appropriations. The advantages to be gained, however, by safe and sound aeronautical developments are worth many times the effort and money necessary to be expended to bring about this result.

CHAIRMAN DAVISON: The subject is now open for discussion.

J. F. VICTORY: I am in hearty sympathy with practically everything that Secretary MacCracken has said. I think that congratulations are in order to the Department of Commerce and his administration for the great advancement made in aeronautics under that Act.

I think it would be in order to refer, just for a moment, to one remark of his, to the effect that the jurisdiction of the Federal Government is limited to the

regulation of aircraft engaged in Interstate Commerce, primarily in recognition of the Doctrine of States Rights. In the interest of historical accuracy, that statement does not tell the whole story. The jurisdiction of the Federal Government is limited largely in recognition of this point of view as well as in recognition of the Doctrine of States Rights.

We have before us the example of strict regulation in England. We have seen how England was quick to establish the equivalent of Federal jurisdiction over all aviation, and we saw in a few years the harmful results of premature regulation and over-regulation as it existed in England, with the result that the vast majority (I understand over ninety per cent of the aircraft that were privately owned and operated at the time the British air regulation went into effect) had been driven out of the air because of the unreasonable regulation.

It was because we did not want to drive out of the air in this country aircraft that might perhaps not be able to stand the strict regulations as to airways, that the Doctrine of States Rights was put forward as one that should be observed in enacting Federal legislation. It was felt also that while uniformity of regulation is desirable, it could be better accomplished by the appeal of a sane, sensible, Federal interpretation of a sound Federal law, rather than by the assertion on the part of the Federal Government of exclusive Federal jurisdiction.

MORRIS FITLER (Mutual Life Insurance Company, New York City): I noted a reference in the Secretary's paper to some accident statistics for the first six months of the current year. I should like to ask Mr. MacCracken if the Bureau of Commerce has recently gotten out a report on the basis of mileage flown and casualties similar to the one issued about a year ago for the year 1926 and the first six months of 1927?

MR. MACCRACKEN: This report which I have here doesn't cover that; a subsequent report was gotten out on a mileage basis. This simply covers all operations. The only thing to do would be to get the airway operation and the experimental operation. The report is in scheduled flying. It is easy enough to get the figures and transpose them. Student instruction: We don't have any information coming into the Department giving the total number of hours flown in student instruction. If we could get those figures we could give this information on that basis. The same is true with experimental and miscellaneous flying. That report gotten out on a mileage basis is available, I am quite sure.

MR. FITLER: Is that up to 1928?

MR. MACCRACKEN: Up to July 1st. The third quarter is of October 1st, and that hasn't been completed yet. The Accident Board has considered all the cases they had up to the first of October.

SENATOR BINGHAM: The question which has just been asked with regard to mileage brings up the subject which I have had in mind for a long time, and noting that it was asked by an insurance man, I want to make one or two observations.

The question obviously is, How many miles you can fly safely, or how many miles do you fly, before you receive an accident? Of course, every actuary wants to know that fact. On it he is going to base his charges for insurance.

I don't want to be severe, and I shall try to be temperate in my language, but I really feel that that is a wholly wrong way to look at this subject. May I illustrate it in this way? Suppose you were asked to insure the life and property of a person going from New York to Boston by water. You wouldn't find out how many miles it was from Boston to New York, or New York to Boston, would you? That wouldn't interest you at all. You wouldn't want to know how many passengers had gone between Boston and New York and multiply it by passenger miles and see how many had been lost, would you? You would remember that on the Coast of Cape Cod, within historic times, 2,000 ships have been wrecked and thousands of lives have been lost. You would want to know

the type of conveyance that the man was going to use in going from New York to Boston. If it was a canoe, you wouldn't insure him, unless the premium was approximately one hundred per cent. If it was in the *Aquitania*, you could give him a very low rate for himself and his goods.

If you were asked to insure a ship sailing from San Francisco to Yokohama and to insure the same ship going from San Francisco to Nukualofa you wouldn't ask what the distance was from San Francisco to Nukualofa because you wouldn't care. As a matter of fact, the mileage is roughly the same between those two points. To be accurate, it is farther from San Francisco to Yokohama than it is from San Francisco to Nukualofa.

The same ship and the same captain going on those two voyages would receive an entirely different insurance rating. In fact, the rate from San Francisco to Yokohama would be fairly low. Why? Because you have got known routes, good charts, aids to navigation at both ends, and you know what the dangers are because they are all charted. The route from San Francisco to Nukualofa is not charted; Nukualofa is surrounded by shoals; there are no aids to navigation; the currents are uncertain; there are no lighthouses to speak of, and the rate is almost prohibitive. The mileage has nothing to do with it.

Now, Mr. Chairman, I feel that with safety in air navigation and with the insurance rates, that the insurance people ought to look at air navigation just as they look at ocean navigation, and every single trip ought to be a separate problem by itself. You ought to know, in the first place, whether it is a canoe or an ocean liner you are dealing with, whether it is a schooner without power or a good ocean-going power boat you are dealing with, or if there is no question about the captain and the ship, what the conditions are over which you are going to sail and what you are going to find at the other end.

Those are the things that, it seems to me, are the measures which insurance should consider. They shouldn't consider at all the mileage. To my way of thinking, the American people would be getting air-minded much more quickly if we were not quite so far away from the clipper ship. It is over one hundred years since clipper ships were successful in ocean transport and were desirable. In those days, we thought in terms of a movable means of transportation, water, air and weather; and we were not thinking in terms of a fixed means of transportation, rails and ballast and mileage.

I grant you that your insurance rates from Boston to San Francisco and your insurance rates from Boston to Pittsburgh vary according to the mileage, but your risks are according to mileage, and safety varies according to mileage.

But in the air, safety varies as to whether you are near a lee shore or a safe harbor. Anybody who is accustomed to sailing knows that if you are sailing along a lee shore and the wind is blowing on the land strongly (a good gale say) and your power fails, you are going to be up against it. If you have a sail boat, you have got a great struggle to get away from the lee shore. In the air, you can't get more than two or three miles away from a lee shore, you can only go up two or three miles, and you have always got the lee shore and you have the wind blowing, because gravity never fails to work, and if your power fails, you have got to come down.

Since you can't get as far from the lee shore as you would like to at sea, you want to be as near as you can to a safe harbor to put into, which leads me to my next point, that flying along an airway such as the Department of Commerce is laying out—and I want to pay the very highest compliments I can to the way in which the Air Commerce Act has been administered by Secretary MacCracken; they have laid out these airways in such a way that when the power plant fails, although the lee shore is there, there is a safe harbor. If you are flying a good ship with a good pilot along an airway with a safe harbor between, your risk is practically nil. But if you take the same ship and fly across moun-

tains and forests with no emergency landing fields and no lights and no charts, your risk is very great.

I want to protest against the question of how many miles you can fly safely. My recollection is that during the administration of the air mail by the Post Office Department, we finally got up to some stupendous figure. I think the loss in life was only one life for more than one million five hundred thousand miles. Is that correct?

MR. MACCRACKEN: Yes.

SENATOR BINGHAM: Only one life lost for one million five hundred thousand miles flown! That is nearly sixty times around the world. And surely if you can take a ship that can go around the world sixty times you haven't a great lack of safety. At the same time the air mail was flying at night one million five hundred thousand miles, you know what was happening to the so-called casual or miscellaneous flying done by ambitious young pilots that want to earn a little money by taking up people for \$1.50 or \$2.50, a joy ride, when that isn't enough to maintain the overhead cost and depreciation on their ship.

I think the work the Department of Commerce has been doing in connection with Federal legislation is magnificent. I think the next step that has got to be taken is to get the States to put into effect laws similar to those which New York State put into effect under the able leadership and suggestion of the chairman of this meeting.

I want to add one thing to what Mr. Victory said about why, when we passed this Act, we made it apply to Interstate Commerce. People like Orville Wright and others felt that the progress of aviation would go ahead if we let each State regulate its own commerce. I wish very much, and I yield the rest of my time to the chairman for that purpose, that the chairman would tell us just what New York has done during the past few months in this regard, because it seems to me that New York has shown the way to other States. I won't mention Connecticut, because Connecticut got aboard the regulatory ship before New York ever heard of it. I wish the chairman would tell us what New York has done, because I think everyone ought to know, and every State that hasn't got a good law at present ought to follow, what New York has done.

Out in California not long ago, one of the pilots told me about a fellow who learned to fly and had been turned loose at the end of four hours flying. He bought an old ship and hung out a sign to the effect that he was an aviation teacher. In order to pay for his ship, he started out teaching other people how to fly. Of course, he and his first pupil were both killed. There was no law in California.

Won't the Chairman tell us what New York has done?

CHAIRMAN DAVISON: Senator, the policy that has been adopted by New York State at the last session of the Legislature is perfectly simple, and without attempting to use the proper phraseology, roughly it is this: The State of New York adopted by law the regulations of the Federal Government in so far as they applied to planes, the licensing of planes and the licensing of pilots, and required that no one could fly a plane and no plane could be flown within the borders of New York State without a Federal license. A violation of those requirements of the law was punishable as a misdemeanor. As a result, every law enforcement officer of the State has the authority to enforce the particular provision of the law that has been violated.

I don't know whether or not it is proper for the chairman to express opinions in these matters, but as I am the chairman and nobody can call me down, I am going to do it anyway. Personally I am a firm believer in this question of uniform regulation. Here is a flight that we all of us take many, many times a year, the trip between New York and Washington. It is only a two hour flight, and yet in those two hours we pass six separate jurisdictions. That is just an every-

day commonplace illustration of the problem that the airplane is up against, and undoubtedly other airways that are flown over very frequently would serve as even a better example than that. It seems to me, therefore, that the Constitution of the United States, being what it is, and the leadership having been taken by the Federal Government in the Department of Commerce, as it has been taken, that the obvious and the logical way for all the States is to follow the procedure that has been adopted in New York. In that way, the standards will be kept uniform, and judging by the experience that the Federal Government has had so far, those standards will be very high.

It seems to me that the danger of giving direct authority to State officials, even though small authority, at the start is this: That they will inevitably from time to time have some disagreement with the Federal Government, perhaps only as to minor details. They think they can do a better job than the Federal Government can do in that particular regard. They will always be branching out and ambitious for more power and more authority, until finally you will find a great conflict between the regulations of the individual States and that of the Federal Government.

New York State eliminated that by giving no authority to any State official other than the authority to enforce the laws which had already been adopted. The Legislature here also took one further step and that was to appoint a joint committee of the Legislature to study the whole problem. They were not given authority at all except to gather information and enforce the regulations. The policy that this committee has been following during the past few months since its existence is to examine the operation of the laws that have been passed, not so much in regard to regulations, although they follow that too in so far as the enforcement is concerned, but in addition to that, the laws in regard to the establishment of airports and managing of airways and that sort of thing; the result being that there is a body, with no authority, following this whole question, responsible to the Legislature, composed of members of the Legislature and therefore having great weight in the legislative body whenever it meets.

I hope that the legislation that was enacted here as it might be adopted to the needs of the various States, may become better known so that the other States can see what New York has done and if they think well of it, as I think they ought to, take advantage of that experience.

SENATOR BINGHAM: Wasn't there another law also authorizing the municipalities?

CHAIRMAN DAVISON: I referred in a general way to that; a law giving to municipalities definitely the power to acquire landing fields and to bond themselves for the equipment of it and out of current revenues only of course, to maintain airports and landing fields.

There was one interesting provision in so far as condemnation of property is concerned which so far as I know is unique in legislative history, and that is, the city governments were given authority to condemn lands for airport purposes outside of the city limits so long as it was within a ten mile radius. The reason for that is perfectly obvious. Very often it is necessary to go outside of the city limits in order to find land suitable for flying purposes. If they didn't have the power of condemnation it would enable the owner of the property to hold up the city government. There was one additional provision put in as a safeguard in recognition of the sound doctrine of home rule, and that is, that the city government cannot condemn property outside of the city limits without the consent of the local authorities outside.

SENATOR BINGHAM: I would just like to make one other suggestion, and this in more of a broad nature to the members of the National Safety Council. Until such time as we can get the Legislatures to adopt uniform legislation (and I suppose those of us who have studied State legislation know that not until the millennium arrives will all the forty-eight States adopt the same law in regard to

anything) until such time as we can get the States, at least, to go so far as to require a Federal license to fly, I believe few things would go farther toward procuring safety and doing away with accidents in the air than if the National Safety Council would urge the people of the United States to do this: When you fly, make sure that your pilot has a Federal license and the ship you are going to fly in has been passed by the Department of Commerce. If the passengers who pay the money will look after their own interest to that extent, then the slowness of State Legislatures need not endanger the progress of aviation as much as they are doing at present.

MORRIS PITLER (Mutual Life Insurance Company, New York City): I should like to make it clear that the question of mileage is not as important to life insurance companies as my question to Mr. MacCracken seemed to make it. If Senator Bingham or anybody else should come to the company I represent for insurance and should state in his application that he has during the past year taken a dozen flights in airplanes, and would probably in answer to some of our questions state that he intends to continue flying for certain reasons, he will undoubtedly not be asked the mileage he has flown or that he might fly, or whither those trips took him. The question of mileage has been forced upon us by the fact that the statistics we can obtain on casualties are based entirely on mileage flown. We are not interested in mileage. We are interested in individuals. We are interested in knowing among how many pilots—full time pilots—did these casualties take place. Those figures are not given to us. The figures state that there were so many casualties in so many miles flown. We get the mileage and try to translate it into the number of full time individuals. We take what we can get and try to translate it into our own terms. That is why we are interested in securing the mileage for the most recent period for which experience is available. We want to translate that also into the number of full time pilots, in so far as we can, so that we can base our rates, not on miles but on full time pilots.

These other considerations, of course, are considerations to us, whether the pilot is licensed by the Federal Government, whether he is flying in a licensed plane, whether he is flying on regular routes, and any other safety consideration that we can think of. The question of mileage has practically nothing to do with it, except in so far as it allow us to deduce other facts in which we are most interested.

CHAIRMAN DAVISON: I feel sure that the Federal Government as a whole—I know it is true in the War Department because I can speak for the War Department—would be very glad to hear from the insurance companies if we can help you by keeping our Federal statistics in any different way than we are doing. If you people can get together and tell us what information you want, I can promise you we will go the limit in endeavoring to adjust our records so that you can have that information. At the present time, there is an interdepartmental board studying that very question, and it seems to me that the suggestions of the insurance companies might be important and helpful in that regard.

MR. PITLER: I promise you will hear from us within the next few months.

MR. BOND (Department of Commerce, Washington, D. C.): It has been my privilege to be employed for the past three years as airway superintendent. During that time I have traveled quite a bit and have laid out quite a few airways. It has been very pleasing, I have found, to everyone connected with aeronautics to see the progress that aviation has made during the two and one-half years the airways division has been in existence.

It is my thought to suggest to you some changes that might be made in the Air Commerce Act. We sometimes are asked to lay out an airway between two cities, and in between those two cities there are numerous towns. The first thing that comes up that the airway superintendent wants to know is, where are you going to fly, from which airport to which airport. He goes to the transportation

company and he likely finds that they have been using a field for carrying passengers and the like but that it is inadequate as an airport for the city. The reason that it is inadequate is because it is on a highway where numerous people travel, and it was convenient for that purpose. They had no thought in mind when they chose the field for an airway. In some cases, they have reestablished their airports with the thought in mind of an airway; in other cases, they have not. In some cases, the local politicians have gotten busy, dug up some old piece of land which no one had use for, bought it at a low price and magnanimously sold it to the city at a large profit. Little thought was used as to whether that field was suitable to the airway, whether it lay to the north, east, south or west of the city, whether a lake intervened between it and the airway, whether the pilots must fly straight to it or have to go around the city. My thought is, that while the Federal Government has no control over municipal matters, some better means of cooperation should be devised. My own thought is that the Department of Commerce at the present time is rating airports, giving them A, B, C or D ratings, and I think they should go further and say that if an airport is unsuitable to an airway, no airway would be provided for that city.

The second thought is that in the Air Commerce Act provision was made that the government would not provide any money for lighting airports. The wisdom of that is apparent. However, there is something else needed. The Federal Government has a chief engineer of lighting, who is in constant contact with the lighting companies, who are continually developing equipment, and he is in very close contact with the new development made in lighting. The cities are in a different position; they have had no experience in lighting airports; they do not know what is required; they do not know what is the best equipment. Sometimes they ask the Federal Government to suggest to them what the best equipment is. My belief is that in the future we are going to have thousands of airports with thousands of different system of lighting, among which, within a few years, some will have fallen into obsolescence, while others will keep up with the progress being made by the lighting industry, and there would be no uniformity so far as regards lighting of airports.

The next point I have in mind is this: Airports generally lie any place from one hundred to three hundred miles apart. In between those airports, there are numerous towns generally, with a population of anywhere from 5,000 to 50,000, where no airport can be established because of its geographical location. However, we generally do place a landing field near such a town with the thought that perhaps in the future a local service might be established. The airways superintendent goes to the Chamber of Commerce, the Town Council or the Mayor and asks them whether they will cooperate with the government in establishing a landing field. In practically every case, they are very glad to cooperate with the government.

Then, the first question they ask is, "What do we get out of this?" We hem and haw and then say, "There is much publicity for your town; and you become established on the national air map and perhaps some day in the future airplanes will land here."

The second question is, "Will the landing field be established here, whether we contribute to it financially or not?" The answer to that is generally, "Yes." Sometimes there is a choice between two towns.

The next question is, "If we establish a landing field what rights do we have upon it?" We answer, "If you establish an airport with all the contributory lights and the beacon, you will be permitted to use the field to its fullest extent." Generally, the cost of that is too high and they can't do it. Many towns have been contributing to the rental of the field and in return the government can't permit them to use that any more than the town that doesn't bring in a single dollar. It is my belief that the government should permit such small towns complete use of the

field, because it will aid the government in getting more landing fields, more dollars per year, and it will encourage local flying and will help to keep the public air-minded.

SENATOR BINGHAM: I would like to ask Secretary MacCracken what changes in the Air Commerce Act will be needed to meet the first two suggestions that his man has made?

MR. MACCRACKEN: I think, Senator, it would require an amendment which would authorize the Federal Government to establish cooperative intermediate landing fields.

SENATOR BINGHAM: I mean the first two suggestions he made.

MR. MACCRACKEN: Perhaps I didn't get them quite as clearly in mind as the Senator has them.

MR. BOND: The first suggestion was that the government have jurisdiction over the choice of an airport; and the second was that the government should cooperate in the lighting of them.

Problems in Government Cooperation

MR. MACCRACKEN: The only way that can be done is, I think, by a single amendment which would provide for the cooperative airport; in other words, if there are cooperative intermediate fields. Of course, it might be that the establishment of aids to navigation between the airports would be regarded as a contribution. In fact, it is at the present time. There wouldn't need to be any amendment to the law in that respect. We could do it by administrative action.

The Act prohibits the Secretary from expending any Federal appropriations toward the maintenance of an airport. If it is an airport in the daytime you can't say it is an airport at night and we are just maintaining a night airport. The law does not state between those.

The same thing is true when it is a cooperative proposition between the small town and the government. There have undoubtedly been some misunderstandings and some hardships growing out of that situation. We have had instances where the people in Town A (we will say) have bought the field and leased it to the government, rented it at \$10 or \$15 an acre and released it to the government at \$1 an acre, because they were public spirited and thought eventually there would be enough aerial activity to take it over and make it an airport of the national airways. The government goes in and pays the rental for the land, \$10 or \$15 an acre, in Town B. The people of Town A want to establish a school or something else, a little flying activity, or maybe one of the prominent citizens has bought a ship and wants to operate from that field. They come to us and say, "Can't we do this?" We say, "We are very sorry, but that is an intermediate landing field. If you want to make it an airport, then you will have to take over the maintenance of it." They don't want to do that. That is a very heavy burden. They are in exactly the same position as the other community. It is pretty hard to explain to these people why in one case we are paying only \$1 an acre and they are standing the real cost while in another case we are paying the full cost.

CHAIRMAN DAVISON: The second paper that was to be read at this conference was by the Honorable T. L. Raymond, Mayor of Newark. As we all know, Newark has taken a front place among the larger cities in the development of airport facilities, and the Mayor has been the leader and extremely active in heading that movement. Unfortunately the Mayor is ill and cannot be here. He has, however, sent as his representative, Mr. Charles S. Dion. I take great pleasure in introducing Mr. Dion who represents Mayor Raymond.

Municipal Legislation Relative to Safety

By HON. THOMAS L. RAYMOND

Mayor of Newark, N. J.

The history of aviation as a new factor in the commerce of the world, its development and its potentialities, has given rise to a problem, the nature and the importance of which demand serious consideration from every American city of consequence. This problem is a dual one, and one to which the continued prosperity of a large commonwealth is, and henceforth must always be, inseparably bound.

Basically the question is this: What can aviation do for my city? And: What can my city do for aviation?

The first part of the question has been, and continues to be, successfully answered. It is with the second aspect which we are to deal—that portion which has for one of its subheads the consideration of municipal legislation relative to safety in aviation.

First—and it may be said without contradiction—intelligent local regulation of a municipal airport is an absolute necessity, and should be placed in the hands of the most competent man available. In conjunction with this, and as a definite aid thereto, there should be close cooperation with State and Federal authorities.

The American Bar Association, at its annual meeting in Seattle, Washington, received a report from its standing committee on Air Law. This committee presented, among others, a recommendation that a uniform State Air Licensing Act be adopted by the various states.

This law provides that the Commissioner of Motor Vehicles enforce his authority by promulgation of regulations which shall follow the regulations of the Federal Government under the Air Commerce Act of 1926 and amendments thereto. It is further provided that aircraft and airmen must be licensed either by the Federal Government or by the State. In a given case where Federal licenses have been obtained, no further action is necessary; but where this is not the case, the state officials under the law are empowered to insist upon the obtaining of a state license. In this manner a great majority of aircraft and airmen would operate under Federal licenses. Actions by the states would then, by wording of the proposed act, follow closely, if not identically, the law and regulations of the Federal Government.

Carrying this idea forward, there should be a provision that in the promulgation of State regulations—which must follow the Federal act and regulations thereunder—there should be specifically included provision for air traffic rules and local regulation.

There is every indication of a nation-wide interest and activity in the question of airports. In many localities these have been put into operation, while in many others plans and possibilities are actively under discussion. In many instances these airports adjoin large cities or towns. And public safety requires that every aid to safety be offered by the municipal authorities.

This can be accomplished by the promulgation of local regulations applying to civil aircraft. These statutes, however, specifically would not apply to public aircraft, meaning those owned by the Federal Government or by State Governments.

What local regulation should be can best be illustrated, perhaps, by citing a few of the general rules which we are promulgating at the Newark Metropolitan Airport. These read, in effect:

1. All airmen and aircraft operating on or from this airport shall be subject to and bound by the rules and regulations authorized by the Air Commerce Act of 1926, and laid down in the Air Traffic Rules, effective March 22, 1927, as estab-

lished by the United States Department of Commerce, and any amendments made thereafter to said air traffic rules will be specifically adopted and be made a part thereof as fully as though the same were completely set forth herein.

2. All persons using in any manner the airport area shall exercise due care to guard against fire and injury to persons or property. No rubbish shall be scattered about the airport area, and the crews of all visiting aircraft shall be required to keep clean the space allotted to them.

3. No intoxicating drinks shall in any way be brought on the field. No passengers or pilots shall be permitted to use or to ride in planes if under the influence of liquor.

4. No person except a pilot or mechanic attached to the personnel of the municipal airport or employed by the owner of a plane at said airport, or an owner of such a plane, or other person duly authorized by the municipal airport shall cross the deadline or enter upon the flying field unless he is to participate in a flight. If such person is to participate in a flight, he shall not cross the deadline until the plane in which he is to fly has come to a full stop and the pilot thereof has signalled that he is ready. Such person shall upon alighting from a plane leave the field by the shortest possible route.

5. No acrobatic flying shall be allowed anywhere within one mile of the field.

6. Motors shall not be run in hangars or within the space between the deadline and the hangars.

7. No airplane engine shall be started without chocks under the wheels. No engine shall be run at any time without a pilot or mechanic in the cockpit.

8. No smoking shall be allowed in any hangar within twenty-five feet of any aircraft or gasoline container.

9. In taxiing to and from the deadline, each pilot shall keep his plane swinging slightly from side to side in order to keep a sharp lookout for other craft on the ground or about to land.

10. All taxiing shall be done at a slow speed. No pilot shall taxi closer to another plane than 100 feet unless the mechanic shall have hold of one wing. No pilot shall approach the deadline closer than 50 feet until a mechanic or mechanics shall have hold of the wings to guide the plane into place on such line.

11. No pilot shall take-off without first looking to the rear.

12. Upon exit from the field, all taxiing shall stop at the deadline.

13. All planes arriving must circle the field at least once before landing.

14. Under normal conditions take-off and landing shall follow a right-hand or clockwise circuit of the field. Ships approaching the field from across country shall make at least one circuit of the field with traffic before landing.

15. United States mail planes shall have the right of way over *all other air traffic*.

16. Aircraft approaching each other head-on shall pass to the right.

17. Aircraft overtaking other aircraft shall pass to the left.

18. Each single motor ship, carrying passengers, must have at least one attendant beside the pilot.

19. Under normal conditions a pilot shall have the right of way over any aircraft which appears on his left side or above him and give way to any aircraft which appears on his right or below him.

20. An airplane which is not functioning properly for any reason or which is landing with a dead stick shall have the right of way over all other aircraft.

21. No flying shall be done directly over the field at an altitude of less than 1,500 feet. No stunting shall be done.

22. Lighter-than-air aircraft shall have the right of way over heavier-than-air aircraft.

In order to carry out the provisions of the above rules the airport officials should provide a trained personnel, including mechanics, uniformed regular and/or special

Legislation

policemen, and firemen. Adequate firefighting facilities should be placed at or in the immediate vicinity of the airport.

The administration building should be so placed, and the airport manager's office so located therein, that the entire landing field shall be visible from this office.

Adequate facilities for determining the direction and velocity of the wind should be installed.

Runways and boundaries of the airport should be specifically marked and all obstructions which are visible in clear weather should be indicated by red lights or flood lights in foggy weather and at night.

Hangar roofs should be painted some distinguishing color. For the purpose of identification the name of the airport should be painted in large black letters on the roof of one of the large hangars. For fields in use by air mail planes, a Meteorological Bureau, operated by the U. S. Weather Bureau, is absolutely essential. This facility is not absolutely necessary for civilian aircraft but it is highly desirable, however, at airports in use by transport companies.

Adequate lighting facilities should be provided so that the landing at night will be comparatively safe for all types of planes. These facilities are absolutely essential on fields in use by air mail planes.

A minimum of safety is provided when the field is made a four-way field, consisting of two runways at least 2,000 feet long in line with, or approximately in line with, the prevailing winds, summer and winter. A paved take-off strip is desirable but not essential.

The greatest factor of safety is provided when the entire landing field is so constructed and the surface of the field is in such condition that landings and take-off may be made in any direction and at any time of day or night.

Briefly, then, we find that local regulation of a municipal airport is not only desirable, but patently necessary; and that such regulation, when adopted and enforced in cooperation with state and Federal provision, is conducive of the best results. This would show that in all cities and large towns where airports are in operation or under way, the prescription of a set of regulations in conformity with others in force over the country at large will tend to bring about a systematized understanding and appreciation of the value of safety in aviation.

In this way a great new airport and its parent commonwealth may, and can, prove of distinct service to the science of aeronautics and its many manifestations; not by being unique in its operation, but by becoming subservient to the general good, and therefore attaining to its rightful place as a servant of flying.

CHAIRMAN DAVISON: Is there further discussion on either Federal or municipal legislation?

MR. MACCRACKEN: May I just offer one comment on what Mr. Victory said about the desire to avoid the experience of England in this matter of regulation? I recall that was one of the matters brought up, and it so happens that one of the strongest advocates of that point of view is a resident of a State which is now figuring on enacting a law which would step up the regulations all along the line for flying within the State. They are even talking about five hundred hours for solo flying for a license to carry any passenger at all, as against two hundred hours for the air transport. So, it presents a very difficult problem.

The minute that you get the individual States prescribing the requirements either for the personnel or the craft engaged in aviation, you won't get uniformity, you are going to get petty jealousies; there are going to be troubles in the legislation and the administration of the legislation. The case that I refer to is one which I hope will never arise, but I understand there is a strong possibility of this act, which is regarded as most drastic, being passed by the Legislature when they convene at the beginning of next year. It has already been approved by some of the people in the State.

In other States, at the outset they have said they wanted to conform to Federal regulation, but the jurisdiction is given to the local authority to make some slight deviation. I know of one State in particular (I don't care to mention the name because it only makes it more difficult to iron out these differences) that when they started out wanted to make the licenses look like the Department of Commerce licenses. They adopted as a policy that they would only issue a license to a Department of Commerce licensee. There was no objection to that as long as they adhered to it. But it only had been in for a few weeks, when one of our inspectors turned down one of the men that someone in the State thought should be licensed. Right away, they did away with all of this requirement for a Federal license as a pre-requisite to issuing their license and issued their own. It takes a careful inspection of the license to know whether it is a Federal license or a State license. That is going to result in endless confusion and added risk. The government might be able to compel them (as we do in private enterprise, at least) to change their license so that it would be more easily distinguishable. I don't know that that right rests in the government.

I can see where there is going to be a lot of difficulty if that goes very far. I appreciate what Secretary Davison has done in getting the great State of New York on the right track. There are a number of other States that will follow suit. I hope that they all will.

CHAIRMAN DAVISON: On that point of similarity, I don't know whether there are any other factors that enter or not, but any State, for instance, which attempts to clothe its police with a uniform that might be mistaken for an Army uniform, can be made to change. Whether there is some specific legislation on the point you raise, I don't know.

MR. MACCRACKEN: It may be that we have something of that kind that we can protect ourselves with.

MR. PERRY: Can you tell me if the government through the Department of Commerce can regulate the Interstate Commerce—that is, all the traffic inside of a State, providing it does not go over another boundary?

MR. MACCRACKEN: The government is doing that in so far as the air traffic rules are concerned, upon the theory that in order to adequately protect Interstate and Foreign Commerce you must have uniform air traffic rules. It was the contention of those of us who argued for a similar jurisdiction with respect to licenses that it was just as necessary to have only air-worthy craft and competent personnel in the air to protect Interstate and Foreign Commerce. Perhaps that is stating it a little strongly. I think the necessity is greater for the uniformity in air traffic rules than it is for the uniformity in licensing requirements. I do believe that the uniformity in licensing requirements is great enough to warrant the government, under the Interstate Commerce clause, to take that jurisdiction. Senator Bingham and I differ on that point. He stated this afternoon that he didn't believe that that was a proper exercise of jurisdiction. There are many lawyers who take the same point of view. He is not alone by any means in that regard; nor do I stand alone on the question, fortunately. The answer is that Congress did not assume that jurisdiction. I am confident that either by Federal legislation or possibly even by Constitutional Amendment, if it should turn out that the Senator and those who take the same view are right in the eyes of the Supreme Court, this matter can be cleared up.

There is another way that it can be taken care of and that is under the treaty making power. That was the case in the Migratory Bird Law Act. As you remember, Congress passed a Migratory Bird Bill which was held unconstitutional on the grounds that shooting birds, even though they flew across State lines, was not the province of Interstate Commerce, even though the game birds might be the subject of commerce between the States. After that law was held unconstitutional, a treaty was negotiated between Canada and the United States to protect

migratory birds in flight in the two countries, with the result that Congress repassed the Migratory Bird Bill and it was held constitutional by the Supreme Court.

MR. PERRY: Mr. Davison, as Chairman, can you tell me about the law in regard to navigable rivers. As I understand it, all navigable waters in, around, and adjacent to the United States are under the control of the government and those waters which are not navigable are State controlled. Is that right?

CHAIRMAN DAVISON: Well, I am far from an expert on that subject; in fact, I know very little about it. Generally speaking, your statement is correct, although there is conflict about a lot of local police regulation. If there is any question as to interference, that is a matter for the government, and under the government that goes to the War Department.

MR. PERRY: All air over the United States should, in my opinion, be federally controlled and not State controlled, because it is dependent upon the whole people for its use.

CHAIRMAN DAVISON: Is there any further discussion on this subject?

J. P. PRICE (National Exchange Club, New York City): I was in at the discussion where Colonel Lindbergh spoke and the question of pilots' licenses was raised. Someone from the floor raised the question of Federal control of pilots' licenses. Senator Bingham in here told us, I think, that one way in which the passenger could bring about very much better conditions was to insist that any pilot who piloted him should be equipped with a Federal license and that the equipment in which he flew should be Department of Commerce inspected equipment. It is obvious when the man over on the other side raised the question of legislation—that is Federal control of licenses—Colonel Lindbergh told him that the Federal government could only regulate licenses where the contemplated flights were to be across State lines—interstate. It is obvious from that discussion and this one that the Federal control would be a fine objective, a very fine thing both from the licensing of pilots and from the licensing of a control airway. I don't know whether that is correct or not.

The same thing occurs to me in regard to marine navigation, where lighthouses in navigable waters are under the control of the government. Am I correct?

CHAIRMAN DAVISON: I can't answer that question?

MR. MACCRACKEN: There are some of the States which have a certain amount of jurisdiction over steamboats in inland waters which are not navigable waters of the United States. Take, for example, the great Salt Lake, which is in Utah, wholly within the State and does not connect with any body of water that is used for Interstate Commerce. There the government does not assume any jurisdiction at all. The common notion is that the jurisdiction of the government over maritime matters is based on what is known as the Admiralty Clause of the Constitution. As a matter of fact, the decisions of the Supreme Court on that subject all show that it isn't based on what is known as the Admiralty Clause of the Constitution. The basis for Federal jurisdiction is the Interstate Commerce Clause, and not the so-called Admiralty Clause. It is simply an application of that same doctrine to aviation that may become necessary if we get into too much difficulty. It is the application of that doctrine that will support the constitutionality of our air traffic rules if that is ever attacked. Of course, if the constitutionality of those rules is not sustained, then we are in a bad fix.

MR. PRICE: Is there anything that Congress can do, that the government can do to enlarge the powers of the government to assume supervision over airways or air navigation or pilot licenses or anything of that sort that a national organization could add its weight of influence to in order to bring about, that you know of?

MR. MACCRACKEN: Well, I am one of those fellows that, if I am beaten on a point and the other fellow succeeds, then I am going to give it a fair trial. I argued very strongly before this Bill was passed for the broader Federal jurisdiction. I lost out on it. I am perfectly willing to give this thing a fair trial and see

if all the States will fall in line as New York and others have done. If they do that, the system is going to work.

There is more than one way of skinning the cat, and we can get this uniformity if the States will adopt the Federal regulations without the government saying, "You have to." Instead of really stirring the matter up in an aggressive campaign to get the Federal jurisdiction extended, I would rather see organizations such as the one you represent and the National Safety Council and all the other national organizations that are interested in this subject concentrate their efforts on the State Legislatures to get them to follow the example of the State of New York and other States. If that is done, there is no need of testing the question of the Federal power on this particular point. But, as I pointed out in my paper, and I think it is well to keep in mind, that if this present system falls down badly as a result of the States, each one of the forty-eight States going their own several ways getting into conflicts and difficulties, why in order to unsnarl the tangle, we will have to go to the government. I am not prepared to say that it has reached that stage at the present time.

CHAIRMAN DAVISON: Any further discussion?

I have here a letter from the two Presidents, the incoming and the outgoing of the National Safety Council to the first National Aeronautical Safety Conference.

The Council Extends Appreciation

To The First National Aeronautical
Safety Conference:

The National Safety Council extends to you its sincere appreciation of the splendid contribution you have made to the Cause of UNIVERSAL SAFETY in the execution of the comprehensive program developed for this First National Aeronautical Safety Conference under the able direction of Mr. Harry F. Guggenheim, President of the Daniel Guggenheim Fund for the Promotion of Aeronautics, Incorporated.

The Council is deeply interested in all phases of National Safety and since its inception has earnestly endeavored to extend its life conservation activities on a strictly cooperative basis.

Fully appreciating the truth of Mr. Guggenheim's statement as expressed in his paper presented at the Sixteenth Annual Safety Congress in Chicago, last year—that Safety is the First Essential for Progress in Air Transport—we deem ourselves most fortunate in obtaining your interest and cooperation in the promotion of this initial Aeronautical Safety Conference.

In order that the good work you have here initiated may be carried on, it is the belief of the National Safety Council that future conferences of this nature should be insured through the appointment of a committee composed of outstanding authorities in the field of aeronautics, and we respectfully urge that you give consideration to our suggestion. In connection with this suggestion we hereby confirm our pledge of cooperation as expressed in the resolution adopted by the members of the National Safety Council at its Annual Meeting in Chicago on September 26, 1927.

NATIONAL SAFETY COUNCIL
HOMER E. NIESZ

President, 1927-1928

HENRY A. RENINGER

President, 1928-1929

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Cement Section

New Section Officers

- General Chairman*—F. E. TOWN, Manitowoc Portland Cement Company, Manitowoc, Wis.
Vice-Chairman—EDWARD H. PARRY, Glens Falls Portland Cement Company, Glens Falls, N. Y.
Secretary—A. J. R. CURTIS, Portland Cement Association, Chicago.
Poster Committee Chairman—R. B. FORTUIN, Pennsylvania-Dixie Cement Corporation, Nazareth, Pa.
Membership Committee Chairman—HENRY A. RENINGER, Lehigh Portland Cement Company, Allentown, Pa.
Program Committee Chairman—FRANK SASS, Universal Portland Cement Company, Buffington, Ind.
Engineering Committee Chairman—S. H. HARRISON, Vulcanite Portland Cement Company, Phillipsburg, N. J.

Retiring Officers

Chairman, F. E. TOWN, Manitowoc Portland Cement Company, Manitowoc, Wis.; *Secretary*, A. J. R. CURTIS, Portland Cement Association, Chicago, Ill.; *Poster Committee Chairman*, R. B. FORTUIN, Pennsylvania-Dixie Cement Corporation, Nazareth, Pa.; *Membership Committee Chairman*, HENRY A. RENINGER, Lehigh Portland Cement Company, Allentown, Pa.; *Program Committee Chairman*, R. FRAME, Alpha Portland Cement Company, Easton, Pa.

October 2, 1928

F. E. TOWN, Chairman

Superintendent, Manitowoc Portland Cement Co., Manitowoc, Wis.

The first session of the Cement Section at the Seventeenth Annual Safety Congress, was called to order at ten o'clock by the chairman, F. E. Town, Superintendent, Manitowoc Portland Cement Co., Manitowoc, Wis.

CHAIRMAN TOWN: You notice one of the first orders of business on the program is an address by your chairman. I do not wish to disappoint anybody, but it may not be so much of a disappointment after all, if your chairman has no formal address. I do not think time should be taken by me from more important matters. I would simply like to touch briefly on some of our safety work during the last few years without going through a great number of statistics.

In the first place, it was only seven or eight years ago that the Cement Section was organized as one of the distinct sections to operate by itself. This, of course, was a natural subdivision of the Council because the cement industry had already started its activities along safety lines. By that I mean, having its Bureau of Accident Prevention and Insurance well organized as a part of the Portland Cement Association with a secretary to conduct the work of accident prevention as we know it today, in so far as its direct relation to the Association is concerned. Three years ago the Cement Section of the National Safety Council decided to organize in a somewhat more permanent form.

The first two or three years Major Reninger, who had been one of the strong workers of the Council as a vice-president, had been acting as chairman of this Section, and we all know how well he had been conducting the activities of this group of men.

About three years ago it was decided the interest had grown so great in these annual meetings and the numbers large enough that it warranted perfecting the permanent organization with a staff of elected officers. At that time Major Reninger was elected officially as first chairman of the Section. The next year it was decided to increase the activities of the Section along similar lines carried along by other sections of the Safety Council, and accordingly several committees were elected. Undoubtedly, from year to year as the needs manifest themselves, it will be necessary to increase the activities by increasing the number of committees to carry on the larger work.

Need of an Engineering Committee

At the present time we have the Poster Committee, the Membership Committee and the Program Committee, and we are about to consider a little later the advisability of an Engineering Committee. In this connection I might say that one of the broadest fields, perhaps, for activities in the Cement Section for increasing the knowledge of the members in a very practical way, may be developed by furnishing a definite line of information pertaining to the cement industry in its accident prevention work; and in order to approach this in the best possible way, it will be advisable to decide on an Engineering Committee whose duties it will be to check over all papers that have been written up to the present time, and which are on file with the Council, as to certain types of hazards existing in plants. They may include valuable information of hazards in the plants in general, as well as in the individual departments.

Statistics have shown the departments that offer the greatest hazards, such as coal plants, quarries, packing departments, etc. This information may be made available under one heading and constitute a small textbook of hazardous conditions in and around cement plants, and their treatments.

It will be well for you to be thinking of the advisability of increasing our committees by adding that Committee of Engineering, as some action will probably be taken at this meeting.

Undoubtedly you have all seen the data as given out from the Association offices from time to time. I hope you read each bit of literature you receive because it is enlightening and shows progress made in all parts of the work and those parts of the cement plants that constitute the greatest possible hazards. I would like to call your attention to an article entitled: "August Goes Over the Top." This shows the cement industry starting along in 1925 and continuing up and through August of 1928. Each one of those months has broken the record, you might say, or has shown considerable improvement over the corresponding month of any previous year. The comparative record of accidents for August, 1928, as compared with July, 1928, and also as compared with August, 1927, lines up somewhat as follows:

Comparative Record of Accidents—August, 1928

August, 1928, lost time 71, fatal 2
July, 1928, lost time 67, fatal 1
August, 1927, lost time 122, fatal 2
Eight months of 1928, lost time 691, fatal 18
Eight months of 1927, lost time 911, fatal 20
Plants with clear record, eight months of 1928—34
Plants with clear record, eight months of 1927—21

August was another excellent month so far as low accident frequency was concerned. In comparing the months of 1928 with the corresponding months of 1927, we find reductions in every case, but the biggest improvement of all between August, 1928, and August, 1927. This is true as to both percentage and actual number of accidents reduced. The August, 1928, accident record demonstrates the prolonged effect of the June no-accident campaign this year and exhibits an almost entire absence of "rebound" or higher accident rate which was previously a noticeable feature during the months following the June campaign.

In view of the greater hazards often supposed to exist during the fall months, a warning to beware might not be inappropriate at this time. However, the many evidences of improvement in the mill organizations, greater interest in safety work and enthusiasm to step out and demonstrate what a "hazardous" industry can do during a "hazardous" season, makes any special word of warning appear unnecessary.

We are learning that a cement mill may be operated about as nearly accident-free as the operating force wants it. We can write our own ticket. October, with cool, comfortable weather, should complete our magnificent six-months record with a new low point!

Fatal accidents are not showing much reduction from last year's experience. A study of several recent fatalities indicates that they are often needless. During August a kiln back-fire caused the death of one man and serious injury to three others. The several grave accidents of this kind during the past two years convince us that the burning and coal grinding departments do not generally realize the very dangerous nature of powdered coal and the necessity for extreme care, good house keeping and wide-awake management at all times.

Whereas a few years ago the thought of an entire year without an accident in any one plant was almost a monstrosity—it seemed to be almost impossible,—we now know what has been happening in the last two or three years with the ever increasing number of members of the "Trophy Club." The last word I had, which I believe was up to about September 1st, there had been thirty-four plants that were still members of the Trophy Club, which means they had not had any lost-time accidents so far this year.

I feel that before I stop I should mention some of the very distinct advantages of our affiliations with the National Safety Council. I just wonder how many of us there are who have visited the National Safety Council headquarters in Chicago or who know the marvelous resources at our command. I had the privilege last fall of calling at the offices and was certainly surprised to see the extent to which the work was carried on; to see the great number of trained specialists, men who are experts in their line, to see the great amount of individual work that is being done in each branch and to see a library, estimated by the Council to be worth a million dollars. In there, they have records and clippings from every line of industry that we may happen to think of. For its operation they employ five trained, graduate librarians. In addition, they have an art gallery containing the original paintings from which splendid lithographs are made. Some paintings are valued as high as one thousand dollars each, and I would certainly recommend to each and every one of you that you make it a point to call at headquarters and

be shown the wonderful work done by the Council. They will be only too pleased to take you through and show in detail what they are doing.

Now, one of the first addresses we have this morning is by Mr. Posselt, vice-president of the International Cement Corporation of this city. It gives me great pleasure to introduce Mr. Posselt.

What Organized Safety Work Has Done for the Cement Industry

By E. POSSELT

Vice-President, International Cement Corporation, New York City

The development of the cement industry in all of its branches during the past 25 years has indeed been marvelous, and among the very satisfactory advancements made, safety and accident prevention rank high.

It is entirely proper and very useful from time to time to review and discuss our performance, and it is a great pleasure to me to have the honor to present to you on this auspicious occasion, the Seventeenth Annual Safety Congress, a brief paper on "What Organized Safety Work has done for the Cement Industry."

Accident Prevention in the cement industry was started deliberately, not accidentally, and today it has grown until it is no incidental part of our activities.

Successful safety work requires the interest and attention of everyone in the organization from the highest official down, and the progress achieved in recent years is certainly powerful evidence of general interest.

Cement company executives who are the guardians of plants and properties, have a very definite obligation to conserve and develop human equipment, which after all is the great motivating force. But, this is not only a moral obligation; it is good business—it gives big returns. A good plant, from a purely mechanical point of view, can be built in a comparatively short time. An efficient operating organization, however, requires much longer time to build up, and the most exacting efforts on the part of the executives in training the men. A broken bolt can be replaced without a great deal of difficulties; a broken arm cannot be restored to normal function except by the natural process of healing which takes a long time. It is true that if a man is injured, he may be replaced, but the training required to make a substitute proficient is usually no small item, and the change involves loss of time, hard work, and risk; with the result that the substitute, with all of our investment in him, may be no better than the man we had originally.

Accidents Affect Morale of Plant

In many other ways as well, accidents destroy the effectiveness and morale of organizations. If one man is injured, the entire force may fear or take a dislike to certain equipment, or may even lose faith in the organization for which they are working. Frequent accidents often drive men to other work, and not infrequently very good men are lost in this way. Consequently, it is not unusual to find high accident rate coupled with a large turn-over, and in such cases it is difficult to decide whether the large turnover is due to the many accidents or the many accidents to the large turnover. Nevertheless, these two undesirable factors are closely linked together. In our own industry we notice that last year 347 out of 1143 accidents were to men employed less than six months, and 486 out of 1143 accidents occurred to men who had been employed less than one year.

Accidents are a drain on industry and a burden on society. While it is, there-

fore, to everyone's interest to reduce them, I hope we can succeed in convincing every individual workman that after all the great incalculable cost falls upon the injured and those who are near to and dependent upon him.

To obtain the proper results in accident prevention, organized efforts are necessary, in fact essential. I would like to emphasize this statement by pointing out my own experience and observations in the plants of the International Cement Corporation. No efforts or expenses are spared to build our plants in the most substantial manner, arrange and install the equipment with every thought of safety, and provide all possible means of accident prevention. We still have a long way to go before we consider that every plant is mechanically perfect as far as safety is concerned, but I have no hesitancy in saying that at least several of our plants are as well protected as modern engineering can provide; and yet we have accidents—in fact we have suffered some very severe accidents in our most up-to-date plants. This, gentlemen, would emphasize that the personal equation cannot be controlled by machinery, and without the interest and complete cooperation of every man in the organization accidents cannot be avoided.

A Big Reduction in Accidents

Now, let us see what the industry has accomplished during the last few years.

In January, 1925, lost time accidents were being suffered at the rate of 28 per one million barrels of cement produced. In July, 1928, this rate had dropped to less than 4 accidents per million barrels.

During 1925 lost time accidents averaged 212 per month. By 1927 this rate had dropped to 114 per month. For the first eight months of 1928, they have averaged 88 per month.

The accident total for the last three months has only been equal to the total for one average month two years ago. The quarter ending on June 30, which is the last one for which figures are available, shows 10 per cent fewer accidents than any previous quarter and the half year ending on the same date shows 15 per cent reduction over any previous similar annual period. Most assuredly these results are worth while, and we can see that we are getting somewhere.

The improvements in the plants and equipment has no doubt been a factor in this performance, but as I pointed out before, without the organized effort of our entire industry through the Portland Cement Association Accident Prevention Bureau, and the individual efforts in every plant, I am sure we would have had another picture to present.

Under the direction of our Committee on Accident Prevention, the Association has furnished us with statistics and information of all kinds pertaining to accidents and their prevention, and has suggested various and sundry methods for the most effective efforts towards accident prevention.

All of this can only be the means towards an end, and each plant organization must after all work out its own salvation, so to speak.

Most of us are inclined to judge the performance on the total and average figures, and without a very careful analysis of all the data pertaining to a problem we may overlook some of the very important facts. This applies to the statistics which we gather on accidents, and if one is content to compare his own performance with the averages and totals of all the other plants, then he may not get as good results as is possible under his particular conditions.

As an example of what individual efforts can produce, I have prepared a table attached giving the accidents and days lost per 100,000 man hours, as tabulated by the Portland Cement Association for 1925, 1926, and 1927, and have shown the corresponding figures for the plants of the International Corporation for this same period.

For our own plants, records are kept along the same lines as those of the Association. We are very strict in the classification of accidents, and under our system and policies there is but little possibility that a lost time accident is not properly recorded.

In 1925, none of our plants were in the first group, and our performance was not as good as the average of all of the 120 plants included in the Association reports. In 1926, we had one plant in the first group, four plants in the second, two plants in the third, and only our foreign plants remained in the fourth group. It is evident that the foreign plants had a good many more accidents than domestic plants, and for this reason we urged the Association not to include the figures of the foreign plants in the statistics, and for 1927 these have been left out.

In 1927, we had three plants in the first group, two in the second, and two domestic plants in the third group, and the average of the accidents in all of our plants was considerably below the average of 134 plants reporting to the Association.

A complete study of the conditions in our own plants, and organized efforts, intelligently guided and systematically enforced, is the only way in which the proper results can be obtained, and I believe the figures presented speak for themselves as evidence of the effect of organized efforts.

While I do not wish to impose on you with too many statements of our own performance, I feel that after all actual experience and observation is the best guidance for further efforts. I, therefore, feel justified in calling attention to just one thing in connection with our experience outside of the United States. Here at home we have all seen accident prevention grow from a rather insignificant activity some 15 or 20 years ago, until its present day enormous importance, and to some people it may be like watching a growing child, it is difficult to realize and to appreciate the changes and the developments that take place.

American Methods in Foreign Plants

Four or five years ago, we began to implant the American methods of Safety Prevention in our foreign plants. Many of us operators who are familiar with conditions were skeptical as to results, and very discouraged during the first few years. We were operating in countries where industry was but little developed, and the great mass of labor instead of being interested in preventing accidents were rather inclined to use any little injury as a pretext for laying off. Real efforts date back only to 1925, and it is simply astonishing to note the interest that the men themselves are taking in this work today, and the figures which are given on the table show a very marked improvement, and I can further state that still better results have been had during 1928. Without organized safety work this improvement would not have been possible.

It is not for me to comment on the methods and details of our safety work. This is referred to on many occasions and is constantly being studied and considered by our committee, and its able chairman. A question that many of us no doubt feel inclined to ask is "Does this work pay dividends?" Does anything which reduces the interruptions in our operations, which cuts down the clerical work, which minimizes labor turnover, which saves medical expenses, and which builds up the morale of an entire organization have any cash value? The answer to these questions is, of course, that it does. We, in the cement industry, are convinced that it does from the results in our own plants. However, this answer was further confirmed in an investigation on Accidents and Production, by the American Engineering Council, and a report on such an investigation was presented before the meeting of the American Society of Mechanical Engineers at the Spring meeting at White Sulphur Springs in May, 1927. The findings of this investigation was based on information from about 14,000 companies and show conclusively a distinct relation between accidents and production.

For the purpose of classifying the performance, it has been customary for the last several years to divide the plants into four groups. The first quarter of the plants reporting and having the lowest accidents come in the first group, the next quarter are placed in the second group, and so on.

This classification shows in every year a very large difference between the first group and the fourth group. The accompanying table shows very forcefully the improvement during these last three years.

I am impressed with the interest the executives are taking. It reflects their belief that accident prevention is worth while, and their desire to be helpful to the men. Without the encouragement of the executives, accident prevention activities have a hard time of it in any mill. I have also been impressed with the awakening that has come to our superintendents and foremen, and it is a splendid sign to see the foremen voluntarily accepting more responsibility of this kind.

Our work has an additional value, incidental perhaps but nevertheless important. It is earning for us the respect and confidence of the public. Industrial publications regard reports of our accident prevention progress as important and give this news the prominence which it deserves. Even the daily newspapers publish current reports of our safety work, because they realize that the progress we are making is of public interest. Comments are not limited to the papers of the small cities and towns where the plants are located, but the leading papers of the country are giving splendid publicity to our work.

Popular interest in our accident prevention work is building popular respect for us among the public at large. The public is beginning to realize that the cement industry is taking active steps towards reducing accidents in mills and that it is working in the interest of its employees. It is beginning to realize that our mills are safe places in which to work—probably much safer than our streets and highways.

But let us not become self-satisfied with results. We still have accidents that must be avoided.

Accident prevention was first taken up as an important Association function in 1913. Our efforts are being better organized from year to year. More and more interest is being taken by the member companies, and the interest of the employee has been aroused to a point where I confidently predict great improvements for the future. There are today in this country a total of 157 plants manufacturing portland cement—137 of these plants cooperate actively through the association in accident prevention work. These 157 plants are owned by 95 companies. Of these companies 80 belong to the association and, therefore, contribute not only by their interest in the work, but by financial support as well. There can be little doubt that the cement industry has developed to its present state of importance largely through cooperation expressed most forcibly by means of the Association. The policy of the open door which has always prevailed with practically all the member companies has been a powerful factor in the tremendous growth and splendid advancement of the industry.

This same open door policy is to the advantage of members and non-members alike, and our organized efforts towards accident prevention reflects itself to the benefit also of the men who work for the companies that enjoy the fruits of the Association's efforts without being members and taking part direct in its work.

While we have made an excellent record in the past, we are looking hopefully to the future. We have proved to ourselves that accidents can be reduced, and during the coming years, we must show the industrial world that cement which is one of the greatest human benefactors, making possible, as it does, safe roads and safe structures of many kinds, can be manufactured without accidents to those who labor to make it.

Cement Section

CHAIRMAN TOWN: It is certainly gratifying to have one of the officials of the large companies with us and to feel that he is interested enough to take the time to address us the way Mr. Posselt has.

We will now take a few minutes for discussion on the paper read by Mr. Posselt and I am sure he will be pleased to answer any questions. Are there any questions anyone would like to ask Mr. Posselt? As each of us knows, these safety efforts would be absolutely impossible if it were not for the interest that is being taken at the present time by the heads of the companies. Safety in the plants is absolutely of no benefit, and it can make no strides whatever, if it does not have the earnest, hearty co-operation of the executives of the company. We had the pleasure a year ago of listening to Mr. Brown of the Alpha Company, who is president of the Portland Cement Association; and I see Mr. Brown present. Although he is not scheduled on the program, we shall be very pleased to hear from Mr. Brown.

MR. BROWN: I did not come here this morning to make a speech, although when it comes to talking about safety I can talk almost any time about that particular subject. I have been actively supporting the work of the safety committee of the Portland Cement Association since it began that particular work, and prior to the time that association began its work I was trying to do a little work with the Alpha Company in a sort of a haphazard way. Indeed, a long time after the association began its work we were more discouraged than encouraged. I think the work was given a tremendous boost when the association decided to give a trophy to the mills making the best record. You have seen the records Mr. Posselt has given you in the memorandum handed around. My judgment is that result came about through the offering of that trophy given by the Cement Association.

We have gone on from that time continually improving the work. Mr. Posselt called your attention to the fact that the mills are represented in four groups, those with the first, second, third and final quarter. Sometimes the association executive committee has thought that perhaps more active work should be taken with those particular mills down in the final quarter, but it has always seemed to me that with the amount of publicity that is given to this work, not only now by the Portland Cement Association, but by the Safety Council, and as you will notice by the technical journals distributed, there is no excuse for any executive; and he should be ashamed to be the president or other executive of any plant who is down in that bottom list. In our organization we had a couple of plants that were pretty far down the list and the president of our company took it upon himself, personally, to talk to the superintendents of those plants and tell them in plain language there is no excuse for it and wanted to see that they were changed and taken out of the last class. The rather curious thing was that the mills we had the most trouble with were not where we had a large number of foreign employees; they were all native American stock. Sometimes I think they know too much; they don't want to be told what to do.

Well, I didn't come here to tell you what to do. You probably all know what to do as well as I. I only want to tell you as a person interested in accident-prevention. I thank you all for the privilege of talking to you. I hope you gain inspiration from your visit here, telling each other what you have done, and that you will go away from here, back to your operations and work with a firmly-fixed idea that you can do just as well as anybody else; and if one of the Alpha Mills could do it—you will pardon that personal reference—we got one or two. I thank you all.

CHAIRMAN TOWN: I am sure that the words of Mr. Brown have been an inspiration and I think this Section should thank Mr. Brown for his generous efforts.

It is my pleasure at this time to introduce Mr. Walter Clinton, the next speaker

on the program, who is in charge of Safety Service, Policyholders Service Bureau, Metropolitan Life Insurance Co., New York City. I am sure we know from that that Mr. Clinton is qualified to address you.

Accident Prevention and Insurance

By **WALTER CLINTON**

Safety Service, Policyholders Service Bureau, Metropolitan Life Insurance Company, New York City

Recent years have developed a decided interest on the part of various insurance carriers in accident prevention. It has been found that a very close relation exists between insurance and preventive measures. As asserted by Professor Albert W. Whitney, of the National Bureau of Casualty and Surety Underwriters, it is recognized that the function of insurance as a preventer of loss is equally important with the function of insurance as a distribution of loss, or in other words, as a great conservatorial medium. The reactions and tendencies of our insurance carriers notwithstanding, it is believed the role of conservator has rightly been undertaken by them. The nature of the business followed, predicted by the operation of economic laws, has borne an influence on such carriers toward assuming this role.

No attempt will be made here to prove this assertion except to example one of the primary forces which govern the existence of an insurance company. Casualty insurance rates, as you probably know, are determined on the basis of past experience of any one industry for a period of years. If accident costs increase, it must necessarily follow that the rates cannot cover these costs and the carrier experiences a loss; but, should the cost of accidents decline, it may be presumed that the rates will be sufficient and afford the carrier an opportunity for profit.

Competition among insurance organizations has played an important part in the reduction of industrial accidents. Casualty insurance rates may be said to be practically identical for experience indicates that should competition be based on rates, these may become so low as to jeopardize the solvency of the carrier. The matter of policy would also be involved for the insured for it might be possible for some organizations to employ methods to secure their insurance at a lower rate while others paid more. Insurance carriers are also prohibited from competing on the basis of commissions paid to representatives because this would bring the rates too high. Competition, therefore, has been limited practically to the field of service, which has introduced our merit-rating system, that is—the establishment of rates on the determination of the physical merit of the risk after certain debits and credits have been allowed according to the schedule rate. This is a desirable form of competition and assists the insured to obtain the best possible rate, reduce his accident costs and to maintain his plant in an efficient manner.

It is not believed that all of us realize the enormity of industrial accidents until figures from some authentic source are presented. It has been estimated by the Statistics Committee of the National Safety Council that the number of fatalities for 1927 is approximately 24,000—about 300 more than 1926; and that non-fatal lost time accidents will approach three and one-quarter millions in number, or an increase over 1926 of almost 800,000.

With these estimates in mind, is it any wonder that insurance companies are vitally interested in accident prevention and are continually striving to curtail this extravagant waste of man power?

A little over thirty years ago, an insurance company hired an inspector to determine the physical conditions of the properties of the risks written. Such an innovation, as it was then, was subjected to much ridicule but the result of the move is

that today insurance companies employ thousands of engineers and expend millions of dollars on preventive work.

Now there must be some reason for our insurance companies making accident prevention a necessary part of their business. There is, for insurance cannot be underwritten satisfactorily either to the carrier or the insured on a rising loss ratio. As mentioned earlier, it is far more advantageous if the business is conducted on a falling loss ratio for price affects the placing of insurance. It is quite obvious that high rates are conducive to self-insurance among risks who enjoy a favorable loss experience, thus creating what is termed an "adverse selection" against the established carriers, or increasing materially the percentage of less desirable risks having insurance protection. So we find highly organized bureaus within our insurance carriers, carrying large staffs of engineers competent to advise employers on safety educational mediums and methods for overcoming hazards.

Two Tests for the Safety Program

Mr. Ethelbert Stewart, United States Commissioner of Labor Statistics, has given us two tests by which the effectiveness of a safety program can be measured with relation to insurance costs. First, consider the attitude of the carrier, which is: How much do we as an insurance carrier have to pay out of the premium rate which we assess against your payroll? The second test is one for the insured to inquire of himself: How many people do we hurt and how badly do we hurt them, and are we injuring fewer this year than last, and even though we may be hurting fewer people is this offset by the severity of the injury so that more lost time and actual suffering comes from the fewer number of cases than the larger number? It is believed these two tests, properly applied and determined by the insured, will not only indicate the results being obtained by his safety work but also the justification of a decrease or increase in rate.

So far in my remarks, I have brought out only some of the economic issues of accident prevention as applied to insurance. While it is a conceded fact that public interest in safety is attached to its humane aspects, it would be unfair to say the tendencies of our insurance organizations are not motivated in a large part through these same principles. Nearly all, if not all of these organizations have realized that they are social service institutions and not merely agencies for the assumption of insurance risks and the payment of claims. Their literature, posters, preventive work and other activities are designed mainly for the welfare of the general public and, excepting perhaps a small element of good will, there is very little tangible return.

Safety work has become a science and it would be pleasant to anticipate a one-fourth reduction of the present accident rate. Insurance may offer a compensation for accidents and their direct cost but it is impossible to insure against accidents, their indirect costs to industry and the suffering involved. Our hope lies then in stimulating a real interest in accident prevention in all industries but meanwhile we must find ways and means to minimize the casualties subject to our "peace time" industrial life.

Many of you will remember the practice of the old time insurance inspector who would enter the plant from the back door, make his inspection of safeguards and depart with but few people knowing who he was or what he was doing. This brings to mind the case of a large lumber company in Louisiana which carried insurance for accidents.

Contrast that procedure with the methods employed to reduce accidents by insurance organizations today. First, upon entering a plant, contact is made by the insurance representative with the highest operating official. It is highly important that this official be sold on accident prevention, his responsibility made known to him and his active support secured. Many officials entertain the thought that the

fact his company is insured for accidents, the burden of prevention rests with the carrier and its engineers. This is a fallacy for no insurance company nor form of insurance can directly prevent an accident. It is true the insurance company through its engineers can offer suggestions and recommendations which assist a plant's experience, but the responsibility and application of these recommendations rests with the operating official who places the recommendations into effect through the superintendents and foremen down to the operatives who actually experience the accidents.

Second, an analysis of accident records is begun, tabulating and charting the records to determine the cause and trend of the accident experience. This study is very important for the solution of any problem demands fact-finding and a knowledge of circumstances surrounding accidents is most essential.

Third, the engineer interviews the supervisory force and foremen to determine their safety attitude and secure their cooperation for without their constant and active cooperation, no safety program can hope to gain proper results.

Fourth, is the study of company organization and policy. This is necessary to determine that type of safety work which would be most effective. It is obvious that a program designed for a meat packing plant would not be applicable to a railroad company, even though the principles of safety in both instances are fundamentally alike.

The fifth factor of the engineer's survey is a study of the existing safety educational work, its effectiveness and possible means for improvement. This study includes safety organization, friendly competitions, advertising safety, first aid instruction and other plans to maintain interest.

The sixth step is a survey of physical conditions and mechanical guarding to remove as many "bugs" as possible from the plant's layout.

The seventh and last part of the survey is a conference with the officials to discuss the findings and to submit a plan adaptable to local conditions and policy.

Such a procedure, with few modifications, can be applied to a small plant as well as a large one. The need of safety work in small industrial organizations is indicated by statistics for generally speaking, a number of small plants with say an operating force of 1,000 men, have a higher rate of frequency and severity than the large plant with the same number of operatives.

In conclusion, may I ask that you consider your insurance carrier as a friendly agency, whether it be your own association, a state, casualty, life or other insurance body. They function as consultants and advisers and no longer follow the back-door policy of creeping in and out of your plant, unseen, unknown and unwanted. Your problems are their problems and they strive to serve you and help you eliminate the so-called by-product of industry—the crippled employee.

CHAIRMAN TOWN: In behalf of the Cement Section I wish to thank you, Mr. Clinton, for your paper this morning. We certainly realize there has been a great change in relations between the insurance companies and the insured and it is a healthy sign of the proper spirit developing in the safety work.

Are there any questions anyone would like to ask Mr. Clinton?

In reference to the committee to be known as a "Committee of Engineering"—I have already explained at that time the purpose of that committee. Is there anybody who cares to make a motion to the effect that we have a committee or another sub-committee in the Cement Section? Has anybody any word to say? Major Reninger?

MAJOR HENRY RENINGER (Lehigh Portland Cement Co., Allentown, Pa.): Mr. Chairman, I think this new Committee is very important. We have an annual report and papers given to the Council and it is the idea of the National Safety Council to have these committees go over the papers and gather material that is of use, making a regular handbook out of it. Another thing: This Engineering

Committee needs another representative to sit in on the American Engineering conferences. Now, we have had no representative up to this time and I think we should have some engineer who is familiar with plant conditions and safety work, act as representative of the Cement Section whenever it is necessary to sit in on the American Engineering conferences.

CHAIRMAN TOWN: Are you ready to make a motion to the effect that we add such a committee to our Cement Section?

MAJOR RENINGER: Yes, sir; I make that as a motion.

MR. FRAME: I'll second the motion.

CHAIRMAN TOWN: Motion made and seconded. All in favor manifest by usual sign and those opposed by contrary sign. Motion carried.

CHAIRMAN TOWN: The next thing will be the election of officers for the ensuing year. Is the Nominating Committee ready to report.

MR. FRAME: The Nominating Committee held its meeting in Allentown. Mr. Weiteknecht having been called to his home town, in his absence it gives me great pleasure to present the following report for him:

Report of the Nominating Committee

By W. H. WEITKNECHT

Chairman

Your Nominating Committee begs leave to submit to the consideration of the Cement Section of the National Safety Council, as officers for the ensuing year, the following:

Chairman—Mr. F. E. Town, Supt., Manitowoc Portland Cement Co., Manitowoc, Wis.

Vice-Chairman—Mr. Edward Parry, Director Personnel Dept., Glens Falls Portland Cement Co.

Secretary—Mr. A. J. R. Curtis, Ass't to Gen. Mgr., Portland Cement Association, Chicago, Ill.

Chairman, Program Committee—Mr. Frank Sass, Safety Engineer, Universal Portland Cement Co., Chicago, Ill.

Chairman, Poster Committee—Mr. Ross B. Fortuin, Assistant General Mgr., Penn-Dixie Cement Co., Nazareth, Pa.

Chairman, Membership Committee—Major Henry A. Reninger, Spec. Rep., Lehigh Portland Cement Co., Allentown, Pa.

Chairman, Engineering Committee—Mr. S. H. Harrison, Ass't Supt., Vulcanite Portland Cement Co., Easton, Pa.

(A motion was made and seconded for the adoption of the report and for a unanimous ballot to be cast by the Chairman of the Committee for all officers nominated. The report was adopted, and officers declared duly elected.)

CHAIRMAN TOWN: I would like to say this time, I certainly consider it an honor to be elected Chairman of this Section. Perhaps you know I was not elected before, but served as assistant chairman and upon resignation of the chairman, it fell to my lot to act as chairman for the rest of the year. At this time I wish to thank every member of the Section, and the chairmen of the committees, for the hearty cooperation they have given me during the past year. If it had not been for the support they have given me it would have been a very different story.

Before adjournment, perhaps Major Reninger, would like to say something about membership. It is the duty of everyone of us as members of the National Safety Council to interest ourselves in the extension of the wonderful work we are doing, and assist the Membership Committee. Major Reninger, would you like to say something at this time?

MAJOR HENRY RENINGER: Mr. Chairman, members of the Safety Council, Cement Section: In regard to this membership problem, I have been interested more than anybody else in it, for after all these years I can see very clearly that if the National Safety Council is to keep on, we must have an increased membership and increased income. I am happy to say that in so far as the Cement Section goes, in the past year, if you look on page 132 of the *National Safety News* for October, 1928, showing the report of the different standings, that in the safety progress as indicated by membership in National Safety Council's Industrial Sections the Cement Section stands first for the year. I think that it is up to every one of us, as we go back to our own communities, not to be selfish, but to get all those people interested.

You people who get the bulletins realize very clearly that there is no organization in this Country today that gives the information that you get from the National Safety Council. We all know that education is 90 per cent of the work, and with the continued turn-over in our plants we must keep everlastingly at it. Over at the Lehigh, where one man jumps from one plant to another, a man has had some training in safety work. This is a big problem. We all realize that it is not only humanitarian, but that it is a big saving in dollars and cents. Now, I should like very much when you men go back to your cities and towns, that you would make it your business to get at least one member during the year; and if we can get every man in the Safety Council to get just one member, we will double our membership and double our income. We are the outstanding industry, practically new,—the steel industry was of course the pioneer in safety work but during the past ten years, particularly since the war, the cement industry has shot ahead. Many times executives told me it wasn't possible, that I was foolish, that it was just an idea, a theory, but since ten plants went through last year without an accident, the cement companies are beginning to realize that plants can operate without killing and maiming their employees.

CHAIRMAN TOWN: If there is no other business to come before the Section at this time, the motion to adjourn is in order.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Quarry and Cement Sections Joint Sessions

October 2, 1928

D. C. SOUDER, Chairman

**Director, Insurance and Safety, France Stoot Company
Toledo, O.**

F. E. TOWN, Chairman

**Superintendent, Manitowoc Portland Cement Company
Manitowoc, Wis.**

The luncheon session was called to order at one forty-five o'clock by the chairman, F. E. Town.

CHAIRMAN TOWN: We have been having a great time over at this table. It has been a question of whether Mr. Souder was going to preside or I myself. However, Mr. Souder has persuaded me to take charge, and as our time is very limited, I will not take time with preliminaries.

I take great pleasure in introducing Mr. R. P. Blake, Sales Engineer, Independence Bureau, Philadelphia. He is here to tell you something new, if there is anything new under the sun, at any rate to inject a little enthusiasm into us concerning safety.

Address

By R. P. BLAKE

Sales Engineer, Independence Bureau, Philadelphia, Pa.

It is a shame to drill down the Chairman but I am going to start in by asserting that I am not going to say a thing that is new to anybody here. My view of how I can be of best service to this group is not to attempt to say anything new but to emphasize.

It seems to me that the present staff of the Safety Movement needs a little more attention drawn to them. A man who was talking with me yesterday injected that idea into the conversation, and it seemed so important to me that I changed my talk clear around to fit it.

He said the thing that is most wrong with the organized safety movement today is that in spite of all the splendid work that has been done, enough American industries haven't seen the light. President Niesz brought that out when he pointed out that about 25,000 deaths occurred in industry in America last year. Had the rate which had been preserved in those plants which are a part of the

National Safety Council been applied to the entire industry, approximately one-third, or 8,000, could have been saved.

Carrying that a bit farther, had all of the American industries done as good work as the leading members of the National Safety Council, such as Union Carbide & Carbon, Inc., and others too numerous to mention, but all doing absolutely first-class work, instead of saving 33½ per cent of the deaths, we would have saved about 95 to 98 per cent of the deaths, and presumably the lost-time accidents in similar proportion.

In trying to get the view of the thing, I attempted to sort of withdraw a bit from close contact with the Safety Movement and tried to get an outline of it as one would get an outline of a big building.

It seems to me that three things stand out as absolutely fundamental. First, enough organizations in every branch of industry in every part of the country, big and small organizations of every type have done excellent work, have achieved excellent accident safety records to prove that anybody can do it. In other words, they have proved that, practically speaking, freedom from lost time through accidents can be achieved as part of ordinary successful operation of any industrial organization or any industrial business.

The next thing is that it pays. It does justify your trying to prevent accidents. In many cases it means from one million to four million man hours of consecutive operation and in small plants without a single lost-time accident. There isn't a single executive who doesn't say that in dollars and cents (keeping off of the humanitarian note) accident prevention work of that kind has paid dividends in returns on the money invested.

You all know, of course, of the very excellent surveys made of accidents, both direct and indirect, by the insurance companies. I take real issue with them in their statement that the indirect cost was a matter of five to one against the direct cost. I believe it is ten to one or more. I am going to attempt to show that here from a brief outline.

First of all I am going to state what I think is the best definition of an accident. An accident is anything that interferes with the ordinary procedure of the work. Only a portion of such accidents cause injury to human beings, but they all cause injury to the operating cost of the plants.

Now those organizations, without exception as far as my knowledge extends, who have done the best work, whether they realize it or not, have attacked their accident prevention work by eliminating unexpected happenings in the operation. It is obvious if we can plan our work accurately and carry it out as we plan it, we are not only going to prevent all accidents from happening, but we are going to attain the lowest possible cost of operation.

The next big cost—and instead of calling it cost I like to call it an indirect saving! Whenever you analyze any operation in any plant, you try to the best of your ability to develop the routine that makes it possible to carry it on practically free from interruption. You have studied your work so that you have not only been able to effect large economies but large opportunities for improvement; and right in there is probably the biggest possibility of saving through accident prevention work. You might call it indirect cost, indirect dividend on safety organization work.

Finally, whenever you organize a plant to an extent where the men work together so well, the entire organization works together so well that you can, practically speaking, eliminate the accidents, you have thereby forged a tool of organization, a tool of personnel, that is going to be extremely effective in carrying out any measure that the management finds practical and profitable. You have formed an organization that is going to carry that particular plant and that particular organization a long way along any path it finds it well to go.

Now, I have mentioned that accidents can be prevented. I have attempted to establish that it pays. I want to draw on the point that anyone can do it. I say this in spite of the fact that only a small proportion of the American industrial organization have up to the present time gone very far in accident prevention work. If they had, what Mr. Niesz said would not apply.

I don't know just how it is best to explain what I mean when I say anyone can do it, except to again recite the fact that in all branches of industry, in all sizes of plants, in plants with all sorts of leadership—by all sorts of leadership I mean leadership with all kinds of industrial theories but reasonably successful—there appear instances where they have succeeded in practically preventing accidents. This leads me to believe that any organization whatsoever that has sufficient capacity, sufficient direction to enable it to continue to exist and make profits under the competitive conditions of industry today, can, if it chooses, prevent accidents almost wholly.

Why don't they do it? I think the first reason is that they don't see the facts. They don't have the figures. They don't get the viewpoint somehow or other, in spite of the excellent work that the National Safety Council has done. In spite of the fact that all over the country are earnest men seeking to reduce accidents, men in every district, in every place in the country, there are a large number of organizations, of moderate size and small, who still don't see the point, who are still running along having unnecessary injury to men and failing to realize the profits that they might have and should have if they are going to deserve the term of reasonably progressive and able people. I think the first reason why more don't is because they don't see it.

Second, there seems to be a widespread idea among the executives of small organizations that because they are small they cannot do it as well as if they were big. I really think that the shoe is on the other foot, because of the fact that the executive of a small plant, with from 25 to 50, maybe 200 employees, has by virtue of his very nearness to those men, the opportunity to inject his own personality, his own energies, his own mental capacity and ability to each individual employee to a much greater extent than the executive of a big plant can, operating as he needs must through his department heads, foremen, straw bosses, and so on.

There are other things that come into the picture; but I have in mind the plant of the American Tar Products Co., with some 18 or 19 men who have operated now something over four and one-half years without a single lost-time accident. There are plenty of other instances but that happened to come to my mind, and the management of that plant, as I size it up, has just the ordinary ability that you would expect to find in any small plant. It probably needs to be less able than would be the case if that plant were an independent organization, because the head of such a plant, one of a chain, doesn't have the financial and other problems that the executive in charge of an independent organization would have. So probably the actual executive ability of the small, independent plant is greater than the plant of similar size that is one of a large corporation, a large string of plants. They just don't see it.

If we should study large numbers of accidents covering all industries, it would be found that as a rule that the special hazard that many plants make so much of is one of the less important hazards, measured in number of accidents, total lost time or any such gauge you care to use. For instance, in the quarry industry, if I recollect correctly, the figures given by the Bureau of Standards, showed tripping and falling as head of the list, and the special quarry hazards such as dynamite were down in fifth or sixth place in the list; and if all of those had been saved the accident record would still have been bad where it was bad in the first place. So that the myth of special hazards as particularly significant

when measured against the total of accidents, is nothing but a myth. If we prevented all the accidents, all the deaths, all the lost time from the special hazards existing in any and every industry, we would still have prevented but a small fraction of the total.

Another point is the human element. It is human nature for us to neglect relatively mild hazards. If in the center of this room were a pair of wide open gears screaming away at us, even though they screamed only for a little while and then became noiseless and we were told that they were still there and still dangerous, we would avoid that spot very carefully, and probably, being creatures of habit, we would continue walking around that spot for a long time after those gears had been removed.

But suppose there were a small depression in the floor, and I called your attention to it and you actually looked at it. In walking around this room later the chances are not one but several that you would stumble and some might get hurt.

Why is it so difficult in many cases to get an organization, particularly an organization of size, to undertake any active accident prevention work? Simply that we have a tendency to neglect the hazards that do not appeal to us as outstanding, and continue to do mildly hazardous things, in spite of the fact that we know that if you do a dangerous thing often enough you will get hurt. The law of averages will get you in the end. There is no dodging it.

Now I have talked about why they don't. How are we to get the organizations that haven't yet seen the light to undertake an effective accident prevention work? I know of no way except to collar the executive or the executives responsible and rub his nose in it until he sees it. Gradually people are seeing it. I have paid so much attention to the saving because I believe that is the way.

In the early days of the safety movement we talked about the fine humanitarian principles. We lost sight, we failed to see practical safety from every consideration of good sense and good operation. It is not a special thing apart. It is not a special humanitarian appeal, but in the last analysis it is a chance to save money and a chance to make money. I believe in emphasizing that, because in the last analysis the most tender part of any man's anatomy is his pocket book. If you can hit that, you have got him.

Now suppose we convince our manager that he really is overlooking an opportunity for making money, and he says, "How shall I go about it?" The first thing I would say to this man is this: The first thing necessary for you to improve your accident record is that you yourself, as head of this organization, must want freedom from accidents; and you must not only want it but you must actively decide to go out and get it, because the path or the way to get freedom from accidents, the details and the endless work are so intimately tied with every operation of every organization that the drive must come from the top, the insistence must come from the top, the check-up must come from the top and the motive power must be furnished from the top.

The chief executive should plan the work. If the organization is big enough to justify a man in charge of safety, that man should report to the chief executive. He should work out his plans with the chief executive. Where it is a matter of authority, so far as is possible within the principles of sound direction of that authority, he should have final authority, and when it exceeds what it is proper to give that man the matter should be decided directly by the heads of that organization and nobody else, unless for some reason of plant policy he wishes to permit a committee to decide; and he doesn't want to do that unless he is willing to accept their decision and see that it is carried out.

Now so much for the start in the organization. He must carry on his work, plan his work with the idea that eventually the thing that he must do is to reach the mind of each and every employee in his organization. In other words, he

must weld his organization into a unit to carry out this policy of freedom from accidents. If he finds individuals in the organization—whether foreman or no matter what they are—who will not take such an attitude, he should no more hesitate, if he is unable to convert them, to separate them from his organization than he would if it was any factory management. In other words if you have an employee who refuses to cooperate in some profit making scheme the management has seen fit to follow, you don't hesitate to convert that fellow or fire him. The same rules apply for safety because I am going to show that safety work is as important as any other branch of operation that you may undertake.

I have no patience with the viewpoint that safety is a sort of special function of a committee or a safety engineer attached to a plant without much authority. It has to be a major function of the management of that plant, or it will not be effective. You will not get much in the way of results.

Each bit of work in the plant must be and should be analyzed. You should find out just what each man does, just what he has to do. As I mentioned at the start of my talk, find out what the hazards are, and find out the best way to prevent them. Right there we run afoul of a characteristic of human nature that is frequently operating to interfere with our accident prevention work; and that is, men dislike routine and monotonous work, like frequently to take chances, and we cannot, therefore, get quite as far as we would like to get. But it is entirely possible to show any man that he can afford to do monotonous work during his working hours in order to be able to do things that are not monotonous outside of his working hours.

Summing up again what I would tell this executive when he asked me what he should do and how he should go about it, I think I should tell him that he would need to use the following qualities in real liberal measure: Imagination, first because he cannot prevent an accident if he cannot imagine it happening. Second, attention to details. A tremendous amount of detail work has to be done by somebody, and probably in the ordinary organization will be done by many men under the direction of the big chief. Third, open mindedness. A man must be open minded to any and every suggestion and try to see all sides of every question. There have been some terrible accidents caused by lack of just that one fact, and I think perhaps more catastrophic accidents are caused by that than any other one thing you might mention. Such a thing as the Pittsburgh explosion which was probably caused by that thing. Such a thing as a tank car in which a number of people were injured and killed and which was probably caused by that.

A plant using a material that under certain conditions might give out inflammable fumes, had this called to its attention by the safety engineer, as a possible source of hazard. It was looked into rather perfunctorily and dismissed as a possibility. Some time later the thing that the safety engineer feared actually occurred. A tank car was put in the plant for emptying and because of improper distillation of the material it left flammable noxious vapors in that tank. One of the two men working in that tank car house crawled up on top and into it to look after something and failed to come out. His partner after a short time missed him and got up and looked in and saw the fellow down in the bottom of the tank and he crawled in and did not come out.

A little later a foreman in the next building wanting one of these men, sent a messenger after them. He came into the tank car house, looked around, didn't see them, crawled in and didn't come out. Finally the foreman came around and looked in and discovered them and called help and rescued them, using a mask and a rope. But two of those three men died.

There was a combination of lack of open mindedness on the part of the management. Failure to go thoroughly into the conditions because they didn't see. If they had probed thoroughly they would have seen the danger. Second, failure

on the part of the men on the job. Perhaps they had not been instructed and hadn't been taught to use common sense and reasonable precaution. The only man who did was the foreman who used it after it was too late to save two men and pretty nearly losing the third.

Next is the outside viewpoint. We all get blind spots. No matter what we are doing, working day after day along the same field we develop blind spots and fail ourselves to be able to see around them. Therefore, the value in having others criticize, comment on, and examine our work from time to time. The ordinary plant expects to have somebody from outside come in and audit their books from time to time, not because they expect to find anything wrong but because the subject is so important that they want the outside checkup and outside okey that everything is going as well as could be expected.

I believe the accident prevention game is so important that the organization, no matter how good work it is doing, that doesn't have such outside, unbiased checkups from time to time is overlooking a serious possibility of trouble.

The last qualification I would mention, and I mention it last because I think in the last analysis perhaps it is most important, is persistent patience. Some of the best accident prevention work that is being done today is being done in spite of the many and repeated previous disappointments and failures. I would point to the accident prevention work history of the Kimberly-Clark Co. As I got their story, they ran for a number of years trying hard to cut down accidents without much success. They finally showed one year in which they made a real reduction. The next year they were worse again. They rolled up their sleeves and kept on and finally they achieved one of the most remarkable no-lost-time accident records that we have today.

That is what I mean by persistent patience. You have got to keep at it and doing the little things and big things persistently regardless of the standpoint. We must keep our courage up regardless of whether we seem to get results, knowing all the time that we will get results if we keep at it. If you use intelligent effort, hard work and patience you get results.

In conclusion I want to say this: One of the most hopeful things in the safety game is that we are now beginning to realize and organizations are now beginning to realize the points I have made. Safety has got to be, by right and virtue of the profits to be made in accident prevention work, regarded as a fundamental feature of the executive direction of any plant, a fundamental feature of industrial work regardless of what you are doing. And I cap that off with this statement—that it is becoming and will increasingly become a measure by which the ability and standing of any organization will be judged.

In other words it won't be long until an organization that is not doing excellent accident prevention work will lose prestige and will be looked at as being not up to the reasonable standard in ability.

CHAIRMAN TOWN: As I have been listening to Mr. Blake I have been wondering whether he is a cement operator or a quarry operator. I think his talk remarkably fits all of our conditions and it is very interesting to get the viewpoint of a man who is not actually engaged in either one operation or the other.

ADJOURNMENT

October 2, 1928

D. C. SOUDER, Chairman
Director, Insurance and Safety, France Stone Company
Toledo, O.

F. E. TOWN, Chairman
Superintendent, Manitowoc Portland Cement Company
Manitowoc, Wis.

The afternoon session was called to order at two-thirty o'clock, Chairman F. E. Town presiding.

CHAIRMAN TOWN: One of the first things we will do is to reverse the order of business a little bit in order that we may take care of any unfinished business that might be necessary while everybody is here. I will ask Mr. Souder if there is any unfinished business that the Quarry Section would like to handle.

D. C. SOUDER (Chairman Quarry Section): There is one thing that the Quarry Section would like to ask. You are well aware of the fact that we are a baby industry in the National Safety Council, and the past three years we have affiliated ourselves with the cement industry in a joint session, and we go on record as asking that we still be given consideration in that respect for next year. We want to be affiliated in this joint session with the cement industry as our men feel that they secure some information in this joint meeting that is very valuable.

The only unfinished business we have is asking for that affiliation.

Joint Meetings Important to Both Sections

CHAIRMAN TOWN: I am going to assume the responsibility of replying to Mr. Souder and state what I feel positive is the viewpoint of the Cement Section in respect to Mr. Souder's suggestion.

We know that in a large percentage of cement plants the quarry constitutes a vital department. There are a few plants, of course, that do not use limestone, but in most cases the quarry is the beginning of the industry, and sad to say our records show that the largest percentage of accidents in the cement industry is traceable to quarry accidents; the largest percentage of increase in accidents during the last eight months was traceable to quarry accidents.

This shows us that something is vitally wrong in the quarry. Because it is so vitally a part of the cement industry, I think there will be no one in the Cement Section that will not feel that it is of just as much importance to the Cement Section that we continue our affiliations in at least one session with the Quarry Section at these annual meetings as it is to the Quarry Section itself. I shall at least check up with the officers of the Section and hope that the Program Committee will see that it is made possible to continue these meetings in this way.

I think perhaps one of the benefits that can come out of these meetings is a mutual discussion of the problems that are existent in the quarry end of the game as well as those that are pertinent to other departments of the cement plant, because in a great many cases they are all traceable to fundamental conditions. Sometimes things that can be worked out to eliminate accidents in other parts of the plant, can also be used in a valuable way in the quarry.

Now we are privileged to have a paper by Mr. J. R. Cline, Assistant Superintendent Universal Portland Cement Co., Pittsburgh, Pa. I am sure that Mr. Cline can handle his subject in a way that will be of interest to all of us.

Putting Safety Across in the Cement Plant

By J. R. CLINE

**Assistant Superintendent, Universal Portland Cement Company,
Pittsburgh, Pa.**

"Putting Safety Across in the Cement Plant" could be better discussed by someone from any of the 34 plants that have gone without a lost time accident for the first eight months of this year; for at the plant where I work there have been only two lost time accidents this year, the same number that occurred last year. Our best record is a period of 369 days without a lost time accident from October 10, 1926, to October 15, 1927.

Never having had a perfect year in safety, it would be better to change the subject of this paper to "How We Try to Put Across Safety in the Cement Plant." The first requisite needed is to have superiors who are vitally interested in safety, higher-ups whose first question is not, "How much clinker have we produced?" or "How much cement have we shipped?"—but "How is our accident record? Are we still free of lost time accidents?"

The first thing done in our plant was the guarding of every known hazardous place. Substantial guards were put on gears, shafts, pits, stairways, ladders and railings, and additional ones are being installed on new places constantly brought to our attention. Guards once placed must be maintained in perfect condition, as they may shake loose, wear out or be broken. If not maintained they become a hazard instead of a safeguard.

After guarding the dangerous places the next thing done was the maintaining of a number of bulletin boards in conspicuous places, with the changing of bulletins at least once a week, to teach by word or picture the sources of danger that constantly surround all employees, and to maintain interest in this source of display.

One feature display on our bulletin boards is a calendar for each department and one for the entire plant, showing for each day of the corresponding month of the previous year the number of accidents, trivial, lost time, eye, or a clean slate, as the case might be, that occurred during that month and the record right up to date of the current month. The figures for the previous day are placed the first thing in the morning and create a lot of interest.

Cleanliness of the plant property is essential. All dirt cleaned up, scrap properly disposed of, passageways properly marked and kept free of obstructions, building maintained in proper repair and grounds kept clean and provided with grass plots and trees to make the general surroundings more pleasant to work in.

Proper lighting is essential for both day and night. Windows and openings should be kept clean to allow all the daylight possible to enter as no light is superior to daylight for general working conditions. For night lighting plenty of electric lights should be at all points in and about the mill so the hazards of darkness cannot exist. Numerous places for plugging in extension lines should be accessible over the plant so there will be no excuse for a man not having proper light to do any work required.

All the things mentioned so far have been physical necessities to put across safety in the cement plant. They are all essential and should be maintained to the highest point of efficiency, but there is still another phase that is far more important. This phase is the education of employees in the safe method of working and getting their cooperation to apply these safe methods at all times so they do not get hurt or hurt someone else.

This we have accomplished best by holding group meetings and getting the suggestions of the men present at these meetings and, as far as possible, carrying out their suggestions.

Our system is to have each department in its subdivisions hold meetings. Foremen usually preside and seldom over twenty men constitute the group present. Items of interest are brought up and any accidents that have occurred, or are known about, are discussed. The Portland Cement Association report on "Significant Accidents" is read at these meetings, as well as the report of any accidents that have occurred at any of the other plants of our company. Suggestions are asked for and as many as sixty suggestions have been received from one of these meetings. We insist that each department hold enough of these meetings so that each man in the department attends at least one of these meetings each month.

A general safety committee composed of all foremen meets once a week to discuss safety problems. Here any suggestions brought up at the group safety meetings, that cannot be taken care of in the regular routine of operation, are discussed and decision made as to their disposal.

A special group of selected men known as safety officers, about one for each twenty employees in the mill, meets, one-third of them, each week so each turn has its representation, and I talk to them concerning safety and any items of general interest that should be brought up at the time. Items they have to report are listed and answers made to any questions they or anyone in the group they represent send in concerning why something has or has not been done in the interest of safety. In addition to mill safety, stress is placed on community safety and no meeting is ever adjourned without the request for each member to "Take Their Safety Home."

Safety is also discussed at the superintendent's meeting. A chart is always on display at this meeting showing the number of accidents, trivial or lost time that have occurred in each department for the previous week and the subject is regularly discussed at its proper time.

Each item reported at any of these meetings is written up on a form provided for that purpose. This form is made in triplicate, the original for the assistant superintendent's office, second copy given by head of department receiving it to workman who signs it on completion of job and returns it to his head of department, and the first copy is signed by head of department and returned to assistant superintendent who has it filed as a record of job completed.

An idea of the number of items reported at the various meetings is obtained when I say that 2,125 were written up for 1927—89.6 per cent were completed, and this year items have been reported at the rate of 2,500 for the year.

In addition to the various meetings, with their groups constantly reporting items to be taken care of, a special committee of picked men is assigned to the job of making a thorough inspection of the entire plant each spring and fall; they report on conditions affecting safety, cleanliness, structural conditions, painting and, in fact, everything that is necessary or will improve the safe operation of the plant. Usually three days is required for this committee to complete its inspection and its reports have sometimes had three hundred items.

Other things we feel have a bearing on safety are good locker rooms; periodic physical examination of all employees in addition to physical examination of applicants; a nurse on duty every day who investigates all cases of employees reported off account of sickness and does considerable community welfare nursing; a doctor who spends one hour each day at the emergency hospital and is subject to call any hour of the twenty-four, all in addition to a well equipped first aid hospital that is completely manned at all times.

To maintain interest in safety we try to have our employees attend safety schools and safety lecture courses whenever possible. Several schools are run by the Western Pennsylvania Division of the National Safety Council, at Pittsburgh, about fifteen miles from the plant. We post the schedule of the meetings and with a little personal advertising are able to get about twenty employees to regularly attend these Pittsburgh meetings. For the last couple of years there has been a

group of meetings held at New Kensington, about 10 miles distant from our plant. We made a special drive for these meetings and provided bus transportation for those not having their own cars who were willing to go. For the seven meetings held last year we had a total attendance of 2,150—average attendance 307—maximum 386—and a total of 697 employees attended one or more meetings—233 attended the banquet and 211 received diplomas for attending at least five of the seven meetings.

This year we intend to hold a series of meetings at Universal. The number of our employees willing to attend a safety lecture course of this type has become so great that we can better arrange to bring the lecturers and entertainers needed to them than to safely transport the great number to other community meetings. We also feel that by holding a set of safety meetings in our own town we will better promote safety throughout the entire community.

We have had over 50 present at each of the meetings and dinners of the Portland Cement Association Regional Safety Meetings held in Pittsburgh the last two years. A representative of our plant has been present at the last four National Safety Congresses and has also attended the Portland Cement Association Regional Safety Meetings held in Allentown and state meetings held in Philadelphia for the last two years.

For the promotion of safety in the community we have each year interested all local organizations in the November Thanksgiving No-Accident drive, and have distributed great numbers of posters for conspicuous display and have seen that each school child in the district has a small picture of the general poster with an explanation of the purpose of the drive given by the teacher or someone from our organization. Occasionally we go through our files and pick out any safety posters that we think would be of use to school children and give them to the teachers to distribute or use in any way they desire to supplement their regular course of studies.

To obtain new ideas for the promotion of safety we encourage the visiting of other plants of our company or of other companies by leading foremen or heads of departments whenever possible. By this means they can see how the other fellow guards his machinery, conducts safety meetings or runs competitions to promote safety and come back with the ideas so they can be worked into our system or make some improvement upon what we are already doing.

Each part of this elaborate system to put safety across in the cement plant, we think, is necessary and has contributed to whatever success we have had; but the one point we feel is absolutely needed is foreman responsibility. The foreman is held responsible for his group. He must be in sympathy with the safety movement and see that every man under him is in sympathy with it. He must be an example to them in safety; order them to work in a safe manner, and then be sure they carry out all the safety knowledge that has been imparted to them. The foreman must see that his group meetings are held; that every trivial injury no matter how slight is immediately reported; encourage participation in all outside safety movements, and lead his men by being present at all outside meetings himself. The success or failure of any group regarding safety is entirely in the hands of the foreman.

"Putting Safety across in the Cement Plant" is not an easy job or one that can be done spasmodically, but it requires the effort of everyone in the organization to be everlastingly at it. That it pays, there can be no doubt, as is easily shown by the results published by the Portland Cement Association and the satisfaction to each of us. "And the end is that the workman: 'all live to enjoy the fruits of his labor; that his mother shall have the comfort of his arm in her age; that his wife shall not be untimely a widow; that his children shall have a father, and that cripples and helpless wrecks who were once strong men shall no longer be a by-product of industry.'"

CHAIRMAN TOWN: I think Mr. Cline's paper has been exceptionally interesting. In fact, having gone very definitely into detail, he has undoubtedly given us a great many points that are of interest and great value to us.

Going back to unfinished business just a minute. Mr. Fortuin, will you please read your report of the Poster Committee for the benefit of the Cement Section?

Report of the Committee on Posters

By R. B. FORTUIN

Chairman

I was appointed chairman of this committee at the national meeting in Chicago, and in turn invited the following men to assist in the work of the committee:

Messrs. David Adam—Lawrence Port. Cement Co.

Fred Hunt—Nazareth Cement Co.

Paul Sandt—Edison Port. Cement Co.

Chas. Benner—Lehigh Port. Cement Co.

Chas. Roth—Plant No. 6, Penna.-Dixie C. Corp.

The chairman of the committee wishes to express appreciation for the fine cooperation of the members of his committee.

A form letter was sent to every member plant on the mailing list of the National Safety Council, asking suggestions for posters. Twelve replies were received, and acknowledgments made to these companies.

The committee adopted a policy that all cement posters should be made up from actual photographs of significant accidents that occurred in the past in the cement industry. To date a total of eleven suggestions, together with photographs, have been sent to Mr. Lee Gardiner, in charge of the Poster Division of the National Safety Council—two more suggestions and photographs will be sent in, in a few days, thus completing the work of the Committee for the past year.

It is very difficult for a small group of men to make up posters that are applicable to the industry throughout the entire country, and the committee would like to suggest that the member plants of the National Safety Council be more liberal in the future with their ideas of how posters should be made up, which will be entirely pertinent to accidents and hazards in the cement industry.

The chairman has considered it a pleasure to carry out the work during the past year.

MR. FORTUIN: I would like to say an additional word to that, gentlemen. It is very hard for any group of men to make up posters that are entirely pertinent to the cement industry and which are of particular interest to your individual plant. The committee sent out these form letters asking for, I believe, five suggestions from each member plant, and out of the 200 members of the cement industry we received only 12 replies. That indicates possibly a small interest on the part of executives in the cement plant, or it may indicate that the form letter did not get to the proper person in the organization.

I would like to ask for the organization that each one of you gentlemen here today make it a point to have some one in your organization send to Mr. Lee Gardner, of the National Safety Council, or to myself personally, suggestions for posters for the coming year.

The posters in the past have covered a wide field. Some of them have not covered the field adequately, and others in possibly the wrong manner. What we would like to do is to pick out the real hazards and significant accidents of the past and have them portrayed on a photograph and then have that made up into a poster. During the past year you have seen a number of the posters that we

made up as appeared in the *National Safety News*. Possibly these posters are not entirely in accord with your ideas, and if not, we certainly will welcome constructive criticism on your part.

The committee gave their time freely and willingly. I know that the members with whom I worked were very pleasant men to work with, and they did all they could to further the work of this committee, but their work is at an end and we need your help to give us further suggestions. I hope that all members will endeavor to let us know what ideas can be made up into posters this coming year.

CHAIRMAN TOWN: I wish to thank Mr. Fortuin for his report of the Poster Committee.

If he will permit, I would like to add a word. Any of you who have had anything to do with active work in the Council know very well that there must be time or energy spent in addition to your regular routine work with the company which employs you; and frankly after you have been looking after those odds and ends or those extra details of work absolutely outside of your regular company business, you realize at the end of the year that you have spent considerable time, with patience sometimes exhausted, and it seems at times like almost an uphill business, as it would be if it were not for the loyal support of active committees.

Two or three men should not endeavor or undertake to do all the work of a section. They haven't in the case of the Cement Section, but it has been delegated to altogether too few, and an important trend in our Section has been to expand. Add a committee once in a while, and now we are in the hopes that these committees by reason of the experience they have accumulated year after year are going to be able to function all the stronger in the succeeding years to come.

Knowing the efforts that Mr. Fortuin and his committee have put forth in this poster work, and also knowing something about the inside work of the National Safety Council I want to suggest that you take everything that Mr. Fortuin said strictly to heart, because the work of the poster committees of the Council depends almost entirely upon the individual efforts of the unit sections of the Council. If each Section is not able to pass in its ideas and suggestions in posters, then the work of the Council is going to be all the more handicapped.

Whenever you are appealed to for this type of work, it would be a splendid thing if you could plan for a competition within your own plant to see what can be done for the cause of this poster work.

I have just received a telegram which speaks volumes. There were three or four of the cement plants who sent word from the Pacific Coast that they regretted very much being unable to have any representative attend any of these meetings of the National Safety Council, because they are having a regional meeting or two out on the Coast this week. They are having one in San Francisco today, I believe, which includes all of the plants of the Northern Pacific District, and they send their regrets that they were unable to come on account of conflicting dates. However, I think the Cowell-Portland Cement Co. feel that they are here.

They have sent us a telegram addressed to this meeting which says:

"Today this company's plant completes 847 days without a lost-time accident.

Cowell-Portland Cement Co."

I say they are entitled to a glad hand.

R. C. FRAME (Alpha-Portland Cement Co., Easton, Pa.): I am going to ask (and you may take it upon yourself to call on me for money if necessary) that you send a telegram to the Cowell-Portland Cement Co. from the Cement and Quarry Sections combined, extending congratulations. I think the fact that they have thought of us and wanted us to know of their good success entitles them to our consideration.

CHAIRMAN TOWN: If you will do that, Mr. Frame, I will appreciate it.

Now we come to that part of our meeting that is always lively with interest and I am going to turn it over to Mr. S. Henry Harrison, Assistant Superintendent, Vulcanite Portland Cement Co., Phillipsburg, N. J. I hope nobody will find it necessary to leave because we want suggestions, ideas and good points from everybody in this part of the meeting.

Round Table Discussion

Led by S. HENRY HARRISON

Assistant Superintendent, Vulcanite Portland Cement Co., Phillipsburg, N. J.

I think we will all agree that mental causes of accidents are a problem of great importance and they are the most difficult to correct even to a comparatively small degree. A man goes to work burdened with domestic cares caused by sickness, financial troubles, or what not. Sooner or later his attention is divided, he is less alert or preoccupied, and as a consequence an accident occurs; for the same reason a locomotive engineer fails to see the danger signal set against him—he drives his train into a block into which he is forbidden to enter and frightful consequences ensue. This phase of the safety question is one of extreme difficulty to correct and one which is well worth our attention.

In starting the round-table discussion we will discuss the various other problems in connection with the safety first movement awaiting solution by the various member companies. Aside from the humanitarian phase of this question, and this is of very great importance indeed,—we find that no matter from which angle we approach the subject of safety first, we are always confronted with the same problem—How can we reduce the great non-productive expense—Compensation?

In the State of Pennsylvania alone for the first six months of this year the total compensation award was \$6,003,183.00, and the total for the year 1927 was \$13,329,557.00.

When one stops to consider the vast sums of money expended each year over the entire United States due to this vast economic loss, it is little wonder that the Executives in various industries have taken a united stand to reduce this item which necessarily must enter into the cost of manufacture of all the products of industry.

One of the large insurance companies has found that in analyzing 75,000 accident cases fully 98 per cent were preventable, and that if the industrial accident frequency could be reduced fifty per cent there would result an annual saving of \$5,000,000,000.00 to say nothing of the misery and hardship which would be avoided.

The splendid results which have been obtained by the Portland Cement Industry promise to be even more gratifying due in no small measure to the fact that the industry at the present time is in the transition stage. Mills that were using machinery of an inferior type are gradually replacing it with equipment of modern design.

Some one has said that the number of accidents on a railroad system is directly proportional to the length or mileage of the system. Such being the case it is only fair to assume that the number of accidents in a factory is directly proportional to the amount of machinery installed and also to the number of men employed.

In some of the older plants in the Cement Industry where the units were designed for comparatively small output per individual machine, it is natural to suppose that more men were required to operate a plant so designed. Today the small units are being rapidly replaced by larger units,—as for instance—Mills of the roller type turning out—say 140 bbls. of cement per day are being replaced by Mills of the Tube Mill type turning out over 2,000 bbls. per day.

The old reciprocating engine driven plant is rapidly fading from the picture.—In its place we have the modern steam turbine with its direct connected electrical generator. In a great many instances the power plant is entirely eliminated—the power being furnished by one of the great electric systems which are rapidly spreading their net work of wires over the entire United States. The old Cement Plant with its multitude of pulleys, belts, shafting, gears, chains, rope-drives, clutches, etc., is being modernized and in place of this hodgepodge of power transmission machinery we have the electric motor drive connected to its load direct or through a gear reduction device.

With the substitution of the wet process for the dry the screw conveyor is largely eliminated, and the centrifugal pump with its attendant pipe lines has taken its place.

The rotary kiln of small size is being replaced by kilns two or three hundred feet and over in length.

Even in the department where dry pulverized material is conveyed the screw conveyor is being replaced by pneumatic conveying systems.

All these changes cannot but produce beneficial results in so far as reduction of accidents is concerned. Incidentally, they also tend to show how much more difficult it is for a cement plant of the older type to come through the year with a clean accident record. Contrast one of the older plants in the Lehigh Valley with one of the modern plants in the Birmingham district and this fact becomes evident at once.

There is another question which it might be well to discuss, and that is the increasing number of low voltage electrical accidents. By low voltage I mean voltages of 220 volts and under. There seems to be a prevailing opinion among electrical workers that a circuit of 220 or 110 volts is harmless. Such is certainly not the case. With the increased use of electrical energy it is surprising that we do not have more industrial as well as more domestic accidents due to this agency.

Recently several fatal accidents have been mentioned in the press. In this city a few weeks ago a man was killed while carrying a bundle of wet hides in a meat packing house. The floor of the packing house was wet—the unfortunate man's clothing was moist, and in carrying the bundle of hides they accidentally struck an incandescent lamp which was broken—the hides came in contact with an electrical conductor with the result that the man was instantly killed. The voltage was 110 volts in this case. Other cases have occurred where men have been killed while working in the interior of boilers or other steam vessels. Death was due to contact with low voltage electrical conductors.

I am bringing this matter to your attention because there are innumerable places, especially in the basements of engine rooms, also in the vicinity of raw material blending tanks where if electrical extension cords are carelessly used fatal results are sure to follow. There have occurred too many cases of this kind where persons have been fatally injured to warrant us in treating this subject lightly.

In discussing this subject with one of the insurance companies their opinion was asked regarding a 35 volt line to be used as a special low voltage circuit in cleaning boilers,—they remarked that they were not prepared to regard 35 volts as harmless. It is all a matter of electrical contact. Perhaps it would be well to treat all electrical circuits as dangerous and have no one enter a boiler with an electrical extension cord, but to use a pocket flash light battery instead, as is the practice with most boiler inspectors.

One of the most difficult problems for the Plant Safety Committee to solve is the problem of converting the confirmed safety skeptic into an active enthusiast in Safety First. I believe that even the most obstinate cases can be cured by keeping everlastingly at them.

Another problem confronting Safety Committees is the problem of fake accidents. For instance—a man reports to work with a pain in his back,—what really ails him is, we all say, Lumbago, but he attributes his trouble to heavy lifting at his work. In this deception his physician often innocently aids him. Many a fine no-accident record has been shattered by this practice.

Perhaps the most hazardous department in a Portland Cement Plant is the Fuel Mill where pulverized Coal is prepared for burning in the Rotary Kilns. As is well known the pulverized fuel is introduced into the Kiln by means of a fuel feeding device and an air blast. Suppose while the device is functioning properly, for some cause or other there is a failure in the air supply *through* the air blast, the Coal will continue to enter the Feeder, the air blast having failed the Coal will be forced out of the Feeder and spilled on the floor in front of the Kiln where it may become ignited by the hot clinker dropping from the discharge end of the Kiln. Such cases have occurred and disastrous results have followed.

Would it not be well to automatically cut off the Coal supply immediately upon failure of the air blast.

Where the Waste Heat System is employed there is always more or less danger of back firing in front of the Kilns should the Exhaust Fans in the rear of the Boilers cease to function. Here too, in this case it may be well to automatically cut off the pulverized fuel supply due to failure of the Exhaust Fans.

It may not be out of place while we are discussing the danger due to pulverized Coal, to consider the subject of "skylarking." I have in mind where a workman while passing from one building into another was struck with a paper bag filled with pulverized Coal, a lighted torch placed on the ground nearby ignited the powdered Coal causing painful burns to the workman's arm and neck. The Coal was thrown from the upper platform in the fuel grinding room and was, doubtless, intended not to injure the man but to give him a dose of coal-dust. It is hard to understand why men indulge in such silly capers, but they do now and then. Needless to say a case of this kind should be treated as a criminal act and the offender dealt with according to law.

However, in a properly supervised Plant "skylarking" does not exist, or rather it is reduced to such an extent that it may be said to have almost entirely ceased. This I suppose is the case with most of the Cement Companies, and is, I believe, one of the beneficial results of no-accident campaign drives.

Before closing these few remarks I would like to dwell for an instant on the question as to the best method of securing reports of injured persons—I refer particularly to accidents which for the moment are considered as insignificant and unnecessary to be reported, as for instance slight cuts or scratches which later develop into infected cases. No reports having been made out in the first case it is difficult to determine whether the injured was really injured at work or at home, or another place outside of working hours. In this case a dishonest workman could claim compensation and the payment of his bills for medical attention, etc.

There are representatives here from many Cement Companies located in different sections of the United States, and we should be able to obtain some valuable opinions regarding the subjects to which your attention has just been called, as well as on subjects which I have not mentioned.

MR. HARRISON: We will now go on with the discussion, but please confine yourselves to three minute talks.

DR. PARLETTE (Pittsburgh Limestone Co., Pittsburgh, Pa.): With reference to fraudulent claims, the Pittsburgh Limestone Co. has a check-out board, and one side has a sign reading, "Check out uninjured" and the other side, "Check out injured." There are blanks there which have to be made out, and if the man has

been injured during the day the first-aid station will report on that patient during that day. When he checks out injured, providing he has not been taken to the hospital, his superintendent or foreman visits his home and that is followed up.

If he comes to work the next day and he claims that he was injured sometime during the day without having checked up as he should, his claim, of course, doesn't go.

I think that is probably the best scheme that I have ever heard of.

MR. HARRISON: I would like to call on Mr. Frame, of the Alpha-Portland Cement Co., and hear what he has to say.

R. C. FRAME (Alpha-Portland Cement Co., Easton, Pa.): This, I think, has been another of the very splendid discussions of safety problems which have been put on for a number of years by the joint session of the Quarry and Cement members of the National Safety Council.

The Alpha-Portland Cement Co. has made wonderful progress in the reduction of accidents at their many plants. We don't have to look back very far before we can clearly recall where we had something like 300 to 400 lost-time accidents in one year. When looking at the records the other day the best that we could count for the first eight months of this year is 24. This remarkable reduction, gentlemen, has only come about through the intense interest of the management in enlisted cooperation, enthusiasm, genuine all-around good work respecting accident prevention and every phase in which it appeals to us.

It seems to be a rather easy matter, after the superintendent of the plant or foreman and safety committees all get started in this work, to post a record of each plant from month to month. Each plant sees what the other one has accomplished, they realize more their own shortcomings and they wonder why they cannot do as well at their plant as their neighboring competitor has done. After all when they start thinking we can look for results.

Mr. Brown told you this morning that the Alpha Co. last year won two trophies from the Portland Cement Association. One of the plants was at Ironton, Ohio.

I give great credit to the telegram which our chairman read a few moments ago from the Cowell-Portland Cement Co., in California, who had their last lost-time accident in May 1926, and I have every confidence in this Cowell organization from what we have learned of them that they are going to continue the splendid record through to December thirty-first.

Alongside of that wonderful performance the plant at Ironton, Ohio, had their last lost-time accident in December, 1926. They won a trophy last year and so far this year the record is clear. Of course, we hope the god of luck and goodwill are with us in our continued effort and that we too will join with Cowell, and that there will be still some other Portland Cement plants that will come through on December thirty-first, so that we will not only have two, but we may have six or eight or possibly more that will win this wonderful trophy for the second year.

Aside from this record-breaking performance at our Ironton plant we have still other organizations to which we can point, such as Bellevue, Michigan. This Bellevue plant some years ago, had their long string of lost-time accidents, permanent injuries and fatalities, but once they started in earnest, they quickly demonstrated that they could cut their safety program off the same pattern. This Bellevue plant has not had a lost-time accident since April, 1927, with every indication that they are going to be a trophy winner this year.

We have been operating a plant at Manheim, West Virginia, since 1908. They have had many problems down there, the principal one being due to mining operation. They have driven columns into the side of the mountain, which brings a problem peculiar to that line of work. With improved conditions, transportation, and light, and all the other elements that go into it, Manheim, not to be outdone

by her sister plants in the Alpha organization, is working heart and soul to attain their trophy for 1928. Their record, as it stands today, shows the last lost-time accident occurred in August, 1927. So they have already finished 365 days without a lost-time accident, but according to the Portland Cement Association code, nothing brings you the prize until you do the calendar year.

It has been felt by those in charge of the Portland Cement Association activities that it is better to set a measured time in which to make this record. Something like a horse race when they all start from a given point and finish at a given point. It seems to me that it takes a little more effort and the record means a little more to us when we get out to accomplish something within a definite period of time.

It may be of interest to you to know the viewpoint of our management at Ironton. You may ask the question, I wonder what is back of this Ironton Organization? I wonder what they are doing out there? How do you go about to produce this wonderful safety record? And it is a wonderful safety record for this reason: Instead of having the ordinary quarry from which many cement plants obtain their rock, they have a mining proposition; no ordinary job. If I remember correctly, their shaft is something in the neighborhood of 600 feet deep, from which they lead out into the rooms, take out the stone, blast the load, bring it to the shaft and hoist it to the surface. They employ some 80 men in this mine.

The records on mining have shown you gentlemen long years ago that it is of a hazardous nature. I venture the open quarry has many advantages over the mining operation, and when this mining operation at Ironton has done so well, in fact has kept pace with the plant operation on the outside, I think we should give them a certain amount of credit for their help in putting over the results.

I am going to read you just a few lines that come, I might say, from the heart of the plant management at Ironton.

Letter from the Alpha Co. Plant at Ironton, Ohio

We trust we are right in assuming that the majority of the plants represented here are members of the 1928 Trophy Club and hope they will be able to complete the year without an accident and win a trophy.

The Cement Association Trophy is a thing of beauty and means so much to those who fought for it that it is only fitting that no expense be spared in providing a suitable dedication. The Ironton plant's trophy was dedicated on May 9, 1928, and this day will be long remembered by the plant employees and the men, women and children of Ironton.

While making arrangements for our dedication we did not lose sight of the fact that accident prevention pertains not only to the cement industry but to the country as a whole, so with this in mind we decided to throw the dedication open to the public at large. Special invitations were sent to the various civic clubs as well as to our neighboring industries. Arrangements were made with the local high schools, both public and parochial, whereby the students were dismissed at noon with instruction to report back at the school at 1:30 p. m. At this time the entire high school student body, about 1200 in all, were formed in parade formation and, headed by the school fifty-piece band, marched to the plant. The day was ideal and our ceremonies were honored by the attendance of five or six hundred little fellows who had heard that there were to be "free eats" at the plant. They began to arrive about noon and immediately captured all the strategic places around the refreshment stand, which they held from noon until the refreshments were served at about 4 o'clock.

The speakers of the day included Mr. Barbazette, manager of operations; Mr. Brown, president; Mr. McKelvy, vice-president, all of the Alpha Industrial Commission of Ohio; Mr. Butler, terminal superintendent, Chesapeake & Ohio Railway

Company, and Mr. Morgan, C. & O. Y. M. C. A. secretary. All of them touched on the wonderful record the plant made and also on the value of safety not only in the mill or work shop, but in the home, on the streets and everywhere. There is no doubt in our mind but that many safety converts, if we may call them such, were made as a result of the stirring speeches.

The refreshments which followed the speaking consisted of the following:

- 2500 packages of Cracker Jack
- 2000 packages of Pop Corn
- 2000 packages of Peanuts
- 120 gallons of Orangeade
- 120 gallons of Lemonade
- 1500 bottles of Pop

Everybody had plenty to eat and drink and left the grounds hoping that the plant will be able to go through another year without a lost time accident.

The question is continually being asked us, "What did you do to win a trophy?" and we will briefly outline our method of handling the job of accident prevention although we feel sure that you find it very similar to the methods used in other plants.

Successful accident prevention is the result of cooperation between every member connected with an organization. We of the Alpha Company point with pride to the cooperation that exists within our company and we doubt whether there is a greater safety enthusiast in the country than our president. The spirit of safety is contagious only when it starts at the top and works downward. If the president of a company is a believer in safety the general manager will be also. Once the general manager is converted the superintendents will not be far behind and you will find before you hardly realize it that the foremen and men are right in line. The management must show a willingness to spend money for things that produce results. Guard rails, etc., should be installed wherever needed as we have found that men can't be convinced of a management's interest in safety if they see on all sides of them unguarded gears, etc., just waiting for a chance to bite them.

Some safety engineers argue that the installation of guards tends to make a man careless and less on the alert than he would be if the guards were not there and he would realize that the slightest sign of forgetfulness on his part meant injury or death. We cannot, however, agree, with this point of view and make it a practice to guard everything or place that may cause trouble.

Our safety committee, composed only of foremen or heads of departments, is similar, we believe, to the majority of other committees. We did considerable experimenting before so organizing our committee, but found that the foreman is the logical member of a safety committee.

Regular meetings are held once a month with special meetings added whenever necessary. At these meetings the condition of the plant as a whole is discussed and various recommendations considered. Especial attention is given to the reports issued by the Portland Cement Association and in our opinion the monthly report on "Significant Accidents" is one of the most valuable bits of information put out by this organization. This report is given a thorough study in our committee meetings and an attempt is made to visualize each accident mentioned or in other words we imagine the injured man as being one of our men. If we then find that a similar accident is liable to occur at our plant we take immediate steps to head it off.

Each foreman is given a copy of those "Significant Accidents" and in addition to this we make out another report of the accidents which are peculiar to his department. The latter are first read and explained to the men and then posted on the department bulletin board.

The Alpha Management made its plant committee's work easier when it started direct advertising by paying a safety bonus. Under this plan 1 per cent of a man's

earnings is added to his check whenever the plant goes through a month without a lost-time accident. While this bonus does not amount to much for each man still it means quite an outlay for the company in a year's time for all of our plants. The average monthly bonus for each man at our plant would be about \$1.25, but it is surprising how our men count on this addition and how they appreciate it.

Prior to 1925 we were having a great number of eye accidents, men were being struck by flying chips of stone and steel and three men each lost the sight of one eye. The committee realized that something would have to be done and done quickly if we did not want the nickname of being a one-eyed plant. So a compulsory goggle rule was put in effect in April, 1925, and each man was given a pair of goggles and a letter explaining the reason for giving them and also instruction as to when they must be worn, as well as the penalty for not wearing them.

These goggles were purchased by the company at \$1.10 a pair and this amount was deducted from each man when he received his pair. The company keeps the goggles in repair free of charge and when a man leaves the service his \$1.10 is refunded to him, providing he returns his goggles, no deduction being made for the condition of the goggles when they are returned.

At the beginning we had some trouble getting the men to wear them and we were given all the stock excuses, such as, "I can't see through them, they give me a headache," etc., but we kept driving away and each time a man turned in a pair of goggles the glasses of which were shattered by a flying chip or were covered with exploded metal we put them on our bulletin board with a full description of just how near so and so came to losing his eye sight. Such advertising proved a big help and now it is a rare case to have to call a man's attention to his goggles. We cannot say just how many eyes or lost-time accidents have and are being saved by this rule, but we do give the goggles a big share of the credit for reducing our accidents.

It is impossible to place too much emphasis on the part played by the plant doctor in holding down the number of lost-time accidents and the record we have made could not have been accomplished had it not been for our doctor.

It is a rule at our plant that every new man must be given a thorough physical examination before he is given a job and each old man is given a periodical examination. By this arrangement the unfit are kept out of our plant and a line is kept on our employees so that if anything develops which might make them unable to take care of their regular job as they should, we can transfer them to another job which they can handle with safety.

The real company doctor is one in whom the men have confidence. He should be a ready and sympathetic listener to all their troubles, both real and imaginary so that the men will be anxious to come to him for treatment. Most men think it effeminate or babyish to run to the first aid room for every little scratch, but the doctor can do more to correct this idea than anyone else. Infection, which may follow the most innocent looking scratch, is responsible for more lost time than any other one thing and will continue to be so unless the men can be educated to the importance of first aid.

In conclusion I might say that the record we have made was not due to any elaborate program carried on in the plant. The methods we use are similar to those used in most plants, but the success of any safety drive is a matter of cooperation and education, convince your men that they are the real beneficiaries of this safety movement. Inculcate in them a determined winning spirit so that they will point with pride to their personal safety record, the record of their department, of their plant and of their company as a whole.

We have won a trophy and have gone 657 days without a lost-time accident, but they only serve as an inspiration for even greater accident prevention effort in the future and we are going to prove to the world that our adopted plant slogan, "Accidents are Unnecessary," is something more than a mere pretty phrase.

In short gentlemen, what I have outlined is only a very brief review of the safety activity that is being carried on in many plants belonging to the Portland Cement Association. The wonderful record that Chairman Town mentioned this morning very ably supports this and I feel certain that the work is going to grow.

The district safety meetings as well as those of the National Council are being well attended, and the free discussion of everything pertaining to the prevention work has been the means of putting Portland Cement where it stands today.

MR. HARRISON: I see we have Mr. Fred Hunt with us, of the Nazareth Cement Co., and we would like to hear from him on the electrical side of the safety first question.

F. B. HUNT (Nazareth Cement Co., Nazareth, Pa.): This is unexpected, but I want to emphasize that whether you fellows know it or not approximately 20 per cent of the accidents occurring in the cement industry last year were due to electrical causes, and at least six—I am not familiar with the number that have occurred since June—but during the first four months of the year six of the fatalities in the Portland Cement Co. were from electrical causes. As Mr. Harrison has brought out in his report, it doesn't necessarily mean when you speak of electrical hazards that it refers to high voltage. In fact several of the accidents this year have been due to low voltage, down as low as 110.

You folks are all familiar with the accidents that occur in the home, such as a person coming in contact with the water line and electric socket at the same time. Well, get in direct contact perhaps with some high tension side or high side of a transformer which you know absolutely nothing about. You may think there are only 110 volts in there, but maybe there are 22,000 or 33,000.

No doubt you know that last evening the papers carried an account of a joke that was intended for a fraternity initiation down at the University of Texas. This is entirely out of the cement line, but you can see what it may lead to.

For a fraternity initiation down there they took two bedsprings and connected the two sides to 110 volts and put a resistance in there. They put the first four men on these springs and gave them a little shock. That was funny. All the other fellows got a big kick out of it. But when the fifth man went on the springs, it wasn't quite so funny. That man died just four hours later from the shock received from those springs. That was supposed to be 110 volts.

Going further into the boiler question, a number of plants have considered the installation of a transformer, dropping a line from 220 or 110 down to 32 for using an extension while cleaning boilers. I believe that is also wrong. Just as Mr. Harrison said, the insurance companies will not agree to even a 32 volt installation.

Go into your boilers with high powered flash lights. It may cost a little more for batteries, but it will be a saving of human lives in the long run.

Just before closing I would like to ask some of the men, especially Dr. Corlett, regarding plants that have gone into the physical examination and examining every man in the plant, what results they have obtained, and whether they have any definite information or definite figures showing what those physical examinations have done?

DR. CORLETT: I just don't know how to answer that. I examined 1,700 men and I found heart conditions 28 per cent, 13 per cent hernia, 78 per cent pyorrhea, and I have forgotten the other figures.

Last week I examined quite a number of men between the ages of forty-five and sixty, rather above forty-five years of age; and 98 per cent of those men had high blood pressure, valve leaks and hardened arteries.

The Carnegie Steel Co. has put on a drive to have men in the high places physically examined at least once a year, and those over sixty years of age examined twice a year, and I think that is entirely proper.

Those with hardened arteries and high blood pressure who have to climb to high places may become dizzy, and they even suffer strokes of apoplexy if required to climb to those high places. It is very hard to tell some times whether the man has died as a result of a fall or the result of apoplexy.

MR. HARRISON: While we are on the subject of electricity, I saw it stated somewhere that a current of about one-tenth ampere, going to the vital parts of the body, is sufficient to kill the person.

DR. CORLETT: That is a question. I was talking not long ago with quite an electrical expert and he told me that 110 volts certainly would kill if the person didn't happen to be in normal physical condition. I am not prepared to say.

It may be possible for us to tell whether a man is in perfect physical condition from the standpoint of the salts in the blood stream, valvular leakage, which uncompensated makes very little noise, and from other standpoints. I do know, however, that 110 volts have killed a sufficient number of people in the United States that we should consider 110 volts hazardous on all occasions.

MR. HARRISON: I have seen it stated also that in judicial electrocutions where 1,500 volts were applied to the head and the lower extremities, a current of ten amperes passed through the criminal's body would indicate that his bodily resistance was only fifty ohms. If such is the case, a 150 volt circuit, if properly applied, would produce one ampere and that surely ought to be sufficient to do away with anyone.

R. C. FRAME (Alpha Portland Cement Co., Easton, Pa.): Some years ago I visited Dr. Lauffer, of the Westinghouse Co., who is an authority, I think, on the resuscitation of those electrocuted. He showed me the apparatus and told me of some experiments he had made to determine the resistance of a person's body. He found the resistance varied with different men's measurements, such as testing a man through the body by his two fore hands, by putting on gloves soaked in brine, etc.

He was able to get resistance as low as 60 ohms, and in his opinion one-quarter of an ampere would kill any man. In other words, I think the evidence is very definite that a man not in the very best of physical condition, if he gets the right kind of contact can be killed easily.

I have personal knowledge of a man being killed on as low as 56 volts direct current. The man got in contact with a large plate of zinc when he was standing in water to his knees, and the current passed through him. He was so cramped that he was not able to get away from it. We don't know how long it took him to lose consciousness—he probably lost consciousness gradually—but he was dead when we found him.

We must regard any voltage above 50 as undoubtedly dangerous under the right conditions, and so handle our low voltage work that we can avoid this condition as much as possible.

MR. HARRISON: I haven't the names of the gentlemen in the Quarry Section but we would like to hear from some one in that Section.

A. C. GOOD (American Limestone Co., Belfont, Pa.): The matter of extension cords is a very vital subject to practically every plant, and I would like to inquire whether anyone has ever used or whether there is such a thing on the market as a cord totally shielded? There are a number of cords which have a ground wire strung through them intended to ground the socket at the end of the cord, but I wondered whether a cord had ever been developed which had a shield around both the conducting wires?

H. W. FRAZER (Charles S. Warner Chemical Co., Wilmington, Del.): One of the greatest difficulties of the quarries is to get a good ground. In cases where the stone deposit has only one or two feet of dirt, one of the hardest problems is to get a good safe ground.

MR. HARRISON: We would like to hear from Mr. Fortuin, of the Pennsylvania-Dixie Co.

R. B. FORTUIN: (Pennsylvania-Dixie Co., Nazareth, Pa.): There is one point I would like to bring out, but before going into that I would like to give you an idea of our experience this year.

In our seven plants we had approximately 50 lost time accidents in 1927. To date in 1928 we have had exactly 10, which I believe is a very good reduction.

During the last three months we conducted a three months' No Accident Campaign among our four plants in the Ludington Division, in addition to the Hercules Cement Corporation, the Nashua Cement Corporation and the Lone Star Cement Corporation, all those plants being located in the Nashua Division. In 1927, we had 20 lost time accidents in those plants, and in 1928, we have had exactly three.

Now the point I want to bring out is this: I firmly believe that our success in accident prevention work is entirely due to bringing out the old idea in new clothing. Each year and each month we bring out the old idea of safety work and accident prevention in entirely different form.

The first of July, for example, we were at a loss to know what we could start or what we could change to make it new. So we started what is called our "Good Housekeeping Campaign." Each month a man is drawn from each of the plants in another division (there are four in number), and that committee goes to each plant and thoroughly inspects it from start to finish. They inspect for sanitation and safety hazards and then cleanliness; and I don't believe there is any single thing that we have ever done that has given greater impetus to the reduction of accidents than those inspections each month.

Cleanliness naturally takes into consideration cleaning up all sorts of debris around the plant. Tidiness takes into consideration the storing of machinery parts throughout the entire mill. Fire hazard takes into consideration the fire hazards in the various departments such as waste paper baskets and the accumulation of combustible rubbish. Sanitation takes into consideration rotten apples and milk bottles that still hold some milk, and all sorts of garbage that may be distributed through the plant by the workmen. Safety hazard takes into consideration those machines where guards have been supplied and are not in place at the time of inspection.

The committee does not recommend new guards or new safety arrangements no matter where it may be.

This inspection runs in competition between departments in the individual plants and in competition with the other plants in the organization, and I want to say that the interest is very keen and no one department wants to have a lower percentage than any other department. Our superintendents are here today and they will vouch for that statement.

Another thing we created this year was a three months' No Accident Campaign running through the months of June, July and August, and had in addition the three independent plants; and the campaign has an appeal not only to our own organization but to the members of the independent organizations. It was something that had never been carried forth before and it created an interest which was unheard of in the past.

When we started the campaign, we had a mass meeting of the employees of all the plants and we finished the campaign in the same manner; we had as speakers men who talked the language of the men in the mill. Our main speaker for the opening of the campaign was Mr. Thomas Quigley. We ended the campaign with the executives of the cement plants only and we awarded a trophy to each plant completing the three months without a lost time accident.

For next year we have in mind our campaigns and also to go into the matter of physical examination. We are preparing that now and expect to put it into

effect on January first. It is the old ideas that we are trying to bring out in new clothing, and that I believe is the reason for the interest that we have carried along in our organization since the inception of the Pennsylvania-Dixie Cement Corporation.

MR. HARRISON: We would like to hear from some of you gentlemen in the Quarry Section. I haven't a list of your names so I cannot call upon you individually.

The Industry in Pennsylvania is Praised

THOMAS J. QUIGLEY (Department of Labor and Industry, Harrisburg, Pa.): By invitation of Mr. Fortuin, I got up here. I want to say that I feel at home in this meeting because looking around me I see so many Pennsylvania people here.

When it comes to accident prevention work, not because this is the cement meeting or joint cement and quarry, I want to say that no industry in the state of Pennsylvania is doing more for accident prevention work than the cement industry of Pennsylvania. They tell you about the wonderful records that some of the steel mills have established in Pennsylvania, the railroads in Pennsylvania, and other industries; but I say that the cement industry doesn't take second place to any industry in the state of Pennsylvania for accident prevention work.

During the No Accident Campaign in the month of June, it was my pleasure to attend about 44 different safety meetings in the interest of the No Accident Campaign. Not only did I attend meetings of the general quarrying industry, but limestone and everything else. For the first eight months of 1928, as compared with the first eight months of 1927, we have shown a reduction of 25 per cent in fatalities in the state of Pennsylvania. For the first eight months of 1927, we lost 28 lives in the quarry industry, that is quarries of all kinds, and for the first eight months in 1928 that number has dropped to 21. In 1927, we had 2,483 lost time accidents in the quarrying industry and for the first eight months of this year, we have dropped down to 1,318.

If we can continue in the quarry and cement industry for the balance of this year as we did for the first eight months of 1928, the cement and quarry industry of Pennsylvania, I believe, will lead all other industries in percentage of reduction in accidents, fatal and nonfatal.

To accomplish that we have had the most wonderful cooperation from all of the quarrying and all of the cement industries. Last week I attended eight meetings in the Western part of Pennsylvania. I went into a new field, into virgin territory to preach accident prevention work.

I went in among the refractory corporations. Never before had safety meetings been held; never before had any person attempted to talk safety to them or to show them how accidents could be prevented in refractory industries. Every plant that I visited had closed down their plants for one hour, paid all the men for their time and some of them even paid the contractors for their loss in the day's earnings to attend the safety meeting. When you get that kind of cooperation, gentlemen, whether it is in Pennsylvania or in Texas, in Missouri or Michigan, you cannot fail to have real, honest-to-goodness results. You are bound to make a success of it. You certainly cannot fail when you get that kind of cooperation.

But to the Cement Association in Pennsylvania belongs the credit for getting all the other quarrying industries working for safety. We can point with pride to the record made by the cement industries and they never failed to come with testimonial and information whenever we called upon them. I say that the records made in accident prevention in the state of Pennsylvania this year and the reduction which we have shown have been accomplished only through 100 per cent cooperation from the cement and quarrying industries; and I am satisfied that our new program which goes into effect January first for a continuous drive for

twelve months in 1929 will put Pennsylvania on the map and we will make the most remarkable showing for accident reduction that has ever been accomplished in this country.

MR. HARRISON: We would like to hear from Mr. Adam of the Lawrence Portland Cement Co.

D. A. ADAM (Lawrence Portland Cement Co., Northampton, Pa.): I just want to say a word this afternoon about something I have talked on before. That seems mighty easy, because if you repeat a thing several times, the sub-conscious mind comes into play and you don't need to care. But I do this because I see today, quite a number of new faces. Not new in accident prevention, but new in our cement and quarry meetings.

Interpreting Safety in Simple Terms

Some three years ago the idea occurred to me: Do the men grasp and know thoroughly what it is the foremen tell them? We all appreciate that the foreman is the key to the accident prevention work in a plant. I thoroughly agree with that; but when we place the responsibility on the foreman we put him in a position that he must answer for every man under his control.

Now, as I said, three years ago the idea occurred to me: Do the men in our particular industries know exactly what the foreman means or what he says? It puts me in mind of a story that illustrates the point.

It was at a dinner party and it was very quiet. One of the guests, to break the monotony, said to the hostess, who was a wonderful piano player, "Would you play for us?"

She played a selection of the great Wagner's and when she finished there was a dull lull. You all know. You have been in circumstances, where a dull silence comes over a company, and anything might happen. Well, that happened there. The lady who had been playing the piano said to the gentleman on her right, who was rather deaf, "Would you care for another before your dinner?", and he said, "No thanks, I had two before I came in." So I think the men sometimes do not really know just what is being said.

So, I decided to call the men together at twelve o'clock just after the dinner hour is over; I sit down and just talk for half an hour. I try to show those fellows why the foreman tells them to do certain things and why they should do them and also the reason why the foreman tells them to do them.

I also ask ever so many of our men questions about the regulation of our plant. "Do you know why you are asked to do that?" "No, I don't know. The boss said to do it."

That is the wrong attitude. If you tell a man to do a thing mechanically, you are certain to get results to a point, but you do not get the full cooperation that you ought to get and must necessarily get to put safety across.

It is the man who does the work that is apt to get hurt and not the foreman, and I felt that I was doing in my humble way a service to help the foreman, on whom we put the responsibility. I don't know whether it is these Thursday talks, but our accidents have tumbled down faster than ever before.

Ladies and gentlemen, we often hear people say, "Well, what is the good of going to a safety meeting? There's nothing new." I agree there, and I feel that when I come to a safety congress, I don't come with the intention of taking something new back to my plant in the way of ideas. But I do feel that I want to come to these meetings to go back with the encouragement and the endorsement given me by those meetings which are sponsored by the National Safety Council and those meetings which are sponsored by the Portland Cement Association.

I feel that when I go back I am on the right road, and it is up to you and me

and every one of us in our respective organizations to solve our own problems because in each and every plant the problems are entirely different. The superintendent and the foreman and the men are different and the environment is different. So I say it is up to ourselves and we must do one thing. We must think.

I read in the paper the other day that only 53 per cent of the American people in organizations think. That is just about right because they say only 51 per cent vote. Out of that 50 per cent, 30 per cent don't get anything out of the thinking, which leaves 20 per cent. Now, I am not going to tell you about the 20 per cent.

MR. HARRISON: I would like to call on Mr. E. H. Perry, safety director of the Glens Falls Portland Cement Co.

A Long Hard Pull to Safety Success

E. H. PERRY (Glens Falls Portland Cement Co., Glens Falls, New York): I really don't know what I can say to you unless I give you a little personal history of the safety work in my own plant. We are rather out of the line entirely and we don't have a great many visitors, and unless one of our men happens to be at one of these safety meetings perhaps our progress in accident prevention is not very well known.

About three years ago, my company went into an extensive accident prevention campaign, with the idea of not getting large results the first year, suffering a reaction the second year and seesawing back and forth like that. We have tried to lay our plans so that we would have a good substantial reduction each year and keep up that reduction until we got down to what might be called the irreducible minimum, and since I have been identified with the company, I have been able to report that we were making improvement; but I never have been able to report that we were in the trophy club for any great length of time.

Three years ago we had some 42 lost time accidents. We went over the problem and the year after we were able to show a record of 18, which was a good improvement. Since then, we have cut it down to 10 and so far this year, we are down to two; so we feel that our plan is more or less sound and that we are gradually getting over our proposition to the men.

The men are taking hold of it and our accident prevention work is getting down to the point where we must scratch right down and get at the cause of these accidents.

Now the peculiar thing is we started out with all kinds of hopes this year of being a member of the trophy club; and we were until May 30th, a holiday, when a man was injured. We were pretty discouraged but at the same time we went at the job and continued until Labor Day when we had another accident. The peculiar thing about it was that both accidents were fractures of the same bone of the same foot of these two men, and they both happened on holidays when no man was supposed to work. Whether that had any connection with the accidents or not, I don't know but they were not necessary accidents at all.

We are most discouraged and regret the fact that we cannot come to one of these meetings and report that we are members of our Cement Association Trophy Club. At the same time we are interested in climbing up in the list, and while we are not contenders for any trophy, we do feel that our safety work is getting results, and that really is the purpose of all safety work.

I don't think that there is anything else that I can tell you fellows except that I want to express my appreciation for being selected as vice-chairman of the Cement Section. I don't admire your choice but at the same time, I am glad to be mixed up in it and glad of the opportunity to do a little more work. I am sure if Mr. Town is in need of a good vice-chairman, he will find me perfectly willing to help him out in every way I can.

MR. HARRISON: Will Miss Weeder, of the Jay & Portland Cement Co., tell us something of the welfare work they are doing?

MISS J. A. WEEDEE (Jay & Portland Cement Co., Egypt, Pa.): I have nothing special or exciting to add to what has already been said. We are not members of the trophy club but we hope to become so during the coming year. We are gradually coming down from a rather high record to two in 1928, and we are going to make every effort to get one of those trophies.

MR. HARRISON: Mr. Cline, of the Universal Portland Cement Co.

J. R. CLINE (Universal Portland Cement Co., Pittsburgh, Pa.): We give every man in our plant a physical examination. This week we have just finished the second examination for the second year. It pays. The men like it and there have been a number of them benefitted by the suggestions given by the doctor. The first few of them who knew they had physical weaknesses of some kind, tried to keep from being examined, but they have come around with suggestions of how they can be benefitted.

We also have group life insurance.

MR. HARRISON: Is Mr. Switzer present?

E. C. SWITZER (Petoskey Portland Cement Co., Petoskey, Mich.): Our experience has been that in 1925 we had a very bad year in lost time accidents and one fatality. We have since that time been improving our record; in 1926, we had three lost time accidents and in 1927 two, and we have had one so far this year, so that we are making progress. We hope to get in the trophy class. Our expectations are to keep at the thing and work until we do. The contest for the trophy has been a very great incentive to progress in safety work with us as with all the other plants of the Association.

Accident Frequency the Important Guide

H. W. HEINRICH (The Travelers Insurance Co., Hartford, Conn.): I want to say just a word in regard to the value of the so-called lost time accidents as a guide to effective accident prevention work in the quarry and cement industries.

It is inspiring to hear man after man get up and recite the experiences in his particular plant. I have no quarrel with that. Surely the reduction of lost time accidents is a very good measure of effective safety work. It is the result we hope to attain, but as a guide to accident prevention and lost time accidents, it is not so good a point to use. It is not so good for instance as frequency of all accidents.

In the very interesting meeting the Metals Section had this morning, one of the speakers referred to the common type of traffic accident where a man driving an automobile across a railroad grade crossing is injured by a passing train. It was referred to in one sense as an unavoidable accident. I want to use that as an illustration in regard to the value of lost time or serious accidents.

In the case of that kind, it is possible of course that a man may, the first day he buys a car, the first mile he drives it, and the first railroad grade crossing he passes, be struck by a train; but it is much more likely that he has driven across railroad crossings many times without stopping to look or listen and is finally struck.

The point I wish to make in connection with that is that the one accident that finally results from a long series of unfortunate mishaps is merely the result of a great many setups of the same situation, and so when it finally does occur, a man is hardly justified in saying that this is the first time I have ever driven across a railroad grade crossing without stopping to listen. He has done it many times before. An effort has been made to determine how many times a man does the same thing that finally results in an accident, or finally results in injury (let me put it that way), and it has been estimated to be from 30 to 40 times.

The point is that there are 30 or 40 opportunities for a good live supervisor who has accident prevention work at heart to see and to control and to observe and to correct these conditions that run along so many times before they finally result in accident.

To go back to my first point, as a better guide to effective accident prevention work, I would take any accident, because not having an accident is nothing but luck and cause is nothing but luck. The accident, however, is not luck. The accident is controllable, but whether through inattention or through some extraneous circumstances, whether the accident results in a serious injury or minor injury, is purely a matter of luck; then why choose the one accident out of 30 or 40 as a guide to prevention instead of 30 or 40 all of which are the same and all of which may lead to a serious accident?

If a man slips and falls or drops something or knocks against an obstruction, those are so-called causes of accidents. A man fumbles something in his hand and lets it drop; it may result in only striking the foot, it may strike one toe and cause a slight injury, and it may strike his instep and cause a lost time accident; but either there is no accident, a slight accident, or a serious accident, and all three of these are a better guide than the one accident which happens to result in lost time.

Improper Use of Electricity Causes Accidents

In this meeting reference has been made to electrical apparatus as a cause of accident. I want to point to the fact that electrical current is a friend to industry if properly used. It is a powerful, effective and useful giant, and a friendly giant. Far from being the cause of accidents, if properly used, electricity might be easily considered the reverse. I understand thoroughly the position of the gentleman who made the remark about 20 per cent of the accidents in the cement industry being caused by electrical current, but he used the term "caused" and although the mere matter of words is of little moment, yet it means something in so far as we use causes in order to correct the conditions that promote injuries.

Electrical current in the instance that he cites was properly not the cause at all. If, through mishandling, electricity causes injury, then the mishandling is the thing that we want to drive at and we needn't necessarily be afraid of current. If the wiring was improper, if sufficient ground was not provided, or if the installation was imperfect, those things of course through the medium of electricity may cause injuries; but I assert that the cause is something other than electricity. And so again in closing, I want to say that the value of any accident, the value of minor accidents, the value of all accidents is a much better guide than is the lost time accident.

The result that we are aiming at is, of course, the reduction of lost time or the serious accidents which we can achieve through concentrating our efforts upon all accidents.

CHAIRMAN TOWN: Mr. Harrison, has anyone any suggestions that he can give to help us out concerning the screw conveyor accident? We all know that the screw conveyor constitutes one of the greatest hazards in the cement industry, probably around some of the crushing plants and quarries, but certainly around cement plants. Has any one anything favorable to offer on the proper avoidance of accidents due to screw conveyors?

WILSON W. RITTER (State Workman's Insurance Fund, Harrisburg, Pa.): Being quite familiar with conditions from an accident and frequency standpoint throughout Pennsylvania, if I were to leave this meeting without saying a word of commendation to the cement industry in the Allentown district, I would really feel condemned.

My friend Mr. Cortell, from Pittsburgh, has said quite frequently that there is more safety per square foot in the Pittsburgh area than any place in the United States. I cannot agree with him. I want to say that there is more safety per square foot in the Allentown district than any place, I believe, in the whole world.

Now, why are they obtaining such remarkable results? Briefly, simply because every man from the general manager on down to the fellow in the ranks is 1,000 per cent strong for safety always. They are obtaining these results by proper safeguarding, by education, proper medical facilities, etc.

A. E. SNODGRASS (Louisville Cement Co., Louisville, Ky.): We are not members of the trophy club but we have a record of thirteen months without an accident. The reason why we are not in that bunch of plants is because we endeavor to get it within a calendar year.

We have our regular monthly meetings and discuss the near-accidents, and it is very amusing to hear the men talk about those accidents which might have been serious but which got by without hurting anybody.

One of our men spoke about putting three or four tons on a one ton chain block, and they put it up to the foreman: "If you saw your men putting a three or four ton block on a one ton block, what would you do?" The foreman said, "I'd tell them to go ahead this time but don't do it any more."

This gentleman's remark impressed me that we are playing in mud rakers. In other words it's the frequency that we should work on. We had 608 accidents in 1926 and one lost time accident; and in 1927, we had 354 accidents of all kinds and one fatality. So it is the number of near-accidents or minor accidents that is the barometer. In other words we had 354 chances and killed one man, and we had 608 chances in 1926 without killing a man. So, I think, as the gentleman who preceded me says, it is the number of chances we take rather than the severity that measures our progress.

An Exception to the Word "Luck"

G. E. DAVIS (Universal Portland Cement Co., Chicago, Ill.): I cannot help but take exception to the word "luck" being used in accident prevention. If we are going to accept it as luck, we had better stop right now. Accident prevention and the reduction of accidents must be the result of work. We must get behind this movement. We must reach the working man.

We all realize that we must start at the top, with the management. We have been doing that for the past twenty years in the United States Steel Corporation. Start right at the top and go right down through the superintendents and the foremen. That is the key to success, but you must get down to the man himself, and that is the question and the problem today—how to keep interesting the man in safety?

I often tell our men that there is a right way to do everything. There is a right way and there is a safe way, and we keep working to that end, working to prevent all accidents no matter what they are.

H. W. HEINCICH (Travelers Insurance Co., Hartford, Conn.): May I reply to that gentleman? I know that I have difficulty in expressing my thoughts, but I am quite sure that the audience in general hasn't taken the same interpretation of my remarks that the gentleman has. However, it may be so and I would like to repeat again I most certainly agree with this last gentleman who has spoken.

Accident prevention is not luck, not by any means. Accident prevention is not luck, not by any means. Accident prevention is a science. It is based upon known laws, and boiled down to its simple fundamentals, it is nothing but finding the cause of a certain trouble and removing that cause if possible.

What I did say about luck, however, was just this: That once the accident happens, which we gentlemen are here to prevent not through luck but through work

—once that accident has happened, its degree of severity is largely a matter of luck.

A. J. EALES (Bessemer Cement Corporation, Bessemer, Pa.): With regard to that, I take exception. I think there is such a thing as luck. While we want to cut out accidents and are working for that, the only accident we have had this year in the cement plant was when a laborer from outside came in to work on the fountain. He put in some cast iron pipe and there was a small piece on the pipe that we wanted out. We just knocked that chip off and it struck one of the workmen in the eye and laid him off for a month. I might call that a luck accident. It was done by an outside man entirely. It loses us a chance for the trophy this year, and that might be luck.

A year or two ago, I saw a safety film showing the method of grating and chaining a hole as we used to do in our quarries. That is take four pieces of fuse and a stick of dynamite on the end and drop it into the hole. That was shown as a safety practice. Until two years ago, we had a man doing the same thing. He had been doing it for six or seven years when one day something attracted his attention and he didn't drop the stick of dynamite in the hole and it went off in his hand and killed him.

We have changed that now. We have a small battery to lower the charge down in the hole and then set it off.

In the early part of the discussion, the mental attitude of the workers was mentioned. We don't know the mental attitude of the worker in this particular case. After he was killed his fellow workers said, although he had been handling that job for six or seven years, he was always afraid of the dynamite. He always figured that he would be knocked off with it. We never knew that or we might have changed it.

A short time after the accident occurred we had a man in the packing department who was riding a car down to the packing house and he sideswiped another car and the man claimed that he had his one leg crushed between the two cars. It did not show any bruises or any damage to the limb at all, but yet he would not put the foot to the ground at all. Feeling that the best thing to do was to have an x-ray taken, we loaded him in the car and took him to the doctor to have an x-ray taken. He screamed when we carried him in the x-ray room and put him on the table to have the picture taken. I waited for the picture to be developed and it showed no break at all. I said, "There are no bones broken and you are all right." He got off and walked to the car and went right back to another car. This shows the mental attitude of the men which you must take into consideration. There are some men whose mental attitude is strange.

The fellow is an excellent worker and we kept him on the job. About two weeks ago he got some cement dust in his eyes. It was taken out locally but still he claimed there was some in his eye, and so I said, "We'll load you in the car and take you to town to an eye specialist." We took him to an eye specialist and he said there was nothing there. He put a few drops in his eyes and the man went back on the job satisfied.

So there are mental attitudes that we must take into consideration. Otherwise, we will get some real lost time accidents.

We have been very fortunate in the accidents in our quarry although we have had some fatal ones. We have been trying hard for the trophy and we rather seem to have a different spirit entirely. Last year we had one accident which cut us off from the trophy. We had one this year that cuts us out.

We had a case where the local doctor said he could not get the chip out of the eye. We took the man downtown to the doctor and the steel wasn't magnetic enough and we couldn't get it out with the magnet there. So we took him over to Youngstown where they have a larger magnet, but they weren't able to get it out either. The eye specialist suggested taking the eye out and said that was the only thing that could be done. This was over twelve hours later and no infection had

set in so I wouldn't let them take the eye out. That afternoon we took the man to Pittsburgh. They put him under an anaesthetic, turned the eyeball out and took the particle out and that man has his eyesight today.

MISS J. A. WEEDE (Jay & Portland Cement Co., Egypt, Pa.): I am awfully sorry to have to get up, but I see the doctor isn't here. You have to know all the inside story of a case in order to appreciate it.

The eye is a very delicate organ, and while the one eye may be all right, there is such a thing as having an injury in the other eye and by sympathetic action it is possible to lose the sight of both eyes simultaneously.

An Unfortunate Accident in the Quarry

G. W. BROWNELL (North American Cement Co., Hagerstown, Md.): I just want to say a word in connection with the element of luck. We have three cement and lime plants, and after plugging mighty hard for safety in 1925, we were awarded the safety trophy. In 1926, our Berkley quarry operation was awarded that trophy, and then again in 1927, our Security Mill operated from January first until November sixteenth without a lost time accident. The accident that made it impossible for us to finish the year as a member of the trophy club was undoubtedly due to bad luck. Again this year we went up until July thirteenth. It was Friday, July thirteenth, without a lost time accident.

In the case this year it was the safety man who lost his life. The first thing in the morning, about six-thirty just before the pillars and shuttle operators went to work, this man being accustomed to go over the place and look for dangerous spots in stone, was at a place where there were several over-hanging stones. He was standing above them prodding down with about a ten foot rod in, I believe, the most approved safety manner, and the stone he was standing on slipped.

About three or four ton of material, of clay and stone, dropping from above, wouldn't have been a hindrance had he been over a little ways and only thirty feet up the face, but he went down with that slide and a small stone, comparatively small—probably a cubic foot—hit him and gave him internal injuries and he died five hours later. I contend that was luck. The man had a reputation for safe working. He was doing a safety act and doing it in an approved manner. I think that was bad luck that kept our Security Mill from finishing any year to date as a member of the trophy club.

MR. HARRISON: One November, we ran 27 days without an accident and the engineer one day stuck his finger in the releasing lever. That ruined the November accident record. We thought we could obtain a clear record during December but on the second of December in going through the engine room, I asked the chief engineer how the accident had occurred and he stuck his finger in it and we had one more accident and one demonstration.

I have read Mr. Heinrich's paper on the Origin of Accidents, and I think anybody reading that article will thoroughly agree with Mr. Heinrich.

(Chairman Town resumed the chair.)

CHAIRMAN TOWN: I think that we will all agree that these discussion periods are highly interesting and educational. It occurs to me that we may possibly have fallen short in a measure from the amount of good we might have obtained, had we laid out our lines of discussion in certain definite directions, and possibly appointed a man to start a discussion along certain definite lines which had been causing the greatest trouble and perhaps been conducive to the greatest number of accidents around the plant, and then drawing out of the discussion ways of preventing those accidents. That possibly could have been worked out in a satisfactory manner and may be something for the Program Committee to think of for next year's session.

A. J. EALES (Bessemer Cement Corp., Bessemer, Pa.): Where we have a free open discussion we hear the other fellow's accidents and they logically come one from the other and I think we get further ahead that way than assigning subjects.

CHAIRMAN TOWN: Just the way they have done this afternoon. Then there is one other thing that occurs to me—one afternoon is far too short for discussions. They are certainly very interesting and much good can be derived from them.

A. C. GOOD (American Limestone Co.): I would like to voice a protest which I understand was made at your meeting this morning, and that is that the future meetings of the Quarry Section and the Cement Section not be held at the same time because there are many of us who want to attend both and we cannot.

CHAIRMAN TOWN: I think that is a very timely remark. As you say, it was mentioned this morning and I believe it will be possible for the Program Committees of the two sections to confer with each other and concur in the program arrangements which will enable those of either section to attend interesting parts of the meetings of the other section.

Is there anything else to be brought before the meeting adjourns?

I feel that this has been a very helpful session and we look forward each year to making the program more and more interesting.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Chemical Section

New Section Officers

General Chairman—DR. LEONARD GREENBURG, U. S. Public Health Service, Yale Medical School, New Haven, Conn.

Vice-Chairman (In Charge of Program)—C. F. WHITEMORE, Western Electric Company, Chicago, Ill.

Vice-Chairman (In Charge of Membership)—E. C. ROGERS, The Grasselli Chemical Company, Cleveland, Ohio.

Secretary—G. E. MINSHULL, duPont Rayon Company, Buffalo, N. Y.

Poster, Slide and Safety Kink Committee Chairman—GEORGE H. MILLER, E. I. du Pont de Nemours & Co., Wilmington, Del.

Publicity Committee Chairman and News-Letter Editor—JOHN ROACH, Deputy Commissioner of Labor, State of New Jersey, Trenton, N. J.

Industrial Poisons Committee Chairman—S. E. WHITING, Liberty Mutual Insurance Company, Boston, Mass.

Engineering Committee Chairman—A. L. ARMSTRONG, Eastman Kodak Company, Rochester, N. Y.

Statistics Committee Chairman—CARL F. COFFELT, Victor Chemical Works, Chicago Heights, Ill.

Executive Committee: THE OFFICERS AND

S. H. KERSHAW, National Safety Council, Chicago, Ill.

I. V. KEPNER, Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.

J. S. SHAW, Hercules Powder Company, Wilmington, Del.

PROF. C.-E. A. WINSLOW, School of Medicine, Yale University, New Haven, Conn.

H. C. PARMELEE, Chemical and Metallurgical Engineering, New York City.

DR. H. E. HOWE, American Chemical Society, Washington, D. C.

L. A. DEBLOIS, National Bureau of Casualty & Surety Underwriters, New York City.

C. E. RICE, The Dow Chemical Company, Midland, Mich.

WILLIAM A. BAXTER, The Newport Company, Milwaukee, Wis.

H. L. MINER, E. I. du Pont de Nemours & Company, Wilmington, Del.

RALPH O. KEEFER, Aluminum Company of America, Massena, N. Y.

M. W. SCHWARZ, Consulting Chemical Engineer, New York City.

Retiring Officers

Chairman, DR. LEONARD GREENBURG, U. S. Public Health Service, c/o Yale Medical School, New Haven, Conn.; *Vice-Chairman*, C. F. WHITEMORE, Western Electric Company, Chicago, Ill.; *Vice-Chairman*, E. C. ROGERS, The Grasselli Chemical Company, Cleveland, Ohio; *Vice-Chairman*, C. E. RICE, The Dow Chemical Company, Midland, Mich.; *Secretary*, WILLIAM A. BAXTER, The Newport Company, Milwaukee, Wis.; *Poster, Slide and Safety Kinks Committee Chairman*, H. L.

MINER, E. I. duPont de Nemours & Company, Wilmington, Del.; *Membership Committee Chairman*, E. C. ROGERS, The Grasselli Chemical Company, Cleveland, Ohio; *Publicity Committee Chairman*, CARL F. COFFELT, Victor Chemical Works, Chicago Heights, Ill.; *Industrial Poisons Committee Chairman*, S. E. WHITING, Liberty Mutual Insurance Company, Boston, Mass.; *Program Committee Chairman*, C. F. WHITEMORE, Western Electric Company, Chicago, Ill.; *Engineering Representative*, A. L. ARMSTRONG, Eastman Kodak Company, Rochester, N. Y.; *Statistics Committee Chairman*, C. E. RICE, The Dow Chemical Company, Midland, Mich. *Executive Committee*: THE OFFICERS AND S. H. KERSHAW, National Safety Council, Chicago, Ill.; I. V. KEPNER, Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.; J. S. SHAW, Hercules Powder Company, Wilmington, Del.; DR. C. L. REESE, American Institute of Chemical Engineers, Brooklyn, N. Y., c/o E. I. duPont de Nemours & Company, Wilmington, Del.; PROF. C.-E. A. WINSLOW, School of Medicine, Yale University, New Haven, Conn.; JOHN ROACH, Deputy Commissioner of Labor, State of New Jersey, Trenton, N. J.; H. C. PARMELE, Chemical and Metallurgical Engineering, New York City; A. L. WATSON, The Koppers Company, Pittsburgh, Pa.; DR. H. E. HOWE, American Chemical Society, Washington, D. C.; L. A. DEBLOIS, National Bureau of Casualty & Surety Underwriters, New York City.

October 1, 1928

LEONARD GREENBURG, Ph. D., Chairman
U. S. Public Health Service, Yale Medical School
New Haven, Conn.

The first session of the Chemical Section at the Seventeenth Annual Safety Congress was called to order at one-thirty o'clock by the chairman, Dr. Leonard Greenburg, United States Public Health Service, Yale Medical School, New Haven, Conn.

CHAIRMAN GREENBURG: It is hardly necessary for me to welcome the members of the National Safety Council to this meeting. To our guests we extend a most cordial and hearty welcome and hope that they will take a most active part in the discussions at all of the meetings.

The Chemical Section is but one of the activities of the National Safety Council as a whole. It is well to bear in mind the fact that the Chemical Section does not belong to the officers of the Chemical Section, to the chairman individually or to the officers collectively. The Chemical Section is your section. It belongs to each and every one of you individually. If the Chemical Section is going to accomplish a great deal in the next year it is going to do it because each and every member of the Chemical Section contributes some little bit to the help and support that the officers and the people who correlate all these activities require.

Safety Prospers Through Cooperation

I can't emphasize too strongly the fact that the Chemical Section requires help from everybody interested in safety in the chemical industry. To all of the men who act in the field with the everyday problems of safety and the prevention of the minor as well as the larger accidents, the Chemical Section appeals for help and advice.

I want everyone here to feel, and the officers of the section have asked me to call your attention specifically to the fact, that at this session and every other session you are free to discuss any one of the papers on the floor and contribute such ideas to the discussion as you seem to feel are pertinent.

During the past year the Chemical Section has made fair progress. Certain parts of the work flourished very well and other parts seem to be highly deficient. We had an excellent mid-year meeting at Newark, N. J. I think the attendance was about 150. The discussions appeared to be very well rounded and we received favorable comment from it. Based on last year's experience as well as the experience of previous years we are going to have another mid-year meeting. They usually take place in about March or April. We feel that the mid-year meeting is an important contribution to the safety movement in the chemical industry because it carries the message of safety to each particular locality. When we have a meeting here in New York it is difficult for the people in the Middlewest to take an active part; but if we can go to Chicago or Akron and have a Chemical Section meeting we bring the problem right home. It seems to us that this should be continued in the future.

Safe Practices Pamphlets in Progress

The production of the Safe Practices Pamphlets has been very successful in the past year. We have one or two of these in progress at this time and after we get a few minor points adjusted we will be in a position to release these at once. The monograph on safety in the Chemical Industry, which has been under way for some three years now, is slowly but surely coming to a finish. We hope it will be ready for the press early in 1929.

On the other hand, contrasted with these achievements, we have had poor success with the *News Letter*. The *News Letter*, by the way, is the medium by means of which we try to pass out to all the individual members of the Chemical Section the inner workings of the Chemical Section during the previous month or two. The *News Letter* must be written by some one who is in intimate touch with affairs as they progress during the interim, therefore it falls back on some one who is taking an active hand in Chemical Section matters. Unfortunately, that person is usually pretty busy and it adds another duty to his long list. But we must do something constructive about the *News Letter* this coming year in an attempt to keep all of the members in closer touch with the progress of the chemical industry.

Increasing Membership Adds Experience in Safety

I must close by asking that every member of the Chemical Section attempt to bring in as many new members as he possibly can. It is only by increasing the number of members and the facts as to how to prevent accidents in the chemical industry that we can pass the good word around and continue to bring down the rate for accidents in this very, very rapidly growing industry.

This afternoon we have one speaker, Dr. Parmelee; and after Dr. Parmelee's talk we are going to have a round table discussion on safety in the chemical industry. The primary object of this discussion is to allow everyone to exchange ideas about his problems. We hope everybody will take part in this second discussion. It is primarily intended so that everyone can benefit by the other fellow's experience and so that everyone can tell us about the unique happenings in his plant which have either made accidents or circumvented them.

It is a great pleasure to introduce Dr. H. C. Parmelee, editor of *The Journal of Chemical and Metallurgical Engineering*, whose long experience has certainly given him an extended and broad view of what each of us see as smaller problems in our own field. Dr. Parmelee has just been abroad where he has been in intimate contact with developments on the continent, and I am sure he will have something very interesting to tell us.

Safety in Chemical Engineering

By Dr. H. C. PARMELEE

Editor, The Journal of Chemical and Metallurgical Engineering,
New York City

One of my editorial colleagues likes to compare his job with that of the forest ranger who climbs to the lookout tower to get a broad view of his surroundings. Of course there are times when an editor—like everybody else—wants to keep his feet on the ground. But for this occasion I should like to detach myself as far as possible from the very important and practical details of safety work in chemical plants in order to view the broader problem of the industry as a whole.

Chemical manufacture involves, in addition to many of the common problems of all manufacturing industries, at least three types of hazards that are peculiar to the chemical engineering group, due largely to the character of the chemical raw materials used. Perhaps the most inherent hazard of chemical manufacture is that of poisoning caused by human contact with toxic material. In the case of vapors such as benzol and cyanogen, the poisoning is through the lungs. In the case of many other products, such as aniline, cyanamid and lead compounds, entrance to the human system is through the skin or through the mouth. The second type of hazard is from burns caused by corrosive liquids. In its entirety, this assumes a very serious menace.

The third, and in many ways the most serious of the chemical hazards, is that from fire and dust explosions.

For all three of these types of hazards, we have built up in this country a tremendous mass of knowledge of prevention as well as adequate physical machinery and equipment for putting these preventive measures into practical effect in our industries.

In the field of occupational poisoning, the studies of the United States Public Health Service, of the various state and local departments of health, and of various independent agencies, have been of immense value. The National Safety Council itself has played a most important role in effecting the practical application of these studies to manufacturing conditions. I am reminded immediately of the splendid cooperative work of your Committee on Benzol Poisoning. Considerable credit should also be given to intelligent management in the industries involved and to the manufacturers who have perfected safety devices and various mechanical safeguards to chemical plant hazards.

Judged by the tremendous loss in life as well as property, the fire and dust explosion hazard commands most serious study. A recent estimate based upon census figures is that 28,000 plants in the United States employing over a million persons and with an annual production of ten billion dollars, are subject to the hazard of dust explosions. In this field the splendid work that has been carried on for a number of years by the Chemical Engineering Division of the U. S. Department of Agriculture under the direction of D. J. Price, has given industry detailed technical knowledge of all of the factors involved in this important problem. Dusts and fumes have been catalogued according to their explosive characteristics. Oxygen and air ratios for safe operation are known. Simple tests have been devised which any chemical manufacturer can use in his own plant to determine whether or not a hazard exists in his manufacturing operations. And for those who are not willing to devote even this minimum attention to the problem, the Department of Agriculture has offered to test the explosive characteristics of any sample of dust sent to it by manufacturers and to report on the preventive measures that should be employed.

I am reminding you of this information and equipment because I believe that its availability places a serious responsibility at the door of the chemical industry.

Unless the chemical industry itself is willing to put its own house in order by applying this information and equipment in its own plants, it may very well expect to be forced to do so by governmental order. Self-regulation is always to be preferred to bureaucracy—no matter how intelligently or sympathetically the latter is applied. We have only to cite the foolish obstacles that the prohibition bureau has at various times placed in the path of legitimate chemical industry to appreciate the withering influence of government regulation. This sort of thing is going to spread unless industry is on its toes to prevent it. Witness the case of the so-called "caustic acid act" that a recent session of Congress put on the statute books of the country. Designed presumably to protect the woman in the household who buys a can of lye from the corner grocery or a bottle of muriatic acid from the drug store, the bill actually contains provisions so broad in character as to penalize established industry in the inter-plant exchange of chemical raw materials. Had the chemical industry protested effectively against this measure, it might very well have prevented this encroaching of bureaucratic control and inspection.

I have in mind another example which strikes a little nearer home with some of us. In May, 1925, the manufacturers of a well known brand of anti-knock motor fuels voluntarily withdrew their product from the American market because of an opposing public opinion, fanned by a hysterical newspaper crusade against its alleged hazard to the general public. An elaborate and costly investigation was made by governmental authorities and after about eight months, the company was permitted to sell its product provided it observed certain rules and regulations set down by the United States Public Health Service. This loss of business and handicap in regaining the good will of the public would have been avoided had the manufacturer anticipated the necessity for a regulation in the sale of the product.

In this case the manufacturer was penalized because he failed to recognize responsibility to the ultimate user of the product. I recall a similar instance a few years ago where a type of fire extinguisher—inherently dangerous for use in fighting a fire in a closed space—was used with disastrous consequences in extinguishing a blaze in one of the New York subways. Had the manufacturer taken the proper precautions, the extinguisher would not have been sold for this purpose. On the other hand, we do often see industries that offer remarkable examples in handling dangerous commodities. By properly recognizing the hazard and taking the necessary precautions, the explosives industry has an accident rate that is less than soap making or coal-tar distillation.

Another chemical industry just now in development offers a real opportunity for safety work and is already making remarkable progress in this direction. I refer to the new era of high pressure technique that has its principal application in the air-nitrogen industry and in the synthesis of methanol. Operations in these processes frequently use pressures ranging up to 4,000 lbs. per square inch and sometimes mounting as high as 1000 atmospheres (15,000 lbs. per sq. in.). As these reactions are carried out in the gaseous stage and as the temperature ranges as high as 700 deg. C., it requires little imagination to foresee the effect if only a single joint were to let go. And in addition these extremely severe conditions are often complicated by difficult corrosive problems. This explains in part why these processes have only recently attained special importance. Of course they have had to wait on proper development of the processes themselves and upon favorable economic conditions, but the impossibility of equipping such plants up to the last few years has been a strong deterrent.

Now, however, the metallurgist has provided the chemical engineer with new materials which retain strength at high temperatures and pressures and in addition resist corrosion to a degree which practically precludes equipment failure from this cause. Such are the chrome-irons and chromium steels. But even with

the material available, the present rapid increase in high pressure processes could hardly have occurred if the technique of fabrication had not kept pace with the improvement in constructional materials. As an example, it is now possible through improvement in welding, both electric and oxy-acetylene, to construct vessels which may be tested to the actual elastic limit of the metal whereas with riveted construction, joint leakage, so serious as to amount almost to failure, would set in at perhaps half this figure. Welded vessels may be tested to actual destruction and thus permit improved design. They may be tested to give any desired factor of safety and retested from time to time to insure continued safety of the operation. With this improvement in fabrication there have also been developed methods of testing that permit the maker and user to know that this equipment is safe. This scientific, intelligent inspection may point the way to worth while precautions in many older industries.

In closing, I would summarize these remarks by emphasizing again chemical industry's many responsibilities as far as safety is concerned. Its economic responsibility is not to be ignored. Any safety program pays directly or indirectly. Some pay immediate returns in eliminating waste and recovering products of value. Other dividends come indirectly through lower insurance premiums for these are or should be based on the results of actual experience. But greater than any other is the ethical responsibility. A chemical executive can, with his stockholders' assent, take any chances he pleases on property or equipment but just as soon as his gamble involves the possible loss of a single human life, he violates his industry's responsibility to the general public. You men through your control of this safety function have the means of building or destroying the position which American chemical industry holds in the public esteem. The responsibility is in good hands if you continue the intelligent, progressive work of the chemical section of the National Safety Council.

CHAIRMAN GREENBURG: I am sure we are very grateful to Dr. Parmelee for his very interesting and cautionary discussion. There is evidence that there is a growing tendency among chemical manufacturers in putting out new products to test the toxicity of these products before they are put on the market. Such is the case with two new products. I happen to know and there must be a great many more.

Dr. Smith, of the University of Pennsylvania, who happens to be here, has done considerable work along these lines testing the poisonous qualities of new chemical compounds being put on the market for industrial organizations.

Dr. Parmelee's very timely warning about high pressures and corrosive substances at high pressures should be borne in mind by every one who is interested in producing products by these methods.

I think that perhaps we lull ourselves into a feeling of security when everything goes well. We have had a recent example of this in New York City where the subways carry ever so many people with a very high degree of safety and only here recently a disastrous accident took place. It just means one thing, and that is that we must always be on our toes watching for the slightest break in what the surgeon calls his aseptic technique in order to prevent disastrous accidents taking place.

This subject is open for discussion and if anyone desires to contribute we would like to hear from him. I am sure Dr. Parmelee will be happy to answer any questions that arise in the mind of anyone.

R. O. KEEFER (Aluminum Co. of America, Massena, N. Y.): I was wondering if this would be the proper time to inquire if any of the men here have had experience with pitch dust explosions recently, or will that come later?

CHAIRMAN GREENBERG: That may possibly come under the round table dis-

cussion of safety, but if anyone has had any experience with it, perhaps he will tell us of it.

MR. KEEFER: That is coal tar pitch, 110 degrees.

CHAIRMAN GREENBERG: Have any of the coal tar people here had experience along these lines? I am afraid we can't answer your question, Mr. Keefer.

If there are no other questions, I will turn the chair over to Mr. John S. Shaw, manager of the Safety and Service Division of the Hercules Powder Co., Wilmington, Del., who is going to lead the round table discussion.

(Mr. Shaw assumed the Chair.)

CHAIRMAN SHAW: Gentlemen, this is rather an experiment. They tell me that they have never opened an informal meeting like this before. You should all feel free to discuss your problems and to ask questions. We will try to find the proper authority to answer them.

I am going to call on John Roach, Deputy Commissioner of Labor of the State of New Jersey, to tell us the status of the chemical industry today in regard to accident prevention from the viewpoint of the labor commissioner. Mr. Roach!

Observes a General Improvement

MR. ROACH: I think there has been a great improvement in the general working operations in plant administration and in a sympathetic plant policy toward accident prevention in the chemical industry during the seventeen years that I have been connected with the New Jersey State Department of Labor.

I don't mean to imply that the industry now is so safe that the rating board would be warranted in placing it in the same column with some of the other risks that are rated extremely low because of the lack of physical exposures, but I do say that at least in our state, chemical production is carried on in a large way on a large scale, plenty of capital back of the industry, with engineering departments organized and developed to investigate the safest methods of industrial procedure, so that a very large part of the industry is covered by the very highly skilled supervision that naturally reflects itself in a low accident frequency and severity.

Of course, the chemical industry is a little different from some of the other industries where unusual hazards are not present. It has its structural risks, its exposure to complicated and dangerous machinery, and the risk that comes from the employment of labor that perhaps is not overly intelligent and oftentimes can't understand the language of the supervisor. Then, in addition, we have to remember that the chemical industry has the risk that comes from handling poisonous, explosive, and corrosive substances that are unusual in themselves and of course offer a greater form and variety of accident possibility than most industries.

I know, through the operation of the numerous safety councils and the very intelligent engineering service that has been afforded by many of the insurance carriers in the state, a general plant policy seems to prevail, and the chemical industry of our state inspires the management to provide competent and satisfactory supervision. I would say that this is a matter of major and primary importance—intelligent, comprehensive, and satisfactory plant supervision. Where it is lacking, accidents do result, and then the moral responsibility for those industrial tragedies can't be avoided by the management.

You might say, "Well, what is meant by plant supervision?"

I was in a chemical plant some time ago where evidently there hadn't been plant supervision. It was during the extremely hot weather. One of our men discovered that in this particular plant a 1500-pound drum of phosgene was located in the open, exposed to the blistering glare of the sun. The plant manager wasn't even aware that the fluid developed pressure from heat above the ordinary room temperature, with the result that unless we had corrected that kind of supervision

the chances are that that drum would have burst and an accident would probably have resulted.

You can't get away from good plant supervision. If you don't have that in industry, all the other precautions that may be adopted are visibly neutralized.

In the old days we worked in a chemical plant and found all kinds of machine exposures. They didn't seem to know that men were liable to accidents from gears and exposed belts; but they do now, and I think if we were to traverse the state from one end to the other that we would find very few dangerous machine exposures.

After plant supervision and the application of machine safeguarding, then, I would say, we must go back on safety education, because if we can't get the man or the men as a group, as a unit, to back up the effort that the supervision has made, we can't expect to avoid accidents in the chemical or in any other industry.

Of course, if a plant manager just says, "Mike, don't breathe that stuff over there, it is poisonous and will hurt you," and the fellow is an ignorant workman who hardly understands the language, that kind of warning is worthless in the extreme. But if you warn the men properly that substances are poisonous, that disobedience to shop rule is dangerous, and you get the men to back up the movement, you are going to make the chemical industry safe in our state and other states, as safe as any other industry that is in the state, because outside of these poisonous substances I can see that there is nothing so inherently dangerous in the chemical industry that we shouldn't expect that after a proper length of time has elapsed in safety work that accident rates will be cut down to an irreducible minimum, below which, of course, we can't normally expect to go.

I heartily endorse the statement made by the previous speaker that the industry should not put out poisonous substances without due warning to the public. It is wrong to do it. It brings a black eye to the industry itself; it discredits us in the minds of normal, sane, thoughtful people, and it certainly works an incalculable hardship on those manufacturers in the industry who want to do the square thing by their labor and by the public as well.

CHAIRMAN SHAW: I am going to ask Mr. Louis DeBlois to talk to us on the same subject. About a three-minute talk, Mr. DeBlois, please, on the subject from the viewpoint of the underwriter. Mr. DeBlois is of the National Bureau Casualty Insurance Underwriters.

The Viewpoint of the Underwriter

MR. DEBLOIS: To the best of my memory, the compensation insurance rates on chemical industries in general are about flat.

Now, I would like to impress upon you one or two points in reference to insurance rates. In the first place, they do absolutely reflect insurance experience. However, there are two factors entering into that experience: one is the number of accidents, the other is the cost of the accidents.

We know that the average cost of accidents under compensation laws is on the increase, due to a variety of causes. So that if a rate maintains rather flat, that is doesn't change much from year to year, the chances are that the frequency is coming down somewhat and the severity also. That may or may not maintain in the chemical industry.

Another fact to be borne in mind is that insurance experience on which the rates are based is always about two years old, so that the present rates do not reflect current experience, but rather, past experience. So that if the chemical industry goes ahead, as I believe it is going ahead, in the reduction of accidents, and will continue to make the very fine progress it has in the past, the rates unquestionably, I think, will come down.

I could say this (I believe the insurance men who are present, company insurance men, will support this statement) that is that insurance underwriter engineers are not alarmed about the chemical industry as they are alarmed by the experience in some other industries—the construction industry, for example, where there is a very distinct upward tendency, and where we know the great body of construction men have not yet taken the accident prevention matter very seriously.

I was concerned to some extent with a recent national research in the relationship of safety in production made by the American Engineering Council under a financing by the Bureau which employs me. The chemical industry was one of the industries examined, and my recollection of the results of that study (and by the way, if you are not familiar with them you should be; they are published by Harper Brothers, under the title "Safety in Production," I believe) is that the chemical industry standing absolutely reflects a correlation between accident prevention and accident reduction, and production efficiency; that is, production per man-hour. You know yourself that efficiency of production, high efficiency of production and accident reduction are both reflections of good and efficient management. The management that can get one gets the other. You can't have one without the other. We all know that.

Now, just a few other points briefly and I am through. To the inherent difficulties in accident prevention in the chemical industry which Commissioner Roach mentioned, I would like to add two. One, the fact that the chemical industry is in a more or less non-stable state. It is in the process of development. When you have any industry which is being developed rapidly you have a danger introduced through the introduction of new processes which have been magnified, have come up from the laboratory scale to the experimental scale and then put on a large production basis. While the most intense care may have been taken to develop safeguards in the laboratory and perhaps in the semi-work scale, when you get on this big scale production you have a multiplication of factors and you may still have very serious hazards which you haven't safeguarded; and I think that is one of the reasons why the chemical industry has an inherent hazard.

The other one is, as we all know, in many chemical processes the amount of mechanical maintenance is higher than in many other industries. The equipment turnover is higher, there is more repair, more maintenance work. Maintenance is inherently more dangerous. It always introduces out-of-the-ordinary conditions where you need a higher degree of supervision, a higher degree of workman intelligence, and a greater interest and foresight on the part of the workman himself in accident prevention.

I can say, Mr. Chairman, that from the little I know of what has been done by your section in the last two or three years, and from what is being done by the industry in general, I, for one, feel absolutely certain that chemical safety is going ahead by leaps and bounds. I think you have the most flourishing group in the National Safety Council, considering its growth from a mere handful of men up to what it is today as represented by this meeting.

CHAIRMAN SHAW: We want to get some experiences, some stories of happenings or mishaps and narrow escapes, or preventive stunts. Some of you men have very interesting stories to tell. The time is going to be limited. I will ask you to cut your stories down to under three minutes as much as possible. But before we go into those stories, I see that Mr. John Spicer of the Department of Labor of the State of Pennsylvania has come in. For his benefit, I will explain to him that we have been discussing the status of accident prevention in the chemical industry at the present time. How is it in your state, Mr. Spicer?

MR. SPICER: I think there is a general trend toward reduction in our state. Beginning this month we are planning to intensify that reduction if possible, by a thorough organization in the state with the help of our department.

The latter part of October we expect to hold a meeting of all safety engineers in the state, and beginning on the first of January, put on a state-wide drive for no accidents.

We feel that we are going to get results. During the past three months we have been receiving reports from individual plants telling about their accident reductions, and in many cases these are appreciable in amount.

I think I can safely say that we are showing very good progress in Pennsylvania.

CHAIRMAN SHAW: You noticed that stress has been placed upon the importance of education. Some persons estimate that preventable accidents run as high as 90 per cent through education. That is, mechanical safeguards can't touch about 90 per cent of them. Dr. Parmelee stressed education, so did Mr. Roach.

To my mind it is little short of criminal for any of us in a supervisory capacity to fail to bring to the workman absolute knowledge in the form of simplified detail of his processes, the machine or whatever he is working with on his job. I have found it possible and practicable to teach workmen chemistry. They grasp it very quickly when you reduce it to simple terms. So when a new process goes in, when a change is taking place in operation, why not, first of all, think: What is the hazard to Bill (or whatever his name is)? Let's go and talk to him and explain the whole thing to him. Let's tell him what happens when these two chemicals come together; whether or not they generate positive or negative pressure. What will be the accident? How should he take care of it to control the apparatus and process and play the game so that he can be as safe on his job as anybody else?

Along that line, Mr. A. L. Armstrong, of the Eastman Kodak Company, has an interesting story to tell us illustrative of the unforeseen. It is the supervisor's duty to anticipate accidents. It is a shame that men have to be hurt in order that we be cautious. Mr. Armstrong will give you his story.

MR. ARMSTRONG: The accident I am going to tell you about happened in Rochester about four or five weeks ago. There were three fatalities and, I guess, up to fifteen seriously injured.

I believe it is the practice throughout the country to handle sulphuric acid in drums. This company, in order to prevent shutting down a process, stored four drums of sulphuric acid, 92 per cent, on the third floor of a building. There was no water, no shower baths provided there. The bungs in the drums were loosened.

They had been there just a year when the workmen started to move them. Two of them were taken out safely. When the third one was lifted it blew up. The man at the end of the drum was knocked forward. He stood against the wall and the drum head hit him and threw him head first into the acid. His head was nearly eaten off. The other chap was covered with acid and died from exposure. The third one was burned so badly that he died in the hospital. There were three or four others who spent quite a time in the hospital.

The thing that happened apparently was that there was some reaction on the drum. In fact, we ran experiments afterward and weighed our drums and found that drums which we were using for 92 per cent acid, after being used a year lost fourteen pounds. We figured that there was a reaction with the acid on the iron, and hydrogen probably formed, and some people have the theory that there was a spark struck when the head of the drum was blown out and that it ignited that hydrogen because there was a terrific explosion.

Dr. Greenburg spoke of the *News Letter*. I have talked to several people about this accident, and no one that I have talked to has had any experience of that kind. Just as soon as I knew about it I wrote John Shaw and Mr. Kepner, of the Pennsylvania Salt Company, and I talked to everybody that I came in contact with to see if we couldn't get some information, see if somebody else hadn't had that experience. No one seemed to know anything about it. I think the *News Letter* for that sort of thing would be of untold value.

In other words, I think you have to carry this program farther than the men. I think many of us would be benefited a great deal if we could get that kind of education. I think one of the best possible ways to get it is to have it come through the *News Letter*.

CHAIRMAN SHAW: Mr. Armstrong, what would you recommend to prevent the recurrence of such an accident?

MR. ARMSTRONG: We have designed a blowout plug for drums which are to be stored for any length of time. That is just an ordinary, extra-heavy black iron nipple with a cap. We cut the center out of the cap and put a piece of tinfoil between a lower and upper gasket. We have tested this device and found that it blows out at twenty-five pounds. So it would be perfectly possible to tip the drum over and not have an accident that way, that is, by having acid spilled on someone, and yet, if there is any pressure generated the tinfoil would blow out.

I might also add that we had a similar experience, although it was not a blowout, when we had a ventilation line plug up several years ago on our large acid tanks. The acid screens didn't take out all of the cotton and some of it started decomposition, heat and pressure were generated and the ventilation was plugged, and this ordinary blow tank (you all are probably familiar with it) stretched at the top just about two inches. If any of you come to Rochester we would be glad to show it to you. It prevented a terrible accident. One of the men went up two flights of stairs and opened another vent on the pipe. If it had not been opened nothing could have stopped it and it probably would have ripped the side of the big tank open, and you can hardly estimate the damage that would have been done in this case.

We have put in all of our blow tanks a sheet of aluminum. That sheet of aluminum is about ten inches in diameter and one-eighth of an inch thick. It is cut around the edges of the gasket and blows out at forty pounds. They have to keep their pressure down below forty pounds or they blow that out. However, those things should be inspected. They are like anything else. They must be inspected very often.

We also use that same type of blowout on some of our vacuum stills where we do crystallizing. We had one of those blow out.

There has been a lot said about pressure here today, but I think one point should be brought to the workman, and that is this: The workman (and I think I might also add a lot of the supervisors throughout the country) does not appreciate what twenty pounds of air pressure means on a drum or on a container. All they think of is twenty pounds. They don't think of twenty pounds per square inch. We have blown up ordinary oil drums with eighteen pounds pressure. I think the time is coming when we will have legislature in this country that will absolutely prohibit the handling of materials by compressed air. Other countries have it now. They have entirely eliminated the handling of any material in that manner.

CHAIRMAN SHAW: We have pressure generated through chemical action just as with the drum. We always have to deal with pressure and watch out for it and provide for the elimination of it, even though we may handle chemical liquids by pump suction, and so forth.

S. W. GURNEY (Liberty Mutual Insurance Co., Boston): I would like to ask if there was any evidence of the pressure in the drum. Was there any bulging in the head?

MR. ARMSTRONG: No. There was absolutely no evidence of it.

MR. GURNEY: I have known a number of cases where pressure has been generated by acid of that strength in steel drums during a period of long storage, but in all cases they showed evidence of it by a bulging head.

MR. ARMSTRONG: This was split down about eight inches. I saw the head before anything was disturbed. They called me in. It was not our company,

understand. It was another concern that had the accident. They called me up immediately and I saw the drum and the head before it had been moved, and the head was perfectly flat. That was the first thing we looked for.

MR. GURNEY: Ordinarily a steel drum would show quite a bit of bulge before it would give. I have known of a number of cases where they have shot a rifle ball through the head rather than run that risk.

MR. ARMSTRONG: I think that would be true if the drum is eaten thin at that point. However, apparently this drum was weakened at the top. The reaction was above the acid level and the drum was weakened at the top and that point where it was weakened opened up, I would say about twelve inches at the end of the drum and ran back to the hoops. It looked as if the drum was weaker at the top than it was at the end.

S. W. ASHE (General Electric Co., Pittsfield): I don't know but that I might have one idea that might be of a little value. With the modern tendency of using gases and other high pressure materials in manufacture, naturally we get pretty big concentrations of energy. That means that when these things let go the severity of the accident is great, and we have fatalities, just as happened in this particular case.

Mr. Byer, a number of years ago, made quite a study of accidents and their causes. Out of that he brought out two rather important things. One was that the frequency of accidents was dependent largely on the amount of educational work you carried on, and the severity of accidents was largely dependent on the amount of safeguarding you did. That is, you couldn't say do one rather than the other, for each of these things had its own definite function. Therefore you can see in the modern trend of going up to these great concentrations of energy that the job really is largely one more of management than it is of the employees. It comes down largely to one of inspection and close supervision and the careful study of those things, and the development of proper safeguards for the elimination of these very serious things. I simply wanted to leave that one idea with you because we are always placing so much stress on the value of educational work and how 95 per cent of accidents are caused by carelessness, yet when we get into problems of this nature, it seems to me the problem of controlling it rests very largely with the management itself.

E. C. ROGERS (Grasselli Chemical Co., Cleveland): I was dragged into this accident that has been referred to, and I have seen the drum that Mr. Armstrong described. The history of that thing goes back to last October when that drum was filled in cool weather. It blew up in August in a room where the temperature was over 90 degrees. No one knew or could tell me how much acid had been put in the drum, or whether an outage had been allowed, although from examining the two other drums that were still in position, it was seen that they had allowed about a four-inch outage in those two. No one could check the drum that had exploded, of course.

Now, there must have been considerable expansion in that acid, filling the drum in cold weather and letting it go on into hotter weather. It was a standard 5-A drum, built to I. C. C. specifications, and I am positive there was nothing wrong with the drum. There was no evidence of bulging in the head.

It seemed to me that there must have been two explosions, the first one a hydrostatic explosion due to the expansion of the acid, ripped the horizontal seam about half the length of the drum, perhaps a spark being caused and setting fire to the hydrogen, causing a second explosion that came so quickly upon the other that it seemed like one explosion.

That drum had been stored with the plug up, and according to the manager of this plant the plug had been loosened, allowing a vent, but after the explosion it was quite a task to remove that plug because of the formation of sulphate that sealed this vent and created, I should imagine, a terrific pressure.

If that drum had been vented every week as it should have been, I don't believe there would have been an explosion. That brings us down to this. We have had papers written and read in this section covering that very same point—papers that have been broadcast and published in various chemical publications. We have Safe Practices Pamphlets. But I have just been wondering whether this section ought not to try to do more to broadcast information concerning the storage of such explosives; whether we shouldn't consider the issuance of data sheets covering the safe handling of those materials in a concise form that could be posted in an acid-consumer's plant, and in that manner try to broadcast knowledge not only of this one commodity but every dangerous commodity.

Another thing, acid drums are not made primarily for the storage of acid. They are made as a shipping container solely, to be emptied more or less frequently and to be tested more or less frequently. That drum was two years old and it never had been tested.

CHAIRMAN SHAW: That was very interesting, Mr. Rogers. I agree with you that a shipping container should not be used as a storing vessel.

Is there anyone else?

LUKE H. SPERRY (Hercules Powder Co., Hennil, N. J.): This has led us to be in accord with the idea that our accident is due to the personality of the men and not to the condition of the apparatus with which they work.

A long time ago, out in Colorado, there was a group of immigrants who came to a river whose bed was full of quick sand. They went in and were lost to a man. The Spaniards who were occupying that part of the country at the time accordingly named the river. They didn't call it Dead Man's River. They called it Rio de los Santos—the River of Dead Souls.

It seems to me that our problem is not one of everyday education but one of the stimulation of the imagination. The trouble with our men is not that they are careless; they are not intentionally careless. The trouble is not that they do things that they should not knowingly do, but the trouble is that they don't think ahead; they don't use their imagination.

In our plant we don't talk of falling missile hazards any more; we speak of widow makers, and it seems to have a wonderful appeal to the imagination of the man who is supposed to be careful of overhead falling missiles.

I just want to make this clear: The stimulation of the imagination of your workmen! Because I think along that line lies a wonderful path toward increase in safety.

R. A. POOLE (Carborundum Co., Niagara Falls, N. Y.): I want to go back to the remarks of the previous speaker, Mr. Rogers. He said he thought the company sending out these drums should give instructions with the drum.

We had what would have been a serious accident from hydrochloric acid in a rubber lined drum. Evidently the lining gave way. A man went by and saw what looked like a cloud of thin steam coming out of it. It got him in the side of the face and he was painfully but not seriously burned. We immediately got in touch with the manufacturer and then they gave us directions as to how to handle it. Had they, when they sent the drums in the first place, given us instructions on how to handle that type of acid in those drums, we never would have had that accident.

I. V. KEPNER (Pennsylvania Salt Mfg. Co., Philadelphia): Getting back to the story of drums and drum explosions, about four years ago in Wilmington I brought up the subject of drum explosions. We had one in our plant. We had some old drums that had been washed and stored empty. A year or so after that we had occasion to ship some sludge which contained caustic liquor from our Daytona plant in the western part of the state, to Philadelphia. We had about eighteen of these drums loaded with this sludge, and they were being rolled into a car. There were fourteen or fifteen, (I don't recall which) that had been rolled

into the car, and the next drum, which I think was the sixteenth drum, exploded.

We never have found out what caused that explosion. It just brings to my mind how necessary it is, after a drum has been used, to clean it thoroughly, and I doubt very much if it isn't good policy to destroy those drums, using almost anything else but an acetylene torch to do it.

I merely bring that up to tell you that from that time on we have never used any old drums for anything else except mixed acid.

CHAIRMAN SHAW: It seems to me right there that a suggestion to have a thorough and periodic inspection would be of value, and after all, the great stimulant for thorough inspection is imagination. I can't imagine a man with an investigative nature who hasn't a lively imagination. When the imagination dies we are asleep. So of course the imagination is a very important thing in safety work. There are many things that are delightful in ferreting out when you are looking for causes. It is really happy work.

One of our small arms smokeless experts discovered some very fine particles of steel in the small arms powder. Nobody could identify these particles at first; nobody seemed to know where they came from. But the imagination of that man carried him from New England to Virginia, where he found that when they were baling purified cotton linters, just prior to wrapping a bale in nice white wax paper so that the cotton would carry through uncontaminated to another plant where it was to be converted to nitrocellulose, these bales were being brushed and combed with little steel brushes, and little particles of steel were coming off of that brush. That never would have been discovered if it hadn't been for imagination.

That gets away somewhat from chemistry and the chemical industry. Of course, it is part of the chemical industry, but it gets away from liquids and pressures, and so forth.

There are lots of stories like that, experiences that you have had. Who has something to give us on the handling of solids?

R. O. KEEFER (Aluminum Co. of America, Massena, N. Y.): I raised this question a while ago to get some information, not to give it. But the way you have put this last statement reminds me that somebody might be interested in our experience along this line.

In making carbon electrodes we use this tarred pitch that I spoke of which is very pliable. Our company has used this pitch for twenty-five years without any trouble whatsoever, and I am certainly safe in saying I believe that nobody with even the slightest imagination after twenty-five years of experience would have foretold that we should have a fatality due to explosion of this pitch dust. But we had it, and about a year later we had another in another one of our plants, and last year I heard about this pitch dust exploding in the Steamer Richelieu in Baltimore Harbor.

The initial pitch dust explosion in our plant took place under special conditions, as most first-time accidents do occur. It happened that the bucket elevator conveying this pitch to a high storage building broke down during the night shift.

This bucket elevator was a belt type of elevator and the belt, of course, fell with the loaded buckets to the bottom and they laid there until the morning gang came on and started to fasten up the belt. Of course, half the buckets were filled with pitch when the elevator broke. The rigger gang, for the most part, were stationed at the top of the elevator casing, but two members of the gang were at the bottom holding an electric light inside the casing and were threading the belt upward so that the buckets would be facing the proper way. The belt was practically lifted up to the top of the pulley when both it and the tackle broke and the belt fell. It broke the electric light bulb and also severed the lead wires to the light. I don't know whether it was the broken wires or the light that caused the trouble. I believe that Mr. Price, who was mentioned before, has since deter-

mined that a broken bulb can ignite dust if it is mixed with the proper amount of air. It was followed by a succession of explosions and a series of flames which set fire to the man's clothing and before they could be extinguished the man was burned to a crisp. His helper was very seriously injured. Fortunately he was not set on fire.

There is an accident, I think, that nobody would imagine could happen, especially after twenty-five years of experience had not shown the danger. Since that time, we have investigated these pitch-dusts and find that they are even more explosive than coal dusts, and we are now safeguarding all equipment to relieve any pressure which may be built up.

CHAIRMAN SHAW: Mr. Keefer, do you always use vapor-proof conduit for your wiring and vapor-proof globes?

MR. KEEFER: Yes.

BERNARD TRUXLER (Kendall, N. Y.): In regard to the cleaning out of drums, I recall an incident some twenty years ago when we had occasion to solder a spud on to an alcohol drum of about 250 gallons capacity. It was formerly used for alcohol. The drum was supposedly washed out with water and it was thought by the mechanic that it was perfectly safe to solder on this spud. The drum was washed out but it was not completely filled with water, thereby not removing all of the vapors. Therefore I just want to mention that it is very important to completely fill the drum so that you remove any vapors in order to make it absolutely safe.

CHAIRMAN SHAW: Right there we come to the cleansing of chemical apparatus. So many hazards arise from improperly carrying out the work of cleansing the tanks, and so forth. There is sometimes a hazard which is not apparent to the workmen. Some gas which he cannot smell, has practically no odor but a very high toxicity. He may or may not have been cautioned about it and because of the lack of odor he may not believe the danger to be there.

For over twenty years we have been cautioned that nitrous fumes are very dangerous. The victim in a great many cases doesn't know that he is receiving a fatal dose until it is too late.

I would like to ask Mr. George Miller, of duPont's, to tell us what he knows about poisoning from nitrous fumes, and give us his suggestions as to preventive measures. I understand the cure is almost hopeless, therefore what preventive measures can be employed?

G. H. MILLER (E. I. duPont de Nemours & Co., Wilmington, Del.): I imagine there are a lot of people who know more about nitrous fumes than I do, but, unfortunately, I know of two recent experiences that may be of interest to you.

In one case the acid was brought in contact with water when cleaning and the man inhaled the nitrous fumes. In the other case two men were washing out a tank that contained mixed acid and inhaled nitrous fumes. Both men were killed by the fumes, or rather, both of them died some time later.

I don't know what part of this subject Mr. Shaw wanted me to discuss. I don't know anything about the medical phases of this problem.

As far as the preventive phase of the subject is concerned, it is impossible to say what concentration of nitrous fumes are harmful, in a way that will be comprehensible to the average working man. We know, of course, but we can't tell the working man so that when he encounters those fumes he will recognize them as being harmful concentration.

In the two cases I have just cited, one was with the duPont Company and the other with a competitive company. It seemed to me that the only instruction to be issued to the men was to immediately leave the scene when any concentration of nitrous fumes were present and not return until they had put on suitable protective apparatus such as gas masks. Such instructions have been issued by the

duPont Company before, but we have again called attention of the plants to it and in probably a more forceful way than we had heretofore.

L. H. SPERRY (Hercules Powder Co., Hennil, N. J.): This is a very live question in the industry that uses a great deal of mixed nitrous acid. We have made it an absolute rule that we won't put a man in a tank which has contained nitric or mixed acid unless it is absolutely unavoidable. We have gone to the extent of cutting holes in tanks so that we can reach in with hoes and hoe out any mud that resists washing out. At the same time we play a fire stream from the top. The only time that we countenance putting a man in a tank that has had mixed acid in it is in case some other man had actually gotten in and it was a case of saving life. In that case, of course, we would take the precaution to lower the second man fully protected by a life line, and if possible, if time permits, with an adequate mask. But under no circumstances would we think of cleaning out a tank by putting a man in as an ordinary routine or repair proposition.

C. E. SEVRENS (Merrimac Chemical Co., Boston): Both the previous speakers spoke of gas masks. What kind do you use? There isn't one designed for nitrous acid.

MR. MILLER: First, I want to dispose of a statement which I probably made. Those men were not in the tanks—not inside. We wouldn't send a man in a tank, whether he had a mask on or not. I think most companies have very rigid rules outlining practices that are to be followed with the tanks. I know that the duPont Company has, and I would be very glad to send anyone who desires it a copy of our pamphlet in regard to safety practices in handling tanks, which we have practiced thoroughly.

S. H. KERSHAW (National Safety Council): Going back to the remarks made by Mr. Sperry and Mr. Rogers, the rousing of the imagination and the furthering of information are two of the fundamentals of success in accident prevention work. There is no question about that in my mind. A successful safety engineer has to have a very vivid imagination. He has to be thinking about the things that other people are apt to overlook.

In line with that, the National Safety Council is striving to do all it possibly can to disseminate information. We of the National Safety Council, of course, service the *National Safety News* which is useful for that purpose. We have various sectional news letters; we have posters which are useful for posting on the bulletin boards and serve to convey ideas and arouse the imagination of the men on the jobs. We also have payroll slips. I could go on and list any number of things, but what I want to talk about particularly is our Safe Practices Pamphlets. Most of these which have been issued in the past have been of a more or less technical nature. They have been designed to be helpful to the supervisors and to the managers of plants. The pamphlets, I think, have filled a very great need; but we are trying to carry the work considerably further.

Just recently our Petroleum Section undertook to develop a series of safe practices pamphlets; I think there are forty-eight subjects to be covered, and these pamphlets are designed to be given to the men on the job to furnish them with ideas as to how to take care of themselves in doing their work.

The first two or three of these pamphlets were published a short time ago, and within a few weeks of publication orders were received for something like 12,000 copies. They are very new but are going fast. In other words, there seems to be a need for just such pamphlets.

I am not prepared to say that the Chemical Section can undertake just that; because of the industry that is to be served; but there is at least a germ of an idea. It is working very successfully in the Petroleum Section.

There is one other thing I might mention: Aside from the posters and payroll slips, there has not been very much in the National Safety Council that could be turned over to the workers. But very recently a little pocket size magazine entitled

"The Safe Workers" was brought out. Due to the fact that it can be printed in very large quantities, the council offered to provide this service to the members at very small cost. I might say that one company, for instance, is giving out 17,000 copies of that magazine to its workers every month. The magazine is so small that we can't hope to go into technical discussions or anything of that sort, but I think it is perhaps a contribution in the line of arousing the imagination of the men, and I think it is filling a very important place.

There is just one more thing. I don't know whether or not you know it, but we have at our headquarters office the largest library of safety literature in existence today. We have a staff of four librarians and we have a staff of quite a number of engineers. All the members of the National Safety Council have a consultation service involving the use of that library and the talent of all of our engineers is available; we want the members to make use of that service. There is no extra charge for it, it is a part of the regular service to council members. Queries come into the office. We handle about seven hundred a month, and they are routed through the office.

First they go to the librarian. Every available bit of information on the subject of the inquiry is taken from the files of the library. That is turned over to one of the engineers who is best qualified to handle that subject. He goes over the literature carefully. If the problem is answered in the literature he either incorporates it in his answer by letter or else he sends that literature to the member. If the answer is not to be had in the literature he immediately tries to find out the members to whom he may go for accurate information on the subject.

In other words, the purpose of the council is to collect and disseminate information. It is the desire of the officers of the council that every member make the utmost use of that service.

C. E. SEVRENS (Merrimac Chemical Co., Boston): Getting back to nitrous gases again, I will tell a couple of experiences that we had. One was cleaning a tank at the top of the battery tower. We had a colored man and a white man working at it. During the day they simply cleaned out the small amount of sludge which is in the bottom of the tank, and they went home at noon time, reporting no ill effects of any kind from the work. That afternoon we received word that the colored fellow had passed away. We immediately checked up the white chap and found that he was suffering some but he didn't seem to be suffering a great deal from the effects of the gas.

We also had another occasion where a black man and a white man were working in a tank and we had the same thing occur to the colored chap. It is evident to us that the colored chap is more susceptible to nitrous fumes than the white chap might be. I don't know whether anybody else has had a similar experience or not.

Another thing that we don't want to lose sight of is the fact that sulphur dioxide fumes can be quite serious. We had a case recently where a young fellow came in to a change and unbeknown to the foreman the chap had quite a heavy cold. He said nothing about it and went to work. The clean gas so irritated that cold that pneumonia set in and he was gone in four days. So that is another thing that it probably might be well to watch out for.

CHAIRMAN SHAW: Prevention, gentlemen, is the stunt.

Mr. Chase, of the Atlas Powder Company, might tell us something about the precautions they have taken against nitrous fumes poisoning.

A. N. CHASE (Atlas Powder Company, Landing, N. J.): We had a case in one of the plants which leads me to believe that the question of the susceptibility of a man to fumes is a very important factor.

Two men were working on an outdoor tank, washing it out with water, and one of them had opened the tank and worked through the worst of it and came through all right with no ill effects. Another one who was sent in to help him, because we knew that the work was dangerous, was dead before the next morning. Afterward

we found that this second man within about two months had had a rather severe attack of flu, and it is very apparent that he was easily susceptible, even to a small amount of gas. The first man who undoubtedly had breathed a good deal more of the gas was in no way hurt, as was determined by examination.

We use the gas masks in all work now where a man is exposed to a possibility of coming in contact with it even in outdoor work, because on damp days or even where there is a shed, the fumes will hang down around the men in spite of the fact that we try to get away from it; and it is the accumulated effects that cause the gradual breaking down of the lungs.

CHAIRMAN SHAW: Have we any more volunteers? If not, I take it the meeting has about run its course. Dr. Greenburg, the chairman of the section, would like to speak to you a moment before we adjourn.

(Chairman Greenburg assumed the chair.)

CHAIRMAN GREENBURG: The sum and substance of all this discussion seems to me to be this: The modern chemical plant, no matter what its nature, has certain inherent and peculiar problems of safety and health hazards, and to you gentlemen who are the supervisors of the human element which comes in contact with these hazards, to you there falls a very sacred duty. If a man is injured, or if a man suffers pain, or if a man meets death in any one of your plants, it means either that somebody has been remiss or some unavoidable accident has taken place. Now, nobody pretends to place the blame for the unavoidable accident, and there are such things) on any of the supervisors of safety or health or any of the officers of the modern industrial organization. But if a preventable accident takes place in your plant, you ought to search your own minds carefully to see whether you should be able to rest easy without making certain that such an accident can't take place again.

There is only one cure for these accidents, and that is a peculiar type of mental alertness which has to characterize the mind and the make-up of every one who hopes to keep from the stigma of causing pain and death in the plant. If you are not mentally alert you won't see these sources of accident, and you won't prevent somebody from suffering undue pain or perhaps death. It is needless to say to anybody who employs many workmen that accidents are everyday occurrences. If this mental alertness is lacking the accidents are going to be repeated.

Now, what can be done if the mental alertness is there? Backing that up you have to have a certain fundamental amount of knowledge, and that knowledge has to take such a course as to lead your effort to supervise each and every operation in your plant so as to make the accident impossible. The accident that happens once is a forerunner in the good plant of excellent safety precaution.

Next, you come to that type of accident which Dr. Ethelbert Stewart, if he were here, could tell us is an unpreventable accident. There are many such accidents. The only thing you can do about the non-preventable accident is to educate the worker. The means of education are many. They have special application in this plant or that plant. They require all kinds of means and expedients, and it is up to the mentally alert foreman or officers of the company to find out what he should do in order to educate his workmen properly.

In addition to this, a certain amount of medical supervision is necessary. It may be of a minor character, from the first aid cabinet up to something more elaborate, such as the medical facilities employed in some of the larger plants.

Lastly, you come to the other aspect of your duty, and that consists in pooling your knowledge with everybody else so that we may build up a ~~very~~ total of knowledge where everyone may enjoy the benefit of it. As Mr. Kershaw explained to you, the National Safety Council is attempting to serve as this agency for the pooling of information. It is a highly cooperative, non-profit-sharing organization, as you all know. The amount of money that each company spends is put in a general fund and expended under the direction of the Board of Directors and

the Executive Committee in a way which seems to the committee will produce the largest and best service results. Everyone is free to bring up through his sectional chairman and officers any suggestion he desires about the way in which he thinks this money should be expended. This is your organization, and if it is going to help prevent accidents in the chemical industry and promote safety in the chemical industry it depends largely, if not completely, on you.

MR. SHAW: Gentlemen, Mr. Armstrong has a little stunt that I think is too good to pass up. He is going to tell you how he gets rid of lacquer drums when they are old and unsafe. It is dangerous to burn them, and he has a little stunt which may be interesting to you.

A. L. ARMSTRONG (Eastman Kodak Co., Rochester): We have been in the lacquer game long enough so that we have had a number of drums that we had to dispose of, and the question came up what we should do with them. The first thing suggested was that we burn them, but that is rather dangerous because we found that several of them would explode. We had enough lacquer and fumes in them so that we would get a terrific explosion. So to prevent that, when these drums get so old that they are unfit for further use, we immediately fill them with water and take them out in the lot some place away from the plant and leave them there during the winter and they freeze up and burst. In the spring they thaw out and we subject them to heat and throw them into the dump.

I thought that might be of interest. That question has come up a great many times before. If anyone knows of a better scheme I would like to know it.

JAMES BRADY (Hercules Powder Co., Kenvil, N. J.): We have some TNT tanks that we destroy by filling with water. That is, we fill them up all the way. I don't believe there is as much danger from explosion when you have them equipped with a ventilator. We fill the tanks completely with water.

MR. ARMSTRONG: In answer to that I would like to say that we had an explosion with a drum filled with water, and it happened because the nitrocellulose had gotten up in close to the top where the water couldn't displace it, and when the heat was applied from the outside it blew the head out. When the lacquer drums are banged around (I don't know about your drums) they have a small space around the top that fills with nitrocellulose and it dries out hard. You can fill that up with water, but if the heat is applied from the outside you will get a slow decomposition and an explosion.

ADJOURNMENT

October 2, 1928

LEONARD GREENBURG, Ph. D., Chairman
U. S. Public Health Service, Yale Medical School
New Haven, Conn.

The second session was called to order at ten-fifty o'clock by the chairman, Dr. Leonard Greenburg.

CHAIRMAN GREENBURG: The first paper on the morning program is by Mr. J. H. Shapleigh, Chemical Engineer of the Hercules Powder Company.

Gauging and Sampling

By J. H. SHAPLEIGH

Chemical Engineer, Hercules Powder Company, Henvil, N. J.

The chemical plant has definite organized operations. Associated with them in an inseparable manner is the operating personnel. In general, chemical operations are subject to sudden, serious changes unless properly supervised and controlled. Safety is largely efficiency of supervision and control.

A properly supervised and controlled operation includes well chosen procedures covering gauging and sampling. It further includes selling that procedure to the personnel in such a manner that cooperation arises. An operation so conducted and established appreciates the benefits derived from safe gauging and sampling.

Gauging and sampling is a daily performance in our industries. Properly performed it is not a routine operation, although it is often so regarded. It is a procedure having more potential risk than one usually classed routine. It is this element or risk that makes the subject worthy of review.

Gauging is carried out to determine a condition with reference to capacity. The safe capacity may refer to a quantity of liquid, solid or gas. If gas, gauging is related to pressure. If liquid, it is likely related to level. In either case, the object is to facilitate the safe handling or storage of material.

To fail in properly gauging material may cause tanks to overflow, burst or even collapse. Every one is familiar with the picture presented by spillage. One sees the floors covered with a liquid, possibly fuming sulphuric acid, or molten nitre-cake. Fumes are all about. It is likely dripping through the floor below. Workmen are rushing here and there, warning those below. Others are frantically trying to stop the flow of acid or other material. Opportunity for accident is all about. The overflow is stopped and the clean-up process begins. The hose plays water upon the material. Sputtering caused by water on acid begins. Acid particles fly and fume rises. Then, finally, it is cleaned up. What has been the result? Possibly acid burns on the face or body. Possibly burned feet or hands; perhaps more serious, all the result of improper gauging.

Elimination of these happenings, which everyone engaging in operating practice has seen, requires the adoption of a gauging procedure. Since gauging molten nitre-cake is different from gauging oleum or from gauging an organic chemical, it is readily seen that a study of each particular gauging problem becomes necessary.

With each problem, there is associated a definite number of chances for accident. These should be known and provided against. For example, goggles may be called for to protect the eyes against a spurting liquid. Rubber gloves may be needed in the case of handling nitric acid. Shielded sampling points may be required for protection against gaskets giving way. These possibilities should be studied and if found present, protection must be provided as a part of a gauging plan.

Gauging procedure requires consideration of many phases. For instance, a study of mechanical conditions surrounding equipment; chemical effects upon mechanical equipment; physical effects upon chemical properties, and combined effects as related to the human equation.

A detailed consideration of the individual case should result in the selection of a method best suited to the conditions prevailing. Then, there is required a plan for effectively putting it in use.

Real benefit is derived from the adopted procedure only when cooperation exists. This must be obtained from the personnel by selling the procedure to them. They must realize it is for their benefit. Forced adoption does not breed cooperation and does not bring about the safe conditions sought. Hence, the educational program is a definite part of gauging.

To provide the personnel with a procedure without schooling is to make gauging a routine operation and subjects the personnel to possible accident through lack of knowledge of conditions. It should be emphasized that the entire personnel can be subjected to unsafe conditions through lack of knowledge of the individual.

The educational work in a particular case may be minor. If so there can be no objection to giving the workman that minor degree of added protection. On the other hand, if the amount of schooling to be done is large, then there is no question but what the hazard warrants it.

Both the study and the educational work should consider possible unsafe conditions from factors such as: temperature, pressure, flammability, corrosiveness, volatility, sensitiveness to reaction with other materials such as water or other chemicals; susceptibility to freezing and separation; presence of contamination; toxic or noxious vapors and gravity.

It is desirable to touch upon some of these factors. Effects produced by temperature are of extreme importance. Change of temperature affects corrosion; volatilization; condensation; creates pressure; causes vacuum; freezing and expansion.

Molten nitre cake is a good example of a material where temperature is important in gauging. This material is pumped around at 500 degrees to 600 degrees F. Not only is it corrosive but it has an immense quantity of heat stored in it. Consider, a process wherein this material is used and let us assume the material is gauged periodically. It is extremely important to keep that material where it belongs through gauging, but to what unsafe conditions can a man be exposed in this case which are outside his immediate gauging problem. First, let us assume the man gauging is helping in the filling of a storage for molten nitre-cake. His part is to determine the quantity to be received and to see that only that quantity is received. To do that, he must be nearby, at least.

Now, let it be assumed that pumping has started, and that molten nitre-cake is on its way. What can happen? Nitre-cake starts at say 550 degrees F. through warm lines but not hot ones. First, it must heat the lines; then they must expand tremendously due to the change in temperature. This expansion has broken many lines, causing streams of molten nitre-cake to pour out. These in turn have caused fires.

However, in this case, let it be assumed that the batch was delivered safely, and some time later a second batch was started on its way. Possibly this batch is going to be switched to a different storage by valve changes. Experience has shown that a wall of hard nitre-cake will build up against the previously closed valve within 15 minutes and although the valve has been opened, the line is now blocked; the fresh hot nitre-cake will not melt it before it overflows from the first point possible and again a spill occurs.

One more illustration of a temperature effect: Let it be assumed that the previous pump line has had access to air over several days of idleness and that the line through insufficient slope is one-third full of solid material which picks

up considerable water from the air. Again, molten nitre-cake is started through the line. The solid material in the line is heated. The water present turns to steam, thereby increasing in volume; a pressure results and nitre-cake is sent forward at a tremendous rate. If there is a vent in the line, the material will be thrown from the vent until the pressure relieves itself.

During these happenings where is the man gauging? Is he still there, or is he on the way to the hospital? In any case, temperature conditions require careful consideration.

A brief summary of other effects is as follows:

Corrosion weakens mechanical equipment; it causes gases to be formed that are highly explosive. Volatilization can cause pressure; it can produce toxic or noxious gas. Condensation may promote corrosion; it can cause partial vacuum. Either pressure or vacuum can cause rupture or collapse of equipment. Freezing may cause cracking, or it can produce critical operating conditions. Expansion can cause rupture, or otherwise weaken constructional material.

Installed equipment is carefully chosen to safely withstand definite conditions. It so happens that such equipment is sometimes placed in a service for which it was not designed. Gauging such equipment is safe only when a study shows the equipment satisfactory for that service. If the service is not proper for the equipment with a wide safety factor and is still used, it is necessary for the critical conditions to be thoroughly understood.

No more important effect is related to gauging than corrosion. The tank, or other container of material, connecting lines, sampling and gauge connections are all subject to corrosion. Careful consideration must be given to the material stored, or in process, and to its corrosive action upon the container walls and connections.

Whether it is active equipment used in a process, or storage equipment, those employed in gauging are subject to accident from corrosive action. It follows that not only should those so engaged be thoroughly alive to the dangers of corrosion, but they should be constantly on the watch for signs of structural weakness. In following this policy, they not only protect themselves but their fellow workers.

Volatile liquids are subject to vapor pressures depending upon temperature conditions. Due to losses involved in storing such liquids, safety seals are generally provided. If the rod method of gauging is used on such a storage it involves having a gauging connection. Upon the removal of the gauge cap, the excess pressure sends out vapors. The built up pressure is slight, due to the safety seal eliminating it, but where the escaping vapor is likely to be inhaled, an unsafe condition exists. An example is ammonia liquor and such materials should be protected from excess temperature, thereby reducing volatility. Covered storage is provided for this material.

The mechanical condition of equipment to be gauged is of direct interest to those employed in gauging. Equipment has a natural life and should be replaced at stated periods. Knowing the mechanical condition of equipment to be gauged is knowledge that should be shared by the personnel, and dangerous equipment should be carefully approached. For instance, the condition of gaskets and pipe threads are illustrative of everyday troubles.

Pressure is used for moving bodies of liquids. An illustration of where pressure and gauging meet in common practice is the blowing of acid eggs by air and the receipt of the material in storage. Sometimes a workman attempts to blow into storage and to gauge while blowing. In so doing he is exposed to the rush of displaced air, but suppose the egg is blown completely while he is gauging. Then the entire built-up air pressure rushes into the storage tank. As a result, much of the material has been known to leave the storage by both gauge opening and vent. Of course, gauging, should not be attempted in that manner, but the after blow can be reduced. Many times the after blow is prolonged due to the size of the air

line feeding the egg or blow case. An orifice plate in the air line will reduce the air inflow and will allow the after blow to quickly reduce to low pressure flow, which can be handled with more leisure.

Pressure can also be built up by increase of temperature in closed tanks. The sun shining upon tank cars containing readily volatile materials is an example. For a workman to gauge such a tank without releasing the pressure is likely to cause serious injury.

The man employed in gauging is open to various injuries unless precautions are taken. He is open to toxic poisoning and asphyxiation, where even small gas concentrations exist. H_2S gas is one example of a material that can kill a man without his realizing the state of his affection. Such gases should not be allowed to escape into closed places or where good draft is not present. Equipment containing vapors such as H_2S should be under suction and connected with a stack for disseminating the gas over a broad area. The atmosphere will then reduce it to a harmless concentration.

Where a man must enter a gas area of toxic concentration he should be equipped with a mask and properly filled canister. Incidentally, the man gauging should understand the use of the gas mask and have one available, as it sometimes happens while gauging that mechanical troubles will cause an abnormal flow of gas or fumes and serious injury can be caused in attempting repairs.

In gauging the eyes are subject to splash, spray and fume in many locations. A more general use of goggles is needed.

The hands are very susceptible to injury through the handling of samples, and sampling and gauging equipment. Gloves are needed more generally for use in such service.

Every now and then, one hears of the death of a man through coming in contact with the 110 volt circuit. The man gauging is handling wet materials and usually working around equipment that form good "grounds," particularly if wet. He also is the user of the extension light. The combination requires extreme care and it is far better to equip the gauging and sampling points with an adequate supply of light.

The examples emphasize that those employed in gauging should be taught to have a wholesome respect for the potential risks existing. They should understand that their information is for the purpose of operating the plant in a safe as well as an economic manner for the personnel employed.

Having considered in some detail conditions surrounding gauging it is desired to select a method for use. There are a variety of methods, both crude and refined, and again the individual case calls for the one most suitable.

The following methods are subject to consideration: The float; pneumatic methods; the sight glass; the measuring rod.

For a particular case, a method should be selected that is well adapted to the conditions existing and which offers a proper degree of safety. For instance the "float" may be deemed desirable to use. This method is justified after proper assurance is had that conditions are reasonably safe and extreme reliability is not required. Where positive gauging is required, the float is not recommended. The float has, however, very useful application in automatic gauging and pumping, and if accompanied by further protection it serves many good purposes. Floats are used in this manner as warning devices, but too much dependence should not be placed upon a single float. They are susceptible to sticking and are not reliable where much is at stake.

Pneumatic methods have extensive use and are theoretically sound. However, in the chemical plant where conditions for their use are naturally difficult, limited use of pneumatic methods is found. Homemade pneumatic equipment in inexperienced hands is particularly to be guarded against, as there is a very great chance that trouble will occur.

A word can be added here as to the principle of the pneumatic method. If a pipe is installed vertically in a tank of liquid, with the bottom end of the pipe open, and then air is forced through the pipe in just sufficient quantity to cause bubbles to pass through the liquid, the pressure required to displace the liquid within the pipe is a measure of the depth of liquid present.

The difficulty of using this equipment in the chemical plant is not with the method but with the equipment used and its maintenance. If for instance, the air valve is one that will not allow a sufficiently small quantity of air to pass but instead a real flow, then the pipe resistance becomes a factor and the correct reading is not obtained. With such a condition the reading will vary with the depth of the liquid in the tank, but it will not be the correct reading and can cause serious trouble.

A small hole corroded through the pipe will also cause incorrect readings. Mud around the base of the pipe is likewise troublesome.

The use of this method requires that it be understood and it is more confusing than the more common ones. Even at their best pneumatic equipment must be kept free from corrosion, from blockage and improper use. The chemical plant is not the place for obtaining such constant conditions. However, there are exceptions, and if conditions are right, pneumatic gauging is very convenient.

The application of pneumatic methods to storage tanks or operating equipment where safety-overflow pipes have been provided is a very useful one. Other examples can be found where the method provides a satisfactory gauge upon operating conditions. Such installations are well justified, but caution is urged against the use of the pneumatic method for positive measurement without first thoroughly investigating the equipment to be used and the care with which it is to be maintained.

The sight glass has very broad use. From its very nature it is installed with a connection below the liquid level. For this reason it requires careful installation which includes protection for the glass. A valve between the gauge glass and container should be provided as further protection and also as a means of allowing repairs to be made when necessary.

The method is quite safe and insures positive gauging where properly adapted. There are cases where the gauge glass is susceptible to freezing. If so it can be protected against freezing without difficulty. The major objection to the method is not in the glass itself, as the glass has proved its value; but in the "below the liquid level" connection. For critical gauging the sight glass should not be used.

Gauge glasses can be obtained that have been tested under 1,000 pounds pressure. They are glass and if cracked in use glass splinters can be driven a considerable distance by the contained pressure. Where pressure is used, safety screens should be provided. These permit easy reading of the gauge and at the same time protect against flying glass.

The measuring rod is a long established institution. Where other methods fail, it functions. There is nothing scientific about it. For that reason, it is such a simple method that it is available for wide use. On the other hand it requires care, as every other method does; but with a moderate degree of care it gives positive results.

This simple method is probably the most exact one in use. Where the material being gauged is such as to cause uneasiness, due to its nature, the method gives maximum assurance of correct gauging.

The method has its limitations. It is an atmospheric pressure method. For measurement under pressure one of the other methods must be used.

From one of the above four types of methods, one can be applied to a given case, which will give positive gauging. It is through positive gauging that safety is realized. Hence, it follows that gauging is a matter for careful thought and wise decisions.

One must sample gases, liquids and solids, and a great variety of attendant conditions exist. Of these, pressure and temperature conditions are particularly important. The chance of accident while sampling requires similar care be taken in organizing sampling as in gauging.

Prior to deciding on sampling methods it is good practice to consider the material to be sampled and the conditions of temperature, pressure, etc., present at several possible sampling locations in order to select the one most desirable. The zone of possible accident about the sampling point needs to be restricted and that zone provided with safety protection. Inspection of the location must be thorough and it should be kept in a satisfactory condition.

The sampling station should be so designed as to allow of free movement. It should allow of egress from more than one direction. Such a provision eliminates the necessity of a man passing across the line of sampling. It should be well lighted and ventilated or under suction to remove injurious vapors.

Possibly, sampling points have been seen located at the top of open tanks in which for instance soda ash was being mixed with acid solutions. At such a time, was the fan providing suction for the mixing tanks operating? If not, was it in condition for operating? Assuming it was running, what about the soda ash feed? Was that too fast for the fan to remove the CO_2 given off from the mixture. If so, how much oxygen was present immediately above the opening of the tank? Such conditions exist and sampling is done at the open top, where a man is liable to be overcome.

The sampling location should have proper ventilation. To provide otherwise caters to lack of care, a hurried job, or poor sampling. While in the latter case the object sought is not obtained, in the first two cases unsafe conditions can be either met with or created.

As in gauging, we find the question of sampling related directly to the consideration of the potential sources of trouble and how to get around them in order to safely perform the assigned task. As before, each case requires individual consideration. In one case, fumes are taken care of by suction hoods, in another, strength and choice of material provides for pressure. In each case is found a planned procedure. The personnel engaged in sampling should understand the care that has been taken to make conditions safe, and should be encouraged to know the situation surrounding their particular task.

In tap sampling, movement of equipment is usually confined to the valve. Moving equipment always provides troubles and the valve is no exception. The sampling valve can be the object of abuse; often it is the object of neglect, but it will itself depreciate. Abuse and neglect should have no place in sampling, but it has to be given consideration in the selection of the valve. All sampling equipment requires careful selection, requires watching in service and must be kept in operating condition.

In choosing equipment for tap sampling, consideration of the type of valve is important. Sometimes gate valves are satisfactory; at other times needle valves are required. Suppose, on account of pressure, a needle valve is desirable but due to contamination such as floating particles of dirt, a larger opening is desired. To provide the larger opening with pressure behind the valve is likely to result in serious injury to the man sampling. If the valve is followed up with small pipe, conditions are improved, but it is better to keep the dirt from reaching the needle valve by using a screen that can be removed for cleaning.

Simple mention has been made to "tap" sampling. The other common method is "dip" sampling. Obviously, the latter is used only in open type equipment, and safety measures relate to protection from splash, danger of falling into the open equipment, and danger from handling the sample. These conditions require planning and regulation, but the problems encountered are easily foreseen and with proper instructions and reasonable care safe routine procedure can be established.

The tap method is widely used. Trouble may come from pressure, poor mechanical or sampling equipment, inexperience, blockage, freezing, or poor sampling conditions. Inexperience implies insufficient knowledge of the pertinent facts. Blockage and freezing are quite closely related to pressure, yet there is a difference in the method of handling. Both blockage and freezing of sampling lines require great care in handling. The seriousness of a case depends upon the material handled, and the ease of handling the trouble and the type of labor used. If the blockage occurs in the handling of hot or corrosive materials the problem is serious. If pressure is also a factor, it is more so. In either case, exceptional care is necessary and a responsible man should supervise the opening of such sampling lines.

A picture associated with sampling is, a workman standing in front of his sampling line, the sampling valve removed. No sample comes forth. The workman is preparing to ram a wire or rod into the pipe to remove a blockage. Have you seen the result from such methods, perhaps the man lying in a bath-tub having his burns washed and treated.

Such accidents indicate that sampling is more than a routine operation.

Sampling under light gravity pressure should be an easy task and requires but brief mention. An experienced man knows that under such conditions a moderate propelling force exists. However, does he keep fully aware of the mechanical and physical conditions of his sampling equipment. The use of a wet sampling bottle for material that water decomposes violently is an example of a poor physical condition. Worn or corroded pipe threads inviting the breaking off of the sampling line illustrate poor mechanical conditions.

These accidents are likely to happen where the tap method is used. The dip method is practically free from these liabilities. Hence, where it can be used, the dip method has much in its favor.

Where higher pressure exists whether moderate or heavy the tap method is practically a necessity. Under pressure the chance for accident is present in two ways, first from conditions directly attendant with the taking of the sample under pressure and second due to the fact that the man sampling is exposed to conditions surrounding pressure equipment. The latter requires that he be aware of the chances existing for sudden leakage or blow-outs from gaskets, rivets, welded joints, gauge glass, etc.

The sampling line should be strong and properly braced to withstand pressure exerted upon it while opening a valve. The material from which the line and valve are made should be chosen with due regard to corrosion and fragility. Depending somewhat upon the pressure, the type of valve should be chosen with care such that the stream emitted is easily within control. Needle valves are particularly adapted for sampling wherever a fairly clear liquor is present and also if a filter or screen is provided before the valve.

The container into which the sample flows should be of a wide mouth type to allow pressure release. Where the pressure back of the stream is sufficiently high to cause splash, the sample can be drawn through a shield.

In sampling, material is likely to drop upon lower levels such as floors, and splash upwards. It may break its fall upon pipe lines and on rebound reach the face level. The eyes are then in the danger zone from indirect results. Such conditions can be remedied by installing the sampling equipment in locations either free from or specially guarded from splash.

Occasionally, sample valves will not re-seat. If the material handled is one that causes particular annoyance that way, a type of valve can be installed that is double acting. One movement will give a seat grinding effect and the other movement will close the valve.

The conditions surrounding the sampling of solids are far more favorable than with liquids.

With solids the chance for accident is largely associated with motion on a different scale than with liquids. Machinery plays an important part in the handling of solids, and sampling of solids usually implies working around types of mechanism.

In general, solids will not flow as liquids do, hence, the methods used for liquids are not suitable for solids. It is usually necessary to go after the sample, to sample direct from the path of moving solid material. If this can be done in a relatively open and well protected portion of that path, conditions are relatively safe. However, plant equipment is not usually planned with an eye to providing secure sampling locations. Too often, it is necessary to sample at inadequate locations, and here we find the quick motion of sampling in its attempt to snatch solids from in front of an approaching crushing roll, or from in front of moving rolls, either type of roll just as unwilling to distinguish between a human arm and the solids being drawn into them.

In such cases there is an obvious need for well planned procedure. Such includes safety protection at every sampling point.

Before closing this discussion just a word should be added from the economic side. First, it costs but little to organize sampling methods; second, it costs less to keep them going; third, it pays.

CHAIRMAN GREENBURG: Is there any discussion on Mr. Shapleigh's paper? Does anybody want to add anything to it? Has anyone some personal experience to recount?

G. H. MILLER (E. I. du Pont de Nemours & Co., Wilmington, Del.): I might bring out one point in connection with gauging—I don't know how widely the practice is followed but some know about it and it will be interesting to hear about it.

Gauging with a rod, of course, is attended with a certain amount of danger if a man's hand is in contact with acid, and sometimes we have used a little neck of iron with a pulley and the rod is suspended on that and is let down with a chain into the tank and pulled out again so that it is not necessary to touch the rod with your hand.

W. C. REIBLING (American Tar Products Co., Cicero, Ill.): Last year we were told of a light reducing transformer which could be put into the socket of an extension line which would reduce the voltage from 110 volts to 35. We were told that that voltage was not a hazard and would not injure a man. I have been trying to locate those socket reducers and have not been successful, and I wondered if somebody here could advise me.

A. L. ARMSTRONG (Eastman Kodak Co., Rochester): The General Electric or Westinghouse will furnish those and make up anything you want. I may be mistaken, but we use a great many transformers in different places in our plant. In fact, we use a transformer and reduce it to six volts. I am sure those transformers are purchased. However, if you care to drop me a line after the conference I will get you all the information on that you wish.

CHAIRMAN GREENBURG: Is there any other discussion or question?

If not, we will pass on to the next paper which is on "The Treatment of the Effects of Irritant Gases and of Superficial Burns." Professor Underhill, of Yale University, has had perhaps more experience with this particular problem than anyone in this country or in Europe that I know of. The problem of the treatment of the effects of gasings assumed immense importance in the early stages of the war when poison gases came into such widespread use. At that time the United States Army conducted experiments on the treatment of gassed animals; Dr. Underhill was responsible for this work. I think we are all highly privileged to have Dr. Underhill with us this morning.

Treatment of the Effects of Irritating Gases and of Extensive Superficial Burns

By FRANK P. UNDERHILL

Professor of Pharmacology and Toxicology, Yale University,
New Haven, Conn.

It is my purpose to attempt to point out very simply the conditions that are induced in the body by the inhalation of irritating gases on the one hand, and, on the other, the effects of superficial burns, and to endeavor to indicate a logical and successful method of treatment which is applicable to both these apparently unrelated conditions. It will be developed that these conditions are only *apparently* unrelated; in *reality* they are most intimately connected in their fundamental bases.

It should be pointed out that irritating gases may be divided into two great groups, one being more or less readily absorbed by the blood and producing its most potent detrimental effects because it induces changes in the blood itself (H_2S being a representative of this group), the other group containing the larger number of detrimental compounds, such as acid and alkali fumes, which are not absorbed at all, or, if absorbed, to an exceedingly limited extent only. It must be obvious that the fundamental effects produced by these two types of compounds are radically different. The effects of H_2S are primarily on the composition of the blood, changing its character and temporarily at least impairing its power to carry oxygen. With a gas like chlorine, for example, the effects are primarily on the mucous membrane of the respiratory tract and whatever change is effected in the blood must be regarded as secondary. In this discussion it is to the second type of gas poisoning that attention will be directed for the reason that it is the form most readily encountered industrially.

Let us consider for a moment the nature of the surface of the respiratory tract upon which the irritating gases produce their effects. Reduced to its simplest terms this surface may be compared to a thin, delicate, membrane separating the interior of the respiratory cavity from a rich bed of blood vessels, the capillaries. Through this membrane under ordinary circumstances there is a free exchange of oxygen into the blood and of carbon dioxide from the blood. Exchange of fluid is probably of slight moment under normal conditions. The situation is entirely different, however, when this membrane is extensively irritated. If an irritating substance comes into contact with this membrane immediately there is a very definite response to the irritating agent. In the first place, such an irritation causes a rush of blood to the irritated spot, and fluid is poured out from the small blood vessels, the capillaries, in what may fancifully be regarded as an attempt either to dilute or to wash off the irritating substance or else to keep moist the injured area. This immediate response to irritation must be regarded as a protective mechanism on the part of the body. The degree of this response to irritation depends upon the extent of injury to the membrane and upon the degree of injury to the underlying capillaries.

Under normal conditions the fluid exchange between the blood in the capillaries and the tissues is regulated in large measure by what may be called the permeability of the capillaries—the membrane of their walls allowing substances to pass only at a determined rate according to demand. If by any means this permeability is changed the fluid regulation between the tissues and blood capillaries gets out of control and abnormal conditions prevail. This is especially true when for any reason capillary permeability is *increased* and excessive fluid leaves the blood and is poured out on the respiratory membrane. When this occurs the quantity of fluid poured out may be so excessive as to fill up the lungs of the

individual—producing what is called edema of the lungs, and it has been stated that a person may drown in the water in his lungs. It must be obvious therefore that a reaction on the part of the organism which ordinarily performs a *beneficent* influence may, if out of control, prove a distinct menace to the organism and tend to produce death.

The irritating gases under consideration must be regarded as agents producing the effects just described upon the respiratory membrane. They irritate the membrane and injure the underlying capillaries to such an extent that capillary permeability is increased and fluid rushes from these vessels onto the respiratory membrane and hence into the lungs with such rapidity and in such overwhelming quantity that the lungs are soon filled and the familiar respiratory distress is then evident. This respiratory distress is at best very painful and distressing because of mere mechanical difficulty in breathing owing to the large water content of the lungs and also because interchange of oxygen and carbon dioxide is somewhat impaired. These factors are in themselves of great importance, but of far graver significance are changes which occur in the blood itself, and which must undoubtedly be regarded as the primary cause of death.

Normally, the water content of the blood constitutes one of the body's constants. Attempts to alter the water content of the blood by introduction of even large volumes of fluid have failed to change appreciably blood composition. The water regulating mechanism is adequate to make the proper compensation quickly. It is only when this mechanism is overwhelmed experimentally or as a result of disease that marked changes in blood concentration occur. Either dilution or concentration effects may then be observed, although, in general, from studies thus far carried through concentration is more commonly encountered than is dilution.

In the blood, concentration to even a moderate degree results in recognizable symptoms. The first indication noted is impairment of the circulation. When water loss becomes great the circulatory deficiency is magnified. The thick, sticky blood finds great difficulty in passing through the tiny capillaries, the circulation here is slowed and the blood is quickly robbed of its oxygen by the tissues. Because of its slow progress through the capillaries the blood becomes an inefficient oxygen carrier and the tissues in general suffer from inadequate oxygenation, resulting in partial asphyxiation. The blood vessels are not properly filled and the heart pumps only a portion of its normal volume at each stroke. There is right sided dilation of the heart. In consequence of the partial asphyxiation of the tissues there may be alteration in the metabolic processes, and when blood concentration has reached a certain level a disturbance in the heat regulating mechanism occurs: the temperature at first, elevated, falls and vital activities are suspended.

A word as to the method of determining blood concentration may not be out of place. Of all the constituents of the blood only the red corpuscle fails to pass rapidly through the capillary wall. From this viewpoint it would appear that the measurement of hemoglobin content of the red corpuscles should serve as an excellent indicator of changes in blood concentration. A consideration of this problem over a period of years has convinced the speaker that for the purpose of observing rapid changes in blood concentration the hemoglobin estimation method is unsurpassed by any other method yet proposed provided various obvious factors are taken into consideration and that the experimental conditions are adequately controlled.

There are many conditions where blood concentration may be encountered. For example it may occur when water is refused for prolonged periods as exemplified in mental derangement. Individuals exposed to the high heat of the desert or subjected to the heat of boiler rooms or of mines often show blood concentration. Vomiting induced by any cause may result in blood concentration.

In persistent diarrhoea much water may be lost to the organism through the stools. In Asiatic cholera and certain forms of diarrhoeas in infants such loss is particularly marked and may be productive of blood concentration to a degree sufficient to lead to death. In infants especially severe blood concentration is likely to occur, partly, from the fact that they have a high water requirement which may not be covered since they are dependent upon others for their water supply, and, partly, for the reason that infection may induce refusal of food, vomiting and diarrhoea, with a subsequent concentration of the blood.

Experimentally a concentrated blood may be induced by restricting water intake, by sweating, by the action of saline cathartics and other drugs.

Aside from changes in blood composition other than alteration of water content there may be another very serious effect induced by a concentrated blood, namely, a distinctly impaired functional capacity of the kidney. This organ only occasionally shows structural changes but the functional impairment lasts as long as does the blood concentration and all evidence of kidney damage disappears with the restoration of a normal water balance. This latter fact leads to the conclusion that the kidney is unable to separate a normal urine from a concentrated blood.

The impetus for our own studies in blood concentration came from experience with war gas poisoning particularly with chlorine, phosgene and chlorpicrin, in which it was shown that the intensive irritation of the respiratory tract called forth a massive edema resulting in very marked blood concentration. The intensity of blood concentration under these circumstances became so great that the heart was unable to push the sticky, viscid blood through the capillaries at a rate sufficient to aerate properly the tissues, resulting eventually in tissue asphyxiation, fall of temperature, circulatory failure, and death. Death was ascribed to the change in blood concentration rather than to pulmonary edema. From a wide experience the impression was gained that within certain well-defined limits, concentrated blood, although not compatible with proper tissue nutrition, is not necessarily a serious condition. Beyond these limits, however, life can be maintained for only a short interval. To put it differently—blood concentration up to 125 per cent of the normal values is not serious, but when 140 per cent has been reached danger enters and life is not possible for long if this limit is maintained.

These relatively wide variations which may occur without serious consequences may be regarded as another example of the factors of safety resident in the organism. That death is due to blood concentration rather than to edema of the lungs can be tested experimentally by gassing two animals with the same concentration of gas for the same period of time. Both animals will develop pulmonary edema to the same degree and both will present the same blood concentration picture. If one is treated so as to maintain blood concentration below the danger level recovery will follow, whereas the untreated animal will die. In neither case does the treatment materially change the lung condition, at least during the critical period.

If we review our discussion we find that when an irritant gas comes into contact with the respiratory mucous membrane, not only is the membrane damaged but the underlying blood vessels are also injured—their permeability is altered and fluid escapes from them to such an extent that the lungs may be filled up. This exceedingly rapid escape of fluid from the blood cannot be compensated for by the water reservoirs of the body and a marked degree of blood concentration occurs which outside of certain well defined limits is inimical to proper nutrition and even to life—death resulting from tissue-asphyxiation. So much for the mechanism of the pathological condition induced. From the practical viewpoint what can be done about it in the way of treatment?

In general nearly all the accidents met with are induced by inhalation of acid fumes and a natural inference is that attempts should be made to neutralize the acid, or the alkali, as the case may be. Such a procedure, however, cannot be

recommended. From my own experience with war gas poisoning the neutralization of these gases by fumes of ammonium salts always led to worse results than if such attempts were not made. The irritant action of the ammonia if unskillfully used may itself add an irritant action to that of the other gas so as to increase the local injury. Moreover, the ammonia would only penetrate to the upper air passages and these would not require the neutralizant, since they would be quickly flushed by fresh air. On the other hand, in the army during the war ammonia was carried in ampoules, and a few whiffs were inhaled at intervals, during the first day after gassing. The benefits were admitted, but the effects were purely *symptomatic* since ammonia acts as a respiratory stimulant usually making breathing easier and less exhausting. Some patients on the other hand are made more uncomfortable by it.

So far as attempting to alleviate the *initial* injury by neutralization such a procedure is entirely hopeless and useless. The damage to the respiratory membrane is instantaneous and once injured neutralization of the offending agent will not help or restore the membrane. Moreover, it should be remembered that the mucous membrane, being made of protein, together with the mucus present, is itself capable of neutralizing to a large extent either the acid or basic properties of the offending agent.

For first aid treatment of gas poisoning the patient should be compelled to lie down and if transportation is necessary he should be carried. Plenty of fresh air is essential and it is equally essential that the patient be kept warm. It may be desirable to allow the patient to drink water, to wash out the mouth. Usually water ingested immediately after gassing is vomited. This is not to be discouraged since any gas swallowed will be thrown out and also probably a certain amount from the respiratory tract will also be regurgitated. Rest, fresh air and warmth are all the first aid treatments that can be given without possible subsequent harm to the patient. The remainder of the treatment requires hospitalization.

In the hospital, in so far as they can be avoided, no drugs should be given. With patients with restlessness and spasmodic cough it may be necessary to administer small doses of morphine but in general morphine should be avoided if possible since it tends to depress respiration at a time when the maximum respiratory ventilation is needed to offset the diminished lung area. Attention should be directed mainly toward maintenance of blood concentration within the normal limits. By following the hemoglobin values hourly for a few hours the state of blood concentration can be ascertained. At the first hint of a concentrating blood measures should be adopted to combat this tendency. The essential feature in the stage of blood concentration is to diminish if possible the degree of concentration, and we have found by experience that it matters little how this is attained. Thus, this purpose may be accomplished by direct venous infusion of salt solution, intraperitoneal injection of salt solution or by oral administration of large volumes of water. If, however, in spite of fluid administration the blood concentration continues to mount, venesection to the extent of 500-800 c.c. should be practised and into the vein should be introduced an equal volume of salt solution. Administration of fluid by other channels should be continued until blood concentration is within safe limits. So long as blood concentration remains stationary even though at a high level, further infusion of salt solution is unnecessary and when the concentration begins to diminish the individual is on the road to recovery. Rest and warmth should be strictly maintained.

Bleeding at the proper state apparently acts as a stimulus to the body to fill up the depleted blood volume and fluid is poured in from the tissues for this purpose.

There are many other details of treatment that might be indicated but here it is only possible to give the bare outline as indicated by an understanding of the mechanism upset by the offending agent. One point should be emphasized, that is,

that when fluid is given it should be given in large volumes and continuously for at least 48 hours—so much every hour so that during the period of a day 4-8 liters should be consumed.

It seems a far cry from gas poisoning to superficial burns and yet in the latter instance the blood may be markedly concentrated and if sufficiently so undoubtedly plays a large contributing role to a fatal outcome. The proof for this statement lies in the fact that if by any means blood concentration can be prevented or abolished the chances of recovery are very materially increased.

A moment's thought will convince one that there is not a great difference in the two conditions. In both instances there is a membrane stretched between the atmosphere and the blood capillaries. In the case of the skin this membrane is covered by a horny layer, the outer layer of the skin. An agent like chlorine which would badly injure the respiratory membrane would have but little influence upon the membrane of the skin protected as it is by the outer horny layer. When, however, an agent like heat is applied strong enough to penetrate this outer horny layer then the same type of condition is induced on the skin membrane as occurs in the respiratory membrane—fluid rushes to the surface of the skin membrane and the outer horny layer is detached, the fluid pushing it up from the surface in the form of a blister or if the force is great enough the blister breaks and fluid exudes on the surface. If the affected area is great enough the quantity of fluid that may be lost from the blood in this way is very large. In animal experiments such losses in less than 24 hours may exceed 40-50 per cent of the total blood volume.

The treatment of extensive superficial burns by heat is a matter of immediate hospitalization. There are two aspects of treatment that must be considered, first the care of the wounds themselves, and, secondly, the treatment of possible systemic effects. The care of the wounds varies according to the different surgeons in charge of such cases, the prime object being to cover the surface to keep it from contact with air, etc., to prevent infection, and to leave as little scar as possible. This phase of treatment is outside our sphere. On the other hand, in our opinion the most serious complication to be anticipated is the systemic effect, namely, a rapid marked concentration of the blood.

Our experience with the treatment of the systemic effects of superficial burns was gained as a result of observations carried through on more than twenty victims of a theatre fire in New Haven.

The patients were admitted into the New Haven Hospital* in the early evening and at once received first aid treatment and were sent to the various wards. Blood concentration estimations were made at once. From the clinical standpoint the patients were divided into two groups (a) those seriously burned (b) those not so seriously burned. The blood concentration of the first group was above the danger level, namely, more than 125 per cent. Those less seriously burned were below this level. The correspondence between the severity of the clinical picture and the blood concentration was perfect. In the first group all patients were placed upon the danger list, in the second none were included in this list. The first point of significance in this investigation is that the determination of blood concentration which takes only a few moments serves as an indication of the gravity of the patients' condition and also points out definitely the type of treatment necessary.

In our opinion the serious condition in burn cases is the concentration of the blood and treatment should be directed to reduce this concentrated blood to a more fluid state. The systematic treatment of these burn cases consisted simply in the forcing of fluids, water by mouth when possible, when the

*Through the courtesy of Dr. Samuel C. Harvey, Surgeon-in-Chief in the New Haven Hospital, opportunity was afforded to us to conduct this investigation. (The details of the work are published in the Archives of Internal Medicine, 1923, vol. xxxii, p. 31.)

patient could not cooperate because of unconsciousness, fluid was injected under the skin, directly into the blood, by the rectum, etc. The quantity of fluid taken in varied from four to eight litres daily.

In a day or two on this treatment the blood concentration fell gradually and the patients' condition steadily improved. All patients so treated recovered although of the group of those severely burned the vast majority could be regarded as poor risks.

"Although from figures and other data relative to these observations one is apparently justified in concluding that restoration of blood concentration is of prime significance in burn cases, nevertheless, to the sceptically inclined there are at least two points at which the above conclusions may be attacked. In the first place, one may assume that fluid intake has only an inappreciable influence on blood concentration, that fluid is excreted from the body almost as rapidly as it is ingested. All the available literature on the subject supports such an assumption. One point, however, must be emphasized, namely, that in nearly all instances in which this hypothesis has been put to the test the organism employed was that of a normal person. Herein lies the crux of the whole matter. It is utterly fallacious to predict the behavior toward water administration of an organism suffering from lack of water from observations made on an organism with a sufficiency of water supply. It is quite true that partaking of large volumes of water by normal man or dog does not perceptibly alter the concentration of the blood. So long as the water regulating mechanism of the body is normal such a result is to be expected. On the other hand, when an animal has been deprived of water for a sufficiently long period, blood concentration becomes markedly increased. Water administered under these circumstances causes a rapid fall in the concentration of the blood. Experiments by others and by ourselves cause us to reiterate the statement previously made that it is fallacious to draw conclusions relative to the abnormal organism when these inferences are largely based on observations on normal persons, and they furthermore dispose of one of the points of attack cited above.

"A second point of attack centers on the query, 'Did the fluid intake in these cases actually influence blood concentration or would blood concentration have returned to the normal without such aid?' To answer this question absolutely control experiments would be necessary. Such a control, however, is obviously lacking. The question receives a partial answer from previous experiments together with our experience with war gas poisoning. Death may follow, but blood concentration is not restored to near normal limits under conditions of water lack unless sufficient fluid has been introduced. We believe, however, that the question is fully answered by our experience with one burned patient treated outside the hospital. A victim of the same fire, this patient was cared for at his home by his own physician. Special attention to forcing of fluids was lacking. This case was especially badly burned and presented the typical signs and symptoms characteristic of intoxication from burns, chief among which was an active delirium, it being necessary to take measures to keep the patient in bed. This was succeeded by a period of collapse and unconsciousness, death being anticipated. After a period of eight days, consultation with the physician resulted in the active forcing of fluids. Previous to fluid administration (two litres of 0.7 per cent sodium chloride solution subcutaneously) the haemoglobin value was 163 per cent. A few hours after the salt solution had been given the patient regained consciousness, became rational, and was capable of cooperation in taking of fluid. Blood concentration fell rapidly and the patient went on to recovery. The point to be emphasized here is that this patient on the eighth day after being burned still had a blood concentration equal to that in some of our own serious cases on the first day. The presumption is valid that if this patient's blood concentration would have returned to normal of itself it should have done so within

a period of eight days, an interval during which none of our own treated patients maintained such a concentration.

"From such data it would appear that water intake is responsible for the decrease in blood concentration observed in our cases, and it is quite safe to assert that without such water introduction blood concentration would not have taken the decided fall observed in every case. We believe, therefore, that the observations recorded justify the conclusion that water introduction in sufficient quantities to restore blood concentration to within normal limits is of paramount importance in the treatment of burned cases. As a result of this type of treatment, it may be stated that only two patients gave any evidences of symptoms characteristic of intoxication in burns. In these cases unconsciousness at first prevailed; this, however, disappeared after restoration of the normal blood concentration. In all the other cases, the patients presented no untoward symptoms, such as delirium, unconsciousness, gastro-intestinal disturbance, haemoglobinuria, albuminuria, etc. Whether such facts are to be interpreted from the viewpoint that restoration of blood concentration prevented the development of conditions responsible for these symptoms or that fluid introduction caused prompt elimination of toxic material so diluted as to be innocuous or both, remains a problem the solution of which can be determined only in the future. At any rate, from either viewpoint it would appear that fluid introduction is a rational method of treatment for extensive superficial burns."

Since the initial experience gained from the victims of the theatre fire we have had occasion to treat a number of burned cases in the New Haven Hospital and have been consulted on cases in various parts of the United States and in general the results obtained from the treatment have been very encouraging.

If one analyzes the pathological states in which blood concentration occurs it must be quite evident, that the one underlying factor common to all with the exception perhaps of shock, is that an extensive inflammatory reaction is prominent, acting usually upon a more or less restricted area, as the respiratory tract, the skin, the alimentary canal, the peritoneum, etc. All are areas plentifully supplied with capillaries.

In order to understand the nature of the mechanism producing the blood concentration a word as to the character of the fluid lost from the blood is essential. From my own observations on gas poisoning it becomes apparent that this fluid partakes of the nature of plasma, diluted plasma, as it were, containing somewhat less protein than plasma, but otherwise of practically the same composition. The fact that significant quantities of proteins are present and indeed the blood proteins, particularly fibrinogen, leads to the view that the irritant factor has changed the character of the capillary wall. In ultimate analysis therefore one may conclude that the direct cause of blood concentration, in the pathological states under discussion, is due to a changed permeability of the capillary wall.

From our experience and conception of the mechanism involved in the loss of plasma from the blood a change in capillary permeability is essential—in the loss of salt solution no such alteration is necessary. We believe that any irritative or inflammatory reaction upon any extensive area of mucous membrane may, if sufficiently acute, cause a rapid loss of plasma resulting in blood concentration. In general it is this type of blood concentration which is likely to prove disastrous to the organism. We shall return to this point later.

Blood concentration induced by loss of water and presumably salts only, results in a concentration by a process of dehydration or real desiccation. This is what occurs when sufficient fluid is not introduced as by experimental water deprivation of animals, or clinically in the dehydration of infants. Again intense secretion induced by pilocarpine or purgation by the saline cathartics will cause a rapid blood concentration. It is significant, however, that this process in general does

not proceed to the point where a dangerous degree of blood concentration is attained. The concentration approaches the danger line but is not maintained. This, however, is only a general statement and is particularly applicable to the saline cathartics and to pilocarpine. If actual water deprivation is pushed for a sufficiently long period blood concentration steadily mounts and death follows. Such a result, however, can be called forth only by drastic measures.

Blood concentration of this type is obviously of an entirely different nature than that induced by an inflammatory reaction. This becomes quite apparent when attempts are made to restore the blood to its normal concentration. In the former case a single administration of fluid is all that is essential. With the concentration induced by an inflammatory reaction a single administration of fluid alone although helpful is not strikingly successful. Why? Because in the latter instance the capillary wall has been modified so that it is no longer capable to the normal extent of retaining fluid. In other words, in the one type of blood concentration the capillary wall is involved, in the other it is not, at least to an extent capable of measurement.

The potency of the agencies which may play upon the mechanism governing blood concentration are determined in large measure by the fluid content of the body at a given moment. Thus, when an animal has been deprived of water to the point where blood concentration becomes significant even though still within safe limits, the saline purgatives no longer cause purgation. With sodium sulphate and rochelle salts no immediate symptoms are in evidence. When magnesium sulphate is employed complete anesthesia takes place and unless treatment is given immediately death follows. This fact may have a certain clinical bearing in the indiscriminate use of Epsom Salts both before and after operation. The administration of plenty of fluid both before and after operations is in most instances a wise procedure. From this viewpoint if a cathartic is to be used it should be one which by its action does not draw fluid from the blood.

It is also quite probable that shock may be much more easily produced in an organism in which the blood is concentrated than in one when the fluid reserves are normal, for in peptone shock the blood concentration curve is distinctly modified and the poison appears to be more potent.

Another point of considerable clinical significance is the fact that it is much easier to prevent marked blood concentration than it is to change it once it has become established. For the prevention of blood concentration large volumes of fluid are essential administered more or less continuously. In certain instances venesection tends to keep down concentration acting as it were as a stimulus upon the reserves of the body to maintain constancy of blood concentration. In attempts of the past to maintain blood concentration the error in procedure has been that only a *single* intravenous infusion has been made or repeated infusions at infrequent intervals. The relief afforded has been only temporary since the fluid quickly left the vessels. Administration of fluid should be more or less continuous and it is essential only to attempt to reduce the concentration to the safe limits. This reduction of concentration by administration of fluid or by venesection plus fluid need be practiced for relatively short periods only—it carries the individual over a critical period—a period necessary for restoration of the normal permeability of the capillary wall—in other words the capillary wall repairs itself which takes from twenty-four to forty-eight hours. It is during this period that fluid must be pushed continuously.

In the treatment of burns, therefore, the essential object is to keep the blood concentration near a normal level until the blood capillaries in the skin injured by the heat have had an opportunity to repair themselves and again become capable of holding within themselves the fluid of the blood in a normal manner.

Just a word as to first aid treatment of *chemical* burns and I am through. Shall such burns be treated by flushing with water alone or by flushing with solutions containing substances that will neutralize the agent producing the initial damage? My own reaction to this question is that water alone is sufficient and indeed is to be preferred to any neutralizing treatment. Usually such a burn is produced by a strong acid or a strong alkali. Whatever damage is done is almost instantaneous but it is self-evident that it is essential to remove the offending agent as rapidly as possible. For this purpose water, preferably running water is to be recommended, first because it is always available quickly in large volumes and secondly because the desired end is to wash away the offending substance. *This*, water will accomplish better than anything else. To pour on a neutralizing solution means to have on hand a large supply in a definite location. Time is lost in obtaining it, and this time is very precious from the standpoint of the patient, and moreover, a chemical reaction may be set up between the neutralizing agent and the offending agent which may make the initial injury worse. I believe that nothing is better than large volumes of water. Of course, if burns are induced by an agent insoluble in water, carbolic acid, for example, then water would not be recommended as a flushing solution. In this instance, rapid changes of a solvent, like alcohol, should be used. Usually, however, the burns encountered industrially by chemicals are those induced by acids and alkalies and I believe that nothing is better in first aid treatment than plenty of water.

(In the absence of Dr. Greenburg, Vice-Chairman C. F. Whittemore took the chair.)

CHAIRMAN WHITEMORE: Our registration cards show that we have a considerable number of medical men present aside from the speakers shown on our program, and of course we have another stack of members who are not medical men. We would like to hear from both of these groups in the discussion of this paper. I am sure there is a great deal to be thought about and discussed at this time.

I. V. KEPNER (Pennsylvania Salt Manufacturing Co., Philadelphia): May I ask the doctor what he would recommend for medical first aid treatment for caustic burns?

DR. UNDERHILL: What do you mean by caustic burn?

MR. KEPNER: I mean a burn from a caustic flash.

DR. UNDERHILL: You mean an alkali. I would recommend water.

CHAIRMAN WHITEMORE: I believe Mr. Baxter, of the Newport Chemical Company, has brought to light some other views on this subject, although most of us perhaps are agreed that the medical treatment with water is preferable. We would like to hear from Mr. Baxter.

W. A. BAXTER (Newport Chemical Co., Milwaukee, Wis.): I don't want to start a controversy between the different doctors, but Dr. Hubbard, of the Ford Hospital, I believe, last year gave us a treatise on burns of the eye, and he recommended as first aid treatment the use of water in large quantities. But since that time I have picked an article from the *American Dyestuff Reporter*, April 30, 1928, written by Dr. Paul Bartholow, and he is not in accord with Dr. Hubbard's view on the first aid treatment of the eye. It is quite a lengthy article. I don't know whether we have the time to read this or not. I might read certain paragraphs and give you the slant on what he says. Would that be permissible?

CHAIRMAN WHITEMORE: A reasonable amount of it would be interesting.

MR. BAXTER: He says in one paragraph:

"I think everyone who has had much experience in treating burns of the eye must acknowledge that washing with sterilized or tap water is very painful, and increases shock. Prof. Fratin has published in the *Policlinico*, 1915, Sez. Prat.

p. 721, his results with isotonic salts solutions which he prefers both for simplicity and speed, to any of the other remedies. They have taken the place of weak solutions of picric acid which recent investigations have shown to be too irritating for burns of the second degree. Evidently picric acid had had its vogue and been passed over for more scientific agents.

"The author whom I am citing makes no distinction between burns by sulphuric acid and nitric acid. The distinction—and its relation to treatment—are well brought out by a writer in *Safety Engineering*, September, 1927: 'Nitric acid burns are different from sulphuric acid burns—they are more like actual burns.' And, 'to destroy the burning qualities of an acid, it is necessary to neutralize it with an alkali. As sulphuric acid takes up water in all proportions with great evolution of heat, it is very dangerous to throw water on it.'"

He also says: "We learn by hard experience the value of the only safe rule—to do nothing in emergencies which we are not absolutely sure is right, and in burns of the eye simply cover them with a clean bandage and wait for a physician and proper remedies. It is wonderful how the eyes escape what seems at first like absolute loss by the rapidity with which the lids close. It is most harmful, therefore, to get in a panic and use the first available solution."

I would like to hear some comments from some of the other physicians present.

W. H. HINKEL (Atlas Powder Co., Wilmington, Del.): I thoroughly agree with Dr. Underhill in everything he has said in regard to the treatment of burns, and I think that most physicians who have had extensive experience with burns of all kinds will agree that the blood concentration is the main thing.

I have done considerable work with burns from mine gases, and also with burns from acids, and I find that after the first aid treatment is finished the subsequent treatment is about the same in all of them.

I want to make one observation that came to mind in regard to the immediate treatment of inhalation of noxious gases, irritant gases.

Some years ago those of you who remember Dr. Hudson, of the du Pont Company, who is now deceased, will remember that he advocated the use of about seven drops of chloroform with a teaspoonful of aromatic spirits of ammonia in water and taken internally—not inhaled, but taken internally as the immediate treatment following the inhalation of these gases.

I have had some experience with that. I haven't found any permanent results as to cures, but there certainly is a great amount of relief following that treatment.

In regard to the paper by Dr. Bartholow which was mentioned by Mr. Baxter, I have had a lot of experience with burns about the eyes. While what he says is true, that the eyes close very quickly and there isn't very much acid gets in them, yet I think one of the main things that you have to guard against is the burning of these very eyelids on the outside; and I think that the same thing that applies to burns on the rest of the skin applies to the skin of the eyelids. Some of the most terrible results that I have seen have been in cases where the eyelids were burned and turned out so that the man was a horrible thing to observe. In some cases it took two or three years to correct that.

CHAIRMAN WHITEMORE: Is Dr. Wade Wright present?

If not, I wonder if Mr. Whiting, of the Liberty Mutual will say something. a question of Dr. Underhill in connection with some of the irritant gases. When our section was getting out some safety practice sheets on chlorine we got into considerable argument as to its irritant qualities, and the point was brought up in certain industries that are making or using chlorine, that there is a hardening

S. E. WHITING (Liberty Mutual Insurance Co.): I would be very glad to ask effect. A man develops either shallow breathing or some other element that makes him more or less immune to the exposure as compared with the person who has not been exposed for years to the gas. Does Dr. Underhill know whether

there is any technical basis for any such hardening in a person exposed to chlorine or other irritant gases?

DR. UNDERHILL: No, so far as I am aware that has not been observed. Of course, most of our experience came from acute poisoning. You are speaking of a chronic poisoning which I regret has not been investigated as thoroughly as the acute poisoning. It is quite possible, of course, that some such effect might be expected. There is a sort of a coagulation, as it were, of certain of the mucous membranes which would tend to give a hardening effect such as you describe. I think it would be quite possible. It would tend to render those individuals perhaps less sensitive to the effects than individuals who had not been continuously subjected to the action of relatively small quantities of gas.

MR. WHITING (Liberty Mutual): There is another question. Would you advise that the workmen should be trained so far as possible to breathe shallow while they are still forced to be in the exposure?

DR. UNDERHILL: I don't think they can help themselves.

DR. PEDLEY (Montreal General Hospital): The men whom I saw die in the war from irritant gases appeared to die from drowning primarily. Is that factor primarily due to the concentration of the blood, and if they do die from drowning, is not a better thing to allow the blood to become concentrated to tide them over the period of great concentration of the blood?

DR. UNDERHILL: That is the obvious feature of edema of the lung, but that is not deadly. You may have your lungs filled with water as much as you please and can inhale to get your tissues aerated in some way. The presence of water in the lungs is not a serious condition. During the war the whole story was one of pulmonary edema and it was soon found that even though that pulmonary condition was allowed to exist that if you changed the blood concentration the patient recovered in spite of the edema. Moreover, in animal experiment you can fill up the lungs with water and yet the animal doesn't die.

R. O. KEEFER (Aluminum Co. of America, Massena, N. Y.): I would like to ask a question about carbon monoxide poisoning. Is there any foundation for the statement that men who are working constantly in low concentrations of carbon monoxide become, you might say, used to it and can stand more of it than a man who is not working in an atmosphere of low concentration of carbon monoxide? Take, for instance, the man in a plant which is not modern and where there is considerable gas: will he become partially immune, or more so, than a man who has never worked there before?

DR. UNDERHILL: I don't know anything about carbon monoxide except in a very general way, but I think your supposition that he can become more or less immune to small quantities may be correct, because all of us who smoke more or less excessively must become immune to small quantities of carbon monoxide.

H. F. BROWN (E. I. du Pont de Nemours & Co., Watson, Ala.): I would like know what area of the body covered with burns would cause the blood concentration to increase rapidly enough to cause that effect?

DR. UNDERHILL: Well, that is a disputed point, but certainly, if a third of the area of the body is burned, and thrown out of condition, the chances of death are very great.

W. A. BAXTER (Newport Company, Milwaukee): I would like to ask Dr. Underhill if the giving of milk is of any value in the treatment of ortho-toluidine and aniline poisoning? I have written to several doctors and talked to them, and some say no and others yes. I wrote to a doctor who had written an article for *Industrial Hygiene*. He recommended giving copious amounts of milk.

DR. UNDERHILL: That, I presume, must be taken by mouth.

MR. BAXTER: Yes, as first aid treatment. Do you think that would be of any value?

DR. UNDERHILL: I should think it would. I should think it might have some value in more or less preventing absorption; but if you do that you should also pump out the stomach, for the milk will do no good in combination with the aniline.

MR. HOLTZ (Pittsburgh): There is a question which has been running through my mind which I suspect has occurred to some of the rest of you in connection with the Doctor's very splendid paper, and that is just how soon does this blood concentration occur? In other words, if a man is burnt reasonably bad, is the first aid for that burn the combatting of the blood concentration, or is that blood concentration something that will occur somewhat later and can be taken care of in a hospital?

DR. UNDERHILL: That is rather a hard question to give a dogmatic answer to. For example, in our cases in New Haven which occurred in the late evening, the blood concentration in some instances was at a maximum in a period of four or five hours. That meant, probably, that the initial concentration began, let us say, within an hour or two hours. Nearer than that we don't know, but from animal experiments the whole thing is over within twenty-four hours; I mean, the maximum is reached. You have a period of two or three hours before you begin to get really noticeable concentration effects.

In answer to your question, therefore, it would seem as though this whole question of treatment of burns, aside from rest and maintaining warmth and things of that sort, is a hospital proposition.

CHAIRMAN WHITTEMORE: Are there any other views to be exchanged on this subject?

If agreeable, then, to the members of the section, we have three other papers this morning and we might very well proceed. I will turn the Chair over to Chairman Greenburg to introduce the next speaker.

CHAIRMAN GREENBURG: The next subject on the program is a "General Discussion of Health Hazards in the Chemical Industry." We discussed safety hazards yesterday and to some extent today, and now we should spend some time on this question of general health hazards. It seemed interesting to discuss this problem from three particular points of view, and then spend as much time as remained on an open discussion of the subject. You see by the program that it is going to be handled "From the Viewpoint of the Department of Labor" by Dr. C. T. Graham-Rogers, of the New York State Department of Labor, New York City.

Health Hazards of the Chemical Industry From the View Point of the Department of Labor

By C. T. GRAHAM-ROGERS, M. D.

Bureau of Industrial Hygiene, New York State Department of Labor

To properly express the view point of the Department of Labor with reference to the health hazards in the chemical industry it is necessary to preface such a discussion with a brief outline of the organization of the department and the functions of a few of its component parts.

The Industrial Commissioner is the executive head of the department and is charged with the administration of the Labor Laws and the Workmen's Compensation Law.

The Industrial Board is in character the judicial and legislative body of the department inasmuch as its duties are to make, amend, or repeal rules for carrying into effect the provisions of the Labor Law, and having broad powers with reference to the carrying out of the sections of the Compensation Law.

The Inspection Bureau constitutes in effect the police agency of the department, for its main function is to see that the Labor Law and Industrial Code Rules are complied with, and likewise to secure a compliance by prosecution measures if so required.

The Compensation Bureau is concerned solely with the administration of the Workmen's Compensation Law. The personnel determine the validity of a claim, the extent of disability and the amount to be awarded the claimant.

The Bureau of Statistics and information compiles and publishes the statistical information gathered by the personnel of the other Bureaus as well as special statistical data gathered by its own personnel, and all with reference to accidents.

The Division of Industrial Codes formulates the Industrial Code Rules necessary to clarify the Basic Laws and so specifically apply the provisions to industrial conditions in that there is afforded measures to prevent accidents.

The Bureau of Industrial Hygiene constitutes the research bureau of the department. Its functions are diversified. The personnel must undertake scientific investigations of industrial processes as well as physical examinations of workers in order to determine the health hazard present in an industry so that the other bureaus concerned with the administration of the Labor Laws may be informed of data necessary in formulating or repealing laws or rules applicable to processes of manufacture and concerned with hazards.

When required, the bureau furnishes the expert testimony necessary to sustain a prosecution for failure to comply with the Labor Law.

Among its province is that of affording the referees of the Compensation Bureau advice as to the processes of manufacture and the accompanying health hazards in industry, so that quick disposition may be made of claims appearing for hearing on the occupational disease calendars.

The bureau compiles and publishes a monthly bulletin of Industrial Hygiene, manuals, and special bulletins dealing with health hazards arranged especially for the physician, industrial heads, and the worker.

Visual education by means of moving pictures and exhibits are carried out as safety measures: illustrated lectures are also given to the workers in the industry. The safety inspectors and medical inspectors are constantly engaged in activities to advise and assist plant executives in installing safety measures for the prevention of accidents. The industries as well as the workers are acquainted with the objects of the bureau and invited to make full use of the facilities, limited as they are, so that all may be impartially served.

This then is but a brief of a few bureaus of the department (and there are over twelve) with reference to accidents.

It is patent that the view of each individual bureau head cannot be expressed in this discussion. My position is of one giving an opinion as derived from observation and coordination with other bureaus; but an expression can be definitely expressed with reference to the view point of the Bureau of Industrial Hygiene.

For a proper discussion it becomes requisite that we first consider the chemical industry as classified by the Department of Labor for use as an aid in applying the laws and in securing statistical data. Such arrangement is as follows:

Chemicals, Oils, Paints, Etc.

1. Drugs and chemicals

(a) Proprietary medicines

Patented medicines and pills

Plasters medicated

Salves

(b) Chemicals

Acids

Alcohol

Disinfectants

Gas mantles

Insect powder

Alkalies	Liquefied gas
Alum	Metal polish
Ammonia	Pharmaceuticals
Baking powder	Potash
Bleaching materials	Saltpetre
Calcium carbide	Soda
Caustic soda	Sulphur
Coal tar products	Washing fluids
Compressed gases	
Cyanides	
2. Paints, Dyes and Colors	
3. Wood Alcohol and essential oils	
4. Animal and mineral oil products	
5. Soap, Perfumery and Cosmetics	
6. Miscellaneous Chemical Products	
Starch	
Glue Mucilage, etc.	
Fly paper	
Paste	
Sizing	
Fertilizers	
Matches and Explosives	
Ammunition	
Fireworks	
Gunpowder	
Photographic supplies and Photography	
Blue print paper	Photographic film
Dry plates	Photographic material (chem.)
Motion picture film	Photographic paper

Second, what is the classification with reference to the so called occupational diseases? This part is not so simple for the various authors British, Continental and American, are not in accord. Quoting one of the pioneers in this field, Sir Thomas Oliver, of England, we find that he limits the chemical industry to the manufacture of lime, bleaching powder, the acids, and also includes aniline and nito benzol, yet in Niagara Falls, N. Y., one of the acknowledged electro chemical centers of the industry, may be found graphite, phosphorous, abrasives, carbides and other plants, so it is evident that for statistical purposes an accepted standard classification becomes imperative, both as to processes as well as to the resulting health accident, a term is preferable to that of occupational disease, which in relation to industrial hygiene is meaningless and confusing.

Hence in discussing health hazards in any industry terms having a definite meaning become indispensable. We are aware that the effect or result of exposure to a hazard is an accident, but the generally accepted meaning of the term accident has been limited to a surgical injury or trauma. Within the meaning of the Compensation Law a claim for illness contracted as a result of exposure to a so called poison or other hazard must be considered as an accident, in my opinion then the terms Traumatic Hazard and Health Hazard and the results Traumatic Accident and Health Accident are more appropriate and definite. There can be no mistake as to just what is implied.

The term poison as applied to material or substance used in industrial processes is too broad and in many circumstances misleading. Under some conditions it is unfair to the industry or product. In my opinion the term harmful substance is more appropriate and should be more in use in discussing health hazards.

What, then, shall we say is a hazard? The chemical industry is similar to other industries in that respect. We consider that a health hazard is poor air conditioning, exposure to dust fumes, gases, vapors, or liquids, extremes of temperature, high or low, glare, and finally, the operation of machinery that requires certain positions. The only difference is that in the chemical industry some of these things may be accentuated. They may be exaggerated and the resulting health hazard may be more severe than that in some other industry. But even in the chemical industry we may have health hazards, that is, to a few of the workers it may be a health hazard, because of their susceptibility or their peculiar physical condition, and yet to a mass of the workers it does not constitute a health hazard. Well, then, we cannot say that the chemical industry is peculiar to itself in a certain health hazard. What we can say about all the other industries is just as applicable to the chemical industry.

Let us consider the early attitude of the Labor Department toward industry. The Labor Department was established primarily as an exercise of police power to provide healthful surroundings in industry, regulate the employment of women and children, and endeavor to maintain a better physical standard among the workers. This program was carried out through preventive measures embodied in the Labor Laws all based upon rules of Health Safety and Welfare.

The gradual expansion of the department included scientific research as to the hazards incidental to processes of manufacture and the health accidents incidental thereto. The chemical industry was not overlooked, but it was apparent that in order to determine the health accidents resulting from exposure to the health hazards present in the chemical industry, statistical data must be gathered and compiled.

The data as to the traumatic accidents are well established. The accident report records of the Inspection Bureau were valuable and the records of the Compensation Bureau in this direction are specific, but despite the fact that the Compensation Law includes some of the health accidents, the compilation of data toward this end is of little aid in determining the actual harmful character of the industry as a whole. Likewise the Labor Law contains a section requiring the reporting by physicians of all occupational diseases, despite this statutory requirement there has been but meager reports of cases occurring among workers employed in the chemical industry. Such data would seem to indicate that the industry was free from health hazards, whereas the executives of chemical plants know a hazard exists and my own experience of over twenty years official investigations confirm the facts that health hazards exist and health accidents occur.

It is manifest that the department expects statistical information be furnished in order to determine to a certainty the actual health accident in the chemical industry.

Industry must carry on and production cannot cease. Health accidents will occur. Protective or preventive measures must be instituted not only to conserve the worker's health, but the industry itself.

A multiplicity of blanket laws is more likely to impede than to aid progress in preventive work. More laws are not only difficult of enforcement, but are less likely to create harmony in industry.

Industry as a rule if properly aided does much to solve its own problems as to health hazards, and this is equally true of the chemical industry.

Notwithstanding the fact that one of the functions of the department is to secure enforcement of the Labor Laws by drastic measures if necessary, yet it must be borne in mind that another function is to ascertain if any measure works a hardship on the industry, and still another function is that of relieving industry of any undue burden, if proper cause for so doing can be established.

The department considers that laws and rules applicable to industry were enacted after due consideration, and expects industry to comply with the provisions of such laws and rules.

The Bureau of Industrial Hygiene looks upon the Chemical Industry as a hazardous one, but it also realizes that to make general statements, not based upon facts, as to the dangerous nature of such an industry is not sound economics.

Statistical data to hand does not actually show the health hazard present, but is hoped for that better information may aid in formulating industrial code rules especially applicable to the chemical industry, which will minimize or eliminate health accidents and still not impose upon the industry an incumbrance.

The industry as a whole is not the most hazardous, for many other industries have as a component some industrial process that could be considered as a branch of the chemical industry, and relying upon data, it would appear to be more hazardous than the chemical industry.

The needed labor for the chemical industry is not as available as it was ten years ago, therefore if labor is to be secured, the industry must not be unduly exploited as a most dangerous work which should be practically prohibited, and certainly the department does not view it in such a light.

Health hazards are known to exist and health accidents do occur in the chemical industry, it is a matter of official records. These accidents cannot be entirely prevented but they can be minimized and this is a matter of official investigation.

Complete Cooperation Reduces the Accidents

To reduce health accidents in the industry requires coordinate action on the part of the state, the industry and the worker. The state and industry must labor to discover harmless substance to replace those that constitute the hazard, and in addition originate preventive devices and measures as applied to the process or product.

Industry must also continue along channels to perfect machinery or apparatus that will eliminate from the process the greater part of the hazard.

The worker must likewise assist.

First: by looking to his own physical well being, this in consulting competent medical practitioners and abiding by the advice given.

Second: by observing the rules of personal and industrial hygiene as applied to himself.

Third: Obeying the instructions issued by the industry he is employed in, and making use of all safeguards as provided for the workers or connected with processes of manufacture or the resulting product.

Until such concerted action occurs the industry will continue to be the target of biased or unscrupulous investigators.

It must be conceded that adequate compensation for health accidents is neither philanthropy nor charity, but an economic duty industry owes the worker exposed to a hazard. It has a value in that the search for protective measures is stimulated, and often there is discovered new hazards for old ones.

The department in its views and action is not merely local in character, but really plays a part in the great general movement of Public Health.

A nation is strong only in proportion to its weakest manpower. There is no reason why workers in the chemical industry should not have a long span of life and be physically fit. It can be accomplished, it spells sound economic conditions in the chemical industry, and becomes an aid in developing a more virile nation.

CHAIRMAN GREENBURG: We will reserve discussion until we finish the three formal papers.

We would now like to hear from Dr. Gehrman, Medical Director of the du Pont Company of Wilmington, "From the Viewpoint of the Industry."

Health Hazards From the Viewpoint of the Industry

By G. H. GEHRMANN, M. D.

Medical Director, E. I. duPont deNemours & Co., Wilmington, Del.

The subject which has been assigned to me for discussion this morning is a very large one, and one which requires a great deal more time than we have at our disposal. I am also sorry to say it requires a great deal more knowledge than we have at the present time. It is my feeling that the actual knowledge that exists on hazards of the chemical industry is nothing short of deplorable.

A few years ago our safety movement was started forward with a tremendous impetus and gathered a great deal of force and accomplished a wonderful amount of good. It is only within the past few years that the true value of preventive medicine has been realized; and when you realize that the life expectancy of the average individual has been increased from twenty years to fifty years in a comparatively short time, you can't help but understand that there has been a great amount of good accomplished. Now, the next step we need is to tie in preventive medicine with industrial medicine, and learn just what the hazards are in the chemical industry.

I think it is safe to say in this day and age that the chemical industry includes practically every industry, because they are all based on chemical research and applied chemistry. For example, in our own organization, nobody would question or doubt the fact that the manufacture of dyestuffs and explosives is a chemical industry. The manufacture of rayon and the manufacture of fabrikoid is not thought of as a chemical industry, but it is purely a chemical process, and it has its hazards as do many other industries. And so we might go on indefinitely, bringing up the various industries, proving that they are all based on chemistry.

Now, what constitutes a health hazard? I prefer to deal with this subject in a general way. I might say that any condition which interferes with normal human health constitutes a health hazard. All of you are familiar with lead, and most everybody realizes the importance and the dangers of lead. I believe that in order to gain a thorough understanding of just what may happen, how human health may be impaired, and how best to safeguard against such results the subject should be approached in three ways: First, a complete study in order to know your industry; second, a careful study of each and every individual employee at the time of employment; and third, a continuous study of each and every one of those employees all during the course of employment.

Now, in order to know your industry, just what is to be done? You must take into consideration every process and every chemical compound which is brought into play. Are the chemical compounds which go to make up your final product individually harmful or not? If they are not individually harmful, are they harmful after you get them together? For example, in making anhydrous ammonia we take nitrogen and we take hydrogen (neither one particularly harmful) and we combine them together under pressure, and then we have a product decidedly harmful.

Are the products which you are using capable of giving off a dust? Are they capable of giving off a gas which is injurious? Will they give off fumes which are injurious? Are you using liquids which are volatile, and the gases of which may cause interference with human health? Are your processes such that you can control each and every one of these individual compounds and limit the conditions which they are liable to produce?

Then, again, you will have to take into consideration that industrial illness may be brought about in three ways: First, chemicals may or it may not be absorbed through the skin. They may produce persistent dermatitis with which we have

some trouble in the industry. They might pass through the skin and produce constitutional symptoms.

Then, again, you have to consider the respiratory tract. Do your compounds enter the system through the respiratory tract either in the form of dust or vapor?

Then we come to the digestive tract. Do your compounds get in through the digestive tract, and if so, how rapidly?

There has been considerable work done in the past on various compounds. You can refer to the literature and you can decide whether or not your compounds and your conditions come within the class which has already been investigated. But if it doesn't, and in a great many cases you will find that it does not, spend a little time and a little money and make an investigation. If you can't investigate it yourself, you will find that there are agencies which will investigate it for you and give you a proper report as to just what to expect.

The point is to study your particular process and your particular industry and know what to expect, and don't assume that everything is perfectly safe as far as human health is concerned.

I recently investigated a plant that was engaged in the manufacture of a product, which I thought was harmful; and I said to the plant management, "Do you have any industrial cases?"

He said, "No."

"Well," I said, "it seems very strange that under the conditions that you are working and the product that you are handling that you don't have any trouble."

"Well," he said, "we don't."

I said, "What is your labor turnover?"

"It is 40 per cent," he said.

"What is the reason for that?" I asked him.

He said, "I don't know."

I said, "Will you allow us to examine a group of your men who have been engaged in this particular industry for a reasonable length of time?"

He wasn't particularly keen about it, but finally agreed, so we examined 20 men, and out of the 20 we found that 18 of them showed definite signs of absorption. We found that his labor turnover was 40 per cent because the men had more sense than he had. They realized they didn't feel well after they had worked for him for some time and they quit.

That brings us to the second point, and that is to know your men at the time of employment. Unless you are in a position to definitely know what each and every individual man is physically, at the time of employment, then you are more or less in the position of being helpless finding out what is happening to him, in the course of his work.

That consists in giving him a careful examination. When I say careful examination, I don't mean a rapid, rudimentary, casual glance deciding whether or not this person is all right to come to you and won't be a hazard for you; but examine him carefully and do the laboratory work necessary to check up blood conditions, kidneys, and so forth, and then decide whether or not he is physically fit to go in a particular department.

It is perfectly obvious you don't want a man working under conditions that will irritate his kidneys if he already has trouble with his kidneys. It is perfectly obvious that you don't want a man with an old healed tubercular lesion working in an atmosphere of gas, which may break down the lesion and start him on a new course of tuberculosis.

The third point is to keep in mind that you must watch these men frequently, and the frequency with which you watch them will depend upon the type of work that they are doing and the hazard which is involved.

We have our men classified into several groups, and we find that we have some that should be examined once a week; we find we have some men that should

be examined once a month, and once every three months, and once every six months; and we find others that need to be examined only once a year. But that can only be determined after you have first studied your process and have realized your condition, and then experience will reach you just how long a period you should intervene between each examination.

You will find that your employees are very cooperative on this plan. We recently had an experience with our men who were to be examined once a week; and after examining them for that period of time for somewhat over a year we decided we were in a position to say that it was no longer necessary to examine them once a week. So we sent out word that once every three weeks would be often enough; and in spite of the fact that these men were not afraid of the process and were not afraid of the material, they sent a committee to wait on us and say that they preferred to be examined once a week; so we have continued to examine them once a week.

By careful and continuous physical check-up you can determine just what is going on in each and every employee, and you can determine just what is the proper thing to do for him—whether you should take him out of his present operation and place him somewhere, where he is not liable to be further injured, or whether he is perfectly well and can continue where he is.

So I am going to conclude this little talk by saying that in the hazards of the chemical industry we should include practically every industry, and if you will know your industry and know your men and continue to know them, we will be able to cut down and eliminate these industrial hazards.

CHAIRMAN GREENBURG: Mr. Walter S. Paine, Research Engineer of the Aetna Life Insurance Company of Hartford, has agreed to discuss this problem from the viewpoint of the insurance company.

General Discussion of Health Hazards in the Chemical Industry From the Insurance Viewpoint

By WALTER S. PAINE

Research Engineer, Aetna Life Insurance Company, Hartford, Conn.

At the Fourth Annual National Safety Congress, held in Philadelphia in 1915, some speculative discussion arose out of the question of rejected man-power from industrial disease which it was thought would occur because of the rapid development of many of the chemical industries then flourishing in Germany but gradually being fostered by American capital in the United States. In all the discussion, no indication was found that we would be attempting to solve the problem of the health hazards in these specific industries with the patience, skill and broad viewpoint that dominates the methods now actually in force. Instead of chaos from "industrial diseases" in the chemical industry, we find the layman, chemist, physician, employer and employee cooperating, for the most part, in a sane research into ways and means of eliminating the hazards and still preserve the industrial contribution of the chemist to promote our industrial arts and supply our social and economic needs.

You have requested us to review these health hazards in the chemical industry from the insurance viewpoint, which subject in a limited time can only be covered within specific limitations. The essential viewpoints of this subject, as we see them, are as follows:

- I. Is the problem of "health hazards" in the chemical industry being solved?
- II. What are the essential social and economic forces producing a reduction of early discovered health hazards?

- III. What is the attitude of insurance companies towards the "industrial disease" exposure?
- IV. Have the insurance companies a part in actually working out the remedies for these health hazards?
- V. A few of our outstanding problems in the chemical field at the present time.

Let us first consider if the health hazards in the chemical industry are being solved. In this paper the term "chemical industry" is extended to include such industries as are, for the major part, dependent upon chemicals or chemical reactions for their final product.

It is doubtful if there is a better barometer of the trend in what is generally termed "industrial disease" cases than the records of the insurance companies. The trend towards well-lighted and ventilated buildings, together with the educational program in hygienic methods as carried out by modern industry has had its effect in reducing this hazard. Having reviewed compensation cases for a period of practically twelve years, there has been a noticeable reduction in the number of industrial disease cases, such as lead poisoning, brass ague, mercury and benzol poisoning, in industries complying with the requests to remove these hazards by providing ventilation, change in processes, a close follow-up under medical advice, and the simple rules of hygiene. Two factors make these findings doubly trustworthy:

First: We are in a far superior position to detect these health hazards today than we were twelve years ago. Furthermore, may we say that industrial medicine is now on a far more efficient basis.

Second: Industrial plants depending upon chemical operations are far more numerous as a part of our stabilized industrial life than they were in 1915, and, as a result, knowledge of the exposure and its alleviation is more widespread.

II. What are the essential social and economic forces producing this reduction in health hazards of a specific type?

The interest of society at large in the human wreckage resulting in some of our industrial plants as the result of industrial progress and economic needs had its effect in calling our attention to the need of action in finding and eliminating the cause. In many cases this social interest, however, confused the problem and retarded real scientific action.

The vital force which produced results was the earnest cooperation of the chemist, physician and industrialists interested in research to find the facts and discover corrective measures.

From the economic viewpoint, the plant managers realized that unless they corrected these health hazards, the insurance costs would be no small part of their overhead. They also realized that production would decrease because of labor turnover, increased labor costs, spoilage of material and the need of increased supervision.

Before leaving this item, may we pay our compliments to the large number of industrial officials who took a real human interest in setting up the most efficient investigation to ascertain the facts and provide remedies for existing health hazards. A large number of them not only backed this work financially but contributed liberally of their time in organizing effectively these investigations.

III. What is the attitude of insurance companies towards the "industrial disease" exposure?

A number of the insurance companies are turning over every industrial disease case to their research engineer, who, after collating all available data from the field relative to the case, reviews the problem with their medical departments. In many cases the medical field adviser covers the case from the physician's viewpoint.

After a complete analysis is made of collatable data, a brief is compiled and forwarded to the field inspector or direct to the plant officials.

Our first obligation is always to the injured man, and corrective measures are suggested to our assured after a most careful survey and research of the case. Any investigation of this type should be carried out in cooperation with the plant chemist. No fact finding research is completed without his assistance, for he, to a large measure, has the key to the situation.

It is believed our attitude to the situation of health hazards can be endorsed by many other insurance companies, and I know of no better method of expressing these viewpoints than by the following:

Because of our membership on the Spray Painting Research Committee, we were asked to express our opinion relative to the place this innovation had in industry. Rather than making a hasty decision and passing out unwarranted, injurious propaganda against any advance in industrial arts, it has been our view that no final verdict should be given until a sane research had been made. Our answer in this case, relative to whether or not spray painting shall remain in industrial plants, prompted us to state that every new invention should be conserved for the use of mankind when it contributes to the social and economic development of the race.

Spray painting, which has already become a unit of production in most of our large industries, when rightly used, is an invention of this type. Every effort should be made to conserve this new development by making it safe for use through correct ventilation, electrical protection and the use of the least harmful paints. Spray painting, when applied according to the suggestions resulting from the research conducted by the National Safety Council Committee, should be less of a menace to the employees from the viewpoint of hazard to life and limb than many of the appliances now employed.

Safety in the use of spray painting must pass through the same process of education that is being used in industry relative to power machinery, electricity, etc. These innovations allow us to keep pace with competing industries of other nations. We are not forfeiting the use of the automobile, power machinery, or even coal mining, with their toll of human life, but we are doing everything possible to educate the individuals exposed to these hazards in the safe methods of operation.

We would find it practically impossible to eliminate these forces which mean so much to mankind, and it will always be thus with every innovation of economic and social value. We must, therefore, attack these problems by making practical researches and discovering the real facts as to their use, and then set up ways and means of making these new developments in industry conform to the safest methods of procedure.

IV. Have the insurance companies a part in actually working out specific remedies to offset industrial health hazards?

A "diagnosis" is essential in finding the solution of every deep-seated problem and an analysis at hand of any chemical hazard based upon actual cases often gives the starting point of such an investigation.

The insurance companies are often in a position to aid in any of these investigations because of their direct contact with cases involved. Case analyses have been furnished as a basis in former and in present researches, and we are urgently advocating the increased use of such information.

The National Bureau of Casualty and Surety Underwriters financially underwrote and personally assisted in the benzol research, which incident is only one of many indications as to their willingness to aid in fathoming these problems. The interest many insurance companies have taken in researches, such as mercury poisoning, spray painting, lead poisoning, dust diseases, etc., exhibits clearly their viewpoint in relation to the health hazards when carried out in a scientific and constructive way.

V. From the insurance viewpoint, what are a few of the outstanding problems in health hazards, as we see them, from the chemical angle:

(a) *Benzol*. While the investigation carried out by your committee was thorough and constructive, there is still a feeling in some quarters that it is not altogether conclusive. This may be said of any piece of investigation for it is well that there are some who never feel convinced that the specific field of knowledge is exhausted. A few suggestions from the field have come to us even of recent date:

1. A study of medical histories of non-fatal benzol cases.
2. Types susceptible to benzol fumes.
3. Diet of employees whose blood picture may indicate benzol poison.

As we have been closely associated with our Medical Department and our Mr. Ralph E. Prouty in a study of some 130 cases, we may at a later date be able to express a suggestion on these questions. It might be worthwhile to instruct your present committee or others to take these suggestions under advisement.

(b) *Chrome Poisoning*. With the advent of chrome plating, there has arisen another source of chrome sores which might well form a basis for a research. More than one plant has developed this hazard and the compensable cases from this cause have increased within the last few years. We are convinced that with proper ventilation, close adherence to hygienic principles and a certain amount of education among the employers and employees as to corrective measures, this exposure can be greatly reduced.

(c) *Spray Painting*. After reviewing many field reports on spray painting, one is convinced that the educational work being carried out by the N.P.P.A., DuPont's, industrial commissions, National Safety Council and insurance companies has had its effect in correcting this hazard in the larger industries. There is, however, a large field still untouched where the promiscuous large and small users of spray painting see no need of any protection either from the explosive or health hazard. It may be advisable, therefore, to appoint a committee which might place in simple form and plain English the principal hazards and methods of overcoming them.

It may be too early to make a definite statement as to the health hazard of spray painting, but our consistent review of this type of risk has failed to find a basis of alarm as portrayed in some reports on this exposure. Someone in our discussion at this meeting may have an entirely different experience.

(d) *Mercury Poisoning*. There is no doubt of the existence of mercury poison, and this exposure was called to the attention of your committee about a year ago when several industrial leaders showed a deep interest in this subject.

Here again, through the cooperation of industrialists, employees, chemists, engineers and physicians, the specific plants involved have partially eliminated this exposure through ventilation, education, medical supervision, hygiene and engineering revision. There is still room for service in this field amid industrial plants having no constructive data on this subject.

(e) *Hydrogen Sulphide Poisoning*. In the oil field and petroleum industry this exposure has, during the past year, made itself felt in our losses more from the medical costs than indemnity. The Bureau of Mines has done much to ward off the deadly results of this gas, but there is still room for constructive research. It is still too early to compile any amount of data on this subject, but as the Chemical Section is bent on safeguarding industry, this field of research may be worthy of your attention.

These are only a few of the health hazards which are now before us in this chemical age. There is still much to be done in the way of research into the dust problem from abrasives, stone dusts, etc., in an effort to reduce our number of tubercular cases. This field, however, is being developed by other departments interested in health hazards and their findings supplement our efforts in our own field.

ADJOURNMENT.

October 3, 1928

LEONARD GREENBURG, Ph. D., Chairman
U. S. Public Health Service, Yale Medical School
New Haven, Conn.

The third session was called to order at ten o'clock by the chairman, Dr. Leonard Greenburg.

CHAIRMAN GREENBURG: The first paper this morning is to be by Mr. Armstrong, Safety Engineer of the Eastman Kodak Company.

Status of the Chemical Industry as Revealed by Accident Experience

By A. L. ARMSTRONG

Safety Engineer, Eastman Kodak Company, Rochester, N. Y.

This is rather a pinch-hit job for me. Last Friday I got a letter from Mr. Kershaw saying that Mr. Coffelt wouldn't be here and that he would expect me to do the job.

There has been a slight increase in the reports sent in to the council, but the same old question comes up every year. We talk about more reports in the chemical sections. If you will send in the kind of reports that will give us an idea what your problems are, then we can attack those problems; that is, we can concentrate on a problem that is the most serious. Unless that is done, we don't know where to start. It is just like the benzol problem and all the other industrial problems that we have had.

These reports come in, I have been told by the statistician of the National Safety Council, and they do not give the proper information; that is, they don't use the right figures. A man sends in a report and instead of using the penalty for loss of a finger he will use seven days lost. Now, that is not permissible. If you are going to send in your report you will have to use the full penalty regardless of the length of time that a man loses. He may not lose over seven days or he may not lose over two days, but it is necessary to use the penalty in making up the final report.

Another thing, the classification is wrong in a good many cases and the company name isn't on it or the kind of chemical industry; that is, they will send in anything that they want to put on. The clerk apparently fills it in and it is necessary to write back and get all the information before the final classification can be made.

Of course, that refers to what I said at the start. Unless the problem or the kind of accidents are properly classified under the proper head, it is absolutely impossible to tell where the first work should be done and where it is needed most in the industry.

When these reports are made out, for a death claim, for instance, under "death" they will put down maybe 600 instead of 6,000. Up here, the total number of hours worked by all employees in a plant where they have 100 maybe they will have 2,500 or 25,000 or maybe 25,000,000. In other words, they use all the ciphers that they can. They have no regard for the number that they put on.

In order for any plant to know how it stands with regard to other plants, it is necessary to keep a very accurate frequency record of all accidents. That is, if you want to know which way you are going it is necessary for you to keep these reports. This sort of thing has been talked of time and again and has been brought up in other sessions, but apparently no one wants to take the time to do

this work as seriously as it ought to be done. The council and the Chemical Section want to be of all the help that is possible and will give you all the time necessary to solve your problems, if you will just tell them what those problems are.

CHAIRMAN GREENBURG: We haven't discussed this problem of the keeping of accident statistics in the Chemical Section very fully, it seems to me, and I am going to make an effort during the coming year to see that all of the chemical companies are receiving statistics forms and filling them out and sending them back to headquarters office.

The point is simply this, as Mr. Armstrong pointed out: In order to know how good or how poor your plant is standing up with respect to accidents, we have to have accurate statistics on the number of men employed and the number of working days they are employed in order to be able to compute the man-hours employed; and then if you have a certain number of accidents carrying a certain penalty, we can figure that out in terms of man-hours. Having a figure like that, we can compare two or three or more companies manufacturing explosives, for example. In that way we can see if a plant has a high rate and another a low rate, and we can see that the high rate plant immediately needs attention concentrated on its accident problems.

That is the aim with which we attempt to get these accident statistics together. If they are imperfectly done, if they are filled out poorly, they are valueless. They are worth less than the time it takes to fill them out. All the figures called for must be carefully tabulated and put in proper places in order that we may get something out of it. It seems so obvious, if one plant can carry on the manufacture (we will say) of nitric acid and have an accident rate of 100 per 1,000 man-hours, that most every plant in the industry should in a general way be able to equal that record; and if a plant has a record of two or three times that the plant needs careful attention.

I don't mean to be dogmatic about this. There are certain peculiar conditions tied up with manufacturing methods which may not make it possible for the second plant to duplicate the first. But at least the record is good to shoot for; and if we don't get the statistics we can't do even that much. The Chemical Section desires and asks your earnest cooperation in this matter so that we may be able to be of more service to all of the manufacturers in the chemical industry.

I. V. KEPNER (Pennsylvania Salt Mfg. Co., Philadelphia): We have been using these accident statistics now for about five years. We use at all four of our plants the form that is sent out by the National Safety Council, and it is really of great interest when we compare our own plants with others. It comes back to you in code and each plant is given a code number that is assigned to no one but yourself. However, it is interesting to have some friends of yours who are sending in statistics tell you their code numbers. I have two or three that are manufacturing acids the same as our company does, and it is really interesting, especially when you know what company it is.

When you are figuring up these statistics per man hours, why, you have it pretty accurate, whether it is a small plant or a large plant. Of course, the smaller the plant, as a rule, the worse your record is going to show if you have an accident. But, just as Mr. Armstrong says, there are quite a number who don't use care when they send in their accident statistics. For instance the man who loses a finger probably rehabilitates himself in about seven days instead of taking the full penalty which he should. He simply says seven days time lost.

I was interested yesterday morning in listening to a paper given in one of the other sections where a man had a sprained leg and he was only off one day. I can hardly see the need of bringing a man back to a plant who is hardly fit to work. I don't think that is fair to your accident record and I don't think it is true statistics.

I merely want to bring this thought to your mind. It is a great help, and I

would like to see everybody in the Chemical Section, the larger chemical industries and also the small ones, send in the statistics. It is really interesting and you will be more interested when you see your own company there and see how you stand in reference to the others, no matter how large they are.

CHAIRMAN GREENBURG: Does anyone else have a word to add or a question to ask?

L. A. SPERRY (Hercules Powder Co., Kenil, N. J.): In regard to the question just raised, I appreciate fully the importance, from a statistical standpoint, of having each accident reported fully and completely on the basis sent out. At the same time there is one factor about this phase of the matter that I think really should have more emphasis than we have put on it.

During the late war when a casualty occurred, it was the earnest endeavor of everybody concerned to remove this man as soon as possible from the contact of other injured men in order that their morale should not suffer. But our problem is absolutely otherwise. We want to get as much comment and as much discussion of accidents as we can. It is really an advantage to us to have Jim go around with a sprained ankle, if he is able to get around at all, in this way: A man immediately next to him in the work will know how this accident occurred, but if we take him away at once from the plant nobody knows.

But suppose the man does go around among one hundred men in the plant and they see him. They naturally say, "What happened? What is the matter? How did you get hurt?" "Oh, I was doing so-and-so, and I admit I was a darned fool about it but nevertheless I got hurt." Everybody concerned then in the plant has a chance to be warned by the trouble that has occurred to Jim. The result is that we get people to think more about it. The matter of the danger on that particular situation is called to their attention, and we think that has a very great moral effect toward preventing accidents from this cause.

I am not arguing that our statistics should be based on something that is not comparable, but I think there is a great advantage for safety in doing that.

MR. ARMSTRONG: I don't want to give the impression that we shouldn't have men back to work. I think that is a problem that must be decided in the company. The point I would like to get over is that if you are going to report your accidents and use these blanks, in order to make the accident record comparable with other plants, it is necessary to use the full penalty, and not put down seven or eight days lost.

I might also add that there has been some criticism in regard to this form. It is to be revised very shortly, and the council would welcome any constructive criticism immediately after this Congress. So if there is anyone who would like any changes made or can suggest anything that would be better than we now have, they would be very, very glad to get it.

J. S. SHAW (Hercules Powder Co., Wilmington, Del.): I think there is a chance of misunderstanding on the part of some who are reporting. I will give you an illustration.

Jesse Shows, at Hattiesburg, Mississippi, lost a finger. He was off duty three hours. After the finger was dressed, with the physician's consent, he was put back to work—three hours, mind you, after losing a finger. The kind of work that he was doing could be done with one hand. We reported it in accordance with the penalty table, although Jesse Shows lost no time. It wasn't a long-time accident. However, the penalty should be reported properly.

So if you do put your man back to work right away with the doctor's consent, and there is a permanent disability we should not overlook it for that is the thing we want in order to make our results comparable.

CHAIRMAN GREENBURG: Is there any other discussion?

If not, I am going to call on Mr. Miller, of the duPont Company, who has kindly consented to come here this morning and speak to you for a few minutes about safety posters. During the past year the safety poster work of the Chemical Section was not on a very high plane. Many of the plants failed to cooperate in helping us get dramatic pictures for safety posters. Now, what I say isn't supposed to be said in the spirit of criticism, but we are very anxious to get this material for safety posters and a great many plants do put out their own posters and have photographs of accident happenings. If you will try to cooperate by letting us know, we can send a photographer down to take pictures.

The duPont Company has recently staged a very interesting contest, and Mr. Minor and Mr. Miller of the duPont Company have had this under their charge. They have kindly consented to come here this morning and give us some two hundred of these posters and explain the nature of the contest to us.

Posters in Accident Prevention Work

By G. H. MILLER

E. I. du Pont de Nemours & Co., Wilmington, Del.

I want to correct an impression, first. While Mr. Minor and I have done work on the poster contest, nevertheless there are probably about five or six men in the safety division of the company in Wilmington, and they have all, of course, helped. In addition to that the plants have cooperated with us, and to them, too, is due a lot of the credit for any success the contest has had.

My part in this thing is impromptu, but since Dr. Greenburg told me I might be informal and brief, I am going to take the advantage of both.

First, I would like to give you a little of the background of the poster contest, and to do that I am going to make two or three statements. I am not going to lay myself open to any questioning about them, and I am going to protect myself by saying that this is the experience of the duPont Company. Yours may be different.

Accidents are largely due to common hazards rather than to process hazards as is sometimes thought. (As I explained a minute ago, that is our experience and you can't question it.)

Furthermore, the responsibility for the majority of accidents is largely with the employee himself. In other words, due to his ignorance of the hazards or a lack of knowledge of them—his carelessness, lack of information, negligence, whatever you call it. That, again, is our experience. But in any case, these two points that I have just brought out, the fact that the common hazards are those largely responsible for injuries, and the responsibility, tell us definitely that some of the work, at least, and probably the major portion of safety work, should be such as will tend to educate the average workman.

Now, the job largely is this: To create general interest, point out specific hazards, teach them how they should be corrected. One of the means that we use frequently for that is the safety poster.

I don't know whether you have found the same minor fault with the general posters that we have found, or not, but I rather think you have. They don't seem to get down to the point, and we were worried about that. We were trying to find some means of increasing the value of our safety poster activity. At about the time we were trying to find the means of doing that, it was rather forcefully brought to our attention by an employee of one of the plants who voluntarily drew a safety poster.

In this particular plant a switchboard was located over the sink and the soap was kept in the switchbox. The poster created a lot of interest—so much so that we decided to have it distributed to all the plants. Incidentally, we cleaned up two or three things.

But we noticed that the author had shown things in the background and that something was the matter with them. For instance, he had tripping gears around and some were not guarded. In going over that, the men of the safety and fire protection division suddenly came to the thought that here would be an excellent way of bringing the common hazards to the attention of our men and teaching them how they should be corrected. That, of course, required some means of interesting the men further in the posters; but in any case, the problem was studied thoroughly and was discussed with the plant managers, and the approval of the plan was secured.

The thought was this: We would somehow find out the hazards that we had generally in our plants, and show those, or project them into these pictures; and we would then send the pictures out to the employees and let them study the pictures; and then a little later on send out another poster showing those things corrected. But we realized we couldn't get the maximum interest unless we had some kind of scheme to encourage the men to study the posters, so this contest scheme was devised.

You probably wonder where we got the items that we put in the posters. First, we went over the accident records of the duPont Company for a period of about five years. We picked out the common hazards and those largely the responsibility of the employee. Then we went through the inspection reports of the plants and picked out the things there which were generally found to be unsatisfactory. We called them undesirable items, undesirable from the standpoint of accident prevention and fire prevention and good housekeeping. Out of that we secured one hundred undesirable items and by grouping them, in a sense, we discovered we could put them into six scenes: a change house scene, a typical house scene, a construction scene, power and electric, warehouse, and a shop scene. That covers the plant pretty well.

To make the contest eligible to all employees we had to give the man some easy means of responding. We had two posters, one called the negative poster, which was the incorrect poster; and then the positive poster, which showed those things corrected.

The contest ran six months. We ran one poster each month and at the close of the month we sent out the corrected poster so that the men could tell what they should have found. In addition, we made smaller posters of the same one that was sent out each month and the men replied on the back of it and told the reason why they thought each item unsatisfactory.

I want to tell you some of the little problems we had. First of all, we got our artist. The man who had drawn the first poster that we had passed around, we felt could do the work. Unfortunately, he hadn't been on the plant much and didn't know much about the work. It was necessary for us to describe certain conditions about the problem. The problem, of course, was very large. It was more or less on this order: If I told you to draw a cat and you had never seen one, the results probably wouldn't look very much like a cat. That was Mr. Whitacre's problem in drawing these posters, nevertheless he did the best he could and we put them out. But there were a great number of items on there that we didn't intend to be there even though we did give the thing supervision. We had some criticisms and I might give you some of those.

First, the contest lasted six months, as I explained, and some thought it was too long (and it may have been), but the majority of the plants (and there were forty taking part) carried the contest successfully through the six months. In a few cases it was necessary to divide the contest into two parts, three months each; and in some, monthly contests, but that was only where they didn't get a good start.

As I explained before, we had lots of things in the posters that we didn't intend (I mean little undesirable items that the men picked out). Sometimes the men

found two or three times the items that we had intended them to find. We also thought that was favorable. The men got a lot of good out of discussing the technical points about the posters that they thought were incorrect.

One of the first criticisms was that the first poster was too easy, but that was, as you may readily see, intentional for we wanted them to get started off with the easy poster and afterwards progress to more difficult ones.

CHAIRMAN GREENBURG: The idea has a peculiar, unique, psychological appeal which certainly, it seems, must strike home. Of course, the trouble with all this poster work of the council and every other organization that exists, including commercial advertising, is that the appeal is a very difficult thing to get and to maintain. Drawing a contest out for six months, I should think, would have a tendency to have every one take an interest in it, particularly when monetary reward is given for working it out.

The next paper on our program is Dr. Vandell Henderson, Professor of Applied Physiology, of Yale University, and we are fortunate in having him here to present his important subject. In many plants, I suppose, gases and fumes and dust play a very minor role, but these sources of illness and death are borne home to every one of us at some time or other. I have in mind a case that happened at Niagara Falls in which several men were asphyxiated while painting the inside of a tank car with a rubber compound. I am certain that there is no subject, in the chemical section which is more misunderstood than gas masks and respirators. There are so many prevalent fallacious ideas about the efficiency of these various devices that we are most fortunate in having Dr. Henderson here to clear them up for us.

It is indeed a great pleasure and privilege to present Dr. Henderson.

Gas Masks and Respirators

By DR. VANDELL HENDERSON

Professor of Applied Physiology, Yale University, New Haven, Conn.

The gas mask is a really extraordinary invention and has been brought to a high degree of efficiency in the protection which it affords. Although it is now manufactured quite cheaply it has been produced at a tremendous initial cost.

In Europe it is sometimes charged that we Americans value everything according to what it costs. This charge is not true, but if it were true, we ought to value the gas mask above every other human invention, for the gas mask has cost more than the steamship, or the steam engine, or the automobile, or electricity. It has perhaps cost more than all these other inventions put together. It cost the entire expense of the great war, for the reason that (so far as I can discover) no good thing whatever came out of the war, excepting only the gas mask. The civilized nations spent ten million lives or more and hundreds of billions of dollars, and yet (as I have seen Europe lately) neither is "the world safe for democracy" nor is "war ended." But one thing civilization did get out of it all, and that is an excellent gas mask. So I recommend this article to you as being worthy of use wherever needed, both because it can save lives, and because of the stupendous price we have paid for it.

The first point which I wish to emphasize is this: There are many different kinds of gases, and these various gases have widely differing chemical characteristics. They are alike only in this one respect that they are all volatile. They differ also in their physiological effects; they have widely differing poisonous actions. They are alike only in this respect that they can all kill. For these reasons when you place a mask upon a man who is going into a poisonous atmosphere, that mask must be adjusted to the kind of gas to which the wearer is to be exposed. I wish to support the point which the chairman made in introducing me, when he warned

against the dangerous fallacies widely believed in regard to gas masks. A mask to be effective must be in good order, and it must be suitable for the particular gas in which it is to be used. Often a factory buys a mask and hangs it on the wall. In the course of a year or two the rubber dries and cracks. Often the mask purchased is unsuited to the use to which it is some day put. Often it contains an absorbent for ammonia when it is to be worn in sulphur dioxide; or possibly it is a mask that would afford protection in carbon monoxide, but when it is worn in "black damp," to which it is unsuited, it costs the wearer his life.

Valuable as are suitable gas masks, unsuitable masks do far more harm than good for they give a false feeling of safety. It is important to reinforce the good and counteract the harm and danger of gas masks. To this end, even in the short time available, I am going to run over the characteristics of the four principal types of poisonous gases. I do this because the protection which the various types of gas mask afford against the different gases, and against particular groups of gases is quite specific. A mask provided with an absorbent which makes it effective against one gas may be wholly ineffective, and therefore dangerous, in other gases.

The gas that was oftenest heard of a generation ago was what miners now call "black damp." It is simply a lack of oxygen in any atmosphere of other gases. There is really no single gas that can be separated in pure form and put in a bottle and labeled "black damp." As it is merely the absence of oxygen, the chemical test for "black damp" is that a flame will not burn in it. Its physiological effect is that a man who breathes it is asphyxiated by the lack of oxygen.

"Black damp" can be produced in several different ways. All of them involve a nearly complete withdrawal of oxygen from the air or the replacement of air by a gas or gas mixture containing no oxygen. The test for "black damp" which has been used for 1,000 years or more is made by means of a lighted candle; if the flame is extinguished, the atmosphere is dangerous; if the candle continues to burn, the atmosphere contains enough oxygen to support life also. This test is effectually applied to wells, sewers, grain elevators, and to silos where fodder is stored. In a silo the material undergoes a fermentation which is essentially like breathing. It thus consumes oxygen and produces carbon dioxide. Because carbon dioxide extinguishes a candle it is sometimes identified with "black damp." But the essential characteristic is not the carbon dioxide, but the lack of oxygen.

"Black damp" frequently occurs in the holds of ships; and many lives are lost every year because of it in the ports of all maritime nations. When the cargo consists of materials like rubber or other organic and oxidizable substances, or of living things such as bananas which breathe in much the same manner as do men and animals, the oxygen in a closed space may be consumed. Carbon dioxide may or may not be produced, it does not make much difference; the essential point is that oxygen has been withdrawn. Consequently when a man goes down into the hold, he falls unconscious and, unless rescued quickly, he dies of acute asphyxia due simply to lack of oxygen.

Many other conditions which cause the absorption of oxygen from air produce "black damp." During the building of a bridge across a river a janitor may be asphyxiated in the basement of a building near the bank of the river. In such cases the series of events is as follows: The bridge builders sink a caisson as a preliminary to erecting a pier. In the caisson air is compressed, so as to prevent the mud of the river bottom from rising and drowning the men at work there. The compressed air diffuses into the mud around the caisson, and thus through the river bottom to the basements of buildings near the shore. As it diffuses oxygen is absorbed by the organic material in the soil. It does not occur to the janitor in a building near the shore to carry a candle when he goes down into the basement where he is accustomed to work. He merely switches on the electric

light, and collapses because an atmosphere which consists chiefly of nitrogen will not support life.

Physiologically "black damp" gives no warning; it produces no sensations. The victim often has no suspicion that anything is wrong until his legs fail and he falls helpless. No pain or even discomfort is involved in being thus overcome. The only discomfort is during a recovery unassisted by proper treatment; for unassisted recovery is prolonged, excessively painful, and sometimes incomplete. This in brief outline is simple asphyxia.

Related to this condition is carbon monoxide poisoning. This also is a form of asphyxia and acts, therefore, in much the same way physiologically as asphyxia by "black damp." But chemically it is entirely different. Carbon monoxide asphyxia has been talked of so much in recent years that I need not say much on the subject. Everyone knows now that he must not go into a small garage and start his car unless he has opened the door first; that is, he must not do this unless he wants to die. Everyone knows now that carbon monoxide is the poisonous factor of illuminating gas, and that it is the constituent of smoke which overcomes firemen. Carbon monoxide results from incomplete combustion. It produces an asphyxiation which as far as the victim is concerned is very similar to "black damp." He feels no sensations in going under and dreadful sensations in coming back. He may suffer permanent injury, particularly to the heart, unless he is resuscitated properly.

On the other hand, from the chemical standpoint, an atmosphere which is dangerously contaminated with carbon monoxide is entirely different from an atmosphere of "black damp;" for a candle may burn well in it and give no warning at all. There is usually plenty of oxygen not only for a candle but for a man also, if it were not for the peculiar toxic effect of carbon monoxide. Even in a very poisonous atmosphere there is not enough carbon monoxide to explode; yet even a small amount is quickly paralyzing and fatal for a man, for it combines with the blood and thus deprives the body of its supply of oxygen. It thus acts as an asphyxiant even in the presence of ample oxygen. And because a man who has absorbed carbon monoxide continues to be asphyxiated even after he is brought into fresh air, it is especially important to apply measures of resuscitation which will eliminate carbon monoxide from the blood as rapidly as possible and thus abbreviate the period of asphyxia.

Much the same description applies to cyanide, or hydrocyanic acid gas, which is used now to kill rats and fleas in the fumigation of ships. Cyanide is a tissue asphyxiant even in minute amount. It differs from carbon monoxide in the fact that, if the victim does not die immediately, he generally recovers quickly and completely. So much for the three principal asphyxiants: "black damp," carbon monoxide and cyanide. We shall see later that each requires a different absorbent in the mask.

Next we will consider the irritants. Practically all the war gases are irritants. They do not asphyxiate directly; they attack the lungs, but in such subtle fashion that it may be hours before the victim drowns in the fluid which the injured lungs exude. Among the irritant gases are the acid fumes, the alkali fumes, and related substances occurring in industry. Chief among them are chlorine, phosgene, sulphur dioxide, the red fumes, or oxides, of nitrogen, and ammonia. Hydrogen sulphide in certain concentrations comes under this class also; indeed at one strength or another it comes under nearly all classes of noxious gases. Mention must be made also of carbon tetrachloride when used for the purpose of extinguishing fire. Carbon tetrachloride itself is practically harmless. It can be swallowed; and it is so used, as a means of getting rid of hookworm. But if it is sprayed on hot iron it undergoes a partial oxidation and produces phosgene which is one of the most deadly of lung irritants.

There is not time to dwell on the individual peculiarities of the irritant gases. Some act in the nose and throat, some well down in the windpipe, and some particularly in the lungs. The deeper the point at which they act to produce irritation, the less the immediate effects, and the worse the ultimate effects. Those which act in the nose and throat produce at once extreme discomfort; and the man who has inhaled them is driven out into the fresh air. On the other hand, the most dangerous lung irritants produce so little irritation immediately in the nose and throat that a man inhaling them is not warned of his danger. Thus a man who has inhaled nitrous fumes from burning dynamite, or from nitric acid spilt on a wooden floor, may go home feeling fairly well at the end of his day's work; but before daybreak the next morning his lungs have filled with fluid and he is drowned by pulmonary edema. With the irritant gases, as my colleague Dr. H. W. Haggard has shown, the point at which they act in the respiratory tract, and therefore the severity of their action depend on their solubility. If they are very soluble they are caught in the fluids of the nose and throat. Of course the nose and throat, and the eyes also, are thus intensely irritated; but the gases are absorbed in this action and do not reach the lungs. On the other hand phosgene and nitrous fumes are not very soluble and do not irritate the nose and throat to an unbearable degree. As they are not absorbed in the fluids of the upper respiratory tract, they pass into the lungs and initiate the inflammatory process of pulmonary edema. Thus the irritants differ markedly from the asphyxiants in their physiological effects; and, as we shall see, they demand different types of protective masks for the men exposed to them.

A third group of gases, particularly important in the chemical industries, contains most of the volatile organic substances such as chloroform, ether, benzol, methyl and other alcohols, and the petroleum distillates. The primary action on the body of most of these vapors is like that of the anesthetics used in surgery. A surgeon could, in fact, anesthetize a patient with gasoline; the disadvantage would be that the patient would probably have convulsions before the surgeon had time to operate. Gasoline is a fairly strong, but poisonous, anesthetic. Benzol is also, but has other marked toxic actions. In fact this statement applies to most of the volatile organic substances included in this group. So much for their physiological characteristics.

Turning now to the chemical characteristics of the organic gases and vapors, we find that while they differ in some respects among themselves they are all, fortunately, easily absorbed by a special form of charcoal which is placed in masks for protection against them. But this absorbent for organic substances does not absorb many of the other groups of gases.

Finally there is a fourth group of gases. Most of those which have been mentioned thus far are not what toxicologists would classify as protoplasmic poisons; but this fourth class includes a variety of substances which are true poisons of the most active type. It includes tetraethyl lead, which killed a number of workmen a few years ago in a plant at Bayway. It includes also mercury vapor and arsenurated hydrogen and other metallic and organo-metallic substances. In any shop where mercury is used carelessly it may be spilled and trodden into the floor, or rubbed into the work benches. After a time there is thus enough surface of this volatile metal exposed to contaminate the air of the work room, and mercury poisoning may result. That mercury is volatile is demonstrated by the fact that, in nearly every chemical laboratory or industrial plant in which mercury is used, a good deal more mercury goes in than appears to come out. It comes out largely in the exhaust air; but unless the ventilation is good it comes out partly also in the bodies of the chemists and workmen.

With these four types of gases in mind let us consider the types of gas mask that are available for protection against them. There are three chief types.

First there is the hose mask. It is simply a facepiece, or hood, or helmet connected by means of a piece of hose to an air pump. The hose is light but wrapped

with wire so that it cannot be kinked and shut off; and it is long enough to reach out of the poisonous atmosphere to an air pump. This pump is worked by an assistant and blows fresh air to the man wearing the facepiece or helmet in the poisonous atmosphere. For all purposes where a hose mask can be used it is by far the safest and best form of mask. Under all such conditions it should be used in preference to any other type of mask. (This remark was applauded by Dr. Ethelbert Stewart.) I wish everybody would applaud that standpoint. (General applause.) The reason the hose mask is the best of all masks is that as pure, fresh, outside air is blown to the man wearing it, it makes no difference what the character of the atmosphere in which he is working may be. That atmosphere may be dangerously contaminated with dust, or asphyxiant gas, or volatile organic poisonous vapors, or volatile inorganic poisons; but the wearer of the mask breathes only pure air.

Unfortunately the hose mask has one unavoidable disadvantage in that it is limited by the length of the hose. In a mine, for instance, the wearer of a mask cannot drag a quarter of a mile or more of hose through whatever obstructions he may meet in the irrespirable atmosphere. For this reason, when the place where the man is to go is too far from fresh air for the hose to reach to it, then the true gas mask comes into use. The true gas mask is the instrument which was developed out of the war and for which we have paid ten million lives and billions of money. It has become a wonderfully fine instrument. It consists of a facepiece of heavy rubber with non-shatterable glass goggles. After an immense amount of experimentation it has proved possible to make facepieces which fit gas-tight on every shape of face, providing the size is right and providing the rubber is new enough to be soft and not cracked. This facepiece is connected by a short piece of non-collapsible rubber tubing to a tin canister containing the absorbent or catalytic materials which remove the poisonous gases from the air drawn through them. Two points must be attended to if the canister is to be used effectively and safely. The first is that there are four more different kinds of absorbent materials that may be put into the canister, and that each of these materials is effective only against certain gases and not against others. The type of catalyst or absorbent in the canister used must, therefore, be adjusted to the kind of gas in which it is to be carried.

The second point is that there is no possible adjustment of a canister gas mask which will make it effective for protection in "black damp," for it cannot produce oxygen. Against all other poisonous atmospheres, however, canisters filled with the correct material are now very efficient. For ammonia there is an absorbent or catalyst, and the canisters to be used at an ammonia plant should therefore be filled chiefly with this material. There is an entirely different catalyst for carbon monoxide, a catalyst which is extremely effective in decomposing this most common noxious gas of modern life. But this catalyst does not act upon ammonia. Ordinarily in an atmosphere containing carbon monoxide there is plenty of oxygen; and the air is, therefore, respirable providing the carbon monoxide is removed. For miners and, as a rule, for city firemen the canister should therefore contain chiefly the catalyst for carbon monoxide. But such a canister is not effective against the irritant acid gases. For them—but for them only—the absorbent which is effective is soda lime.

The fourth type of absorbent is activated charcoal upon which vapors like benzol and gasoline and methyl alcohol will condense. This form of charcoal is extremely effective against volatile organic substances. It is, however, quite ineffective against carbon monoxide.

In addition to the masks with specialized canisters there is the so-called "all service" mask. It contains a little of every kind of absorbent and is thus effective for a short time in any atmosphere, except "black damp." It is particularly useful when the nature of the atmosphere is unknown, as for instance in the smoke

and fumes from a burning factory or warehouse containing many different chemicals. But as the "all service" mask can contain only a little of each absorbent its life, that is the period during which it can afford protection, is short.

The most important rules to be followed in using gas masks are therefore as follows: If you are going into a poisonous atmosphere where a hose will reach, use a hose mask. If you are going into a place where the hose will not reach and you do not know the character of the gases, use the "all service" mask. But be sure to carry a candle or a miner's lamp with you. If the flame of the candle or lamp goes out because of lack of oxygen, come out into fresh air quickly. The candle and the miner's lamp are extinguished in atmospheres containing 17 per cent of oxygen, while a man is in no serious danger of being overcome until the atmosphere is down to about 14 per cent of oxygen. If you are going into an atmosphere contaminated chiefly by smoke, use the mask with a canister containing the carbon monoxide catalyst and a smoke filter; but carry a candle or lamp. In case the candle or lamp is extinguished, then, but only then, it is advisable and necessary to use the third type of mask, which I have next to describe. In other words, use this third type only under conditions in which neither the hose mask nor the canister mask is practicable or safe, that is in atmospheres which do not contain enough oxygen to support life and in places which cannot be reached by a hose.

This third type of mask is the so-called "self-contained oxygen apparatus." While there are a number of different types of such apparatus, they all consist in principle of a breathing bag, a canister of soda lime, and a cylinder of oxygen. The wearer breathes back and forth into the bag; the carbon dioxide which he exhales is absorbed by the soda lime; and oxygen is fed into the bag as the wearer consumes it. A minor disadvantage of such apparatus is its weight and clumsiness. The great disadvantages are that its use requires training and experience, and that it is largely composed of rubber which deteriorates rapidly. Unless the rubber is very well taken care of, it cracks in little more than a year. The crack may not be noticed; gas may enter through it; and the wearer may be thus overcome and killed. The last time I investigated the matter, some years ago, I found that this type of apparatus had cost as many lives as it had saved. Rescue crews wearing oxygen apparatus may go into wrecked coal mines and bring out injured men; but unless the utmost care is exercised, and sometimes even then, a little crack in the mouthpiece of the apparatus, or some other defect, may cost the life of one of the rescuers. Oxygen rebreathing apparatus is an exceedingly valuable instrument; there are conditions in which nothing else can be used. But it should be used only by men especially trained to wear it, and only under the most carefully controlled conditions. It should never be used if either of the other forms of gas mask will serve the purpose.

There are one or two other matters, which are related to this general topic, that I think I should touch upon. One of them is the treatment of edema of the lungs from inhaling an irritant gas such as the oxides of nitrogen. The difficulty is that in many cases there is no way to be sure that the patient is going to have lung edema until matters have gone too far to do much to help him. Yet unless precautions are taken, and even in spite of all precautions, twelve hours later the lungs may fill with water exuded from the blood, and the man dies. On this account it ought to be the rule that whenever a man has inhaled chlorine, or phosgene, or the red fumes of nitrogen, or any other irritant gas, he should be carried on a stretcher and put to bed, and kept in bed. Even if he feels quite well and protests against this treatment, he should be kept perfectly still. After the edema has developed, a doctor should under no conditions be allowed to ask the patient to sit up, so that he can listen to his lungs. Although the doctor finds out about the lungs by listening to the râles, he can do little to relieve the edema; and the patient who is required to sit up is likely to demonstrate his own condition by

suddenly falling back dead. It is wise, therefore, to limit the methods of diagnosis and leave the patient alone. He has little chance at best.

In the treatment of carbon monoxide asphyxia and of intoxication by any of the organic substances, such as bootleg liquor (however taken into the body), or by gasoline, or benzol, or any similar gas, vapor or liquid, the most important object is to eliminate the substance from the blood and tissues as soon as possible. For such a substance as methyl alcohol to be completely excreted through the kidneys may take weeks; and this alcohol is burned in the body only slightly and slowly. That is one reason methyl alcohol is so dangerous and cumulative a poison. If it has been inhaled as vapor or drunk as liquid, it takes a long time for removal from the body, and the elimination occurs chiefly through the lungs. The elimination of carbon monoxide is wholly through the lungs.

In treating men poisoned with such substances, it is of the first importance therefore to stimulate respiration and thus to cause such vigorous breathing that the volatile poison may be rapidly ventilated out of the body. For this purpose my associate, Dr. H. W. Haggard, and I have developed the treatment by inhalation of oxygen and carbon dioxide. Carbon dioxide is nature's own stimulant of breathing. It is the stimulant which we all experience every time we make a physical exertion and breathe more vigorously because of it. This inhalational treatment is now widely used here in America and is being adopted in Europe also. We have introduced essentially the same treatment into surgery; it is used at the end of anesthesia to hasten the elimination of the anesthetic and to prevent post-operative lung complications. This treatment is now being used also to resuscitate newborn babies, if they do not start breathing of themselves. Even in Germany, where the pulmator was invented, that apparatus is being discarded and inhalators for oxygen and carbon dioxide are being introduced. In fact, all over the civilized world this treatment is being adopted. So far as I know the only two agencies which do not fully accept its advantages are the U. S. Bureau of Mines and the U. S. Public Health Service. They will ultimately.

This has been a rambling talk touching only on salient points. If you really wish to know about this subject, I recommend a book called "Noxious Gases" by Henderson and Haggard. In recommending it I have no mercenary motive, for the total royalties on a really useful book rarely pay more than the stenographer's bill. I recommend this book merely because it is the only one that attempts to describe systematically all the poisonous gases of industry, their effects, their treatment, and the different types of gas masks.

If, however, you do not care to get this book and inform yourself about a rather appalling subject, I will give you an even simpler and more practical piece of advice. The manufacturers who now produce gas masks are of high character,—especially that concern which has done more than any other agency to bring the gas mask to its present perfection—I mean the Mine Safety Appliances Company. If, therefore, you need a mask for certain particular conditions, never mind about my book; just write to the Mine Safety Appliances Company, or any other reliable company, and tell them of the gaseous conditions you have to meet. You can depend upon them to give you the type of mask that will afford protection. But do not fail to get their advice or the advice of someone who is competent in this field.

The sum and substance of the whole matter is this: A mask which affords perfect protection against one gas may be wholly ineffective against other gases. Be careful to get the right mask.

I. V. KEPNER (Pennsylvania Salt Mfg. Co., Philadelphia): I was very much interested in Dr. Henderson's paper. There was one thing I was in hopes he might bring out and that is the care and use of a gas mask. So many of us that are familiar with gas masks, but we merely purchase them and put them away and when we want to use them very often we will find that they are not

in the best of condition. I want to bring to the attention of the section the need of a Safe Practice Pamphlet on that subject. I think it is well worth while.

CHAIRMAN GREENBURG: We are again fortunate this morning, ladies and gentlemen, in having with us Mr. Yant, of the United States Bureau of Mines, who has kindly consented to speak to us on this subject. The United States Bureau of Mines is a governmental agency and has had more experience with the design and testing of gas masks than any other federal agency.

W. P. YANT: I feel somewhat honored to be asked to attempt to add to the remarks of Dr. Henderson because we consider Dr. Henderson the dean of investigators in respiratory equipment. He started out early in the war and has followed it through, and is still keeping in touch with it. He has so adequately covered the subject that I don't have a great deal to add except this:

We have strongly considered this subject of the care and maintenance of apparatus, for even though you have good equipment, if you don't keep it in shape it will deteriorate or it won't be in the proper condition when you are ready to use it. It is not like other equipment that you use daily and see when it fails; but it is something you put away until you need it in an emergency, and then you need it and it must be ready. So there is only one way to take care of it and that is care in inspection, systematic inspection from time to time so that it is ready and you can see when it is in proper condition and when it begins to disintegrate.

I might add to the classes which Dr. Henderson has made, it is not really a special class of respiratory equipment, but it is something coming into use more and more, and it is one which has been considerably neglected in the field of development. I might say that there is really some good work being done now and very good devices coming out, but it lagged behind in other equipment, and that is a small type of what is known as a respirator. All these devices have names. To some people a gas mask means anything from oxygen breathing apparatus or anything else. But each one of them has a special name. Well, the industry has more or less attributed the name respirator to a small device that fits over the nose and face, but the canister is much smaller.

This respirator is used in such industries and for such uses as spray painting and to keep out silica dust, and for such general use as that. It is not as large as a mask. It does not cover the face and it is not cumbersome.

Again, some people take a respirator as a panacea for all troubles. They may have benzol vapor and buy one with a wet sponge or a flannel in front and think it is doing good. But there again you must choose the respirator for the job you have to do. For jobs like spray painting you must have an appliance that has an absorbent or a charcoal to take up the vapors. It is the same type of material you use in canisters, only it is a smaller canister. For example, if you are interested in dust, charcoal won't stop it. You must have one with an adequate filter—whether it is cotton, felt, or filter paper—something that is specific for that particular thing.

So the point I want to make is if you buy a respirator, be sure you buy one that meets your needs.

You might say that the people of this country, the men who have developed face masks and respirators can be quite proud of their work, for there is made in this country now a respiratory protection for practically every need that comes about.

I remember when they first started drilling in the Texas Panhandle oil fields, they encountered high sulphur gas and when closing the wells it rendered many men unconscious. It was due entirely to hydrogen sulphide. While there were many chemists on the job, yet of all those chemists there was not a single one that recognized that the hydrogen sulphide would be the offending agent.

They said it couldn't be, that they had smelled it in the laboratory and had no ill effects. By merely using a hose mask, or a gas mask where the hose mask didn't give the freedom of operation desired, they could close the same wells in an hour or two without any trouble.

Another instance where I might say the operation or process depends entirely on gas masks, was in the use of a mixture of benzol and acetone. The process was developed and the plan went into effect. The process in this particular plant consisted of pressing a wax cake that had been extracted by benzol and acetone in the filter press at a temperature of fifteen below zero. After it was all ready they had so much acetone vapor they couldn't go in and open up the filter press. By merely getting some gas masks they carried the process right through and they are conducting it in that manner at this time. Whether they will finally get rid of it by ventilation or making a more enclosed system, I don't know, but the present plans of the company are to open up the filter presses using gas masks. There is an example of a process which would entirely fail if it weren't for this gas mask which Dr. Henderson says cost millions of lives and billions of dollars, and I am glad to say we are getting some dividend back.

I want to add a comment to Dr. Henderson's manner of testing for oxygen. I highly approve of it, but I don't approve of the candle for in many cases you come out sooner than you expected. It is very good in most cases where you just have low oxygen, but in a considerable number of cases I wouldn't advocate its use. It is very good in a metal mine. You seldom find any gas. In most tunnels it would be dangerous, and also in sewers. I highly approve of the part where he said he uses a flame safety lamp, but not the candle. I think he didn't stress that; he was merely bringing out the point of the flame going out, so I will grant that.

CHAIRMAN GREENBURG: This whole question of masks and respirators is a very live one. I am certain that if we started an open discussion we could run right along until four o'clock. Unfortunately, we can't do that. We have a little of the Society's business to bring up this morning and we have other papers. However, it seems unfair to close discussion on this important subject, and if anybody has anything important to contribute I think we ought to hear it.

J. S. SHAW (Hercules Powder Co., Wilmington, Del.): Two years ago in Detroit we were recommended to use ammonium carbonate in the case of a workman being fumed with acid gas. Does Dr. Henderson recommend that?

CHAIRMAN GREENBURG: Dr. Stewart?

DR. ETHELBERT STEWART (U. S. Bureau of Labor Statistics, Washington, D. C.): The Bureau of Labor Statistics in making an investigation of spray coat painting found that the mask was an abstract question and in many instances it is worse than nothing at all. When Dr. Henderson said that the best thing was the hose mask, I certainly hope that that will be in the record. I want to quote it and I want to quote it often and hard.

The whole question of spray coating is getting to be something terrific. You have no idea how many thousands and tens of thousands of little concerns rent a little shed and start refinishing furniture and that sort of work, using a spray coating machine, with absolutely no protection whatsoever. Now, because their victims don't die in fifteen minutes, why, it is perfectly safe.

Again, the benzol question: I am told by perhaps as good authority as any, the du Pont people, that benzol is unnecessary; that there are substitutes that will take its place in every case, so far as thinners for spray coating work is concerned.

I think we have gotten them on the run so far as the kind of mask, the kind of protection that they need. The only question is the rate of air per lineal foot that is necessary in these cases. We get all sorts of arguments. I am

told sixty-five feet is enough. I have recommended two hundred feet and I am told that is too low. I would like to know—of course, I recognize that it is something which is dependent upon the constituents being sprayed—but I would like to ask Dr. Henderson if he can give me some information as to the lineal feet of air current that these hose masks should carry in order to be absolutely safe. We have no trouble with the big concerns. It is the little concern that gives us the trouble, and I want some light on that subject if I can get it.

CHAIRMAN GREENBURG: Any further questions?

DR. W. H. HINKEL (Atlas Powder Co., Wilmington, Del.): I just heard mentioned acetone poisoning in connection with benzol. I have tried for some time to get some information about acetone poisoning—whether there is such a thing or whether there isn't. I would like to know, if I can, if there is such a thing.

CHAIRMAN GREENBURG: Are there any other questions relating to gas masks and respirators?

MR. KESSEY (Virginia Chemical Corporation): We have had some unfortunate experience in acids-breaking down. We have lost several men. I would like to ask what we should use to protect our men in doing that work.

MR. SLATER (Eastman Kodak Co., Rochester): Dr. Henderson told of some of the things which the doctor ought not to do, namely, not to raise the patient, not to examine him, but to keep the patient quiet. Would he be able to indicate what other things the doctor might do in treating pulmonary edema due to acid?

W. A. COOK (Travelers Insurance Co., Hartford): I am wondering if any effort is being made along the line of establishing standards for respirators. Perhaps Dr. Yant might help us out along that line.

CHAIRMAN GREENBURG: I am afraid we will just have to stop. Dr. Henderson is about overwhelmed and we may have to carry him out.

Final Discussion by Dr. Henderson

DR. HENDERSON: I heartily agree with Mr. Kepner regarding the inspection of gas masks. In fact I think I would go even further; for I would require training under service conditions. If the mask was intended for use against ammonia I would occasionally send a man into dilute ammonia vapor with the mask on. Then I would bring him out, take the mask off, and send him in again without it. He would thus learn how to use the mask when the need comes, and to appreciate its protection.

I agree also with everything that Mr. Yant has said. I concede him the candle. I remember once, when Dr. Haldane of England, the great authority on this subject, was here in America, we went through a mine in Cripple Creek. Dr. Haldane is an enthusiast in regard to atmospheres low in oxygen. He said to the engineer who was taking us through the mine: "What I want is some bad air." So the engineer took us down a disused and unventilated passage. He went on ahead with an acetylene lamp, while the rest of us followed with candles. He went on and on; and first one candle went out and then another, until finally there was nothing left but the acetylene torch. At that point even Dr. Haldane was satisfied, and we turned back toward more oxygen. I think I should always like to come out before the acetylene torch is extinguished, and I expect even Dr. Haldane and Mr. Yant would be willing to come with me.

In regard to hydrogen sulphide: when its escape into the required air cannot be controlled in any other way, it may be decomposed and then limited as a health hazard by releasing small amounts of chlorine into the air also. Hydrogen sulphide and chlorine react and eliminate each other. This is also the simplest and most effective way of deodorizing many industrial processes. A very little

chlorine gas added to the effluent vapors of a garbage plant, for instance, is effective in freeing the neighborhood from its stench.

As regards the use of ammonium carbonate and smelling salts in resuscitation or in neutralizing the effects of acid fumes, the best that can be said is that it is innocuous bunkum (laughter). It does no good and probably no harm either. It is just nonsense.

With regard to the question that Dr. Stewart asked concerning spraying methods of painting and the proper velocity in linear feet of the air flow through a hose mask to a man directing the spray, I would suggest that the requirement should be expressed not in linear feet, but in cubic feet of air per minute. A man working hard may breathe twenty liters of air per minute or more. Half of the time he is inspiring and half the time expiring. Thus as a minimum the air supply should be at least fifty liters a minute, that is 2 cubic feet of air per minute should be blown through the hose into the helmet. This figure may be turned into linear feet by dividing it by cross-section of the hose.

As to Dr. Hinkle's question of the possibility of acetone poisoning, I must admit that I do not know of any cases. But I should think such poisoning would be quite possible. I have drunk acetone myself to determine the effect; and I found it an unappetizing drink. From the pathological standpoint it is noteworthy that diabetic coma is associated with acetone and in the blood and breath. In this disorder acetone is produced in the patient's own body, although the coma is not believed to be due to any great extent to acetone. While acetone is, therefore, not extremely poisonous, its inhalation should certainly be avoided, just as the inhalation of any industrial vapor should be avoided even in the absence of seriously harmful experience.

For the protection of an acid plant hose masks should be used, if possible. If canister masks have been used and the men wearing them have been overcome, it is probable that all the alkali in the canisters has been exhausted by combination with the acid. If this is correct the canisters, or at least the soda lime in them, need merely be renewed in order to afford protection. There is, however, another possibility. Sulphuric acid may form not only a vapor but also a spray of very finely divided droplets. Such a fog will pass through alkali and charcoal and in fact through anything except a filter. I should suggest, therefore, that if the trouble at the sulphuric acid plant is not overcome by new canisters of soda lime, filters to take out the fog or spray should also be inserted in the canisters.

So far as I know, no cases of mercury poisoning have yet resulted from mercury engines, but it certainly seems that sooner or later some mercury vapor must escape; and if this happened the results would be serious.

In the treatment of edema the patient should be kept absolutely quiet. The physician should be allowed to listen to his lungs, but not to move him or to ask him to move. If anything is to be done oxygen should be administered; not oxygen mixed with carbon monoxide, but pure oxygen mixed with air; and this inhalation should be begun as soon as the patient is at all cyanosed, that is blue around the mouth. The amount of oxygen should be adjusted to keep the patient's color normal. It should not be used to excess, for prolonged inhalation of oxygen is slightly irritant to the lungs. It is best also to conserve oxygen in case there is more than one patient to be treated. In an industrial plant where the physician may be called upon to treat pulmonary edema resulting from irritant gas poisoning, it would be well for him to be provided with an apparatus for administering oxygen diluted in air. The same inhalator as that used for treating carbon monoxide poison can be used also for treating lung edema; but for lung edema the cylinders of oxygen and carbon dioxide are replaced by pure oxygen.

Finally let me express my high appreciation of the kind things that have been said here regarding my work and particularly my appreciation of what Mr. Yant has said. Mr. Yant and his associates at the Bureau of Mines do such splendid work that there is a very keen competition, a friendly sort of race between their laboratory and mine. Several times lately I have found them ahead of us. But that only stimulates us to work the harder. I judge that our competition has the same effect upon them. It is a fine kind of competition, and a race in which everyone wins.

CHAIRMAN GREENBURG: Now we will have the report of the Nominating Committee by Mr. Kepner.

Report of the Nominating Committee

We, the Nominating Committee, appointed to select a suitable personnel of officers, to serve the Chemical Section for the ensuing year, have attended to that duty, and after careful study and due consideration, the following names are placed in nomination:

Chairman: Dr. Leonard Greenburg, U. S. Public Health Service, Yale Medical School, New Haven, Conn.

Vice-Chairman: C. F. Whittemore, Western Electric Co., Chicago, Ill.

Vice-Chairman: E. C. Rogers, The Grasselli Chemical Co., Cleveland, O.

Secretary: George E. Minshull, DuPont Rayon Co., Inc., Buffalo, N. Y.

Chairman, Engineering Committee: A. L. Armstrong, Eastman Kodak Co., Rochester, N. Y.

Chairman, Industrial Poisons Committee: S. E. Whiting, Liberty Mutual Ins. Co., Boston, Mass.

Chairman, Publicity Committee: John Roach, Deputy Commissioner of Labor, State of New Jersey, Trenton, N. J.

Chairman, Program Committee: C. F. Whittemore, Western Electric Co., Chicago, Ill.

Chairman, Membership Committee: E. C. Rogers, The Grasselli Chemical Co., Cleveland, O.

Chairman, Poster, Slide and Safety Kink Committee: George H. Miller, E. I. DuPont, deNemours & Co., Wilmington, Delaware.

Chairman, Statistics Committee: Carl F. Coffelt, Victor Chemical Works, Chicago Heights, Ill.

Executive Committee, The Officers, and: S. H. Kershaw, National Safety Council, Chicago, Ill.

Ira V. Kepner, Pennsylvania Salt Manufacturing Co., Widener Building, Philadelphia, Penna.

John S. Shaw, Hercules Powder Company, Wilmington, Del.

H. L. Miner, E. I. duPont deNemours & Co., Wilmington, Del.

L. A. DeBlois, National Bureau of Casualty & Surety Underwriters, New York City.

Dr. H. C. Parmelee, "Chemical and Metallurgical Engineering," New York City.

Prof. C. E. A. Winslow, School of Medicine, Yale University, New Haven, Conn.

Dr. H. E. Howe, "American Chemical Society," Washington, D. C.

C. E. Rice, The Dow Chemical Co., Midland, Mich.

Wm. A. Baxter, The Newport Co., Milwaukee, Wis.

Ralph O. Keeper, Aluminum Co. of Am., Massena, N. Y.

Maurice Schwarz, Consulting Chemists, New York City.

Respectfully submitted,

John Roach,
John S. Shaw,
J. H. Barnholt,
Ira V. Kepner, Chairman.

(Upon motion regularly made and seconded it was voted that the report be accepted.)

CHAIRMAN GREENBURG: The next subject on the program consists of three brief contributions on "The Safe Handling of Compressed Gases." The first speaker is Mr. J. I. Banash, Consulting Engineer, of Chicago.

MR. BANASH: With the Chairman's permission I would suggest that, since our time is short, we have two guests who are not members and I would like to defer to them so that you will be sure to hear them. I will remain in the hall and tell you then what I have to say, if that meets with the Chairman's approval.

CHAIRMAN GREENBURG: In that case, let's call on Mr. H. M. Mabey, of the Mathieson Alkali Works, New York City.

MR. MABEY: It is a great pleasure to be here, gentlemen, but my duties involve largely transportation, and the only thoughts I could express along these lines have to do more with dangerous articles regulation.

As I visualize your work, the safety to persons is involved and the safety to the public; but beyond that, as I look at it, there is a question involving the welfare of the industry itself, and after all, if we once succeed in safeguarding that we won't have these other problems.

Nearly all the compressed gases, as you know, are transported under the regulations of the Interstate Commerce Commission, known as the dangerous articles regulation. I think everyone here is familiar with that.

As I see it, there is no industry where cooperation between those engaged in industry is of more importance than this branch of the chemical industry, when we are producing compressed gases.

We have all seen within the past few years a great increase in the production of various gases, not only by the older companies but the entry of newer people into the field. Following my line of thought, I think it should be impressed upon every one of us here, that we have a common interest in the prevention of any accident within the industry. It is not that an accident will cost us money individually, but we each are dependent upon the other. One accident within the industry reacts against the entire industry, and that is almost equally true whether that accident be within an individual plant or whether it be within the field of transportation.

These regulations are not in the interest primarily of the carriers, the railroads; they are in the interest of the public; but more than anything they are in our interest, as producers. We have made these regulations, we, the industry. They are broad in their scope. They intentionally in many cases do not go into extreme detail very specifically. In my opinion, therefore, it is not to the interest of anyone within the industry to see how near to those specifications they can walk, but to try to go beyond that point and live up to the spirit of the specifications, realizing that the specifications for the handling of dangerous articles are broad. The Interstate Commerce Commission, having authority from Congress, is limited somewhat in its powers in this matter, and naturally does not want to and cannot go beyond those powers. It cannot go beyond the field of interstate commerce. That field naturally begins when a product is offered to an interstate carrier in transportation. It ends when the interstate carrier ceases its job of transporting the product. Before and after those times the regulations technically do not prevail.

The greatest thing that can be done, in my opinion, is to foster an exchange of all the experiences of those who have been engaged in the handling of these commodities for years, freely, one among the other, with the aim of arriving at standards of practice and the standardization of plant practice.

This, I know, is a bit afield from the ordinary safety work that you are engaged in, as I visualize it, but nevertheless it is of the greatest importance. The

accidents—they are not really accidents—they are casualties. There has been very little physical damage so far. There has been practically no damage to human life, but a study of those accidents has almost invariably shown that they were probably the result of a departure from standardized methods, the results which have been arrived at as a result of the common experience of those who have been engaged in the industry for many years.

That, I think, is the only message that I thought it worth while to convey to you. Summed up, as I see it, these dangerous articles regulations of the Interstate Commerce Commission are the life-blood of the industry. They protect us more than anything else. They have made it possible for the industry to ship in interstate commerce, and that is what we are in business for—to sell products, uniformly, throughout the United States. They have replaced conditions whereby an individual railroad of its own volition could say whether or not and how it would handle these products.

This, therefore, is a plea that each one of you in your safety work go beyond the letter of the specifications, into the spirit of the specifications, and honestly leave nothing undone which will tend to lean towards safety in the detail operations within your own plant.

CHAIRMAN GREENBURG: The next speaker is Major John C. Minor, of New York City.

MAJOR MINOR: I realize fully that the time left is very short, and I know that I can put everything I have to say in a few words. The fact that I think I occupy the lone position of a man who has been both a gas manufacturer and a manufacturer of cylinders to contain compressed gases has just led me to the thought that I would speak of this question from the viewpoint of the gas container.

Mr. Banash, whose paper you haven't heard, has probably covered the field very completely.

There are, as you know, a great many ways to do a thing wrongly and generally one way to do it rightly, and I just want to touch on a few of the high spots regarding wrong ways to do the thing because it is in that direction that we find the basis for safety protection.

You have heard some words with reference to the Bureau of Explosives. I think it is generally known to everybody what the function is as the operating arm of the Commission. Before they entered the picture, sixteen years ago, when a man wanted to buy cylinders for compressed gases he simply went to the manufacturer and asked the price, and that was all there was to it. There was a tremendous responsibility, therefore, placed on the cylinder manufacturers at that time, and it is tremendously to their credit that they lived up to that responsibility. That is, given a tremendous hand in that way without any control outside, either by the Bureau or by any other authority. They turned out the best that the art permitted in those days.

After the entry of the Bureau of Explosives there came the formation of the Compressed Gas Manufacturers Association, and they have worked hand in hand with the Bureau of Explosives. As Mr. Mabey has suggested, they have striven not merely to adhere to the letter of the specification, but they have been active frequently in initiating steps toward the developing of the spirit back of the specifications; and today, the compressed gas cylinders that you see floating around the city (maybe you instinctively walk away from) are one of the safest things in the world. But they are safe when they are used for the purposes they are made for, and unfortunately, they aren't always used only for those purposes.

I think, perhaps, you may not all have a clear understanding of what it means to manufacture a cylinder today. We start, either with a sheet of steel that is formed up into a cup or we start with a billet from which a cup is formed by piercing it. Therefore, those short, heavy-walled containers, open at one end,

are passed through draw benches, and being supported on a mandrel of the proper size to take the desired inside diameter, they go through rings and are brought down to the proper wall thickness for the purposes desired. It takes two or three passes to do that. After each pass the cylinder has to be heated again, and at the end the neck is formed and then it is annealed and slowly cooled, and you have the final cylinder. But all sorts of requirements are necessary to do that. Disinterested inspectors test the steel. Tests are made on the stress at a suitable test pressure; giving a high stress to the cylinder requires that the cylinder can't show more than a certain expansion. Representative cylinders are crushed to show that the metal is sound. Of course the usual physical tests and all those things have produced a cylinder that we have reason to take pride in.

This association of ours which I spoke of, the Compressed Gas Manufacturers Association, is rather unique in that it isn't concerned in any trade practices except those involved in questions of safety, and we are constantly working through committees in an effort to develop further protection of the cylinder after it has passed out of the manufacturer's hands and into the customer's hands so that the customer will be able at all times to satisfy himself of the safety of the cylinder. I don't suppose that work will ever be completed but we have achieved great results and we look forward to more; and that phase of the work, I feel, is emphasized right here by this large attendance at a meeting like this. It is through cooperation, the cooperation of the big fellows who have the laboratory facilities, and they have turned them over so that even the smallest man gets the benefit of the work.

This association of ours has prepared a list of regulations that should govern the safe handling of compressed gases. Of course, in so far as it isn't state work it is out of the state Bureau. It is up to us, ourselves. There is a long list of things that should be done. I don't want to go into those except to touch on a very few of the things and show you what they mean. Some are obvious, some may seem trivial, but they are all based on experience. The proof of this is that last week I read in a Philadelphia paper about a truck carrying four or five oxygen cylinders. It was upset and they rolled to the bottom of an incline. There was nothing left of the truck, but the cylinders were perfectly all right and were delivered to the customers.

Of course, it is perfectly obvious that you don't want to drop a cylinder. I don't think that you stand much chance if you do. But it is just as well to caution you, because I don't suppose any man feeling that he has a lot of cylinders around with a stress inside amounting to perhaps 30,000 pounds, would care to take the chance on (we will say) the exceptional cylinder. Even the exceptional cylinder, I believe, is eliminated before it gets to him. But what he may do, or some customer of his may do, is the cause of the exceptional cylinder that crops up from time to time.

It is obvious that you shouldn't use a lifting magnet or rose slings on a bunch of cylinders. I have seen a cylinder hoisted fifteen stories with just a rope sling around it. It is unnecessary to say what that might mean to this assemblage.

Don't attempt to mix gas in a cylinder. You simply can't get away from the human element, and we sometimes associate the human element with people of feeble understanding in so far as the cause of accidents is concerned.

At Harvard, I think it was, two years ago, a research work was being carried on in their low temperature place. There was a hydrogen and an oxygen cylinder standing there, and the operator who had been working there for several years (he was of the Bureau of Standards and a very valuable man with high standing), in order to save the oxygen from his liquid air so he wouldn't have to go out and buy two dollars worth of it, used a hydrogen cylinder to put it in. He knew perfectly well that was a vitally wrong thing to do, or should have known it. I can't conceive that he didn't. He must have had to strip his valve threads and

force it on, nevertheless he did it. Of course there was a frightful explosion and there just simply wasn't anything left of that laboratory or the operator, and most of the people who were around there were injured.

Cylinders are used for rollers. We have seen it. I have seen a house moved with empty gas cylinders. They are not built for that kind of a strain.

Of course, you want to keep any compressed gas cylinders away from heat. You may have a safety device on there that can't operate. In a bottling shop where they were making carbonated water with carbonated gas I saw a pipe which contained water at 212 degrees and that water was running off all the time so that they could get the gas over and not freeze.

We have accidents in gauges. You can't afford to take the chance of taking your oily hands and working around an oxygen valve. It is not going to explode every time—nobody knows why it doesn't, but you are taking a chance when you do it.

Going back to that question of mixing gases, only last week our association took occasion to write to a paper, a trade paper in the petroleum industry which had described an experiment in which an empty oxygen cylinder was used as a storage reservoir for oil products.

Sometimes water is put in a cylinder. Carbonic people selling to bottling shops frequently have cylinders returned to them with water in them. The result is that in cold weather it may freeze and you get a strain that will start an initial crack.

All of these things have doubtless been commented on, but I do feel that, speaking for the gas industry and speaking for the cylinder manufacturers, we find that it pays to be safe. It costs money—it costs a good deal more to make the modern cylinder today with all the precautions surrounding it than it did the old one, but every one involved in the question agrees that it pays to be good.

CHAIRMAN GREENBURG: We certainly owe these gentlemen a debt for coming here and speaking to us, and I apologize for having to urge that the talks be brief. We might have a word from Mr. Banash by way of summary.

Industrial Gases

By J. I. BANASH

Chemical Section, National Safety Council,
Consulting Engineer, Chicago

As safety man engaged in chemical work, the field covered by gases and their industrial application is vitally interesting to us and your observations not only in your own plants but of industrial conditions in general have no doubt indicated to you a continually increasing use of materials in gaseous form so that the whole subject is of particular interest at present, and likely to become even more important in the future. For this reason we are having this little symposium, and as other speakers will treat of certain specific gases, I will try, with your permission, to analyze the general gas hazards and attempt to indicate how safety men should look at it.

Regarding any individual problem, information is available to cover practically all conditions, I think, and if you do not have the necessary data about any specific gas readily accessible, an inquiry will undoubtedly bring the information or a helpful reference from the main office of the National Safety Council. Also, there have been published in the *National Safety News* and elsewhere, articles on the subject. In the June, 1926, issue there was a very valuable article entitled "Common Gases and Their Hazards," by that very able chemist, A. C. Fieldner of the Bureau of Mines, who, in addition to being chief chemist of the Bureau, also has

the safety viewpoint. Valuable suggestions for the safe handling and use of compressed gas cylinders will be found in the rules of the Compressed Gas Manufacturers' Association which were published in the *National Safety News* and reports of which are available. The manufacturers of compressed gases are fully aware of the necessity of safe handling of their products and these rules are a valuable contribution to safety work.

Both of these specifications and Safe Practices No. 71, itemize the details relative to safe handling of gases in general and also itemize recommendations regarding a number of individual gases.

Solids and liquids are more familiar to us than gases because for one thing they stay put better than gases since they need not usually be stored under pressure whereas practically all gases are under more or less pressure at some time in an industrial establishment. For example, liquids lend themselves much more readily to specific classification according to their hazards, than gases. Underwriters Laboratories has succeeded in classifying the more common liquids according to their fire hazard by a group of numbers based on ether as 100 so that you can readily be informed as to the comparative hazard of almost any commonly used liquid by simply being told the number of the group into which it falls. It is hoped that some time this work can be extended into the field of gases but it is questionable as to whether or not a single classification can be made to take care of both fire and accident hazards. Also, even if we had such a classification of gases, although it would be very valuable from an actuarial point of view, the safety man would still want to know how to handle safely the particular gases which come into his plant.

Dr. Fieldner classifies gases into two principal groups: first those which burn, and therefore, when mixed with air may explode, and secondly those which have some pathological effect such as asphyxiation by the exclusion of the oxygen of the air or poisoning by their effect on the human system. Of course, we must also consider gases which have combinations of these properties and which may also have an anesthetic effect without being really poisonous.

Safety men have to look at very intimate details to cover all angles of the problem. Since all gases are held under some pressure, which if released at any point such as a leak, will cause the gas to escape into the atmosphere, the first thought which occurs to the average person is protection against accidental escape. This is a natural thought but from a safety viewpoint we have to consider much more than this. We must cover the safe use and application of gases in industry which includes shipping, receiving, transferring and storing such materials and eventually bringing them to the point of utilization without hazard to life and property.

As far as the shipment of gases is concerned, we are fortunate indeed that the Inter-State Commerce Commission has remarkably successful standards for containers which have been worked out by the Bureau of Explosives of the American Railway Association over a period of years so that they are now commonly accepted as part of the industrial fabric of the country. All cylinders used for the storage and transportation of compressed gases should be manufactured in accordance with I.C.C. specifications and marked in accordance with I.C.C. requirements effective at the date of their manufacture. Containers manufactured under these specifications for individual gases and so marked and used for no other purpose, may be classified as safe and the plant safety man need not go into details of construction if the supplier is a reliable concern and uses containers specified for the particular product.

Where gases are used as a regular part of the production schedule, your chemists have undoubtedly worked out the reactions which they want, and with their cooperation it should not be difficult to get complete protection which can be worked out with the establishment of the process. It is up to the safety man to get protection built into the process and see that it is maintained. When a process

is first worked out on a laboratory scale, the chemical department may not have considered all the safety angles, which subject should be brought up by the safety man before the process is put into production. It is not always easy, as you know, to induce your chemists to work as safely on a laboratory scale as will later have to be done in production, but if the safety man can keep in touch with the laboratory his cooperation from the beginning will be of value.

On the other hand where gases are incidental and only used at times, the burden of checking up on the receipt, storage and use of such material should be at least in part a function of the safety department.

Some gases are more or less on the border line between liquid and gaseous phases. They may be received as liquids and can be handled as liquids under comparatively low pressures up to the point where it is necessary to use them as gases. Certain classes of compressed hydro-carbon gases come in this classification and their use is increasing rapidly. The hazards of such gases are mostly from ignition and precaution should be taken to limit as far as consistent and practical, the amount which may accidentally escape. When such materials are received as liquids and utilized in the gaseous phase, it is considered safer to expand the liquid into a gas outside the main buildings when practical, and pipe the gas instead of the liquid into the building with the installation suitably designed in compliance with safe operating practice. Constant inspection is necessary, especially with gases which do not have an odor which is readily detectable. Usually only a comparatively small percentage of gas in the air is required to make an explosive mixture, and every precaution must be taken in the first place to prevent leakage, and secondly, to have the areas and ventilation as great as possible and keep sources of ignition away from places where gases may leak so that the possibility of getting the combination of a leak, an explosive mixture with air, and a source of ignition at the same time and at the same place will be remote.

Piping should be laid out so that the pipes used for various gases may be easily distinguished. Welded joints give great satisfaction in industrial piping because when they are well made, there is little likelihood of leakage. Never interchange gases from one shipping container to another and do not mix gases in the shipping containers. Combustible gases are shipped in cylinders which have left hand threads on the valves, and no adaptor should be used or other change made to defeat the purpose of these left hand threads. Also, keep in mind that no cylinder should ever be used for gases under pressure in a plant or in Intra-State Commerce which does not meet with the requirements of the Inter-State Commerce Commission as previously noted.

A gas which is irritable when breathed, is, of course, easily detectable and gives warning of leakage so that those in the room can leave until the hazard has been overcome. Piping, fittings, etc., should obviously be of materials which are chemically effected by the gas itself to the slightest possible degree. Easily accessible shut-offs must be provided so that in case of a leak or a break, only a minimum amount of gas will escape.

Special detecting apparatus is available for locations where leakage of flammable gases may be anticipated and such apparatus can be arranged to give ample warnings. Medical specialists have already on record treatments for poisonous and irritating gases and the development of gas masks, (as a result of the war) has been, as you know, of tremendous value industrially. Gas masks form a large subject by themselves, and we have available masks of various types from the emergency mask (good for about one-half hour), up to the specialized mask where men have to be exposed for longer periods. In any consideration of gas masks it must always be remembered that, with the exception of the oxygen helmet, and the hose mask in which air is pumped to the user, they do not supply oxygen and cannot be used where there is not enough oxygen to support life.

The Safety Engineer should accumulate and have readily accessible, all available information regarding the gases used in his plant which will include the specific antidotes and methods of protection for each gas, which cannot be gone into thoroughly in one short paper such as this. It is hoped that the record of this meeting, particularly the discussion, will show the main items of interest which possibly may form the basis for further Safe Practices Pamphlets wherein almost any amount of useful data may be compiled, and that after the next two speakers have finished their comments, the discussion will be general and will form a record which will indicate the proper trend for further work on the subject.

CHAIRMAN GREENBURG: Our time is about up. On the other hand, if there are one or two important questions to be raised, I think we should not stunt the discussion. Does anyone have a really important problem?

MR. AMRAM (Hamlin & Co., New York City): I happened to think that the greatest catastrophe which has occurred since the last Congress in Chicago, occurred in connection with the storage of natural gas. I don't know whether that comes under this heading or not. I am referring to the great catastrophe in Pittsburgh. The reason it is so vivid in my memory is that I happened to arrive in Pittsburgh fifteen minutes after it had happened. I think there were 15 instantly killed, 15 others died, and 100 were injured.

CHAIRMAN GREENBURG: As I recall, that wasn't a case of the storage of gas. That was a case of using a blow torch on a gas tank while there was still gas there. It wasn't purely a question of the storage of gas.

MR. BANASH: You mean that explosion of gas in Pittsburgh? That was a question in all probability of not having entirely cleaned out the holder of all flammable liquids. There should be proper procedure control.

MEMBER: I happen to know another detail there. I am interested in flame welding and I would like to say that it was due to electric welding.

CHAIRMAN GREENBURG: We will have to close. This is just a milepost in safety work, but the fight goes on continuously. During the past year we have had our ups and downs, as might be expected. Our *News Letter* has been a decided failure, for which I take the discredit. I hope next year you get a better man for this task. Unfortunately, it has to be written by a man in intimate contact with the work and so often he doesn't have the time.

I wish to add a word of thanks to those who have been associated with me and to all the men on the Executive Committee; and I would like to say that the success of the Chemical Section during the past year depended on their wholehearted cooperation and interest, and that the failure largely belonged to the chairman.

ADJOURNMENT.

***The Industrial Poisons Committee
in Co-operation with the
Health Division and the Rubber Section***

October 2, 1928

S. E. WHITING, Chairman

Assistant Chief Engineer, Liberty Mutual Insurance Company
Boston, Mass.

The luncheon meeting of the Industrial Poisons Committee of the Chemical Section, in cooperation with the Health Division and the Rubber Section at the Seventeenth Annual Safety Congress was called to order at one twenty-five o'clock by the chairman, S. E. Whiting, Assistant Chief Engineer, Liberty Mutual Insurance Company, Boston, Massachusetts.

CHAIRMAN WHITING: The meeting will come to order.

DR. LEONARD GREENBURG (Chairman, Chemical Section, U. S. Public Health Service, New Haven, Conn.): The Rubber and Chemical Sections of the National Safety Council have been interested in the subject of benzol poisoning for some time. The result, after some three years of research and study, was the publication of the final report of the Committee on Benzol Poisoning.

We had at that time about buried the ghost of benzol, but apparently we didn't finish the job, as several people have since thought it good to have an open discussion of the subject once again. This meeting falls into the hands of Mr. Whiting, who is the chairman of the Industrial Poisons Committee of the Chemical Section. I am now going to turn the meeting over to Mr. Whiting.

CHAIRMAN WHITING: The question is whether we should do anything more on benzol poisoning and if so, why we should do it, and then, what we should do? Unfortunately, we have only a half-hour left and the speakers will have to pardon me, if I begin to click my glass when they are going beyond their allotted time.

Mr. Armstrong, of the Eastman Kodak Co., will speak first, and he may have two minutes.

MR. ARMSTRONG (Eastman Kodak Company, Rochester, N. Y.): I am not going to speak, I am going to ask a question. When the Benzol Committee made their report, I believe the findings were that we should reduce concentration below 100 parts per million. We reduced ours to 35 parts per million but I feel we still have some evidence of benzol poisoning.

CHAIRMAN WHITING: We hope to get an answer to that question of Mr. Armstrong's. Dr. Shirley, of the Hood Rubber Company, has had very considerable experience in benzol, as you all know.

DR. SHIRLEY (Hood Rubber Co., Watertown, Mass.): Mr. Chairman, I think our benzol is of the same consistency we always used, perhaps a little less, but there still, in my opinion, is a hazard. However, on three different occasions during the last year where I have been asked for an opinion on certain cases, there was only one which I believed to be benzol poisoning. In our own plant we still use it, and I have three jobs in which I am pretty fussy in checking the physical condition of the men. I believe the hazard still exists, but perhaps to a less extent than it did before the study was made. That is all there is to say at present.

CHAIRMAN WHITING: Although Mr. Cook of the Traveler's Insurance is really the one who started this luncheon meeting, we have so little time that Mr. Cook has agreed that we call on Mr. Paine, of another large insurance company, which has had wide practical experience with benzol. Mr. Paine will have five minutes.

WALTER S. PAINE (Aetna Life Insurance Co., New York): I did not know I was going to be drafted into this, but I would like to say just a few words. I think that the Benzol Committee report we made went rampant through the country. I think there are cases where the interpretation of that report has been taken so literally that it has really hampered some of the industrial processes.

Mr. Gumaer knows one case which we had, where this report went to the manufacturer and he took it literally. He was supported in that literal interpretation by an inspector. A thorough investigation convinced me that there is very little hazard in that particular industry.

I said all I want to suggest on this subject in my report this morning in the Chemical Section. I have in mind (and this is actual experience) a certain plant making a specific product. I have watched that plant using benzol over a period of five years, and I have not had the semblance of a case in that plant. There is another plant making the same product, maybe by a different process, but I have had in that plant a number of benzol cases, some of a minor degree and some of a major degree. I believe that our committee could well afford to go further to answer some of the questions which have been brought up by Mr. Gumaer and others. Relative to how far you should go in controlling the use of benzol, I believe that no more thorough investigation could be made for a basis than has been made already by Dr. Winslow in his work at Yale University.

Before this investigation starts as a stampede, I would like to see five or six individuals selected to review the field very thoroughly to see if there is need of further investigation or if there is need of further interpretation of the code or findings as sent out by Dr. Winslow's committee.

CHAIRMAN WHITING: There is a question from the floor, Mr. Paine: what was the relative concentration in the two plants you mentioned?

MR. PAINE: If the man who is interested will see me at a later time, I think I can give him that.

CHAIRMAN WHITING: Roughly the same?

MR. PAINE: No, I think there is a difference. I am positive there is a difference. I think that, before I would make any statement, I would investigate further the cases I named this morning as a hint in my paper. My inclination is to be somewhat conservative in such matters as this is a relatively new form of poisoning.

CHAIRMAN WHITING: One of the large manufacturers of benzol is the Barrett Company, and Mr. Gumaer has for some months, or possibly a year, been studying this problem from the standpoint of the manufacturer and, of course, from the standpoint of the user. Mr. Gumaer may have five minutes, please.

P. W. GUMAER (The Barrett Company, New York): I asked a physician once what white blood corpuscles were made up of. From the look I got, it seemed as though I had asked foolish question number ninety-nine. I found later that nobody knows. I have been asking foolish questions for six months on benzol. I learned a lot about it and I have also learned there are a great many things no one knows about it.

Some time ago I was retained by the Barrett Company to devote full time to the health hazard of benzol. I visited about fifty plants using benzol in that time. I want to say this before I continue: I do not want anything I say to be an inference in any way that the Barrett Company is urging or encouraging the poisoning of any individuals. If benzol is used in industry, we want it to be used safely. I could elaborate on that, but I haven't the time.

When I started on this work I decided, as in any engineering work, in order to get anywhere, you have to have a quantitative method of measuring what you are doing. My first work was to get an instrument by which I could measure the amount of benzol in the air and do it immediately. I could not wait three days to know the results. We recently calibrated an instrument for this work, which is

about three feet long and five inches in diameter. We can measure with an accuracy of plus or minus 25 parts per million.

I made a few preliminary tests in factories and found a great variation in different parts of the plant. We can detect where the benzol concentration is greatest and determine the best means of ventilation. It will, I think, eventually be of great help in improving the ventilating systems.

I have been surprised, in going around factories, to observe the obvious mistakes made in ventilation. A very large manufacturing concern has a very capable engineering staff, one of the largest in the country, but in a small room where they were using benzol and naphtha, they had a large fan near the ceiling and absolutely none near the floor. Everybody who has had experience with those solvents knows that the fumes when at room temperature sink to the floor and stay there. In another case, they actually pulled the vapors past the workmen. In trying to get the vapors out of the room, they were drawn past the men's faces, unintentionally aggravating the conditions. Such conditions I have corrected in a number of cases.

The really important condition you find in getting around to different plants is that there is no uniformity at all in the medical supervision they give. Of course, the very small plant has no medical department. A large plant like the Eastman Kodak has very careful blood counts made. There is another firm I have in mind that made periodic blood counts for three years. They discontinued them in 1924. This firm has been using benzol for twelve years. A neighboring firm has been using it thirteen years. They claim no benzol cases. One has had three suspected cases—very mild and only suspected.

In my mind, the way they apparently prevent serious benzol cases is by their elaborate medical department. A man must report to the medical department if at all ill before he goes home. In that way, they detect the case in the preliminary stages.

The small firms without medical departments that I go to often ask me what they can do to make benzol safe. I am not a physician and I find that there is such a wide difference of opinion, particularly between the investigators and the practical users of benzol, that there is no recommendation that I can give them.

Here is something where I think the National Safety Council, insurance companies, or some other organization could be of assistance in doing—something I can not do myself. That is to get together the best medical minds on the supervision of benzol employees. I do not mean the treatment. If you have proper supervision, you do not have many cases and do not need much treatment. If you can decide on proper supervision of employees, then I can have a practical code of instructions to give to the factories that ask me about benzol poisoning prevention.

There are a great many things we do not know about benzol. For example, what is the action in the body? There is really nothing known about it, how it is absorbed or in what form it exists. Why are white blood corpuscles attacked by benzol? Then, it is generally conceded that there is a tremendous variation in susceptibility of individuals. If we could get a test for susceptibility in order to test a new man, it would be of tremendous value. There is doubt as to whether it can be done, but it would help a lot. Apparently from what I have been able to pick up, alcohol increases susceptibility. A strong drinker is apparently more susceptible than others. Mr. Paine brought up this morning the question of diet. That is also apparent in a number of cases.

I visited a factory where they use tremendous amounts of benzol. The conditions were very, very poor there. I had to judge by smell as I had no instrument at that time to measure with. The plant was located out in the country, where the men apparently had plenty of good food and fresh air. They claimed to have had no benzol cases in spite of the high vapor concentration.

At the present time, if a man is exposed to benzol vapors and he has a low white blood cell count, that is legal proof that he has benzol poisoning. Doctors I think will agree that there are a number of other substances that will give a low white blood cell count as well as benzol. That places a hardship on the compensation insurance people because they feel they have to pay benzol claims where benzol may not be responsible.

There is also the question of impurities in benzol. Benzol is not an absolutely chemically pure substance. It is separated by fractional distillation so that the best commercially pure benzol you can get on the market has a 1° to 2°c boiling range. There is apparently (as far as I can find in the literature) no research work on this phase of the subject. Absolutely chemically pure benzol is a very difficult thing to get.

I believe it is desirable to do some research along the lines that I have mentioned. I do not think it is up to the National Safety Council to attack these problems. However, I think that the possibilities are good that some of these questions will be definitely answered in the next few years. I cannot make any further statement at the present time. In the meanwhile, we must use precautions in the use of benzol by medical supervision, ventilation, and so forth.

I have the facilities to make a very thorough study of ventilation and benzol concentration in all parts of a factory as I can take several hundred readings a day on benzol. Any factory that wishes to know the concentration of benzol vapors to which their employees are exposed or desires to improve the ventilation where benzol is used may have a thorough test made by writing The Barrett Co., 40 Rector St., New York City.

As has been suggested by Mr. Paine this morning, if we could get a continuing picture of the history of benzol poisoning in different cases, it would be of value. I think the work of the National Safety Council was very admirable. It was primarily a field study. The National Safety Council, due to limited funds, was able only to make sort of snap shots in different factories. If we could get a sort of moving picture, that is, a continuing history of a large number of employees using benzol, it would be of value. Cooperation along that line of studying the health of benzol employees in connection with ventilation is something I think could be worked out and would be of value.

CHAIRMAN WHITING: Thank you. The chairman of our Health Session, Dr. Wade Wright, of the Metropolitan Insurance Company has made suggestions in this connection.

DR. WRIGHT: I have nothing whatever to contribute. I have never made any study of the benzol problem. What I have to contribute is wholly speculative. Those impressions are, I imagine, very similar to those of all persons who have ever studied benzol, that is, consternation that it strikes as it does, and equal consternation that it does not strike in the presence of appalling exposures. I do not know of any data whatever regarding the amount of benzol in use at the present time. I do not know whether information is to be had accurately, but I certainly feel from my general contacts that benzol is used about as plentifully as it was some years ago.

There are so many blank spots in our knowledge of the problem that it is hard to get anything definite. Benzol creeps in and out of industrial processes in a great many industries. The whole picture is such that I feel we are perfectly sure in saying we do not know the whole answer to the problem of benzol. We do not have the thing within our grasp. I should eagerly welcome further basic laboratory research to determine the action of toxic substances as well as the determination of impurities in their toxic effects, and coupled with that, sound clinical observation in various centers under a more or less standardized procedure.

CHAIRMAN WHITING: The man who made the last field study of benzol in connection with spray coating is here. We would like to hear from Dr. Smyth.

DR. SMYTH (University of Pennsylvania, Philadelphia, Pa.): I agree that we have not anywhere nearly solved all the problems in connection with benzol poisoning. The more we get into it, the more difficulties we still see ahead of us. I am very much interested indeed in the apparatus that Mr. Gumaer speaks of. It will be of very great advantage in field studies such as those we have conducted. It would have simplified our labor tremendously if we had had such an apparatus available.

When I looked over this program for discussion, I was first struck by this first consideration: "The compilation of the continuing histories of all available cases." In our studies in Pennsylvania as well as in the National Safety Council, I was particularly anxious to do something which I was not permitted to do in either case. I couldn't do it simply because finances would not permit me. I wanted to go back again after a year or two and examine all of those who were still working at the same job and presumably still exposed to benzol, to find out whether the changed picture we have observed was a continuing progressive change of the white cell count, or whether possibly these men had been helped by their first exposure to low concentration of benzol and they would show improvement in time; or whether it was simply a steady picture below the normal or different from the normal picture.

I tried to express that thought in our reports, but unfortunately in either case, the funds did not permit of such follow-up work, and unfortunately in both instances also, those back of the researches were anxious to get results quickly. With our National Safety Council survey, we concentrated all our field work into two months. In Pennsylvania, we spread it more. Neither of these surveys was long enough to get those continuing pictures or continuing studies. As to whether the impurities of benzol were responsible for the blood picture, I have heard that question raised before. I have discussed that question with representatives of one of the larger producers of benzol in this country, the Carnegie Steel people. They felt that undoubtedly the benzol product was not pure. Some impurity, I can not recall just what it was, they had isolated and shipped great quantities of it at a former time for some special work. In all events, they felt this impurity was far more toxic than benzol, and in the same direction. The removal of that material adds a great deal of expense to it, and if the best benzol usable in the market is that with the 2° boiling range, then industrially the picture is not satisfactory.

In such cases as Mr. Armstrong reports, where there is very low concentration, we do not say (I do not think Mr. Paine meant to imply) that no one exposed to less than 100 parts per million would get benzol poisoning, but that was the limit which would protect the average person.

Both in the National Safety Council report on benzol and in the Pennsylvania report and in National Safety Council report on Spray Painting, we endeavored to emphasize the importance of periodic medical examination to protect the susceptible individual and weed him out before he was dangerously injured. No matter what precautions we take, there will be occasional individuals that will be poisoned. We can not eliminate all hazards from any operation, but if we present reasonable regulations that will protect the average worker and then protect the susceptible worker by periodic medical examination, we will have tremendously lessened the hazard in industry. I think there is no toxic substance that may be used in industry that cannot be used with a fair degree of safety by the average worker if we are willing to pay the price of adequate supervision.

CHAIRMAN WHITING: Dr. Hamilton, we should like to hear from you.

DR. ALICE HAMILTON (Harvard University, Cambridge, Mass.): I think it will take me only a minute to say what I have to say. In talking about benzol poisoning we really do not know just what substance we are dealing with, and that is one problem that should be settled as soon as it can be.

We may have two individuals exposed to the same hazard. One succumbs and the other does not. It is a matter of individual susceptibility, but all who have had experience with benzol in industry know there are cases of apparent group susceptibility, so we can not accept that explanation. There will be a plant in which the benzol hazard is comparatively low. I have in mind, for instance, a patent leather shoe plant in Massachusetts, in which there were two fatal cases recently, and a plant out in Cincinnati where hides are doped with benzol dope, a plant which, for the two years previous to my visit, had had no cases of poisoning, although the men had slight supervision. There can be no question in anyone's mind which group had the more serious benzol hazard to face.

I cannot see how we can explain that discrepancy except that the two plants were not using just the same substance. I think that subject should somehow be dealt with, and is one of the first to be solved.

CHAIRMAN WHITING: You all know upon whom I shall call to close the discussion, but if there is anyone here who, in one minute, would like to add some point that has not been raised already, I would like to hear from him.

W. A. COOK (Travelers Insurance Co., Hartford, Conn.): Just this one thought; the first investigation was the basis upon which a great deal of activity has been based since 1926. It does seem to me that the results of all activity in the various circles in getting blood counts and in getting concentrations of benzol in various plants might possibly be gathered together to advantage at this time.

MR. DOWN (Sloan Company, Birmingham, Ala.): We manufacture benzol, and we are down in the South, but I would like to get on the mailing list of this discussion and if possible, make some tests when I get back of men that we have had in our employ for ten years in the manufacture of benzol.

CHAIRMAN WHITING: That would be very useful. We shall see that you get a copy of this discussion. The National Safety Council's Vice-President for Health, as you all know, has led us in our entire benzol investigation from the very beginning. I will call upon Dr. Winslow to close the discussion, if you please.

DR. C.-E. A. WINSLOW (Yale Medical School, New Haven, Conn.): No one appreciates more fully than I the need for more light, and the imperfections in the work that we did. I am a little gratified to find, however, that the criticism, dreadful as it is, comes from two opposite sides, inferring apparently that Mr. Armstrong thinks the standard is not high enough, and Mr. Paine thinks it is a little too high. That is a wholesome thing.

I do think in the main that the points brought out are valuable. No one questions that the use of benzol in industry is a substantial and important hazard. No one, I think, doubts that in such processes where benzol can be replaced by other substances, it should be done. Where it cannot be replaced, I think most of us are agreed that exhaust ventilation of a high degree, respirators and so on, will help materially.

I think perhaps one of the most valuable by-products of the whole study on spray coating has been the growing recognition that the positive pressure respirator is the only kind of value for more or less continuous use. In addition to these things, just one word as to the ventilation. Mr. Gumaer brought up the question of upward and downward ventilation. Some of you will recall that this entire problem arose for action at one of the meetings of the National Safety Council as a result of the argument as to upward or downward ventilation between Mr. Horan and Mr. Paine.

I think we feel now that that is a thing that depends on circumstances. They were both right. Whether you use upward or downward ventilation depends on the temperature at which the process is conducted and other local conditions.

Whatever you do, you must have adequate medical supervision. The standards we suggested for that are available. They may be too high for practical use, but they are the standards which I think are necessary for safety. As to the new

problem, there are several ways in which, it seems to me, this subject can be approached. In the first place, I am entirely convinced that it would be sound to have the practical side of this subject reviewed to make use, as Mr. Cook suggested, of the records that have been accumulated from the increased number of examinations; to study with great care in the field such conflicting plants with conflicting results as those of which Professor Hamilton spoke. Such a field study I think would be of the greatest value, and it might help to explain a great many things we do not know.

In the second place, as Mr. Gumaer said, it would be very desirable to conduct more extensive animal experimentation—along three major lines. The question of impurities I am not sure of, myself. As Dr. Smyth suggested, it is a rather academic question, but that could be quite completely solved by animal experimentation within a reasonable period of time. Also, in the question of individual susceptibility, much light could be thrown on it by animal experimentation. The effect of diet, alcohol and other conditions upon benzol poisoning should be worked out. Finally, as the third of these rather obvious laboratory problems, there is the question as to what happens in recovery, what happens after? We do not know anything like enough as to the process of recovery in animals or human beings.

Besides those studies, field surveys might be undertaken. If they are, I think it would be of great advantage, in the first place, if the National Safety Council should undertake a field study of what is developing in plant experience. It would be of great advantage to have any laboratory study carried on in intimate connection with that. It would be far more effective if correlated with it and if placed under the direction of the same body. I think that funds are likely to be provided for this laboratory research.

Again I mention, that would be invaluable if tied up with a field study which I think this Council is so well equipped to make. If either of those investigations—field study or laboratory study—is to be made, funds will be needed. We were over-optimistic in estimating our funds in the other study, and did not allow enough to do it as thoroughly as we wish it could have been done. These things cannot be done without money.

One other point in closing. I do not think the Council will undertake these things unless the funds are available, and if it does undertake them, I think the studies should be set up under a committee which is constituted somewhat as the original Benzol Committee was constituted, to represent the various parties interested, with scientific experts, individual industrial experts and insurance experts on it. But the members who represent these various interests should be carefully selected so that we are quite sure they are going to face whatever facts are brought out in the investigation. I speak of that because the Council has experienced serious difficulty with other committees where they were set up on a political rather than a scientific basis.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Construction Section

New Section Officers

General Chairman—W. R. RICHARDS, The Associated General Contractors of America, Inc., Washington, D. C.

Vice-Chairman (In Charge of Publicity and Statistics)—J. WILSON ROBINSON, Everett Winters Company, Detroit, Mich.

Vice-Chairman (In Charge of Slides and Membership)—EARE F. TUCKER, United Engineers and Contractors, Philadelphia, Pa.

Vice-Chairman (In Charge of Program)—W. A. DEARBORN, Federal Mutual Liability Insurance Company, Boston, Mass.

Vice-Chairman and News-Letter Editor—GEORGE WIDUA, Woods Brothers Construction Company, Lincoln, Nebr.

Secretary—CHARLES H. BLACK, Stone and Webster Engineering Corporation, Boston, Mass.

Poster Committee Chairman—ROBERT MCKINLEY, General Accident Fire and Life Assurance Corp., Ltd., Detroit, Mich.

Engineering Committee Chairman—F. A. DAVIDSON, Chesebro, Whitman Company, Inc., Long Island City, N. Y.

Executive Committee: THE OFFICERS AND

W. F. AUSTIN, President, W. E. Wood Company, Detroit, Mich.

W. G. WHEELER, Building Trades Employers' Association, New York City.

W. F. TUBESING, W. F. Tubesing Company, Milwaukee, Wis.

Retiring Officers

Chairman, E. C. HARDING, The Ferro Concrete Construction Company, Cincinnati, Ohio; *Vice-Chairman in Charge of Publicity*, C. H. ALMSTEAD, The Patent Scaffolding Company, New York City; *Vice-Chairman in Charge of Stereopticons and Slides*, J. F. CONNER, The U. G. I. Com., Building Trades Employers Assn., New York City.

October 1, 1928**E. C. HARDING, Chairman****General Superintendent, Ferro Concrete Construction Company
Cincinnati, O.**

The joint meeting of the Construction Section at the Seventeenth Annual Safety Congress with the Building Trades Employers' Association of the City of New York was called to order at one-thirty o'clock by the chairman, E. C. Harding, General Superintendent, Ferro Concrete Construction Company, Cincinnati, Ohio.

CHAIRMAN HARDING: It is indeed very gratifying to me, and I know it is to the other officers of the Construction Section, to see this large assembly. It is, indeed, a very representative turnout and I am sure the Construction Section welcomes you to this Congress. I want to invite you all to our other sessions which will be held Tuesday morning and Wednesday morning at nine-thirty. I urge your attendance.

Our address of welcome this afternoon will be given by Mr. Walter S. Faddis, President, Building Trades Employers' Association of the City of New York.

Address of Welcome

By WALTER S. FADDIS**President, Building Trades Employers' Association of the City of New York**

As president of the Building Trades Employers' Association I bring you welcome from that organization. We are glad to see you and we invite you to use our beautiful rooms at number two Park Avenue, as if they were your own. If we can acquaint you with our beautiful, progressive city in any way, our time is yours. We congratulate you for having chosen the time and the place of your deliberations when much of beauty and joy can be had for the asking.

We heartily commend your spirit of public service in seeking to lessen the grievous physical pain and the great financial loss caused by accident. The construction industry is considered to be an extremely hazardous one, from the moment the wrecking contractor turns loose the men whose job it is to break things down, up through all the various stages of excavation and construction until the last bit of dust is swept away. Only through extreme vigilance by everyone, and the best of equipment, can accidents be prevented, with their constant loss of health and time.

Alive to this situation, the Building Trades Employers' Association has organized a safety department to conduct a campaign among the membership for the purpose of educating all concerned in proper safety measures to lessen the severity of accidents on buildings. The committee functions through a department, with men prominent in the industry in control. They devote considerable time to this work, which will be outlined by Mr. Lohmann, who is to make an address before you tomorrow.

There is a meeting in Philadelphia today of seven thousand bankers who will discuss credit requirements. There are two thousand men meeting in New York today to discuss postponement of old age. A strict adherence to the demands of the former and the advice of the latter will greatly enhance our safety. After a lifetime of very active participation in the industry, thirty-seven years of it being in the construction end in this city, no one can appreciate the most advanced means to lessen distress among my fellow workers more than I can.

As a man, I singularly regret the loss of dear friends through momentary

forgetfulness. As an employer, I see the great benefit from continued service in teaching safe methods of scaffold building, the proper placing of ladders, and so on. While fully appreciating all the work that this Council has done and is doing, I hope you will not resent a word of caution. Do not add to our present burdens by making further restrictive and mandatory laws. The old maxim says, "He is governed best who is governed least." Accident prevention can be advanced by education, cooperation, and efficient supervision, teaching men to act and think safety, until it becomes instinctive and characteristic. This will cause more progress in this direction than the passing of mandatory laws and codes.

I bid you welcome.

CHAIRMAN HARDING: Mr. Faddis, we appreciate your invitation. The next speaker will tell us "How the architect can contribute to safety"—Mr. R. H. Shreve, President of the New York Building Congress, New York City.

Architects' Cooperation in Safety

By R. H. SHREVE

President, New York Building Congress, New York City

It is my privilege on behalf of the New York Building Congress to extend to you a hearty welcome to New York and to wish you success in your activities here.

In order that the welcome which I am allowed to express may come to you with full effect, I should tell you that the Building Congress embraces in its membership representatives of all the elements of the Building Industry of this city,—architects and engineers, builders, sub-contractors, material supply men, labor, the real estate operators and the financial group. The Congress is the only organization active in the Building Industry of New York in which all the essential factors meet on common ground, and from all of these elements of the Industry I bring you greeting.

During the past few years, the Congress Committee on Safety, of which Alexander Kelso is chairman, has actively cooperated with the Safety Committee of the Building Trades Employers' Association, for whom Mr. Faddis speaks to you.

Mr. Faddis urged that no mandatory provisions be placed upon the industry. Whether specifications can be considered mandatory or not, I shall leave to Mr. Faddis. The architects are not convinced that the final truth is in either of these. We see merit in both.

At a recent Congress luncheon the Hon. James A. Hamilton, the Industrial Commissioner of the State of New York, addressed us on "Safety and Accident Prevention." Throughout all recent efforts to promote the cause of safety the Committee of the Congress has been among the leaders, but there is still much to be done, and I have been asked to state in what way the architect may contribute to this work.

Until recently, individually, in actual practice we architects have not done very much. The complexities, the dangers of building have increased faster than the provision by architects of safety precautions.

We have been participants in the discussions with which you are familiar, on the merits of codes or laws as opposed to education as means to assure safety. We are unable to agree fully with either extreme contention;—in our judgment the best results must finally be obtained by the adoption of both methods.

A great majority of the causes of accidents lie in the failure of the human element. To remedy this there must be education, training, discipline and intelligent supervision, but all of these must be based on suitable standards. Education must have its text-book, training its manual,—discipline its code,—and supervision its standards and tests; back of them all must be system, control,—coordination.

This need is fully recognized today by those who understand the tremendous financial losses occasioned by accidents in construction, losses due to death or injury of the workmen, losses due to insurance carried to cover excessive risks, losses through necessary medical care, through destruction of material and interruption of construction schedules, or through turnover and disorganization.

All of these are important, but above them rises the cause of humanity. How many of us who prepare drawings or specifications, contract for work or supervise its execution, picture ourselves in the places of the men who daily face the risks of the building, men who carry steel to giddy heights or blast the solid rock from beside our careless pathways. What if we had to do that which we set them to do? Would we then fail to provide protection to the utmost limit? And shall we now deny that protection to them? My own sympathy and understanding go out fully to Labor which, in the absence of other compulsory protection, seeks the help of the law. To do these men justice and to provide reasonable standards before we are perhaps saddled with unreasonable ones, we should seek effective action as you are to do at this session of the National Safety Council. With this purpose the Committee on Health and Safety of the American Institute of Architects, of which Mr. D. Everett Waid is chairman, is preparing through the assistance of Mr. Rudolph P. Miller, the committee's consultant, a statement or specification of safety standards.

This set of requirements will be put forward as a part of the General Clauses of the Standard Specifications of the American Institute of Architects and can be made applicable to all work on which it is intended that it shall be effective. It should supersede the less complete clauses now in use,—and afford a basis for fixing responsibility for the maintenance of proper working conditions and practice.

As architects, we believe heartily in the work you are undertaking and we pledge our cooperation in this endeavor to the workers, to the American Engineering Standards Committee, to the Association of General Contractors, and to you, the National Safety Council, in a task in which the cause of humanity works hand in hand with economy.

CHAIRMAN HARDING: The chair will make a change in the order of our program. One of our speakers has to leave to catch a train. Our next speaker is one who has devoted years in the cause of safety and I take pleasure in presenting the Hon. James A. Hamilton, Industrial Commissioner of the State Department of Labor, New York City.

The Economic Value of Safety to the Contractor

By JAMES A. HAMILTON

Industrial Commissioner of New York State

The title of this paper does not, I am sure, suggest to any one present the idea that safety is of economic value to the contractor only. All of us recognize the economic importance of safety to all employers. The achievement of safe production is a problem common to all industry. This is witnessed to by this Seventeenth Annual Session of the National Safety Council under whose auspices we are today gathered. The roll call of the more than twenty different sections, extending from "Automotive" to "Woodworking," into which the National Safety Council is divided, is evidence of the fact that there is no field of modern activity exempt from the necessity for consideration of the safety problem.

The rather elaborate subdivision, as indicated by the numerous sections of the Safety Council, of the question of accident prevention is indicative also that the problem is being analyzed in such a way as to develop it to a degree that would

be impossible without such subdivision. "Divide and conquer" was a maxim of Napoleon, and it holds true in this matter of accident prevention just as it was proven true in military affairs by the great Corsican. Although the general objective is much the same, namely, safe production for all industries, yet the methods of attack are far from being the same. The specific hazards of each industry, the materials handled, the composition of the working personnel, and other features peculiarly incident to one industry as contrasted with another must be considered if effective progress is to be made in the prevention of accidents.

Effect of Compensation Legislation

It might also be pointed out here that the enactment of workmen's compensation legislation, now well nigh universal, was designed to bring economic pressure upon employers to bring every effort to bear for the attainment of safety in industry. This legislation has, of course, an humanitarian aspect. With some employers humanitarian motives had been a sufficient inducement for safety even before workmen's compensation laws were enacted. But general recognition of the necessity for bringing a distinct economic pressure into play, which would apply with equal force to all employers, led to the enactment of compensation legislation which reenforced humanitarian motives, where such existed, and supplied the missing incentive for safety work where it did not exist. Employers who had previously been interested in safety work welcomed such effective support for their activities, and the others have, with rarely an exception, come to accept it as a necessary factor in industrial life.

Relation of the Contractor to Safety

Turning from the general aspect of the question, what specific value, if any, does safe operation have to the contractor? Is his safety problem differentiated in any way from that of other employers? Evidently, the Safety Council thinks so, as witness this luncheon session under the auspices of the Building Trades Employers' Association, and the sessions on Tuesday and Wednesday with detailed programs on safety in construction work.

Some Facts on the Accident Situation as Related to Contractors

First, let me give you a general picture of the accident situation in New York State. I quote first the figures as to compensated cases only in New York State for each of the four years ended June 30, from 1924 to 1927. This indicates an annual increase, but it should be borne in mind that the reduction in waiting period from two weeks to one week, which became effective on January 1, 1925, greatly increased the number of compensated cases for temporary disability.

TABLE I
Number of Compensated Accidents by Year of Closing

Year ending June 30—	All disabilities	Death	Perma- nent total	Perma- nent partial	Temporary
1924	72,983	1,109	22	15,526	56,326
1925	76,216	1,302	50	16,000	59,064
1926	*99,673	1,110	41	17,327	*81,195
1927	*98,984	1,042	41	18,518	*79,383

*Reduction in the waiting period from 14 to 7 days brought a large additional group of cases under the law.

The second table breaks up the total figures into industrial groups. It will be of especial interest to you to note that the "Construction" group had a greater increase in compensated accidents than any other.

TABLE II
Increase in Compensated Accidents by Industries

Industry	Number of Cases Year Ending June 30—				Increase (Decrease*)
	1924	1925	1926	1927	1927 over 1924
All Industries	72,983	76,216	99,673	98,984	26,001
Manufacturing	32,533	31,254	41,245	39,837	7,304
Construction	13,361	15,632	20,464	21,606	8,245
Transportation and public utilities.....	13,654	13,561	17,627	16,666	3,012
Trade	5,931	6,759	9,218	9,167	3,236
Service	5,589	7,030	9,091	9,559	3,970
Mining and quarrying.....	688	762	970	981	293
Agriculture	458	519	684	752	294
Other	769	699	374	416	*353

The third table furnishes information, for the years 1924 to 1927, by industries of the serious compensated disabilities. In this table, the "temporary" disabilities are omitted, while fatal cases, and permanent disabilities, whether total or partial, are included. Here, again, it will be seen that "construction" accidents had a greater increase, both in number of accidents and in amount of compensation awarded than any other group.

TABLE III
Cases Other Than Temporary Disabilities

Industry Group	Number of Cases Years Ended June 30—				Increase (Decrease*)
	1924	1925	1926	1927	1927 over 1924
Manufacturing	8,169	7,403	8,148	8,412	243
Construction	3,000	3,702	3,974	4,491	1,491
Transportation and public utilities.....	2,617	2,688	2,741	2,890	273
Service	1,298	1,562	1,745	1,880	582
Trade	1,165	1,343	1,485	1,587	422
Mining and quarrying.....	161	190	192	200	39
Agriculture	92	126	139	126	34
Other	155	138	54	15	*140

Total Compensation					
Manufacturing	\$8,127,670	\$7,709,239	\$7,550,524	\$7,953,668	*\$ 174,002
Construction	4,469,493	5,414,513	5,509,944	5,942,520	1,473,027
Transportation and public utilities.....	3,974,263	4,030,334	3,852,453	3,439,401	*534,862
Service	1,780,802	1,902,551	2,120,392	2,187,196	406,394
Trade	1,296,786	1,580,538	1,583,386	1,462,170	165,384
Mining and quarrying.....	356,977	352,455	429,881	441,207	84,230
Agriculture	109,084	153,112	167,218	132,176	23,092
Other	155,715	130,785	39,689	14,555	*141,160

I thoroughly appreciate the fact that safety in construction work presents peculiar problems. An ordinary manufacturing establishment has a fixed place of work and much greater routine in its operations than does a construction job. These conditions tend to render easier the working out of a safety program. I do not need to stress this point since the difficulties of perfecting a safety program amid the constantly changing conditions which confront you, are only too apparent. The message I would like to leave with you is that the problem of safety presents a challenge that should summon your ingenuity and sustained effort. And I also offer a word of congratulation on the efforts you are now making. You have realized as never before the seriousness of the problem and are engaged in what, I am sure, will prove the most successful effort yet made to produce safety in the construction industry.

CHAIRMAN HARDING: Thank you, Mr. Hamilton. Now we will hear from Mr. John Sullivan, the President of the New York State Federation of Labor.

Address

By JOHN SULLIVAN

President, New York State Federation of Labor, New York City

Organized Labor is a thorough believer in organized safety methods for industrial work places. It is impossible to conceive of any person having more interest in industrial safety than the employee. The entire hazard of workplace danger faces him. When the disaster comes it is the employee who receives its first and fullest impact and who is the last to recover from its evil effects.

This is an elementary fact quickly driven into the consciousness of those who must earn their bread in the sweat of their brows. It is most quickly realized in the construction trades where accident so frequently attends its processes, almost all of which are in the open air and often above ground surfaces. Within the factory and in the underground trades the frequency of accident, notwithstanding the greater opportunity for control of ways and means, usually keeps the possibility of disablement before the worker. Long contact with impending danger sometimes creates the indifference which leads to the careless act that invokes injury and death.

Thoughtful workers are keenly aware of and fully estimate all of these hazards that surround them in their employment, and seek by individual and by collective action to minimize them. They suggest and concur in shop rules that make for safety, and in their organized capacity propose legislation to make ways and means compulsorily safe by law. It will not be disputed that the interest of the organized workers in the safety of all workplaces is chiefly responsible for the laws and codes now operating to safeguard workers in all occupations affected with danger to life and limb. It has been the principal work of the organization of which I have the honor to be president to seek during the 65 years of its existence statutory law prohibiting or regulating workplace practices that were found by the workers to menace life and limb and health. Yet, notwithstanding all this desire to prevent and effort to limit, it is acknowledged that industrial accidents are still common happenings and the army of the crippled and widowed and orphaned is being added to every day.

Any continuous period of experience with workplace accidents and of genuine effort to reduce the most apparent causes teaches us that vigilance must be constant if results are to be gained and maintained. In fact, there are no absolute methods of accident prevention that, once devised and set in motion, perform their humane mission automatically. Complete suspension of workshop activities is the only absolute assurance of absence of workshop hazards. None of us want to purchase

immunity from accident at such a price. As an alternative we have created Workmen's Compensation Laws, the double purpose of which is to promote prevention of accidents and to compensate the victims of accidents whether preventable or not. Cooperative carefulness by employees and management supplemented by mechanical safety devices can and do reduce the causes and totals of factory accidents. A wider and more sustained cooperation will assuredly add to these beneficial results.

No one any longer accepts workshop accidents as inevitable. At one time they were considered as acts or omissions of a Divine Providence. Now we are coming to recognize clearly that many of them are due to human improvidence. A particular accident at its first occurrence may involve no personal fault, but its recurrence in the same workplace usually does. Where the fault is originally in the ways, works or machinery, its recurrence is plain negligence and thus becomes personal fault. Without inquiring as to whether personal fault is attributable to either an employer or to an employee in any given instance, we can all join in the conclusion that personal fault can and should be corrected and stay corrected. Such a correction is a task of cooperation, and such corrective cooperation is a mutual duty.

Much as we who are engaged in industry wish and work for that ideal and practical form of cooperation where all workplace problems can be considered and solved in conferences between employers and employees, still there is a function for government to perform in assuring workplace safety that is apparently indispensable. Our state factory laws and codes and protective statutes have been enacted almost wholly to safeguard the life, limb and health of workers against the ignorance, indifference or greed of a class of employers that is happily diminishing.

Enlightened and humane employers greet these laws as allied forces in accomplishing workshop safety. By imposing equally on all competitors in an industry workplace conditions conservative of life, limb and health, the pernicious effect of degrading competition is largely overcome by such laws. Their value as allies of workshop safety resides entirely in the quality of their enforcement. If they are poorly or partially enforced, then the employer who observes them in principle and practice is deprived of the shield of the laws against evil competition, while masses of workers are bereft of their protection. Full enforcement of such safety laws and codes is of vital importance to the aims and purposes of this gathering. Departments of Labor charged with such enforcement can only be effective when fully supplied with competent agencies.

No labor organization will absolve any worker who contributes to accident or risk by personal carelessness. We hold that every worker should not only do all he can to prevent and avoid accident, but that he should bring to the attention of those who have the power to remedy it any violation of the safety laws and codes occurring in his place of employment. We encourage the doing of this as a contribution to efficient enforcement of the Labor Laws we have secured. We hold that worker to be culpably negligent who refuses to employ the safeguards provided for the power tools he uses, and to be morally responsible if his indifference or intentional neglect causes the disablement or death of a fellow worker.

On behalf of the New York State Federation of Labor and its hundreds of thousands of employed members, it is my privilege, as its president, to pledge to you that we are anxious and willing to continue to do our full share in making all workshops as safe for the worker as human foresight and carefulness will permit.

CHAIRMAN HARDING: Thank you, Mr. Sullivan. I am sure that the Construction Section wants to convey their thanks to the Building Trades Employers' Association for this afternoon's session and especially to Mr. Wheeler, who is responsible for the program. I trust we will see you all in the morning.

ADJOURNMENT.

October 2, 1928

E. C. HARDING, Chairman

**General Superintendent, Ferro Concrete Construction Company
Cincinnati, O.**

The second session was called to order at nine-thirty by the chairman, E. C. Harding.

CHAIRMAN HARDING: We will take up the reports of the committees. Mr. Robinson, the secretary, who also has charge of the statistics will give us his combined report.

Report of the Secretary and the Statistics Committee

By J. WILSON ROBINSON

Everett Winters Company, Detroit, Mich.

As the Executive Committee did not have a meeting this year, there is no report along that order. The only thing we have is a report on your membership. From the last Congress up to the present seventeen memberships have been accepted and eighteen cancelled, so that our membership at the present time stands one less than it did a year ago, giving us a total of one hundred and twenty. The year before it jumped from ninety-six to one hundred and twenty-one, and we have contended right along that the requirements of this section were a full time paid secretary who can give his full time to the business of meeting members and seeing that they get something out of belonging to the National Safety Council.

We regret to say that this has fallen through. Last year we reported to you that the Council had appropriated the necessary funds and it was a question of finding a man for the job. It seems we were having some trouble to do this.

On statistics I have brought a summary which goes back several years so that you might make a comparison based on the hours worked and lost, per thousand hours. In 1922 the members of this Congress recorded that they had lost 49 9/10 hours; in 1923 it dropped to 47 9/10 hours; in 1924 to 46 4/10 hours; in 1925 it jumped to 57 1/10 hours; in 1926 it dropped back to 55 4/10 hours; last year, 1927, it was 49 2/10; so we have an average for the six years of 48 6/10 hours lost every thousand hours worked.

That is based on the man-power worked, as shown by the records of twenty-nine million and some over, as against one million hours worked, giving 64 6/10 for every thousand hours worked. It may seem from these records that we did not make much progress in 1927; but when you take into consideration the difficult factors with which we contended in the construction field, you will find that if the effort had not been put forth which has been put forth during the last five or six years along the line of accident prevention, it would be hard to tell what the ratio would have been for last year.

Take into consideration the great expansion of the automobile industry, which has led the field along the construction line, and has forced other industries into that same pace. This means that if an owner contracts with you today he expects a building built tomorrow, and the result is that you have your carpenters, and all others, working on night and day shifts. Taking those factors into consideration one can see the hazards have at least doubled and probably trebled, because there is no question but that men working at night are working under more hazardous conditions than in the day time. So that I may say, even though it does not appear on the surface that our records for 1927 are favorable with other years,

yet a good deal of it can be accounted for in the way I have just mentioned.

CHAIRMAN HARDING: Thank you Mr. Robinson. Would anyone like to ask Mr. Robinson any questions? If not we will call on Mr. Almstead.

C. H. ALMSTEAD (Safety Engineer, Patent Scaffolding Company, New York City): The Publicity Committee reports slight progress. I cannot give the exact amount of progress, but I want personally to compliment Mr. Wheeler of the Building Trades Employers' Association for the splendid cooperation and publicity given the meeting of yesterday, and I hope we can depend upon the Building Trades Employers' Association for the same kind of support we had yesterday.

CHAIRMAN HARDING: I hope so too, now that we have them interested. I will now call on Mr. Widua.

GEORGE WIDUA (Supt., Safety Dept., Woods Brothers Construction Company, Lincoln, Nebr.): As news letter editor of the Construction Section I would like to report that we have published seven news-letters for our members and in every one we have asked for suggestions from the members to help better the letters. I want to thank the members who have contributed to the *News-Letter* this year and hope next year our *News-Letter* will be better and bigger.

CHAIRMAN HARDING: I think you deserve a lot of credit for the issues, particularly the last one, because it was very complete. Now we will hear from Mr. Black, chairman of the Poster Committee.

Report of the Poster Committee

By CHARLES H. BLACK

Insurance Manager, Stone & Webster Engineering Corp., Boston, Mass.

My experience has been very interesting and enjoyable. In obtaining the proper personnel for the committee, I felt that it was quite necessary to select persons who would offset my inexperience in the preparation of posters applicable to construction work, and thanks to Howard L. Cates, Ralph Pendleton and S. J. Steinmann, and to their employers, the Employers' Liability Assurance Corporation, of the Massachusetts Safety Council and the Indemnity Insurance Company of North America, I was very fortunate in having them serve as co-workers on the committee.

We endeavored for a time to persuade some of the contractors in greater Boston to allow their employees to serve with us and furnish construction posters, but we finally gave up trying to secure additional members because we were losing time.

Our being unfamiliar with the system of poster preparation followed by the headquarters of the National Safety Council proved somewhat discouraging at first. We were not certain how much expense should be incurred in the preparation of posters or what would happen to the prepared posters sent to headquarters. It seemed as if everything we thought would make a good poster has been previously used in a similar manner. We hesitated to send in our ideas because we felt they lacked originality. We appealed to contractors with whom we were acquainted for poster suggestions but we obtained nothing. Very few of the contractors made use of posters to any great extent and those that did were satisfied with the posters obtained from the National Safety Council.

The situation looked dark when Howard Cates, with the assistance of his co-workers in the Employers' Liability Assurance Corporation, prepared three posters. We felt that these were very good and that they should be sent to headquarters. We understand that the General Poster Committee accepted them and that they will be used in the future. This approval by headquarters gave courage to your committee.

Shortly afterward, the Massachusetts Safety Council sponsored a contest among

Massachusetts construction jobs and distributed copies of the picture displayed on the rack in this room. Considerable enthusiasm was shown by construction men, and although this contest was not started to aid your poster committee it did aid considerably and paved the way for us to approach the bosses of the jobs for permission to take pictures. A great deal of credit is due Ralph Pendleton, of the Massachusetts Safety Council, a member of our committee, for the preparation of this contest. Through Mr. Pendleton's efforts material was sent to the National Safety Council for display, and, at his suggestion, General Series Bulletin No. 2151-B, showing National Safety "17 Things Wrong In This Picture" was recently published in the *News*. Mr. Steinmann solicited material from many in his territory and drafted letters to members of the Construction Section, requesting new ideas. Just how much material reached headquarters we don't know—only the display at this Congress will tell.

Many of the old "standbys" of our section gave valuable suggestions. Once again Howard Cates, our good friend, and the Employers' Liability Assurance Corporation, came to our assistance. Mr. Cates shortened his vacation, and with the assistance of Mr. MacNeil, also of the Employers', spent a number of days in securing photographs, twenty-three in all, of the safe and unsafe practices on construction jobs. Their labor did not end then; they prepared ten fine posters which are displayed there in original print to be later made up for distribution.

As an inexperienced committee we feel that we were not altogether dormant, but we should like to have done more. We feel that we accomplished something at very little expense to our employers and to the National Safety Council. The securing of poster material applicable to construction activities is a problem. It is serious enough to warrant some action at this meeting which will bring about more assistance to your next year's Poster Committee.

The area over which the construction industry extends is, without doubt, one of the greatest of any section meeting here this week. Its operation is not staple as a mill, a public utility, railroad, etc. Its activities are changing from day to day. The members of a Poster Committee cannot always find the particular example suitable for safety poster material in its neighborhood and the average contractor does not wish to be annoyed by having posing photographs taken on his job.

Because of my experience this past year I wish to give our next year's Poster Committee the benefit of my observations and I feel that it is necessary to recommend the following:

First; the responsibilities of the Poster Committee would be greatly lightened if all of the members of the Construction Section would cooperate.

Secondly; through the results obtained from circular letters it does not seem that they are worth while; the personal contact is necessary.

Third; a large committee is more preferable and its personnel should be selected from various sections of the country.

Fourth; the individual members of the Poster Committee should act as sub-chairmen with a committee of their own and they should exert every effort to obtain poster material from the contractors in their immediate neighborhood.

Fifth; the sub-committees should operate through their chairman and this chairman in turn should operate through the chairman of the Poster Committee, of which he is a member.

I believe that better results would be obtained if some of the members attending this meeting would volunteer to serve on the Poster Committee and act as chairman of a sub-committee for his section of the country.

It is practically impossible for a poster committee to efficiently carry on without cooperation from all our members and it is the duty of each one who is not engaged in other duties in our section to volunteer his services as a committeeman.

or a sub-chairman. With such assistance I feel that your next year's Poster Committee will have the finest record ever and will set an example for the other sections of the National Safety Council to attain.

In closing I wish to thank all those who sent us material, particularly the Employers' Liability Assurance Corporation, the Indemnity Insurance Company of North America and the Massachusetts Safety Council, for permitting Messrs. Cates, Pendleton, Steinmann and their other employees to come to our aid.

CHAIRMAN HARDING: I think you are to be congratulated on the fine work that you and the Poster Committee have done during the past year. Since there are no more reports we will hear our first speaker of the morning, Mr. H. W. Lohmann, of the Building Trades Employers' Association.

Safety by New York Contractors

By H. W. LOHMANN

Chairman, Committee on Accident Prevention, Building Trades Employers' Association, New York City

I have been requested by the Building Trades Employers' Association of New York to address the National Safety Council on "Safety in building construction by New York contractors." No one familiar with modern building construction can overlook the growing importance of this factor in the protection of human life.

We hear a great deal these days of the increased number of building construction accidents in this state over a period of years, but we hear little as to the principal contributing causes for that increase. Statistics are apparently not available to show that the main reasons may not be for such causes, for instance, increased production or the haste in which a modern structure is oftentimes erected, so for present purposes, at least, we must be content with the bare facts as published in the reports of the Department of Labor, which certainly do show an upward trend.

We also hear much of the great dangers connected with the work, and incidental thereto and the necessary methods to be applied to eliminate them, about which I will direct my talk today. We all know that building construction is hazardous and will continue to be so. The first steps in any of the various jobs in the erection of a building are usually dangerous but, I believe, that dangers in the ordinary progress of the work have been overestimated, especially as far as the immediate future is concerned, and I say this advisedly.

The cardinal principle of American business men has been to reduce waste, and as they, either individually or through their association activity, gradually eliminated the main source of it, they directed their attention to the less conspicuous ones. Many large industries, influenced by legal, humanitarian and financial reasons, adopted organized safety methods with astonishing results in the reduction of accidents and accident costs, and proved that accident prevention eliminates human and economic waste. These definite results are sufficient in themselves to justify concentrated safety activities in the building industry, which has and still is suffering a real but unnecessary economic loss due to the establishment of its unfavorable accident record.

It has been said that the test of any big business is in honest competition, integrity, usefulness of purpose, elimination of waste and freedom from unnecessary encroachments, rather than the size of the business. Building contractors, representing an industry which is the backbone of the nation's progress, would not be measuring up to that standard of business men, which they are, if they

did not profit from the experience of other industries and seek to do all that can be done to combat this increasing business disadvantage.

Waste from building construction accidents in the past was passively accepted by the contractor as inevitable. "A worker killed for every floor" which was a current saying a short time ago, is now considered as plain bunk. Preventable accidents on buildings is a challenge to the brains and courage of contractors and any endeavor by them in safety work is bound to pay good profits in dollars and large profits to the industry as a whole in the saving of man power and the relief of human suffering.

The Building Trades Employers' Association of New York, spurred to action by the increasing number of accidents with resultant loss of life, suffering and misery following in the wake of these casualties, and because of the remarkable success of other industries which blazed the trail along this line, decided that it should extend its activities to include accident prevention among its membership for their mutual welfare and the good of the industry. Frankly, our members do not retain their membership for philanthropic purposes, but rather for business reasons with the expectation of a return in some form, which we hope to give them. In the past they have concerned themselves more with the harmonious conduct of their business and business relations rather than with safety. It is true, that some of the more progressive ones realized the advantages of safety years ago, and have practiced it each through individual effort with some very remarkable results. Reduction of accidents by members of the Building Trades Employers' Association, through their own efforts, has been substantial but, regardless of it, accidents in the industry have increased, as is evidenced by statistical reports and the increase of insurance rates. The need for an organization movement became apparent—team work was necessary for effective results through a well directed campaign to reach all classes of contractors.

The association organized a committee known as the committee on accident prevention and provided for an annual appropriation to defray its expenses. It is composed of seven members, four representing general contractors and three sub-contractors. Sub-committees were appointed for each of the twenty-six affiliated trade associations, whose duties are to bring all matters on safety requiring attention to the notice of the general committee and to advise on matters pertaining to their trades. The committee serves gratuitously but has employed an executive secretary to direct the detailed management. It has been functioning since October 1st, 1927, and holds its meetings twice a month. A study has been made of local conditions and the requirements for conducting a continuous safety campaign, which will follow prescribed safety methods.

An appeal has been made to our members for safety, both from the humanitarian and economic side, and the contractor who does not believe that safety is his paramount moral duty readily appreciates it as an economic necessity. New York contractors, through our efforts, are now more or less sold on this matter of safety, and, it is believed that when they have all been instructed in the approved methods for building up their organization for carrying on accident prevention, it is an assured fact that they will make an honest endeavor to eliminate this class of waste as unworthy of the industry, and place building construction into the sphere where it belongs.

In my humble opinion safety measures have not kept pace with the stupendous increase in the size and height of buildings wherein all possible hazards are encountered and which requires the formulation of entirely new methods of protection. Formerly, safety measures were left entirely to the discretion of the superintendent on each job and if this man was careless or indifferent, nothing was accomplished. In recent years, however, many of the large construction firms have given considerable study to this problem and their executives have planned and have personally gone into this matter, made detailed scientific studies

of methods by which the greatest degree of safety can be obtained for each branch of the industry and prescribed safety measures that must be followed by their administrative force, inside superintendents and their superintendents and foremen on the building.

Realizing that "first things come first" our pamphlet No. 1 was "Accident Records—How to Compile Them and How to Use Them," and was based on the standards of the National Safety Council. Provision has been made for members reporting their accidents annually directly to the committee for the purpose of compiling statistics, which will be published in a report similar to that of the council.

Safety work in building construction, to be effective, must be directed toward its two main elements, namely, safeguarding and education. The burden of responsibility for accidents to workers is placed upon the employer of labor by the compensation law, while the erection and maintenance of safeguards are mandatory on contractors, each for his own employees, under the labor law and industrial code of this state. It has been estimated that the lack of physical safeguards and the improper maintenance of them accounts for twenty-five per cent of the major accidents on buildings. Most of these accidents are preventable and can be eliminated provided that all contractors comply with the requirements of the code. Accidents occurring through a violation of these rules are, in most instances, inexcusable and directly chargeable against the industry.

The contractor who is honest and careful, in the business to stay, and who erects and maintains safeguards on all his jobs, and has an active accident prevention organization can be relied upon to continue that work regardless of assistance because he knows that it pays. But there are two other classes which require real attention if accidents are to be substantially reduced. They are as follows:

1. The so-called speculative or owner-builder, not in the business to stay, and who knows little or nothing of accident prevention or the requirements for safeguarding.
2. The contractor, who may term himself a general contractor, but who either does not know how to erect safeguards or will not do so on account of their cost.

The committee is interested in reaching both of these classes, but when it is realized that over fifty per cent of the building in the metropolitan district is done by the former class, who belong to no association, the problem of how to effectively reach him is readily appreciated.

Building construction work with its constantly changing conditions is hazardous employment. New hazards quickly appear and alertness must be ever present to prevent accidents. In manufacturing plants, due to the more or less stable conditions, an accident may be practically eliminated by the installation of permanent safeguarding equipment. A similar safeguard in a building under construction may shortly have to be removed on account of progress. Again, workmen may remove guards, either in the course of their regular employment or to use elsewhere for a similar purpose and they are not immediately replaced. An improper safeguard, or one not maintained, creates a new hazard. Accidents are rare where a man falls down a wholly unguarded floor opening during working hours, but falls do occur where the workman depends on a safeguard which proves either to be weak or insufficient.

It is axiomatic that faulty protection is worse than no protection at all. To explain further—where a protective measure has been installed workmen and others are depending on its being in a proper and safe condition, whereas if there is no protection such dangerous places are avoided. Take for instance, a temporary walk over areaways. The public does not examine the walk before using

it and has every reason to assume that same was built for that specific purpose, namely, for pedestrian traffic and if any knotty plank is used or the walk is poorly constructed and is unsafe, and it gives way, the accident happens, whereas if there is no walkway at all, pedestrians will avoid such places. The same thing applies in building in the covering of hatchways, ladders and the like.

The construction of a modern building, due to the many different trades on the job, is a complicated undertaking, and in order to be safely and economically carried out requires a carefully organized machine. As a matter of economy, in view of the many different contractors on the work, proper safety provisions cannot be fully expected unless the architect upon whom the primary responsibility for the operation rests, carefully specifies the safeguards to be made and by whom. Our purpose, however, is to build up a human machine rather than a purely economic system and thus increase the efficiency and productivity of the industry, and with the final and even stronger urgency on the grounds of humanity.

Upon contractors rests the secondary responsibility for faithful execution of the work and without the promulgation of sound basic safety rules for the guidance of all of them, maximum results in accident prevention will not attain. Our committee felt that the accident movement should start with the architect who really is the fountainhead, and with this in mind, prepared a safety specification composed of fifteen articles entitled "Protection and Safety Work." It was sent to contractors and architects in this district with the recommendation that the entire specification be embodied in the general specifications in all building construction, and cooperation was requested in its application and use. The adoption of this plan would definitely fix the responsibility for safeguarding on the contractors, each for his own employees, by virtue of his contract. It would not be inequitable for the reason that it would definitely place the responsibility for safeguarding upon each contractor only in so far as the protection was applicable to his work, avoiding confusion as to who should safeguard a particular piece of work, and tending to eliminate duplication in bids for the cost of such safeguarding. Contractors including this cost in their bids would not rely (as is sometimes practiced) upon the safeguarding equipment of others, thereby cutting down a prolific source of accidents caused through the removal of a board, etc., which renders a safeguard inoperative. Due to its far-reaching effects, hundreds of contractors and architects are in accord with this plan and have voluntarily signified, not only their willingness to cooperate, but their intention to use this specification in all of their work.

The committee on accident prevention came to the conclusion that if it was to do a real job the educational campaign on safety being conducted among its membership should be extended to all of the elements engaged in the work regardless of affiliation and it is continuing its work along that line. The general plan adopted is to awaken the general public, the owner, architect, engineer, contractor and the mechanic to the accident conditions that prevail and to obtain their support in the movement. A newspaper and trade journal publicity campaign has been under way for the past fourteen weeks, with the result that our entire line of activity has reached millions of readers. Fourteen of the largest metropolitan newspapers have printed stories on our work and fourteen trade journals have done likewise.

Our Bulletin No. 3 was a broadside with appropriate illustrations on the gruesome type designed primarily to awaken contractors and others to the seriousness of the present accident conditions. It was sent to members, contractors who are not members, architects, engineers and insurance companies, and the supply of 10,000 copies originally printed has been practically exhausted.

Heretofore we have sought to create an interest on the part of the employer,

but in accordance with our plans, we are now directing our attention to the employee. Our Bulletin No. 4, which is now being prepared for distribution to workmen, is our first attempt toward their education. It will graphically depict some fifteen admonitions, with an urgent plea for their cooperation in the movement. Plans are also under way to conduct a poster contest, similar to the one used in Massachusetts and Pennsylvania, to further stimulate their interest. It will be open to competition for all workmen engaged in the building trades and large cash prizes will be awarded to the winners.

We plan to hold safety meetings for superintendents and foremen of our members regularly during the fall and winter months, and we will, from time to time, issue safe practice bulletins on various subjects, such as the installation and operation of material platform hoists, arrangement of ladders, guards, etc. We will be guided by the suggestions of our members and the committees representing the trade groups, together with such other information and advice obtained through our own study including conferences with cooperating bodies whose activities are centered in building construction. We intend to continue selling cooperation in accident prevention to the employer and his superintendents and foremen and through them to the workers. We believe that we have a problem, but that the best factors in facing that problem will prove to be proper supervision and inspection, complete observance of safety requirements, installation of protective devices, exercise of care, eternal vigilance and determination on the part of both employers and employees and all associated with them that preventable deaths and accidents can and must be reduced.

The New York Building Congress, among its other activities, has a committee on craftsmanship awards, by which craftsmen are given recognition by award of certificates for high class workmanship. This has been a wonderful stimulus to the workmen in putting forth their best to do splendid work in their craft and it is my belief that superintendents should be given similar recognition on the basis of a low average of casualty which could be calculated on a man-hour basis. This would stimulate those superintendents in furthering the cause of safety.

CHAIRMAN HARDING: I think we all enjoyed that paper. We will now hear from the next speaker on our program, Mr. F. H. Westmeyer, the Insurance Manager for A. Bentley & Sons Company, Toledo, Ohio.

Minimizing the Damage of Accidental Injuries

By F. H. WESTMEYER

Insurance Manager, The A. Bentley & Sons Company, Toledo, O.

Much has been said about the prevention of accidents in industry, a large amount of thought and effort has been given to the subject and a considerable measure of success has been achieved. Why all this thought and effort? Why this great meeting here today? The answer is, to immediately reduce and, if possible, to eventually eliminate the loss to society and the losses to individuals which result from personal injuries.

The subject needs no apology, but these introductory remarks have been made for the purpose of bringing to your minds quickly the fact that there is a very close relation between the prevention of accidents and the minimizing of losses resulting from accidents, because efforts in either direction have a common purpose. If accident prevention was wholly successful, there would, of course, be no need of discussing the means of caring for the injured. Unfortunately, however, the position of sincere and active accident preventionists is very much like the position of a certain enthusiastic golfer.

One of his friends said to him, "Bill, do you play golf?" and Bill answered "No, and I can't quit it."

Accidents still occur and a great many men are still being injured. In the state of Ohio alone, the number of injured for the first half of this year exceeded *one hundred thousand*. In the construction industry, particularly, the frequency rate is high. It is not especially difficult to understand why this is so. The reason lies largely in the fact that there are more hazards in the construction industry than in other industries. You can get some idea of the relation of hazards in construction to industrial hazards generally from this—the workmen's compensation rate manual of the Ohio Industrial Commission, which does not vary greatly in its classification list from the rate manual used by private insurance carriers, lists 590 occupations or classes of hazards. Of this number 78, which is more than one eighth of the total, are distinctly contracting operations, and 51 more are allied classes of work which are, in some few instances at least, carried on by contractors.

All these hazards; a large labor turnover; seasonal occupation; continually changing physical conditions at work that is under way; and various other conditions peculiar to the construction industry are all obstacles to successful prevention work. These obstacles, serious and discouraging as they are, should not deter us from prevention efforts; rather they should spur us on to greater efforts; but as long as men are injured, it will be necessary to care for them and to limit as far as possible the extent of the damage resulting from their injuries.

Now, what is the damage, what is the loss which results from personal injuries? Disregarding here the pain, suffering and anguish caused, because these are items which cannot be considered economically, although they should always be kept in mind, there are quite a number of items which go to make up this loss. The most important of these are the immediate loss of productive capacity of the individual injured, through loss of time immediately following the injury, and the lessening of that productive capacity, through any impairment of bodily function which may result from injury. In addition, the cost of supervising the care of injured, fees for medical and various other kinds of service, hospital and nursing costs and various lesser items must be considered. The various workmen's compensation laws provide what portion of this loss shall be borne by the employers, and that portion is borne either directly by self insurance, or by a great many employers, collectively, through the medium of insurance with privately or publicly conducted workmen's compensation insurance companies or funds. Keep in mind, always, the cold, hard fact that insurance companies or funds bear no portion of this loss; that they merely act as administrators in the distribution of it, always collecting, or at least endeavoring to collect, a respectable fee for their service.

To attempt to set forth specific rules for the care of injured and to expect such rules to fit all cases would be a useless effort. Above all other things, it is necessary to adopt the mental attitude of putting yourself in the place of the injured man and, prompted by that attitude to do for him, as far as possible, the things you would like to have done if you were in his place. This advice loses nothing either in value or practicability because it happens to be the oft repeated general advice given some nineteen hundred years ago by the greatest philosopher of all times. Amplifying this, there are certain sound, fundamental practices which may be applied, with sundry changes in detail, to all cases, and these practices will be discussed here, not in the order of their importance, but in the order of their need or occurrence.

FIRST—The acceptance of the idea that accidents will occur. This item is probably the most important of all, because if it is not a part of your scheme of management, it quite naturally follows that no plan for the care of injured will be made until an injury is actually sustained. Caring for injured, like any other human activity, proceeds more smoothly and with less error if this work is planned in advance of its execution.

SECOND—The centering of responsibility for the care of all injured in some one person and the making of some provision, as nearly perfect as possible, for the prompt reporting of all accidents to this person. A reasonable measure of authority must, of course, go with this responsibility.

THIRD—The selection of certain definite agencies for the repair of the damage wrought by accidents. This should include the selection of a doctor or doctors, X-ray man, ambulance and hospital. Having made a selection, your field force should be kept fully informed as to just what agencies are used. Arrangements should be perfected for the making of quick contacts with these agencies, and these arrangements should provide for substitutions when for any reason such contacts cannot be quickly made when needed. An injured man does not feel any better in mind or body, if he is compelled to wait, without proper attention, while those around him are wondering what to do next.

FOURTH—The presentation to your field force and the acceptance by that force of the idea that when an accident has caused a disabling personal injury, the most important piece of business at hand is the care of the injured person. Common decency suggests this, but quite aside from any humanitarian reason for promptly and properly caring for disabled persons, there is the fact that all serious accidents cause disorganization; and reorganization will not take place until the injured is removed from the scene of the accident if he is disabled.

FIFTH—Maintaining a genuine interest in the physical welfare of the injured employee, allowing him to know that you have this interest.

SIXTH—The exercise of great care in the selection of the agencies used for the care and treatment of injured. Only thoroughly competent physicians and surgeons, preferably those specializing in industrial work, should be used. If you were injured and were unwilling to have your own case handled by the doctor whom you select for the treatment of your injured employee he is, by that token, not good enough to treat an injured employee.

SEVENTH—Close cooperation between doctors and employers. This applies as well to agencies of repair other than doctors. You should be advised at frequent intervals as to the physical condition of any injured employee whose injury is at all serious, and the doctor should receive the support and influence of the employer in any measure intended for the good of the injured employee. There is an idea, prevalent in the minds of a great many people that, once a man is injured, the whole responsibility for him until his return to work should be passed on to his doctor, and that any attention to him on the part of anyone else is an almost sacrilegious infringement on the rights of the injured person or the prerogatives of the medical profession. This idea, which does a great deal of harm is, fortunately, not held by any great portion of the medical fraternity.

EIGHTH—An understanding, in a broad sense, of the purpose of workmen's compensation laws in general and a specific, detailed knowledge of the workmen's compensation law which is applicable to the particular work being carried on by you. Where the liability imposed by the workmen's compensation law is passed on to an insurance company, this does not relieve the employer of all moral obligation. It is essential that all injuries be promptly reported to the insurance carrier and it is equally important that the injured person receive, without any undue annoyance or delay, any workmen's compensation benefit due

him and no more. Keeping compensation payments within the legal limitations applies only to compensation for wage losses, for there are a great many instances where it is economical to disregard entirely the legal limitations for medical and hospital service and to go far beyond those limitations. It is unfortunate, indeed, that the present practice of insurance carriers generally, including state funds, is such that losses which might be curtailed by certain early attentions, possible only through close contacts with injured persons and the agencies of repair, are permitted to get out of bounds because of the inevitable delays always incident to remote control.

All of the practices outlined, are viewed from the standpoint of the employer and it is entirely proper that they should be, because under the modern concept of responsibility for industrial accidents, the employer is held wholly responsible and he should, therefore, not be barred from using any available means for reducing the losses from accidents, so long as the means employed do not definitely work to the harm or ultimate damage of the injured employee.

It is very difficult, if not impossible, to point out in minute detail just how the damage is minimized in any particular case or to show just where some saving is effected. There is a way of knowing, however, whether or not reductions are being effected. Records can and should be kept showing the direct cost of accidental injuries. These records should show not only the cost in money expended for supervision, medical, hospital and other service and workmen's compensation benefits to injured employees, but the time loss as well. The loss in money, considered apart from the loss in time, and the loss in time, considered apart from the loss in money, should be set against the total number of hours worked during any given period. In this way, *relative* costs may be established and comparisons made. Another method is to keep a cumulative record of the employer's whole cost of accidental injuries and a cumulative record of all payroll expenditures and compare the cost figure with the payroll figure. This method is faulty, as will be explained in a moment, but it is the only method by which workmen's compensation loss costs can be compared with workmen's compensation insurance costs. The method used by insurance carriers for measuring workmen's compensation loss experience and for fixing premium rates is to take the payroll of the employer as a basis, using each one hundred dollars of payroll as a unit of measurement. This method is wholly unreliable, because of changes in wage levels between one period and another or between one locality and another, and it should not be used if loss experience records are desired in such form that the record for one locality or for one period of time may be compared with the record for another locality or for another period of time.

So many petty details enter into the proper handling of accidents and employees' workmen's compensation claims, that a great deal more of a detailed nature might be said, but time is not available for that purpose. It is, moreover, easier to form a good mental picture from the description of some specific case, than from general rules or suggestions, so we will now follow such a case from the time of the injury.

The particular job on which this injury is to occur is a new factory building, located at the edge of the city, some six or seven miles from your main office. The site of the job is visited before a spadeful of earth is turned, and you learn while going there just which will be the smoothest route for an ambulance to take if one needs to be called. Charlie Stelker, the superintendent who will have charge of this job, is on the ground and, the job being quite remote from the center of the city, you arrange with him for the early erection of a small but clean shanty for the keeping of first aid supplies and for the reception of men in the treatment of minor injuries. This is done because it is less costly than to suffer the loss of time occasioned by men with minor injuries going down town for treatment or to take the inevitable loss following failure of men to get

proper attention to nail wounds and other lesser injuries.

You explain to Charlie that the doctor will call on him at the site of the job, at any reasonable time, to arrange with him the details for attending to minor injuries, and you ask him to make his own appointment with the doctor. Again you tell this superintendent that no injury may be regarded as trivial, although you have told him this same thing some twenty or thirty times before. He already knows what doctor will attend the injured, what ambulance will be used and to what hospital disabled men are to be sent. You remind him that as soon as his first aid shanty is up it should contain, in addition to ordinary first aid supplies, one or two stretchers or cots, and that the doctor may recommend some additional equipment. If you have not already talked with Doctors Post and Crane about this particular job, you do so without further delay and ask them to make such arrangements with Charlie Stelker, for the treatment of minor injuries, as will be mutually satisfactory. Possibly, you will make some special fee arrangement for service at this particular job.

Two or three months later your telephone rings and Jim Gridley, the time-keeper at this job, tells you that an employee, named Dave Bendel, has just fallen and appears to be quite seriously hurt. You ask whether Bendel is bleeding and, being assured that he is not, you learn that he has been picked up and placed in a fairly comfortable position. You may ask whether Bendel is conscious and whether the nature of his more serious injuries is quite evident, but you spend no time now asking about the accident. You already know that the accident has just occurred and you learn that no ambulance has been ordered. You tell Gridley that you will order the ambulance, that a man should be stationed at the entrance to the plant premises to direct the ambulance driver when he arrives, and that the ambulance driver should be directed to take Bendel to St. Vincent's Hospital.

You then order the ambulance by telephone, being careful to learn that one is actually available immediately and, when giving your order, state that Bendel should be taken to St. Vincent's Hospital. You may make some suggestion as to the most direct route to the job and the smoothest route from the job. Then you try to get into communication with one of your doctors at the office of Doctors Post and Crane. If the accident occurs in the forenoon, you will probably not locate either doctor there, but as they do much industrial work they are accustomed to receiving emergency calls and have their affairs so arranged that their office attendant can probably locate one of them with almost no delay and, after telling her that a patient, Bendel, seriously injured, is on his way to St. Vincent's Hospital, you enlist her services in locating either Dr. Post or Dr. Crane, requesting her to advise you definitely within a few minutes whether or not she has been successful. You then call St. Vincent's Hospital and arrange for the reception of the patient, learning at the same time whether or not either Dr. Post or Dr. Crane is there. If either is at the hospital, you ask to have him immediately located and sent to the emergency dressing room where the patient will be received. After doing these things, you will probably not have to wait more than two or three minutes before you hear from the doctors' office attendant. If she has not been able to locate one of them, you ask her to continue her efforts and tell her that you will call her again from the hospital in a few minutes. You then leave for the hospital and, if your plans have been well ordered, you will arrive there at about the same time that the patient does. On arriving there, if neither of your doctors is at hand, you arrange either with the hospital interne or with some more experienced doctor, as the obvious condition of the injured suggests, for Bendel's immediate medical or surgical needs.

Unless Bendel is unconscious or is suffering pain of almost unbearable intensity, you learn, without much talk, just where he lives, and what you can do for him in the way of small attentions, such as having his tools on the job picked

up and put away for him, taking care of his automobile if he has one at the job, and at the same time assuring him that you will promptly notify his wife or family of his misfortune. Right now is a good time to learn what kind of reactions you may expect from his people when taking this piece of bad news to his home. In the case of a serious injury like this, it is usually impossible to learn immediately the complete extent of the injuries. However, it is usually possible to learn in what way the man is most seriously injured, and in most cases you can learn whether or not the injuries will probably terminate fatally. It is well to have this information in advance of carrying to Bendel's home the news of the accident, because any gross understatement or overstatement of the extent of the injuries destroys confidence, and this confidence may be much needed in a short time. Moreover, bad news travels fast and, if Bendel is not dangerously hurt, you will find a great measure of relief in being able to so advise his family, in case some exaggerated story of the accident has preceded you.

After notifying Bendel's family and attending to such minor matters as need immediate attention, you investigate the accident fully, preferably by an early visit and inquiry made at the job, report the whole matter to your insurance carrier and then feel that your responsibility has ended. Is this really so?

If, instead of having passed your liability over to an insurance company for a premium, you were facing the cost of this accident directly by self-insurance, your interest certainly would not stop here. You would know that only one course was open to you. You would know that your actions would be finally approved or disapproved by a board or commission with autocratic powers, interested in very little that you might have to say, but quite interested in what you might be able to show in the way of results. After some contacts with injured men, that spirit of neighborliness, that all humans have in some degree, would probably assert itself and impel you to further interest and action; but if it did not—if you were possessed of about half as much warm blood as an oyster—that sense which enables you to carry on in one of the most highly competitive and hazardous businesses that exist, would urge you to see to it that every available agency was used to repair, as fully as possible, the damage done. You would not be satisfied if Bendel had to suffer some permanent disability, if by any means at your command that prospect could be avoided. You would want to know from your doctor whether any special knowledge not possessed by him or any agency not at his immediate disposal was needed for the better care of Bendel, having always in mind the final result, and your doctor would not take umbrage at your action, for he would know that the medical and surgical field is large and that no one man surveys it all. And if some special knowledge, some further agency was needed for the better repair of the damage, you would, through proper channels, set that knowledge, that agency to work; because you would know that you were a partner with Bendel in his loss; in a partnership that could not be dissolved until your portion of the loss had been fully paid. And, if you are a partner in this serious loss, you are also a partner with each injured man in every other loss caused by personal injury and, therefore interested in the result in each instance.

Without considering at all the humanitarian aspects of the situation, a very close attention to detail and a willingness to go beyond the legal limitations in the expenditure of money, time and effort for the repair of damage wrought by personal injury is economical. If this last statement is correct, if these methods, these practices are economical for those who bear the employers' portion of the financial burden of this loss directly, would it be advisable to use such methods, such practices where the loss is borne indirectly through insurance? And, if these practices, these methods are advisable where the loss is indirectly borne, and the agencies used for the distribution of this loss are not now using these or similar methods or practices, is it worth while for you who furnish collectively,

the money to pay these losses, to give some thought to the subject, with a view to bettering the situation? These are questions which you must answer for yourself.

There is much more to this subject than what has been mentioned. Have you ever considered the *meaning* of workmen's compensation laws? Have you ever thought of them as other than bothersome rules that have been injected into your business? Have you ever thought of the laws, collectively, or of workmen's compensation as an idea? Well, this idea is society's notice, brought forcibly to your attention by laws on the statute books of nearly every state in this country, that the forces of industry, *employers and employees alike*, have failed to make, without interference, sensible, practical, workable provisions for a reasonably equitable distribution of the economic loss resulting from accidents in industry. More than that: where compensation laws have been once enacted there has been no repeal, no change to some other system or method; and this is the open confession of the forces of industry, employers and employees alike, that their failure to handle this question has been complete. *Shall we fail too in the reduction of this great loss as we have failed in its distribution?*

CHAIRMAN HARDING: Thank you Mr. Westmeyer. Now, our next speaker will be Dr. S. W. Grafflin, the Religious Work Secretary of the West Side Y. M. C. A., of New York City.

First Things First

By DR. SAMUEL W. GRAFFLIN

Religious Work Secretary, West Side Y. M. C. A., New York City

I was asked to speak on "First Things First" and I have a paper here on that, but someone wanted me to repeat what I said yesterday on "First Principles" and it does not matter a particle to me. But before I do that let me explain how I came to be a Y. M. C. A. secretary.

For sixteen years I had a very wonderful job in the sash door and building game, with open machinery in which we killed a man a day and the whole thing was just a nice happy proposition. We encountered very drastic opposition when we wanted to put guards on some of the machines. There were more reasons why that should not be done than anything else on earth. But after a while the organization drafted me to take charge of the Y. M. C. A. work and have given me a roving commission to go where I please and I happen to be here this morning to talk to you about "First Things First."

Before I talk about that I will talk about the "First Principles" because while there are certain first things (I will name them in a moment) the text would be; "He who knows and understands his customers will have trade." I might add; "He who knows and understands his competitors will have safety, he who knows and understands his business will have riches, but he who knows and understands his workmen will have peace."

The first thing would be the ability to think straight and after that to look out for the most dangerous man in the world, the conscientious ignorant man. He is the one who makes all the trouble.

When the historian comes to speak of this day and age I think he is going to say four things about it. First, that it was the age of the political opportunist. There are no statesmen in this age. It is the age of industrial readjustment, and it is also the age of the decadent home. The great American tragedy is the non-praying woman.

I had to speak to about fifteen leading highbrows the other night. One thousand were men and they had five hundred wives along with them—only half brought their wives. I asked how many of them had children between two and ten and quite a large showing of hands went up. I asked how many had had a child by their knee to hear a Bible story and I got eleven weak hands. I had my doubts about some of them, but anyway that is typical of the generation that has lost the one thing that helped the last generation.

This is the age of the conservation of the bodies of men. There are two sides to that question. The race never would have been as far, and as fit, and as fine as it is if the primitive peoples had cared for their unfit.

The boy or girl who could not march with the crowd was left behind. If he could not run with the pack he was simply left to die. Society has gotten as far as it has because of the elimination of the unfit. That sounds hard but it is a grand thing. Nothing in the modern trend is more dangerous than the fact that we are doing everything to save our unfit and get them up to a point where they can get married and raise another crop of unfit.

Now between the first great business enterprise, the building of the Tower of Babel, and the next great business enterprise of the world, the building of a bridge across the Firth of Forth, in Scotland, there was no accident insurance or preventive measure. In the latter job they put in an estimate to give two hundred pounds to the family of every man who was killed on the job, so that shows how recent this whole proposition is.

If you should sit along the banks of the Euphrates and see the old brick-yard that was used seven thousand years ago, you would notice how up-to-date everything looks, and you might learn how the workers refused to work facing the sun and how they did not want to walk home in the evening facing the sun; and I haven't a doubt in the world that at the building of the Tower of Babel they had their first aid staff and their litters to carry away the injured and all the rest. But from that date no further progress was made until this bunch of Scotchmen built their bridge. But in order to put over any great universal project there are certain underlying principles that I want to talk to you about, and the first is the courage to pioneer.

Gentlemen, may I say that there is not anything that calls for greater courage than the ability to pioneer? The world has been made by its pilgrims and its prophets, and its immigrants and its inventors, the men who dared to do something new. When Mr. Howe walked into the office of a Yankee that day and said: "Gentlemen, I am going to take the eye out of the stern of the needle," do you know where he spent the night? In the hoosegow. They said: "After ten thousand years this nut is going to place the eye in the point of the needle. Lock him up!" When Mr. Morse, America's greatest scenic artist, walked into a Baltimore office and astounded them by saying he was going to send a message around to the City Hall on a wire, they sent him to the City Hospital. Was the Mayflower launched by courage?

"Oh, launch your Mayflower boldly,
And steer o'er the wintery sea."

It takes courage to pioneer and the men who did anything in the past where the men who had the daring to do something along new lines. That calls for all the courage you have got, as I can testify after having attempted to have two or three safety devices installed in the old shop. You would think I was trying to commit murder when I wanted to have a guard put on the bandsaw. It takes courage to pioneer.

Now the second thing is the will to investigate.

I know of a son of a friend of mine who was offered a little chance to take over a factory in the country, that was under the guidance of Edison. He didn't

even take the time to go out and look it over. Now he is in the hands of the sheriff.

When God got ready to bring industry into the world he brought six thousand brick-layers up out of serfdom and welded them into a religious commonwealth. He took that man who was to pool those forty years of education and forty years of mature reflection and sent him a Regent's examination. I hate to think what the State of New York would have done with him at the end of that time. For when Moses saw the bush burning and turned aside to investigate it, he was the first scientific investigator. No matter how many sheep he had, he still had time to see why that bush burned and was not consumed. Let us come down to the great American tragedy.

George Washington decided to go scouting in the valley of the Ohio and he found a stream that ran pure grease and he took notes about it and decided that it would burn. But he turned his back on the stream of running petroleum. Petroleum was not drilled for until nearly one hundred years later; and at the very hour when Washington turned his back on this, Benjamin Franklin said: "If these sparks would jump off the cat's back they would jump off the clouds if I had a big enough pussy." At the very hour George Washington turned his back on the petroleum Benjamin Franklin was being decorated by an English society for the discovery of the electric spark. If Washington had brought one drop of that petroleum back to see if it would burn we would have had the internal combustion engine, the industrial revolution, and the tragedy of coal would have centered in petroleum. Nothing that makes smoke should ever be taken away from the mouth of the mine, it should be reduced right there to power. But one man did not have the will to investigate. We have got to have the capacity for new truths.

That is one reason I sympathize with the preacher. Every Sunday he has to get up and make the same talk. He thinks, "What did I preach about last Sunday morning?" No wonder the world is making such slow progress spiritually. They have not got the degree of understanding sufficient to recognize old truths, let alone the capacity for new truth. We become conservatives.

Once about nine or ten years ago when I was lecturing in Chicago, after I had completed my talk, a young Jewish lad, who might have passed for Joseph or Jesus, came up to me and said: "Mister, you sound honest." I said, "Thank you; and what can I do for you?" He said, "I am a widow's son and I am in high school, but I have a little laboratory and I have made a great chemical discovery." Well, I tightened up and said, "What is it?" He answered, "I have discovered how to eliminate a certain chemical from a certain process." I said, "Your fortune is made;" and he answered again, "I have learned how to eliminate that chemical." I asked him to tell me about it and I would see what I could do for him. Then he indicted me as I have never been indicted before and he indicted all of big business in a way that ought to make every man here ashamed of himself. He said: "There's not a big business man who wouldn't wring me dry."

I told this story at a meeting once where the poorest man was worth a million, and one of the biggest men there said: "Sure, that's the game. I have wrung a dozen of them dry." Shame on them that that boy was able to indict them!

I asked this boy to tell me what he could and he told me that the headquarters where this was used was in New York and he asked me if I could get them to send out a man to look over his process. So since I had been reading the two page national advertisements of this concern I walked right up and sent in my card and got the great American lie, "that Mr. A. was in conference."

When you go to an office now you have to see everybody from the office boy up and they all tell you this great American lie. Some years ago Richard Hobson Pierson said to me: "If you want to learn something keep your door wide open,

you can save more time this way." In all the years since then I have never closed my door except to change my shirt. Yes, you will save time, because the people in the other office can see you and will hurry on.

Well, anyhow, I got the lie that he was in conference, but since I have devilish persistence, as Mrs. Grafflin says, I sat down in the outer office and pretty soon Mr. A walked out. I went right up to him and he growled that he had sent word that he was in conference and what did I want with him anyway? I told him that I knew of a little lad who had made a great discovery and that he would like to have someone look it over. Mr. A brushed past me and said, "If he wants anything let him come down here, and I'm not interested anyway. The interview is at an end."

I walked out and I was mad. I was so mad I got a Red Book—I mean a telephone Red Book. I looked down the list until I found a firm in this same line and when I found one with a star, which meant they were rich enough to have a switchboard. I went down, and in three minutes I saw the young general manager, and he said that if what the kid has said was true he would have a man in Chicago that day. Five years later they asked me what I wanted as my fee, but that would have ruined the game. I took one cent. I have more fun doing things for nothing than I ever would by getting paid. So when this large firm, about that time, was bought out by the smaller firm, this young fellow, now the general manager, asked me if I wanted to see him fire the bird that turned me down that day.

I realize that this is neither Quaker or Christian, but I said, "Oh boy! I'll be right up"! And I walked over there and when this man came in they handed him a check for three months and said that they did not want a man who did not have time to look at anything as promising as this had been. So you see you have got to have the capacity for new truths which are showing up every minute and against which we are closing our minds.

The fourth thing is to have a tolerance of radical youngsters while we hold steady. Heaven save me from a bunch of dissatisfied old men and satisfied young men! The old boy who is up in the air at fifty will never come down, and the young fellow at twenty who has not started will never go up. I don't want any conservative or settled young men around me. We have got to have these radical youngsters because the progress of the world is right in them. Mrs. Grafflin said, "If there were any settled young men calling on our daughter that she wanted me to get the axe." I want none of them around me. I wasn't a settled young man myself.

By the same token, I don't want any of these radical old ones. We have got to have this tolerance of young men while we hold steady and let them try out their stuff. In the group with which I am associated as head, we have graduated a group of twelve of America's leading men in the educational and religious world. That is due to the fact that the nominal head of the department is an old boy who is out wandering around and talking to councils and things, and just comes back to look them over and cheer them on.

I am going right from here to an Interborough shop meeting and see how it is running. I am going to stand back in the crowd and watch one of my boys run it better than I ever dared.

"New occasions make new duties,

Time makes ancient good uncouth."

You keep a tolerance for radical youngsters while you hold steady.

After this there must be a sense of responsibility to society. There must be a sense of responsibility to God. My own daughter once wrote that "Nobody is fit to serve humanity unless he loves God and desires to serve Him, loves men and desires to serve them, and has or is willing to have lived himself." She is the head of one of the greatest social movements in this country. You cannot conduct

great enterprises by a correspondence course. I want to tell you the little story about the first Christmas we weren't broke. I think it was the last, too. My wife didn't believe it.

I have always sympathized with Mr. Stanley Mitchell's famous story of the man who was dying, who sent for the minister to make final the arrangements for his funeral. "Who will you have for your pall-bearers?" inquired the dominie. "I guess the local bankers will do," was the reply, "they have been carrying me all my life. They might as well finish the job."

However, having convinced the good lady that we owed nothing and had money in the bank, we were promptly informed that she needed clothes. "That is what Eve said," was our answer. But we trimmed her out in fine style. Then we asked our eldest daughter what she would have. She asked for a little set of books. We asked our second daughter, whose request was for fruit cake, sponge cake, pound cake, apples, oranges, doughnuts, candy and something to eat. Then we asked Don. Running true to form (for he is one of the kind if he fell down a sewer, would come up with a gold watch in one hand and a diamond ring in the other), he said: "I want a little store with bins and things to sell. I want a little cash register and I want a little horse and wagon with which to deliver the goods."

Came Christmas morning, and after early church and breakfast the parlor was opened and the abundance of presents displayed and everyone was happy. Five minutes later the children were dashing back to inform me that Don was not giving them the goods. He was selling them. I knew that, so I divided my small change, all that was left, equally among them, and business began. Time and again he sold out the little stock, finally looting everyone's Christmas stocking and his mother's cookie jars. As the neighbors' children came in he sold the very cubes of sugar from the bags in the pantry.

About eight that evening there was a great quiet in the parlor—a quiet that could be felt. We rose from where we were reading, my good wife and I, and walked to the portieres and parted them. I wish you could have seen the picture. Ruth in a big Morris chair, her little shelf of books before her, head down, in the middle of Adam Bede, read out, all in. Dorothy flat on her back, sweating like an ice pitcher, full as a tick, but happy as a lord and sound asleep in the middle of the floor. Everything that she had, had perished with the using, but there was no question about her having had and having enjoyed it. And Don—the little horse in the stall, sold out, his arm around the store, his left hand literally leaking pennies, nickels and dimes.

We stood and looked at the picture for a few minutes and then I took Ruth's little set of books, set them back on one of the library shelves, carried her up stairs and her mother put her to bed. Then I carried Dorothy, eats and all, up and laid her on her bed and her mother put her to bed. Then I came back and took Don's little store and stood it in the corner, placed the horse in the stall, emptied his hand into mine, put the money in my pocket and carried him up and put him to bed.

When I returned, my good wife was seated by the student's lamp, not reading, but with moist eyes. "What is the matter, sweetheart?" "Nothing," she said. "Did you see that picture?" I replied, "Oh, yes."

But all life is just like that. God gives us books and banquets, stores, cash registers, nickels, dimes, and pennies to play out this little thing which we call "Life," and someday we are going to fall asleep and the Great Father is going to come to the parlor door and look us over; and He will come pretty nearly knowing how we play the game by the way in which He finds us.

It is a great thing to be trusted with the lives and limbs of men. It is a great thing to hold the health and happiness of humanity in the hollow of our hand. It is a great task with great responsibility. May God give us the understanding of

the thing which we are trying to do and an interest in the hearts and lives of those with whom we are trying to work that we may get a maximum of results.

If you have the courage to pioneer, the will to investigate, the tolerance of radical youngsters, you must have a set of convictions. No man ever continues persistently except from a set of convictions. No other thing but a great conviction that the thing is worth while will make a man stay with an enterprise. There must be a sacrificial persistence.

We have just begun. We have killed and maimed too many, not of the unfit but of the fit, not to realize the task that is before us; and I hope the Almighty will help us to conserve the fit as never before. If we have the courage to pioneer, the will to investigate, tolerance and convictions we can put it over.

CHAIRMAN HARDING: Thank you Dr. Grafflin. We will now hear from Hon. C. A. Waters, of the Department of Labor and Industry, Harrisburg, Pennsylvania.

Safety in the Construction Industry from the Viewpoint of the State

By HON. CHARLES A. WATERS

Secretary, Department of Labor and Industry, Harrisburg, Pa.

Education and the development and enforcement of adequate regulations are the means by which the Pennsylvania Department of Labor and Industry is undertaking to promote safety in building construction. Education is put first because of what experience has shown the Department to be its relative importance.

Regulations are peculiarly inadequate in themselves to produce any considerable degree of safety in construction. A machine may sometimes be well enough guarded to make accident to the operator next to impossible. The same certainly cannot be said of a construction operation. So construction comes under a new general plan of the Department for advancement of safety through education, the most important feature of which is a study of the individual working force and the individual operation.

Up to this time the Department has largely endeavored to promote safety in construction and in all other lines of industry by systematic inspection under a block system whereby all industrial plants and industrial operations have been visited in the order in which they have been found in the locality. It has more and more been impressed that this system does not make the most effective use of our limited inspection personnel. Under its operation those who are doing quite effective safety work of their own get as much, or almost as much, attention as others much more in need of assistance. It was realized that some means must be found for determining just what factories and just what contractors were having bad accident records and of concentrating attention on them.

Today the Pennsylvania Department of Labor and Industry is preparing to introduce something new in the field of state-wide accident prevention work. It is preparing to utilize individual accident records to advance safety. Through its Bureau of Compensation the Department receives reports of all lost-time accidents in industry in Pennsylvania. Preparation is now being made to apply these records in inspection.

Within a few months the Bureau of Inspection of the Pennsylvania Department of Labor and Industry will be in position to know exactly what plants and what contractors are having more accidents than they should have in relation to the general average. Trained inspectors will then be prepared to sit down with these concerns and help them figure out where their weakness lies and how it can be

remedied. Much is expected from this new plan which has the hearty endorsement of all associations of employers and workers to which it has been presented.

The need of adequate safety regulations and their enforcement, and the fact that the state can alone properly apply such regulations is not overlooked. A special drive for accident reduction in building construction covering the last two years developed inadequacies in existing regulations which are now being studied with a view to their correction. The so-called "Scaffold Regulations" of the Pennsylvania Department of Labor and Industry, which are in effect building construction regulations, are to be developed into such in fact. As revised, they will include regulations for building demolition which has been shown to be badly in need of safety restrictions. Recently the need of some other treatment of builders' hoists than the existing sweeping restriction against workers riding on them was shown to be essential, particularly when hoists afforded the only means, other than ladders or stairs, for workers to reach the upper floors of tall buildings under construction. Today workers in Pennsylvania are permitted to ride on builders' hoists when they are equipped with certain safety devices.

The Department is at this time engaged in the development of regulations to govern construction of trenches and excavations of all sorts. These regulations, as all others developed by the Department, are presented to both employers and employed in tentative form at public hearings for criticism before they are adopted, so that as finally applied they represent the best thought of those whom they will most affect, rather than a lot of closet-developed theories.

In teaching safety and in applying regulations in construction the first aim of the Department is to develop each contracting unit into a self-sustaining safety factor. It is recognized that safety organization is particularly difficult to apply to such contracting operations as building construction. On large operations there may be many sub-contractors working with their individual forces under a general contractor. The Pennsylvania Department of Labor and Industry has applied with considerable success on these operations a type of safety organization in which the general contractor appoints a safety committee chairman and each sub-contractor appoints a representative on the committee. This committee holds a meeting at least once a week during the course of operation and discusses its safety problems with Department inspectors. Each sub-contractor fixes responsibility for the safety of his working force on one or more individuals, usually superintendent or foreman. This plan has been applied in the construction of the new \$3,000,000 North Office building at the State Capitol in Harrisburg. While too early yet to state the final result, this operation to date has been remarkably free from lost-time accidents. The fixing of responsibility on supervisory workers has been found in Pennsylvania to be the best means of attaining safety in construction operations, taken along with the state's aid through education and application of regulations. The transitory type of worker engaged to so large an extent in construction does not lend himself readily to development of the highly efficient sorts of safety organizations we find in many industrial plants.

An important feature of Pennsylvania's new plan for dealing with the accident problem in construction work is the development of a staff of building inspectors who are specialists. The desirability of safety inspection by specialists in any line of industry need not be stressed. Up to this time it has not been found practical to extend such inspection to all types of industry. Building construction, because of its very considerable hazard and its very special problems, has seemed to warrant this sort of treatment and after a year's application the Department already feels justified, through the extent of cooperation it is receiving from the industry, in feeling that no mistake has been made in extending to it this special safety service.

October 3, 1928

E. C. HARDING, Chairman

General Superintendent, Ferro Concrete Construction Company
Cincinnati, O.

The third session was called to order at nine-thirty o'clock, Chairman E. C. Harding presiding.

CHAIRMAN HARDING: Our first matter on the program this morning is the election of officers. We will have the report of the Nominating Committee. They submit the following for your consideration:

Chairman, W. R. Richards of the Associated General Contractors.

Vice Chairman in Charge of Publicity, J. Wilson Robinson of the Everett Winters Company.

Vice Chairman in charge of program, J. W. Dalzell of the Ferro Concrete Construction Company.

Vice Chairman and News Letter Editor, George Widua of the Woods Brothers Construction Company.

Vice Chairman in charge of the Poster Committee, Robert McKinley, General Accident Insurance Company.

Secretary, C. H. Black of the Stone and Webster Engineering Corporation.

If there are no objections or further nominations the officers for the next year will stand as read.

Will someone conduct the new Chairman to the platform? Before retiring as Chairman I would like to thank the officers who have served with me for all the good work that they have done and it has been a pleasure to have worked with them.

(Mr. W. R. Richards took the chair and presided as Chairman.)

CHAIRMAN RICHARDS: Gentlemen: I do not know how I came to get this position, but I am certainly going to do the best that I can to fulfill it and I hope I will be as successful as Mr. Harding has been. I want to ask every one of you to give me all the cooperation that you can. It is not a one-man job. We have got to have cooperation to increase this section. It has been growing pretty rapidly and I would like to see it doubled up in the next year. If Mr. Black, the new secretary, is here I would like to have him come to the platform.

(Mr. C. H. Black came to platform and took the chair as Secretary of the Construction Section.)

CHAIRMAN RICHARDS: The next item on the program is a talk by Mr. Frank E. Cudworth, Resident Engineer of the New Hudson River Bridge.

(At this point Mr. Cudworth showed a number of interesting lantern slides illustrating the methods employed to prevent accidents in the work he is engaged in.)

CHAIRMAN RICHARDS: I want to thank you, in behalf of the Association, for your talk. Are there any questions anyone would like to ask Mr. Cudworth?

MR. STEWART: It may be a little bit off the line, but we are making an investigation at this time to determine the relation of labor companies to material companies. Of course, we are not taking into consideration jobs where there are such an amount of materials and labor, so that it is taken away like your scaffolding; but I would like to know where it would be possible to get the ratio of labor cost to material cost on a building like that.

MR. CUDWORTH: Well, in the general contracting work I would say that the ratio was about fifty-fifty.

MR. CHAPIN (Independents Bureau): I would like to ask about those work-ways along the chutes. What kind of screens do they use?

MR. CUDWORTH: They use half-inch mesh.

CHAIRMAN RICHARDS: If there is no further discussion we will proceed with the next speaker, Mr. R. B. Thomas, of the Structural Steel Board of Trade, New York City.

Safety in Steel Erection

By R. B. THOMAS

Counsel, Structural Steel Board of Trade, Inc., New York City

The safety engineer who has the job of cutting down the accident record of a large construction project is indeed in an unfortunate position, for he not only has plenty of hard work but at times it would seem that every man's hand is against him. By its very nature construction work is dangerous and economy of cost demands speed in building. The owner wants the building completed before the next renting season. The contractor wants to keep the cost at a minimum and also wishes to satisfy the owner. The men resent interference and what seem to them unnecessary precautions. The constant labor turnover makes safety education difficult.

Again, the contractor is not selling a staple commodity at a definite market price. If, because of expensive safety measures peculiar to his own organization, and not general in the trade, his costs rise, he is placed in a bad competitive position. His instincts are all on the saving side, particularly after losing a few jobs to a lower bidder. The more obvious and important safety requirements must be a matter of law with adequate inspection, but the better way for the construction industry would be for the architects and engineers to write into the specifications, the precautions that must be taken on the particular operation. In that event all the bidders are on the same basis and the cost element disappears.

We, of the steel erection fraternity, are popularly supposed to be the bad boys of the building industry. We take unnecessary risks and have little regard for the safety of other trades. The lay public has the idea, fostered somewhat by the press, that a New York skyscraper "costs a man a floor." No doubt too many men are killed in this work, but the actual facts make the popular idea ridiculous. During the calendar year of 1926, 27 structural steel workers met their deaths from accidents in the course of their employment, in the state of New York. In that year considerably more than 500,000 tons of structural steel went into buildings in this state. Roughly, that means that one man was killed for every 20 apartment houses, say 15 stories in height and 100x100 feet in ground area. During the same year 15 were killed in New Jersey. There the tonnage erected was somewhat less, but the proportion was probably not much different. This information is from the respective State Departments of Labor and is surely authentic.

However, steel erection is not the safest work on the building, because of its very nature, and the industry itself is most anxious to reduce accidents. Our insurance costs are very high and we would welcome the saving, aside from the humanitarian view. The members of the New York Structural Steel Board of Trade, with which I am connected, believe and hope that they can reduce the number and severity of their accidents. But we are making haste slowly until we can find out just what needs to be done. The first of this year we started to receive duplicate reports of all accidents from our members. We hope that at the end of this year we may have sufficient data as to the causes of our accidents, that we may dope out ways and means of preventing a large percentage. It is possible, from the reports already received, to draw some conclusions which may be helpful.

Our most bothersome types of cases are those which are constantly with us, not the ones which are almost in the nature of catastrophes, in which more than one are hurt. In this latter type the causes can nearly always be traced to the carelessness or neglect of some man, or more frequently, the foreman or pusher.

For instance, in one case, in order to put a strain on the line, the men had passed a hoisting cable that was being wound onto the drum of a hoisting engine, around the wooden foot block of the derrick, on top of which two men were rigging up. The line became entangled, the engine kept the drums moving and the foot block was pulled loose, with the consequent fall of the derrick. Again, one erection gang was racing another, they had just raised their derrick to another floor and were lifting the first load. Someone had neglected to see that there was no slack in the lashing holding the derrick footblock to the structure. The foot of the derrick moved, snapped the lashing and the whole thing fell into the building. The handling of heavy erection equipment requires meticulous care on the part of those in charge.

However, such cases as have been presented are few and far between and their number, as compared with the increasing tonnage of steel erected, is on the decrease. The other classes of case, minor in severity but major in cost and suffering, are always present. While it is necessary to prevent the serious wrecks, if possible, if active steps are taken to cut down the other risks these infrequent serious accidents will decrease in consequence.

A few simple and necessary rules to be followed in steel erection on buildings are:

1. Forbid riding on loads and cables on the outside of buildings.

There is no necessity for this practice and it is only undertaken by the men in a spirit of bravado and to save a tiresome ladder climb. A sudden change in the speed of the hoist or the swaying of the load against the building may loosen the man's hold and he nearly always falls to his death.

2. Keep up a constant inspection of hoisting equipment.
3. Check carefully the possibility of overloading the derrick.

Erection gangs often save time by taking up more steel in one load than can safely be lifted by the equipment provided. The margin of safety should be large, for a jerk on the cable when "booming up" or through lack of smooth operation on the part of the engine, multiplies the strain on the cable many times. This is particularly to be avoided when the angle between the mast and the boom of the derrick becomes a large one.

4. If at all possible, do not permit the throwing of rivets toward the outside of the building.

It is usually not necessary to throw toward the outside and if passed inward, a missed rivet has some chance of being stopped by a floor. On the outside it is almost sure to carom down into the street, where if it injures no one, it may do damage to property or cause a fire.

5. Provide cone-shaped cans for catching rivets.

These are not expensive and are easy to handle. Rivets often bounce out of flat bottomed pails, which are not strong enough for the purpose in any event. After some use the rivet is liable to go clean through and injure the catcher.

6. Insist that burners wear goggles.
7. Provide tote boxes for the bolters up and see that they use them.

Many injuries are caused by loose bolts and rivets lying around the building and which fall down below.

8. Be sure that the erection floor is clear of any loose objects before the planks are raised to the next level.

It is easy to clean a plank by turning it up on edge but that doesn't protect those below.

We find that about one-third of all our accidents come from "falling objects," not heavy pieces of material but rivets, bolts and tools. About one-half of those or one-sixth of the total are injuries to men of other trades on the same building who are working below the ironworker. Directly below, on the usual operation, are the carpenters building forms and the concrete laborers putting in the concrete floor arches. If these men were afforded some protection the risk would most certainly be lessened.

The erection gang raises the beams and columns, sets them and bolts them in place. Then along comes the riveter, who takes out the bolts and replaces them with rivets. The floor on which the erection is going on is always planked over, but the riveters are usually at work on the two floors directly below this and immediately above the concrete men. It would seem that if an extra floor of plank, or some other protection, was interposed just below the riveters, a number of these distressing head and back injuries would be eliminated. Unfortunately we cannot do this in New York because of statutory requirements that compel the concrete arches to follow closely the steel erection. This particular law should be changed so that the proper protection could be afforded, but even in that event it would be necessary to have the requirement written into the job specifications so that the careless and unscrupulous contractor would not reap the benefit of the lower cost. The erection floor plank are comparatively easy to handle, as they are lifted to new levels through open space, but to provide an extra floor of planking below would prove somewhat more expensive. Perhaps if the arch requirements were not so stringent it would be possible to leave this extra floor in place for some time, and that it would only have to be handled a few times during the whole building operation. In that event the concrete men would not be on the job so soon. Falling bolts cannot injure men who are not there.

The heavy character of our material makes it difficult to handle and we have a number of cases in which men suffer contusions and bruises to their hands and feet. A beam rolls over or a connector pinches his fingers between a beam and a column. These account for one-fifth of all our accidents. Strains from lifting cause another 2.8 per cent. Apparently there are no safeguards for this class of cases except the education of the worker and competent and careful supervision.

"Foreign matter in the eyes" is the cause of 13.6 per cent. The stronger breezes up high on the skyscrapers blow around a lot of dirt and dust. Some eye injuries come from steel chips and others from sparks from forges and burning torches. Obviously the burners should wear goggles during the actual burning operation, during which they are generally settled in a stable position. For the other men the cure might be worse than the disease, for the man who walks a beam at a dizzy height needs his full range of vision.

"Falls of person" cause 11.1 per cent of all the accidents, but peculiarly the ironworker seems to be careful when he is in a dangerous position. More than one-half of these falls occur on the level. I know of an authentic case in which an ironworker who had walked beams for 20 years, slipped on the Times Square curb and gave himself a bad spinal injury. Sometimes our man falls into an unauthorized opening or one that is improperly protected.

This would appear to be a frequent cause of fatal accidents. Proper protection of openings is one of the essentials of safe building construction.

Again, our heavy material is the cause of another class of accidents. It must be lifted under power and at the end of cables sometimes many stories in length. The swaying and swinging of loads and cables cause 6.3 per cent of our cases. These can only be cut down by extreme care and watchfulness on the part of the men.

In 2.9 per cent of our cases the men injured themselves with their own tools. In 1.8 per cent they were injured by tools wielded by another. Various miscellaneous causes account for another 1 per cent. Failure of equipment causes only 1.7 per cent.

In 9.5 per cent of our cases our men are injured through the fault of employees of other contractors, 2.8 per cent from "falling objects" and 6.7 per cent from stepping on nails protruding from lumber lying around the building. The latter is one of the greatest causes of injuries in building work that can readily be eliminated. If the concrete form lumber is taken care of as soon as it is torn down and either piled or nails removed, a lot of ironworkers would be happier. Many is the foot infection that prevents a man from earning his livelihood for a long period.

Perhaps the welding of structural steel will become an actuality in a few years and we will have fewer rivets to throw and drop, and no one would be more thankful than the steel contractor if the accidents that could be attributed to him would be materially reduced as a result. I am sure that the construction industry may rest assured that the steel erecting contractors are more than anxious to cooperate with the rest of the trades to the end that buildings may be put up with a maximum of safety.

General Discussion

CHAIRMAN RICHARDS: Thank you, Mr. Thomas, for your fine talk. Are there any questions, or any discussion on this subject?

MEMBER: I would like to ask Mr. Thomas if he knows of any cases where safety belts were used?

MR. THOMAS: No, I do not.

MR. LOWELL: I would like to ask Mr. Thomas about the self insurance that has been issued.

MR. THOMAS: Most of our self insurance here is in steel erection. We have one company that has been insured since the law went into effect in 1913. There are some others who have been self insurers for several years. The initial cost is very large in steel erection because a man just going up once is apt to be killed, while others may be on the job all the time in less hazardous occupations. The company realizes this and stresses it, so that the careful man will save a lot by self insurance.

MR. WHEELER (Building Trades Employers' Association): You spoke of first aid. Is it customary to have a first aid kit on your job?

MR. THOMAS: That is a matter of cooperation. On some of the larger jobs the general contractor provides a first aid room. On this job there was a very well equipped first aid room. They had a shanty fixed up and a doctor there all the time—or he could be reached by phone, and he appeared there so many times a day.

MR. CHAPIN: Some years ago, while the Delaware River Bridge was being built, I had an opportunity to see some of the work there. I also learned of some accidents that it was my duty to investigate. One of the men walked off a beam and before the day was over the coroner found that he only had one eye.

That seemed to indicate a laxity in finding out what kind of men were put on the job. In another case we sent a man for tools and he seemed to have something else on his mind and walked right off the bridge. Now that showed a mental deficiency. I am just citing these instances because they may be helpful here. Someone mentioned that it might be possible to leave the safety devices to the architects, and I was just wondering how many architects would be capable of specifying the safety measures to be used. We might hear from some of the architects on that.

MR. THOMAS: Not so long ago a company here used the new machine for the passing of rivets that they use on ship a great deal. That is used best when you have a lot of rivets to be put in close together. But this company put in the new automatic riveter. The superintendent was quite in favor of it. He had it set up and had the chief engineer of the company see it work. The chief engineer put a rivet in it to try it. It flew out and took off his hat and went out into the street and caught a girl's fur coat and they had to buy her another one.

Then in regard to the personal deficiencies of men. You have to be careful of that or they will accuse you of running a black list, but obviously there are certain men who shouldn't be on any job.

CHAIRMAN RICHARD: I think the time is only a short way off when we will have to pay a lot of attention to the physical condition of the worker, then there won't be so many accidents.

MR. WELLIN (Travelers Insurance Company): Mr. Thomas stated that a large number of accidents are due to materials falling from the erection floor. He believed this could be avoided if the floor below the erection floor were covered, but there was some objection because of the cost of the material. However, this would be low for the same material could be used on several jobs.

MR. THOMAS: I will show you where some additional cost comes in. That planking is very high, because you have to hoist it around with the derrick and move it and it all costs. Occasionally there is a job in New York where we do that. There was a job a few years ago over on Sixth Avenue where they added six or nine additional floors and they had to open the roof of the existing building. Now the specifications on that job called for a floor of plank to be left over that roof and to be moved once. I do not know what it cost to raise the planking in a building like that, but I do believe it cost about four hundred dollars to raise it once. It had to be taken down and up and spread again.

F. A. DAVIDSON (Cheesboro-Whitman Company): Apparently the matter of co-operation is one of the outstanding difficulties we have, but more often than not we only hear the contractor's side of the story. I wonder if the time has not come when we could put into effect at the places where building operations are going on, the rules of a safety organization that would function according to its own craft, that is for the particular job.

I am familiar with a scheme of organization worked a number of years ago. At first it worked very successfully. We had a foreman's committee that met and represented the different crafts. Once a week they inspected the entire job. It took an hour, and then they would meet in the superintendent's office and report anything which they had found that needed attention. No man served more than a month on this committee and that kept the foreman rotating. They were usually in a committee of three. This was a very long job and the foremen all had a chance and they were all very careful, because if they found anything wrong on any of the other operations they knew that they were liable to have some of the others discover something wrong with their portion of the job when he was on the committee.

I believe that could be done in New York City, and I don't believe there is a man in this room who does not remember when he used to call in the sub-contractors regularly just to talk. There were no such general meetings to

discuss the different phases of the work. Now if the time has arrived when we believe that safety promotion is an important enough thing, the general contractor could have a day set aside for an inspection by the safety committee, composed of the foremen on the job. Let each foreman serve three weeks. I believe that would be of great assistance to you, and I believe it would work out very effectively.

J. J. COFFEY (Department of Labor, Philadelphia, Pennsylvania): That experiment has been tried out in Philadelphia and it has been very successful. The committee is made up of the superintendent on the job and each of the sub-contractors. They meet once a week. The general superintendent makes it very easy to offer criticism and desires it. They keep written minutes of the meeting and a great deal of good help has been derived from them.

MR. WHEELER: In that connection I would like to say that James Stewart & Company have had that plan in all their jobs. In Japan they are using the same plan in many jobs, and furthermore the Building Trades Employers' Association through its Committee on the Prevention of Accidents is about to recommend that plan among all its members. I have visited a number of places where it has been tried this last year and it has been very successful.

CHAIRMAN RICHARD: I have visited a great many of the jobs where they are using that method and are getting good results.

MR. CANE (Bricklayer's Union): It is very unfortunate that everybody is not giving as much attention to this subject as you gentlemen and you should be complimented. But the trouble is, a lot of people are not cooperating. We have rules for contractors and rules for architects in New York State, but they are not adhered to by many. We had one job around on Sixty-sixth Street where they gave the bricklayers a scaffold that was an outrage. We insisted on a different type of scaffold and they gave us another that was supported by two-inch and four-inch boards. It was not safe. We called our men off the job and they put out a patent scaffolding. About three or four days after that the steel workers were hoisting their load of steel, the derrick gave way and fell on the scaffold but the scaffold did not fall. If we had not have had this type of scaffold fifteen or twenty men would have been killed. I think now a movement has been made for stricter enforcement of that rule.

I think the State should take more interest in that kind of job, because even though the masons and the builders give the men everything they want, it is those who are not connected with them who are responsible for a great many of those accidents. If we recommend a great many more safety measures then we would accomplish something.

CHAIRMAN RICHARDS: The time is getting short and we will hear from our next speaker, Mr. D. F. McMurchy, of the Industrial Commission of Ohio, Columbus, Ohio.

Wire Rope and Safety

By **D. F. McMURCHY**

Structural Engineer, Industrial Commission of Ohio, Columbus, O.

It is my pleasure, gentlemen, to give you a few observations upon the use and abuse of wire rope from the standpoint of an engineer with a state safety department. This item of equipment has done more to facilitate the construction of our larger structures than any other in that it made possible the power equipment used in excavation, erection and transmission without which our construction operations would be seriously hampered. Its ability to withstand abuse, combined with its great strength and flexibility, recommend wire rope for the severe service required of such equipment on construction work, and it has been

my experience that the majority of wire rope failures are not the fault of the rope but are due to improper care, use and connections.

Construction of Wire Rope

If we consider for a moment the construction of wire rope we immediately sense its limitations. As the name implies it is rope made of wire. The construction most familiar on building operations being 6x19, that is, 6 strands of 19 wires each twisted around a hemp center to form a rope. Three grades of wire are most commonly used in its manufacture—iron, crucible steel and plow steel. The latter two, because of their combined strength and flexibility, are generally used on construction operations as rigging for hoisting, transmission and excavating equipment. Frequently cables that have been removed from this equipment are again placed in service as guys on towers and derricks and as lashing, slings, etc. Other constructions are manufactured to serve various purposes requiring greater strength or flexibility but the 6x19 construction more nearly satisfies the contractor's requirements. Being made of wire it is not as flexible as hemp rope and cannot be bent sharply without seriously affecting its strength.

The contractor in ordering rope has to rely almost entirely upon the integrity of the supply dealer in the matter of getting the rope specified. Few workmen can tell by the appearance or feel of a rope whether it is iron, crucible or plow steel. Like Chinamen, they all look alike but their strengths vary considerably. Iron rope having about 40 per cent and crucible cast steel about 85 per cent of the strength of a plow steel rope of the same diameter. Iron rope when bent with the hands does not have the tendency to spring back that crucible or plow steel rope have and may be detected in this manner, but the difference in spring between the crucible and plow is hardly perceptible and the test is not sufficiently reliable to determine the quality of the rope.

To overcome this uncertainty the proposition of weaving into the hemp core a narrow tape containing information as to the material, strength and manufacturer has been advocated by several speakers and writers on the subject and I am informed that one manufacturer is labeling his rope in this manner. For the benefit of the manufacturer, dealer, consumer, and public such procedure should be followed by all wire rope manufacturers, thus removing the uncertainty of using a rope of less than is required.

The Three Major Factors

Three major factors govern the life and strength of wire rope, external wear, internal wear and kinking. A new rope being circular in section, presents only the surface of one or two wires of each strand at any section to external wear against the sheaves and other objects with which it comes in contact. Abrasion against the sheaves augmented by gritty substances contained in the dust and mud ever present around construction operations, tend to wear these outside wires very quickly, reducing their sectional area. As the process continues the next adjacent wires begin to wear but rarely more than three wires of any strand present a wearing surface to the sheave before one wire breaks. This failure increases the load on the other wires and with their decreased sectional area they fail rapidly.

As a means of reducing external wear on rope it is essential that the sheaves be properly aligned and that the grooves of the sheaves are kept in good condition. Sheaves with broken flanges or that have oversize bores, not only increase the wear on the cable but also the hazard of the line jumping the sheave which often produces disastrous results. Running lines should be clear and well lubricated

and should not be allowed to wear against any material which will tend to abrade them. The question of the use of hard or soft sheaves depends upon existing conditions. In some instances it is more economical to replace the sheave than the line; in others the opposite is true. A rope should be replaced according to the Bureau of Mines when the diameter of the outside wires has been worn to 65 per cent of their original diameter or if 6 broken wires appear in one twist or lay of 6x19 rope. It is recommended that rope be discarded if five wires are broken with 10 per cent wear on outside wires; four wires are broken with 20 per cent wear on outside wires and three wires are broken with 30 per cent wear on outside wires.

Another factor affecting the life of wire rope in service is internal wear. Being flexible there is considerable internal motion in the rope as it changes direction under load as when passing over sheaves. The outside wires of the rope passing over a sheave are stretched more than the ones adjacent to the sheave. This unequal stretching produces internal motion within the rope which unless thoroughly lubricated tends to wear the rope from within. Where the rope is subjected to reverse bends as in the case of the load line on a derrick passing from the hoist engine under a sheave at the bottom of the mast and over a sheave a short distance up the mast, this stretching shifts from one side of the rope to the other, increasing the internal motion and consequently the internal wear. It follows that the smaller the sheave, the greater the stretch in the outside wires. Wire rope manufacturers recommend sheaves of a diameter in feet equal to 4 times the rope diameter in inches for crucible steel or plow steel rope.

Lubrication Reduces Internal Wear

Internal wear can be materially reduced by proper lubrication and the use of larger sheaves. The latter is not always possible, being limited by the design of the equipment, but larger sheaves will pay their added cost in increased rope life where conditions permit their use. The value of lubrication cannot be stressed too strongly and the additional cost of lubricating them is negligible when compared with the increased life resulting. Proper lubrication will minimize the breaking of interior wires which weaken the rope and which cannot be detected by casual inspection.

A third major factor is kinking. To sever a wire without the services of wire cutters we kink it and it breaks easily. Kinking has the same effect upon wire rope, it being nothing more than a twisted bundle of wires. We know also by experience that the harder the steel the more brittle it becomes, having broken soft iron or copper wire in one instance and steel piano wire in the other, the latter breaking with much less kinking than the former.

Kinking is probably the most destructive of the three major causes of wire rope failure as little warning is given of the weakened condition. Great care should be exercised in taking wire rope from the reel to avoid kinks. It is a good plan either to roll the reel along the ground or floor or to mount the reel on a bar and run the rope off as needed. When wire rope is taken from a coil—roll the coil along the ground rather than to pull it from the coil laying flat. Wire lines are frequently snarled when a clam shell turns over or a load slips. Such occurrences very often produce kinks and sometimes snags. Snarled lines should be straightened very carefully and inspected for snags or cuts before subjecting them to loads.

There are other factors affecting the strength of wire rope such as unlaying of strands due to lack of sizing, corrosion from various causes, fatigue and others

but the majority of failures in wire rope are traceable to the three major causes given above providing of course that the proper kind and construction of rope was selected for the work in hand.

Different Types of Connections

At this point I would like to say a few words about connections. Of the various connections manufactured the clip is used more frequently than any other type on construction work. Its cost, ease of application, efficiency and adaptability are responsible for its extensive use in preference to other types with greater efficiency such as leaded sockets or wedge socket connections. Clip connections can develop efficiencies of better than 80 per cent when properly applied but connections of this strength are rarely found. Many riggers prefer to stagger clips on clip and thimble connections for no other reason than that they have always made such connections in that manner. The "U" bolt when drawn too tight as they frequently are, crush the wire line at the point of application—kinking the strands at that point. If the "U" bolts are placed on the free end of the line, the friction around the thimble reduces the load on the line at the clip, thus offsetting in a measure the decreased strength due to the crushing effect of the bolt. When applied in the opposite manner the full load is subjected to the weakened section directly under the bolt. Better connections are made by using more clips rather than to apply a few in such a manner that the rope is crushed. Clip connections on new lines should be watched very carefully until the line takes its stretch. As the strands adjust themselves under load and compress the hemp center, the rope decreases in diameter, thus loosening the clips. The contractor's standby, much maligned by safety men as being dangerous, is far more efficient and dependable than some clip connections commonly found on construction work. While the half hitch kinks the line and reduces its strength probably 50 per cent the connection is dependable up to this limit even when applied in a relatively careless manner and the load on the line rarely reaches 50 per cent of its ultimate strength. The wedge socket has some advantages over other connections in efficiency and ease of application but is more expensive and does not have the adaptability of the clip.

Wire Rope Accidents

Accidents in which wire rope is a factor are not limited to those caused by the failure of the line itself. Our records show that accidents due to wire rope failures are quite infrequent, there being only one in the construction industry this year. In this case a boom line on a derrick parted and two men were struck by the falling boom. There are others, however, in which wire rope is a factor but not the cause of the accident. Just recently a laborer on an operation in Cincinnati was killed when a splice in a hoist line made with one clip failed, allowing the platform of the inclined hoist to run to the bottom of the incline, crushing the workman against a pile of lumber. Two workmen were electrocuted in Akron when the lines of an excavating machine came in contact with a high tension wire. A workman received a fractured skull when a hook pulled off of a lug on a section of steel stack which was being moved along the floor by means of a winch. He was standing about 20 feet from the stack and about 3 feet from the line when the hook snapped back and struck him in the head. We receive numerous reports of lacerations and falls caused by men running into moving lines placed near the floor and not infrequently reports of mangled hands and arms which have been drawn into snatch blocks and sheaves located within reach of workmen.

Accidents of this kind are of sufficient frequency and severity to warrant the

constant attention of the safety engineer on construction operations. Some of our contractors put their sheaves up out of reach and provide barriers for all running lines near the floor or ground as a means of preventing accidents from this source. In my opinion, rules of standard practice governing the use and care of wire rope and the various types of connections should be made available to every user of wire rope as a means of increasing the life and safety of wire rope and of reducing the number of accidents in which it is a factor.

CHAIRMAN RICHARDS: I want to thank you, Mr. McMurchy, on behalf of the Association. Now Mr. Widua wishes to make an announcement about the news-letter.

GEORGE WIDUA (Woods Brothers Construction Company, Lincoln, Nebraska): We are trying to make our *News-Letter* a monthly letter. Last year we sent out seven letters. This year we want to do better than that, but we must have your help in order to do it. If any of you have anything which you think would be fitting for our *News-Letter*, won't you please send it to Lincoln, Nebraska?

CHAIRMAN RICHARDS: There can be a lot of good done by means of the *News-Letter* and I would like to see everyone cooperate with the committee.

ADJOURNMENT.

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Electric Railway Section

New Section Officers

- General Chairman*—E. K. EASTHAM, St. Louis Public Service Company, St. Louis, Mo.
Vice-Chairman—H. K. BENNETT, Providence Safety Council, Providence, R. I.
Vice-Chairman—MELVIN W. BRIDGES, Chicago Rapid Transit Company, Chicago, Ill.
Vice-Chairman—GLENN H. SHAW, Northern Ohio Power and Light Company, Akron, Ohio.
Secretary—PAUL HOBSON, East St. Louis and Suburban Railway Co., East St. Louis, Ill.
Poster and Slide Committee Chairman—L. R. BROWN, New York State Railways, Rochester, N. Y.
Membership Committee Chairman—SAMUEL H. REID, Bureau of Safety, Inc., Chicago, Ill.
Membership Committee Vice-Chairman—ARTHUR GABOURY, Province of Quebec Safety League, Montreal, Canada.
Publicity Committee Chairman and News-Letter Editor—BUELL W. NUTT, The Safety Equipment Service Company, Cleveland, Ohio.
Program Committee Chairman—T. G. BRABSTON, Birmingham Electric Company, Birmingham, Ala.
Engineering and Statistics Committee Chairman—EDWARD MALTZ, The Cleveland Railway Company, Cleveland, Ohio.
Executive Committee: THE OFFICERS AND
R. W. EMERSON, The Cleveland Railway Company, Cleveland, Ohio.
G. T. HELLMUTH, Chicago, North Shore and Milwaukee Railroad Company, Chicago, Ill.
D. L. FENNELL, Kansas City, Public Service Company, Kansas City, Mo.

Retiring Officers

Chairman, A. W. KOEHLER, The Milwaukee Electric Railway and Light Co., Milwaukee, Wis.; *Vice-Chairman*, H. K. BENNETT, United Electric Railways Company, Providence, R. I.; *Vice-Chairman*, E. K. EASTHAM, The United Railways of St. Louis, St. Louis, Mo.; *Vice-Chairman*, MELVIN W. BRIDGES, Chicago Rapid Transit Company, Chicago, Ill.; *Secretary*, J. E. STOTT, Georgia Power Company, Atlanta, Ga.; *Poster and Slide Committee Chairman*, L. R. BROWN, New York State Railways, Rochester, N. Y.; *Membership Committee Chairman*, W. H. BOYCE, Pittsburgh Railways Company, Pittsburgh, Pa.; *Publicity Committee Chairman and News Letter Editor*, BUELL W. NUTT, The Safety Equipment Service Company, Cleveland, Ohio; *Program Committee Chairman*, GLENN H. SHAW, Northern

Ohio Power & Light Co., Akron, O.; *Engineering Committee Chairman*, W. F. HANNA, United Railways and Electric Company, Baltimore, Md. *Executive Committee*: THE OFFICERS AND R. W. EMERSON, The Cleveland Railway Company, Cleveland, Ohio; G. T. HELLMUTH, Chicago North Shore and Milwaukee Railroad Company, Chicago, Ill.

October 2, 1928

A. W. KOEHLER, Chairman

The Milwaukee Electric Railway and Light Company
Milwaukee, Wis.

The first session of the Electric Railway Section at the Seventeenth Annual Safety Congress, was called to order at ten o'clock, by the chairman, A. W. Koehler.

CHAIRMAN KOEHLER: Doubtless many of you were present at the opening session yesterday, have already been officially welcomed, and have had extended to you the greeting of the President of the National Safety Council, but there are some who perhaps came in this morning, so I think it not out of place to extend to you a very warm welcome to the first of our meetings of the Electric Railway Section.

According to the custom, which was adopted a year or two ago, and one which I think is a good one, I am going to ask you to rise and very briefly state your name and connection so that we may break down any little formality that may still remain.

(Each member in turn then arose and announced his name and business connection.)

CHAIRMAN KOEHLER: Now that we are better acquainted and all know one another, we may proceed. I think it is inspiring to learn to know one another as well as the respective interests we represent and to know that there are many men here from all sections of the country. If there is any doubt in the mind of anyone, of the interest of the electric railway industry in accident prevention, I think that doubt will be dispelled by such a demonstration as we have just had.

According to the program, you might be led to expect some remarks from your chairman concerning the noteworthy accomplishments of the section during the past year. I do not want to take away from the officers of the section, the members of our committees, the leaders of those committees, the privilege of telling you personally what their respective committees accomplished during the past year. Were I to even attempt to sketch their various accomplishments, it would simply be a duplication and a repetition, so that I know you would much prefer to see these men who have done these things and hear from them the things that they have accomplished.

I am going to satisfy myself (and I think you) with a statement of a very few concepts that have come to me as a result of my observation of the trend in accident prevention in the electric railway industry. I think it is encouraging to find a growing disposition on the part of electric railways to delve more deeply into facts. I think in the past we have confused cause and effect. We have been prone to jump at conclusions. We didn't search deeply enough. We said that this man was injured because he fell. The cause of that fall perhaps wasn't clearly established. We were prone to say a man was injured because he was careless. That is an easy thing to say. Perhaps we are all guilty of being just a little bit lazy mentally. Perhaps we ourselves had a greater responsibility for accidents in the past than we cared to acknowledge or admit. Perhaps our methods

in every instance weren't in keeping with the progress that we had made in other directions. Perhaps our supervision wasn't as keen as it might have been. In any event, I am convinced that now, we are searching more deeply and we are finding enlightening facts. We are able to determine causes, and we are promoting accident prevention work in the electric railways in the country in a way that it hasn't been done before. I think it is very encouraging.

The safety engineer has an ally now in the general manager, the assistant manager, the superintendent, and in the foreman. There has been promoted a spirit of cooperation between departments that unhappily didn't exist all the time in the years past. We are going to hear a lot more about that in the papers that are going to be presented very shortly.

With these few remarks I am going to at this time call upon Mr. Allison, who will report for Mr. Boyce, who is unable to be here. Mr. Boyce is Chairman of the Membership Committee. Membership is one of our most important activities, because without membership, all of these other things would be in vain. Mr. Boyce has had a very important job and he has filled it as ably as all other jobs he has ever undertaken.

Report of the Membership Committee

By W. H. BRYCE
Chairman

As quickly as possible after October 1, 1927, I was so fortunate as to accomplish the formation of a committee composed of fifteen gentlemen all of whom are well known either for their safety activities or in the management of railway properties. I assigned to each territory comprising one or more states, the size of the territory assigned depending upon the number of street railway companies in each district classifiable as fair prospects for membership.

Each of the committeemen was furnished with a list of the prospective properties in his territory and I have kept in touch with all by correspondence supplemented by suitable literature produced by the Chicago headquarters of the Council, such as *News Letters*, etc., which have been sent to the committeemen in sufficient quantities to permit furnishing copies to each of their prospects.

I wrote letters to the ranking officials of each of approximately 110 holding or management corporations throughout the United States and Canada, outlining benefits to be derived from association with the National Safety Council. Very courteous replies were received from fourteen of these companies.

It is regrettable that the membership of the Section shows a net loss of five companies for the year, seventeen companies having withdrawn, while twelve companies have become associated with the Council. As of October 1, 1927, the Section had a membership of 245 companies. The membership now is 240.

I would make the recommendation that Chicago headquarters continue its efforts to obtain an accurate list of railways which have membership as a result of affiliation with some of the large holding companies. In several instances my committeemen have reported that roads solicited by them have replied that they held membership because of affiliation with some holding company. This condition makes it rather embarrassing to the committeeman making the solicitation.

I want to take this opportunity of thanking Mr. Koehler, and Mr. Cameron and his staff, and all the gentlemen who have so generously given of their time and efforts as committeemen and for the thorough cooperation shown. The fact that we show a loss for the year is due, I believe, not to any lack of conscientious effort on the part of your committee, or the staff officers of the National Safety Council, but rather to the unhappy situation in which the electric railway industry finds itself at the present time.

CHAIRMAN KOEHLER: You see from the report just read by Mr. Allison, the extensive organization created by Mr. Boyce and the imposing personnel of his committee. He has done a masterful job. We are certainly greatly indebted to him.

I am going to ask Mr. Shaw if he now will give us a report of the activity of the Program Committee.

G. H. SHAW (Northern Ohio Power & Light Co., Akron, Ohio): I haven't prepared any extensive report of the activity of your Program Committee. The program should speak for itself. I want to say that this was not a one-man committee or a one-man job. I had very capable assistance in preparing the program that you are about to hear. The other members of the committee were Mr. Koehler, Chairman, Mr. Hellmuth, Past Chairman, and Mr. Bush, of Boston. We have endeavored to bring out subjects which we thought would be of interest to all of you. We solicited suggestions from the membership and officers of the section, and received a large number of useful suggestions, of which a great many were used.

The Chairman mentioned the fact that in former years we have not had sufficient time for discussions. Therefore, we attempted to arrange this program so that you will have time to conclude all discussions. You will notice on the last day, or Thursday, there are about two items on the program. We would like to have you make notes of any questions or anything that you want to ask, and if you don't have the opportunity prior to that time, present them on that morning. I don't think it is necessary to say anything more about this program. You can draw your own conclusions. If you like it, we will be pleased. We only hope that you will be able to take something home with you worth while.

CHAIRMAN KOEHLER: Thank you, Mr. Shaw. Is Mr. Buell W. Nutt in the room? Mr. Nutt is chairman of the Publicity Committee. All of you have received copies of the *News Letter*. The *News Letter* speaks for itself. I needn't go into detail to tell you all of the things Mr. Nutt has done. I might say this, I believe we are the only section that has had a printed *News Letter* put out in the forms in which you have received it. That was begun in the previous administration and was continued through the year. We found too, that there was no interruption. Mr. Nutt began where the previous committee had left off. He worked untiringly and did a splendid job. He had hearty cooperation from various members of the section. The vice-chairman of the section as well as other members, contributed very largely to the material that you found in the news letter.

I will now ask Mr. L. R. Brown to report on the activity of the Poster and Slide Committee.

L. R. BROWN (New York State Rys., Rochester, N. Y.): Our committee got under way early in the season. The new committee was appointed and working by the first of November. The first thing we did was to review all the old posters which had been issued by the Council for the Electric Railway Section. There were about three or four hundred of them, I think. We selected from those old posters, subjects for new posters. It was a rather hard thing to do, as you can imagine. We had to go to work on those 400 or so, old posters, to find subjects for new ones. However, we got quite a few under way, and then we sent out circular or personal letters to 50 of the most important of the electric railway companies in the United States.

We asked those 50 companies if they wouldn't send in some suggestions for posters, and if they would be willing to cooperate in sending in photographs. We received just one reply from those personal letters. In that one reply the company stated if we would be more specific, they would send in a photograph. We immediately sent back a specific problem or specific subject, but we didn't get that photograph.

However, we had previously received from other companies, several photographs, and we also went to work on the photographs of the National Safety Council, so in a short time we had out a sufficient number of posters for this year, and probably there will be one left for next year.

Recently, during the latter part of the year, the subject of slides came up. Mr. Schrieber, from Albany, brought that to our attention. Our lantern slides were pretty well out of date. Most of you people probably know that. In fact, lantern slides themselves are out of date. Film strips are now the thing. Most everybody has a machine for film strips. We started in to revise the lantern slides and get out film strips. At the present time, we have a list of 50 subjects to go on the film strips. We followed out the idea Mr. Schrieber had, which was to approach the subject of a train man's activity from the time he left home in the morning until he got back home at night.

For instance, the first slide shows the train man leaving home in a happy frame of mind, kissing his wife goodbye, and so on. The idea is, everything must be happy in the home if he is going to have a successful day, without any accidents. It will be the work of next year's committee to get those fifty subjects in order so that the film strips can be gotten out. I think that is the entire report.

CHAIRMAN KOEHLER: Thank you, Mr. Brown. Mr. Bennett, won't you give us just a brief report of the activity in which you were particularly interested?

H. K. BENNETT (Providence Safety Council, Providence, R. I.): The only factor I had anything particularly to do with during the year was the proposition of having a permanent secretary for the section. You know, the Petroleum Section started two years ago with a permanent, paid secretary, who devotes his entire time to that industry.

It was suggested at one of the Chicago meetings that the Electric Railway Section might find itself in a similar position and desiring to have a man do full time work for the Section. The result of that was, the committee queried the membership. Whether the committee did not fully apprise the membership of just exactly what was intended, or didn't make it understandable enough for the membership, is accountable for only around fifty replies (if I remember correctly) being received, I cannot say. It was found that it was a fifty-fifty proposition as to whether or not such a thing was deemed advisable.

I am not going into the details of the replies from each one of the members, because that would entail too much time. But your committee feels, and the national officers of the Council feel, that it is a matter that should not be dropped at the present time. They feel if the membership is made more fully acquainted with the desirability of having a full time secretary, that they will give the matter more favorable consideration. I might say in passing that a number of the members thought that the American Electric Railway Association should have a paid man on their staff, who would function with the Electric Railway Section of the National Safety Council. That matter is still under consideration. I had a conference with Mr. Storrs and Mr. Welch in that connection a few months ago.

In any event, your committee recommends, owing to the desires of the National Office and the broad scope of the question itself, that the matter be not allowed to drop with the indefinite report of your committee at the present time, and that either the present committee or another committee carry on the work during another year with the assistance of the National Office, and bring again to the attention of the membership perhaps with a broader viewpoint, this matter, so that they may better understand the situation. Perhaps a year from now, the committee may have a more satisfactory report.

CHAIRMAN KOEHLER: Thank you, Mr. Bennett.

The first speaker scheduled to address you this morning, according to the program, is Mr. John J. Reynolds, Claims Attorney, Boston Elevated Ry. Co., of

Boston. Mr. Daniel Fennell, the second speaker, has requested that he be permitted to speak first. Mr. Reynolds has very kindly consented to that change, and we will now listen to the discussion.

Overcoming Transportation Hazards

By D. L. FENNELL

General Superintendent of Transportation Kansas City Public Service Company, Kansas City, Mo.

The chairman of your Program Committee in requesting that I prepare a paper for this meeting, has assigned a subject so broad in scope, as to make impossible to properly cover in any reasonable time, but I will endeavor to keep within the limit allotted.

The matter of accident hazard is one in which every transportation man, particularly those engaged in the Electric Railway industry, is vitally interested, and of major importance in efficient operation in this day of unlimited competition. The advent and popular use of the automobile and motor propelled trucks has given to the transportation operators within the past fifteen years, a problem more difficult of solving than any other that has confronted the industry since its inception.

Prior to 1912, the use of motor driven vehicles was confined to a limited number, but since that time, the production and use of such equipment has increased by leaps and bounds.

Organized accident prevention work on the part of Electric Railways was, in so far as I can ascertain, almost unknown fifteen years ago. Today, all wide awake Electric Railway managements are carrying on accident prevention campaigns.

In 1912 there were less than two million automobiles. Today, there are in this country approximately 23 million, and hundreds of thousands of trucks, with street capacity much less than fifteen years ago. Few cities have as yet awakened to the necessity for a prohibition of parking to increase street capacity, and very little has been done towards actually widening our traffic ways. In every city thousands of automobiles are parked along the side of car tracks, and an almost countless number are constantly driving on, crossing and re-crossing these tracks, making the problem of safe operation of electric cars a most difficult one.

That the safety work of the City Electric Railways has been successful, is I believe, conclusively shown by the fact that in 1912, there were approximately 3,000 fatalities in street railway operation, and only 1,661, according to National Safety Council figures, occurred during 1927. Of the 1,661 fatalities in street railway operation the past year, 500 occurred in collisions with automobiles or trucks, thus reducing to 1,161 those attributable to other causes. This decrease despite the fact that the street railway speeds have been materially increased the past fifteen years to meet popular demand and competition of motor driven vehicles.

In addition to the accident hazard, due to the increased use of automobiles and trucks, Electric Railway operators have been confronted with the matter of decreased revenues, due largely to automobile competition, which has made necessary reduction wherever possible in expenses, of which amount, that paid out for injuries and damages, is no small part. A condition such as existed fifteen years ago when there was practically no accident prevention work, if still in effect today, would, no doubt, spell bankruptcy for any street railway.

Rapid strides have been made recently towards reducing accidents in all lines of industry, particularly in the Electric Railway field, and the National Safety Council has rendered invaluable assistance to our Industry.

It is my desire to confine myself to the accident hazard only in so far as it concerns actual operation of the cars, as I feel the matter of employees' safety

can, and has been more efficiently covered in other Papers presented at this, and other meetings of the National Safety Council.

My observations lead me to believe that in general, little attention was paid fifteen years ago by Electric Railway operating officials to the accident prevention problem, and such a lack of interest, of course, existed among car operators. Today, every employee is thoroughly alert to the necessity of careful operation.

Your chairman, in extending an invitation to appear before this meeting, requested that I present for your consideration, activities in effect on the property of the Kansas City Public Service Company, with which I have been connected for many years, and with which I am familiar.

I know that there are some properties much more advanced than we in Kansas City, in accident prevention work, but the results that we have obtained, have in my opinion, been so successful, as to be worthy of your consideration.

Fifteen to eighteen years ago, neither the operating Officials nor the trainmen in Kansas City were greatly concerned with accident prevention, although men were disciplined, if, in the opinion of officials, accidents occurred due to gross carelessness on trainmen's part. Today, an entirely different situation exists, and it might be of interest to know how this change has been brought about.

It was necessary, of course, before any comprehensive plan for accident reduction was put into effect, to make a study as to where and how accidents occurred. An addition was made to the general transportation force in the way of a statistical clerk who compiled data of all accidents occurring over a long period of years, and made careful analyses and comparisons. The next step was to secure active cooperation of division operating officials, which was done through meetings of an educational nature, and explaining the need for intensive work throughout the entire transportation organization. Having information as to facts, the division and general transportation officials next carried the problem to those who actually operate the cars;—the trainmen. In a series of meetings held at the various Divisions, the men were given an outline of accident conditions, data as to number occurring, cost, etc., and their cooperation solicited towards obtaining the desired reduction and improvement.

Analyses made as to accidents, developed an excessive number of so called "Boarding and Alighting" accidents; apparently due to the fact that persons were attempting to get on or off cars while in motion. As an aid in improving conditions, the Management equipped all cars with folding doors and steps, thus doing away with open platforms.

The mechanical department cooperated by putting into effect a much more thorough system of inspection and maintenance of equipment. This has been a most important factor in reducing accidents. With this assistance from the Mechanical Department, it was found that car operators were much more interested in reporting defects in equipment, which heretofore they had been prone to neglect.

Educational work among the operating force has, of course, its limitations, without the public in general assisting in reducing accidents.

The aid of the Kansas City Safety Council was solicited, and officers and officials of our company have been taking an active part in the public safety work of the Council. Through the activities of the traffic committee of the Safety Council, much has been accomplished in the way of improving operating conditions, through reduction of traffic congestion. This committee of the Safety Council is composed of men in many lines of industry, including representatives of Taxicab companies, Steam Railroads, engineers versed in traffic studies and City planning work, as well as representation from our company. The Director of Public Works of Kansas City, is at the present time the chairman of this committee, and active in the work of the committee are the Police Commissioners, and captains of the traffic and motorcycle force. The personnel of this committee has the respect of

the general public and newspapers, and gives a contact into all branches of City Government which would otherwise be impossible to obtain.

We are also very fortunate in having had since its organization, men as directors of the Kansas City Safety Council, well fitted for the position they held. The loss of Mr. Julien Harvey to the National Safety Council was considerable of a blow to safety activities in greater Kansas City, but Mr. F. C. Lynch has proved a worthy successor.

The traffic committee of the Safety Council is called on by the City Council to make recommendations on all ordinances affecting traffic, and while there is still, of course, much unaccomplished, conditions have been materially improved. Also, traffic problems in general are handled through this division of the Safety Council. Accident prevention work among the thousands of school children is another part of the Safety Council activity. This aid has been invaluable in our efforts to overcome transportation hazards.

Automatic traffic signal lights at certain congested intersections in the outlying districts have materially improved the accident situation, and the City Council now has under consideration, a bond issue to install automatic signal lights in the business district, which will be a further aid, if installed.

Last December, on recommendation of the Safety Council's Traffic Committee, the Police Commissioners put into effect, pedestrian control at all down town intersections where traffic officers are stationed, which has materially speeded up our operation at these intersections, and reduced the possibility of collisions with persons crossing at these corners.

Some few streets used by our car operation have been made arterial or stop streets, and this has resulted in a less number of collisions with vehicles crossing the tracks.

At the present time there is pending before the City Council, a proposed ordinance recommended by the traffic committee to make certain streets stop or arterial streets, which streets include those on which practically all of our main car lines operate.

Safety zones have been installed at all car stops in the business district, and at many outlying points. With vehicles prohibited from driving on track through safety zones, a marked reduction in collisions with automobiles and trucks has been obtained, and also speeded up operation.

Yellow lines on pavement marking overhang of cars, have been placed at many locations where our studies found that accidents to vehicles and pedestrians being struck by rear end of car, had previously occurred. This class of accidents has been almost eliminated at such locations.

So much for prevention methods on the streets, and through public safety work, and through work of the traffic committee.

Within the past few years, a much more careful selection has been made in the employment of men as car operators. After filling out a preliminary application, applicant is given an inspection to determine fitness for work, by either general superintendent of transportation or assistant, and then must pass a rigid physical examination before being turned over to instruction department. Three days are spent in the instruction school, prior to actual road instruction, and where some fifteen years ago a man was considered competent to operate a car with one week's instruction, our present training period is from twenty-one days at the smaller Divisions, to thirty days at the larger ones. The first seven days of operation alone, a man is checked daily by a representative from Instruction Department, and for a period of ninety days is followed up on an average of once a week, by a travelling instructor. A careful record is kept, through a card index system in the Instruction Department, and this follow-up is not a hit or miss system.

All accidents are carefully investigated by division superintendent or assistant, and the man concerned, interviewed the day that accident occurs. Division super-

intendents send in a written statement, made out in duplicate; one copy of which is sent to the adjustment department, and the other filed in the operator's record.

Twice yearly, the division officials compile accident records of car operators, and the man is called in personally by division superintendent and commended if he has a good record, or advised as to improvement necessary.

Formerly, men involved in accidents due to carelessness on their part, were disciplined by serving days at the foot of the extra list or by suspension. Some five years ago, this feature was discontinued, as it was found that discipline of that kind did not tend to improve a man's work, and also was a hardship on his family, due to reduced pay, and had a tendency to keep his mind on personal matters, rather than on proper operation of his car. Before making this radical change in discipline, the matter was taken up with the division and general transportation committees. In meetings with the men, it was explained that a six months' trial of this would be made, and that final decision would depend on results secured. Although some of the division superintendents were somewhat skeptical as to the outcome, an immediate improvement was noted, as the men were trying hard to reduce all classes of accidents.

To keep the trainmen fully advised as to results, a daily system of bulletins was inaugurated, showing in chart form, the number of accidents, a general classification of those chargeable to each division, and explanation as to number apparently avoidable, and how same could have been prevented. These bulletins are posted at divisions not later than noon of the day following, and although this system has been in effect for many years, we find the men still greatly interested.

Early in 1919 our employees and officials worked out and adopted an Employee Representation plan for handling all matters affecting operation and working conditions. Much assistance has been received from this committee system. At each division there are elected each year from the employees, committees of three men at larger divisions, and two men at each small division. These men, with division superintendent, and assistant, constitute division committee. Equal representation of division officials and elective members of their committee, make up the general transportation committee, of which general superintendent of transportation is chairman. Similar committees function in all other departments.

We have never tried the bonus system in effect on some properties, but as an incentive towards improvement, and to create rivalry among divisions, an accident table was worked out by operating officials and general transportation committee.

Under this plan accidents are divided into five major classes and a certain number of points are allowed for the best record in each class, according to the importance of that particular type of accident. Points are also awarded for the greatest percentage of improvement over the month previous and over the same month for the year previous. All accident comparisons are made on a basis of car miles operated, or 1,000,000 passengers carried.

A prize of \$50 per month is awarded to the division making the best record, and a \$25 prize to the division next in line. A \$25 prize is also given to the motor coach division making the best record; there being only two divisions operating coaches. Division making best record for year in accordance with this schedule, is given a banquet or outing, and a trophy to display at their headquarters.

In competitions of this kind there is usually a tendency on the part of a few to avoid if possible, reporting all accidents in order to better their own, or division record. These unreported or "Blind Accidents" constitute a serious problem for the claim or adjustment department, and also cause the company to pay out large sums of money. To minimize this class of accidents, our plan provides for the awarding of prizes to those divisions making the best record in this respect. Each "Blind Accident" charged to a division carries such a high penalty that an other-

wise splendid record would be practically wiped out, and minimize the chances for division winning the monthly prize.

Prior to our intensive safety work, we were involved in many car collisions, serious in nature, and costing thousands of dollars, and resulting in serious and some fatal injuries to passengers. In 1912 there were 333 of this class of accidents, as compared with 106 in 1927, a reduction of 68.2 per cent. A comparison of 1922 with the year 1927, shows 164 in 1922, as against 106 in 1927, a reduction of 35.4 per cent. In 1912 we had 1.43 car collisions per 100,000 car miles, and last year, 0.44. Our record for 1928, based on eight months' experience, will be even better. Of the 106 car collisions occurring last year, few resulted in other than bent fenders or touching bumpers, and little or no injuries to passengers. This has resulted in a big reduction in amount paid for injuries and damages.

In the early part of 1927, with revenues constantly reducing, it was necessary to make drastic reductions in operating expenses, and decision was reached to put into effect one-man operation on all cars in greater Kansas City.

Prior to July 1st, 1927, 37 per cent of our car miles were one man operated, and between July 1 of last year, and July 16th, 1928, changeover to 100 per cent one man operation was made. To accomplish this in the short space of a year, it was necessary to instruct approximately 600 conductors, and 250 motormen in the details of one man car operation. This greatly increased the work of the instruction department, but we are able to say that changeover has been made without a single serious accident that is in any way chargeable to the change to one man operated cars. Our peak schedule calls for approximately 700 cars in service.

In making this change to one man operation, all possible safety devices were installed on cars, including rear exit treadle interlocked with brakes, as well as features to make door operation impossible when car is in motion.

All of our cars are single end, and unfortunately the majority of outlying termini are so located as to make looping impossible, so a "Y" movement must be made. Accidents have occurred to vehicles and pedestrians being struck by rear end of car during the backing at "Y," and in making changeover to one man operation, there was installed on these cars a rear end control feature which enables operators to back car from rear end. Although this safety feature added \$30,450 to the cost of remodeling cars, it was thought necessary to install, and eliminate this accident hazard. With one man cars backed from rear making "Y," there have been no accidents of this nature since changeover to one man operation.

As an aid in reducing the number of so-called "Falling in Car" accidents, sometimes caused by sudden starting, a line breaker switch was also installed on cars at the time of rehabilitation. This switch between controller and motors, opens if operator attempts to feed too rapidly which would cause surge on motors. Opening of this switch automatically prevents car jerk from improper feeding of controller. Installation of this feature was at an expense of \$81,720.

Safety meetings conducted by division superintendents and assistants, are held each week with all men at divisions on the extra board, and once each month, a general meeting for all men at the divisions is held. This really is two meetings, in that one is a day, and one a night meeting.

Our committee system provides for safety committees, meeting once a month with division officials and taking up the many details of accident prevention work.

Men at each division by popular vote, elect from their own number, team captains, who in turn select from operating personnel, their own teams; and the winners on these teams each month receive various prizes.

While we have made reductions in majority of accidents, we have not been so successful insofar as vehicle accidents are concerned. This is largely accounted for by the great increase in automobiles in Kansas City. In 1912 there were 4,519

automobiles in Kansas City; in 1927, 79,763; over sixteen times as many as were on streets in 1912. Vehicle accidents during this same period increased 104 per cent, with 2,571 in 1912, and 5,254 in 1927. A large part of this increase, however, can be attributed to conditions existing the latter part of 1918 when almost the entire transportation force left service, making necessary our hiring and training some six thousand men to obtain a force of 2,000 competent trainmen.

A comparison of 1922 with 1927 shows 4,980 vehicle accidents in 1922, and 5,254 in 1927, an increase of only 5.5 per cent. In this five-year period, automobiles in Kansas City increased 54.3 per cent; from 51,688 to 79,763. Vehicle accidents in 1912 were 1.11 per 10,000 car miles; in 1922, 1.99 per 10,000 car miles; and in 1927 there were 2.16 for each 10,000 car miles operated.

Most gratifying of all is the reduction in fatal accidents; there being only 16 chargeable to car operation in greater Kansas City, in 1927, as against 33 in 1912; a decrease of 51.5 per cent during this period. Also, the majority of such fatal accidents occurring in 1927 were ones which our operators could in no way have averted, they being due to gross carelessness on the part of automobile drivers. This total of 16 deaths in street railway operation is considerably less than the number killed by automobiles in Kansas City last year, and we can say without fear of contradiction, that the street car is today the safest means of transportation.

From January 1, 1923, up to and including the first eight months of 1928, we carried in greater Kansas City, 693,751,207 revenue passengers, and 369,317,933 transfer passengers, or a total of 1,063,069,140 passengers, without a passenger fatality.

Starting two years ago, I requested and have been receiving accident data from fifteen or twenty companies comparable with Kansas City as to size, operating conditions, etc. This information is charted and posted, along with comparison of Kansas City record, at our divisions. This has been of benefit in keeping our men interested in their endeavors to further reduce all classes of accidents, and make as good if not a better record than other companies.

We are not as yet satisfied with our accident record, and must constantly carry on if we are to improve, or even hold our own, in the battle to overcome transportation hazards.

Before concluding, I should like to make a statement with which many may disagree, and that is: It is possible to go to extremes which may react unfavorably. I sometimes wonder if we have not already gone a little too far in being overly cautious as to attempting to prevent accidents with automobiles and trucks. As it is, most of us are constantly telling our men to slow up, and have car under full control at all street intersections, and I am inclined to believe that this hesitancy or giving of right of way to autos, makes the drivers more careless, and puts the burden of preventing collisions almost entirely on the railways company. No doubt, were we to dispute the right of way with truck or auto drivers, there would for a little while be a considerable increase in accidents with vehicles, but I am of the opinion that within a short time conditions would be much improved over what they are today, in that drivers would become more cautious.

CHAIRMAN KOEHLER: We are very grateful indeed, Mr. Fennell, for this detailed account of the activity which is being promoted by your company. Doubtless Mr. Fennell's remarks have caused many others to think about the things he has said, and have precipitated some questions.

S. J. HENKEL (Pittsburgh Railways Co., Pittsburgh, Pa.): I understand the \$50 is awarded to the division making the best record over the previous month. How is that awarded, how is it distributed, and in what way is it used?

MR. FENNELL: Well, it would be quite difficult to explain how it is awarded other than through the schedule of points. We worked out these tables so that it

gives every division a fair trial, no matter what number of miles they operated or what the conditions are under which they operate. The money itself is given to the division committee, which is composed of the general committeemen and the Brotherhood trustee of that division. They put that into a fund. Each division, through its Brotherhood organization, is allotted out of the general treasury of the Brotherhood, so much each month for social activity. They add this to that. For instance, one division that has been most fortunate in winning the \$50 Accident Prize, was economical and hung on to their money for a year. They added it to what they received from their allotment and gave to the entire division force, a chicken dinner picnic. They had about 950 pounds of fried chicken.

L. R. BROWN (New York State Rys., Rochester, N. Y.): Are the men paid for their time in attending those meetings?

MR. FENNELL: Generally, they are not. That is, these meetings I speak of. Last year, we inaugurated, not so much for safety, but for things in general, what we called (for want of a better name) "Sales Conferences," where we brought in to the main office groups of 50 men at a time, including every car and bus operator. We had them for an all-day session after the morning rush at nine o'clock, until four-fifteen in the afternoon.

W. F. KEELER (3rd Avenue Railway System, New York): Do you use mirrors in one-man cars? We do in buses.

MR. FENNELL: We use them both inside and out. The outside mirror gives a vision of the rear step. We have an exit at the rear, and the outside mirror is so focused that the operator can see a person stepping off when the door opens, thereby eliminating the danger of the passenger's clothes being caught in the door.

W. J. ROUNTREE (Georgia Power Company, Atlanta, Ga.): I wanted to ask Mr. Fennell in awarding the division prizes, if the operating conditions on the various divisions are sufficiently similar to avoid getting a reaction from one division that another division had the better chance to win. What brought that up was your statement that one division had been very successful in winning the prizes.

MR. FENNELL: We think, and the men think (in working it out with the committee) that they have equal representation. Each of the divisions has practically the same conditions, the same open track, and the same congested sections. By putting it on the mileage basis for every 100,000 passengers carried and so forth, we feel it is very fair. We have never had any criticism of that nature at all.

MR. ROUNTREE: We found it necessary, down in Atlanta, to change our system from straight monthly competition, to improvement over the same month of the preceding year, each division thereby working against its own record made the previous year.

MR. FENNELL: Yes, I also mentioned that we use the records of the preceding year as a means of determining progress.

MR. STOUT (Altoona Valley Ry., Altoona, Pa.): In connection with the window wipers, I just wondered what success you had with them?

MR. FENNELL: It depends upon what you call success. They clean off snow, rain, and a light sleet.

MR. STOUT: Our company experimented quite a bit and hasn't found anything yet that is entirely satisfactory. Of course, on the buses, the window wipers work all right.

J. R. NOTT (Pittsburgh Rys. Co., Pittsburgh, Pa.): The question of conversion to 100 per cent one-man operation, no doubt, has been very interesting to our entire delegation. How did you take care of the surplus men?

MR. FENNELL: We felt in going to one-man operation, that it was an economy measure principally, but at the same time, we felt that the public should receive consideration in that economy. We increased the service some 25 per cent, which automatically took care of the men who had come off of the rear end. We anticipated this some eight or nine months prior to its becoming effective, and

we hired no men prior to that time. It now stands that way. We haven't hired any men in Kansas City since January of 1927.

MR. NOTT: No men were let out?

MR. FENNELL: No men were let out. There were some men, however, that would, within a very short while, have been in order to retire. Even without the one-man feature, those men have been retired on pension, or have been furnished lighter positions. For instance, one man is now running the elevator in the main building. We are very proud of the fact in Kansas City that we have never had a wholesale forced reduction in our transportation department, and we don't expect ever to have one.

CHAIRMAN KOEHLER: If there are any further questions relating to this paper, will you please reserve them for the discussion on Thursday morning? Our time is getting shorter and we must proceed.

Our next subject is the Promotion of Accident Prevention Through Interdepartmental Cooperation. That subject is going to be presented by Mr. John J. Reynolds, Claims Attorney, Boston Elevated Ry. Co. Mr. Reynolds also represents the Claims Association of the American Electric Railway Association, with which our Section has very cordial relations.

Promotion of Accident Prevention Through Interdepartmental Cooperation

By JOHN J. REYNOLDS

Claims Attorney, Boston Elevated Railway Company

Accident prevention work falls logically into two principal divisions: Industrial and Public. We shall deal chiefly with the former.

A minute inquiry into the possible causes of *all* accidents would carry us too far afield and is beyond the scope or needs of this paper. We shall, however, refer suggestively to certain conditions under which accidents may, and in fact do, happen.

We know that education, cooperation, safety organizations and methods, rather than mechanical safeguarding, are given larger emphasis in safety work because it is at bottom really a problem of organization and education—that to get the right attitude, to arouse and maintain interest and to get started toward constructive action and follow it up, is the big task.

Right here I wish to refer briefly to one thing which doubtless works toward interdepartmental cooperation, and that is the welfare policies now pretty generally adopted by Electric Railways. I mention it not only as a humanitarian policy, and as a way to keep employees in the service, thus minimizing labor turnover, but as one which promotes both individual and collective interest.

The industrial accident problem and the Workmen's Compensation cost that the railways are seriously facing today, make this subject a particularly timely one. The tragedy of preventable accidents has been like a huge shadow obstructing the sun. Well may we be dismayed by it. Earnest men and women have been sincerely and intelligently laboring for many years to drive that shadow away. To think of it, is like awaking from a bad dream. The heavy toll demanded by this common enemy is the price of carelessness. In spite of all the work that has been done, in spite of all the money its prosecution has cost, in spite of all that has been done to focus public attention upon this awful toll in human life and suffering, it continues to sweep through the country and the industries like a sand storm, leaving in its wake a deplorable human wreckage. In spite of all the efforts that have been made to create a conception of its staggering economic waste, a survey of current accident history makes one pause and ask: What curious impulse is it that causes men to be careless?

Is it any wonder, then, that this accident prevention question is now attracting the widest attention? Never before, it would seem, has so large a public displayed such an interest, not only in the cause itself, but also in what it means humanely and economically. We now take part in safety movements and discussions, and witness experiments which are not limited, as formerly, to a very few restricted groups of industries, of railways and of safety organizations. It is a hopeful sign of our age that even the general public is devoting a keen interest and oftentimes even a passionate interest, in this great work.

If it is true that "there's a sneaking suspicion in some unregenerate quarters that employees get fed up with safety programs," as we recently read in a technical journal, it is unfortunate. That such safety programs are imperatively necessary and important to both the employee and the public may be seen by studying the recent general accident history. "Approximately 95,500 persons were killed in accidents of all kinds in the United States in 1927. A total of 100,000 deaths may occur in 1928 unless greater efforts toward prevention are made." (*Accident Facts-1928-N. S. C.*)

In considering this subject "the element of fatigue should not be lost sight of, for it is a prolific cause of accidents and its economic cost is said to be over two billion dollars per year in production alone. This is at least four times the actual fire loss, and it is not for one year alone, but it occurs, like the fire loss, year after year." (*See: Practical Methods for Relieving Fatigue—Safe Practices Pamphlet No. 50, National Safety Council.*)

Those states in which accident prevention activity has been of longest duration and has been given the most serious consideration have the lower accident frequency and severity rates.

It must be admitted that for the length of time in which Workmen's Compensation has been in operation in the United States, and for the length of time in which intensive accident prevention work has been going on, we have achieved really remarkable results. Since the tendency is toward liberalization of benefits, however, it is manifestly important that there shall be no let up in either activity or intensity to reduce accidents to an irreducible minimum.

From the economic standpoint alone, this necessity is emphasized by the fact that a more liberal policy on the subject of Workmen's Compensation was followed during 1927, by the Legislatures of 31 States, two Territories and by the Congress of the United States, the laws having been extended to cover more workmen, to increase benefits, or to make the laws more effective and just.

Now to discuss briefly the question of departmental dependence. The first fact to be considered is, shall we interpret it as a term of limitation or of extension? We have elected to treat it in a broad or comprehensive sense, since departmental action has an influence on human life beyond department limits, even when such department is not consciously aware of this influence. It excludes the idea of any logical halting place between a thoroughgoing spirit of earnestness and a thoroughgoing feeling of interest. Where obstacles in the road of progress cannot be surmounted, they must be removed. Departmental efficiency is clearly influenced by the number and seriousness of its failures and accidents.

While the performance of each department is measured largely by the results it achieves, they are not in any practical sense isolated departments, and failures or accidents in one frequently are but the beginning of a train of events which affect other parts of the organization. To illustrate, briefly—a preventable failure—a preventable accident—defective car equipment or cars which are not maintained in proper running condition—improper or inadequately designed mechanical or electrical parts—improperly constructed or poorly maintained roadway and track—inadequate power supply—unskillful overhead construction, which is infrequently and carelessly inspected—all affect more than one department, and chiefly, of course, that of revenue.

Departments function only through individuals who represent them. Too often some employees seem not to have had a proper appreciation of the fact that the goodwill and success of the railway is built up or destroyed through their actions, their failure to act, their failure to cooperate, just as much as through failure of the management itself.

The policies of all departments may properly be said to have the same general objectives, hence they should be formulated with a view to protecting not only the interests of *the* department, but of the whole organization. To get the best results in our efforts toward this 100 per cent interest, it is fundamentally important that there should be as few individual differences as possible in the interest of employees, not only in their own special job but in the general business welfare and success of the employer, too. This phase of our problem is not without its difficulties, however, for it presents a question which is rather exploratory and inclusive, in that it may be somewhat of a puzzle to find just the best way to dissipate the individual difference in interest manifested by some employees. Such an attitude should not discourage us, however, since that which puzzled Solomon may well puzzle us also. The entire responsibility to do this rests, in fact, on the management, on department heads, and on all employees generally. Every department is affected by the manner in which this duty is realized and performed. It is this interdependence of all departments of an organization which makes the individual interest and actions so important. Should there be a tendency toward the development of a departmental, as distinguished from an interdepartmental outlook, then obviously it is not conducive to the best interests of the organization as a whole, in that there is then the danger that it will result in taking a restricted view of the *railway's interests*.

This does not mean, of course, that in dealing with other departments a department head and its employees should not protect his department's interests. It simply means that high standards should be observed and that the situation should be viewed in the light of the probable results in the long run, rather than the immediately apparent advantage to be gained.

Heads of departments, superintendents, foremen, and other supervisory officers have in all probability been selected because of special skill which has been acquired, no doubt, through long experience in their particular field. Their training has tended to give them a broad outlook, thus giving them special knowledge upon which to base an appeal for constructive interest. This is particularly true of foremen, inspectors and other supervisory officers, because they ordinarily spend a good part of each day among the workmen, and in that way are able to keep in close touch with, and informed of conditions and tendencies of employees. These close contacts place them in a position where they can be of great service in developing this spirit of interest, and if they are awake to their opportunities, may often make suggestions which will result in spreading this interest to other departments. They have opportunity for constant and more immediate personal contacts than heads of departments, for whom, unless they are big, broad-gauge men, and their action might be colored by what appears to be their own interests. men, the organization is narrowed down to the perspective of their own department.

Departmental activities susceptible of standardization, should be standardized. In some departments many activities can be standardized, although for the operation of the department as a whole, perhaps it is never possible to reach the ideal of complete standardization. Accident prevention work is made effective in day-to-day operations by means of operating procedures. The methods of control of necessity employed by railway managers under modern conditions, tend to focus attention upon such devices. Not that there is anything novel in their employment in the railway business—for a procedure is merely a statement of the accepted way of doing a thing, work—but because of the realization that, with the necessary

delegation of operating details to subordinates, management must assume responsibility for their systematic instruction by providing standard methods.

There is necessity for frequent review, (this cannot be too strongly emphasized for governing conditions are seldom static) and any unusual occurrence or requirement is likely to disturb the existing plan of procedure and require a revaluation of the standards.

The question of the attitude of the individual department employee is too important to be left entirely to chance and his own discretion. It is of grave concern to the railway, and if proper control is to be exercised and systematic interest secured toward the elimination of accidents, the policy defining these relations should be thoughtfully conceived and consistently applied. Only by such means can a uniformly high standard of performance be hoped for. What constitutes a proper standard of conduct from the standpoint of the relation of one department to another is perhaps sufficiently answered by the statement that it ought always be such as will contribute to the best interests of the whole organization—and to its interests only, where there is a conflict of interest.

Interdepartmental interest and coordination is the road to profitable operation of the railway as a whole. It is of no avail to save a minute here or a dollar there in machine work or assembly, if that saving is lost in slow interdepartmental appreciation of the cost of preventable accidents, which not only waste time and lower production, but gnaws at the very vitals of the railway revenue. And so we see that every executive, each department head, superintendent, foreman and employee owes it to himself and to his company, to get the facts on what is being done in his department to prevent accidents, and contribute what he can from his experience toward their complete elimination. Every department head, yes, every supervisory official, is or should be interested in providing ways and means by which his subordinates may receive adequate training and acquire technical skill, and safe habits of conduct, as well as a spirit of cooperation with other departments.

Heads of departments should requisition the purchase of modern machines or tools only, to secure the utmost efficiency and the safety of workmen using such instrumentalities; or, where machines or tools used, are manufactured by the railway, permit the use of only those which are built according to skillful and safe design. Supervisory officials should labor with employees to find the safest way for them to do their work, by seeing that they are trained to be skillful in the use of tools, and by helping them to better ways of working.

Probably no one thing in railway department operation is more important than the safety of employees. Experience has taught that working conditions have a tremendous influence on the safety spirit, and on the character of the work that employees will turn out. That a safe workman is the best safety device, is axiomatic. That more will be accomplished for the prevention of accidents by educational methods than through any other means is an accepted fact. But we must not overlook the further fact, that this presupposes that the railway itself has done everything reasonably practicable to make the place of work safe, both physically and mechanically. Obviously, for accidents due to causes or conditions which were capable of causing accidents, which were beyond the immediate control of the workman, as distinguished from an accidental condition or from a simple act of carelessness or individual behavior, the railway's officials are themselves not free from fault.

Almost every department has some spot where accidents may happen, where some condition is a special accident hazard. Perhaps you already know of such spot or such condition, and are trying to remedy it. Perhaps you are like some other department heads foremen or employees, who do not fully realized the opportunities for greater safety, for greater efficiency, through the use of special guards to protect such spots, and through prompt cooperation to remove those

conditions. In either case prompt attention on meeting such conditions may help you to easily, quickly and cheaply solve many of your accident problems, and thus provide another major economy factor for your department.

Just as vital to the economical and safe operation of the industrial plant of the electric railways as lungs to the life of man, is the question of shop heat and ventilation; therefore, I wish to say just a word about it. Take the two elements, for instance, of heat and ventilation that enter into the question of safety and morale. Are some workers in your shops air-starved, or warm and comfortable while others are too cold to work properly, which, of course, means to work safely? Then why expect efficient or safe work from a shop force where heat and ventilation are neglected? Entirely aside from the obvious humanitarian viewpoint, neglect here is evidence of inefficiency. Men do not work up to standards of either quality or safety, under uncomfortable circumstances, whether of poor ventilation or heat.

Another thing of great importance is your scheme of lighting shops or other places in which men work, for good lighting is the bulwark of good morale and safety, in that it will throw a stimulus around men and women workers that will help them give their best. Deep shadows, sharp contrasts, dark corners and both direct and indirect glare reduce speed of vision, make men slow up; increase eye-strain and early fatigue, which first and last is responsible for a great many accidents. Tired eyes and eye-strain in your shops cost you money. Under the influence of good lighting, however, men are more alert, they remain cheerful at accustomed tasks over longer periods of time, and there are fewer accidents. It may thus be seen how important is this matter of lighting in any undertaking to prevent accidents.

Just as essential as heat, light, ventilation, or safety devices, to preserve the health and safety of your workers, and to help them fight the fatigue which causes accidents, is pure, cool, refreshing drinking water.

Still another important thing in this war on accidents is that you have a clean and an orderly department, and adequate room or space for your men to work in, for cramped working space spells accidents. There is profit in order. A well ordered shop increases safety, increases personal efficiency, and greatly increases output.

In some of the shops of the electric railways, employees are obliged to do their work while seated, which leads us to point out that even such an apparently unimportant thing as a simple work chair, is a factor worthy of consideration in connection with the efficiency and safety of the worker. At home you like a certain chair. Why? Because you rest or work more comfortably. Imagine sitting eight hours or more every work day in the year, on any old chair that was given you. It is not at all remarkable that such an employee becomes tired and fatigued, less efficient, an unsafe worker and more liable to accident. Surely you will agree that employees with spines held erect by proper chairs, lungs breathing free and easy, heart functioning normally with natural blood circulation, are more alert and efficient, that they work more quickly, accurately and safely.

What a wonderful satisfaction a department head must get from knowing that conditions in his department are safeguarding his men, are conducive to health, to cheerfulness and to safety! He is doing his utmost for his men, which should mean that they will do their utmost for him.

Another thing to be considered in any movement looking toward accident prevention, is the necessity of having a prompt and full report of an accident, since a systematic compilation of accident records is the foundation of a well organized accident prevention. Therefore, it is imperative to have an adequate system of reporting accidents, a proper method of analyzing and classifying them, and a workable plan of coordinating the accident activities of the different departments for purposes of effective prevention. It is not by chance that records and

reports of accidents have come to occupy so respected a position in the estimation of the modern executive. As long as the number of accidents remained low, a measure of knowledge of them could be maintained without great reliance upon formal records; but with their increase, this personal knowledge has become impossible and the executive has been forced to develop new methods of keeping informed. His complete dependence upon the accuracy of the reports and records thus requires that their preparation shall occupy an important place in the organization. It has been truly said that statistics alone will not prevent accidents, but the study and analysis of statistics are essential in determining what to do. Maximum success in accident prevention work necessitates tabulations of accidents that will show who, and what, was responsible for each accident, all leading to the formulation and administration of definite plans for prevention.

Still another important thing in our work for accident prevention is to have a "Fact-Finding Body." This has been found to be of great help in reducing accidents, in that it has developed both individual interest and organization efficiency. It is therefore obvious that to do the best work for prevention there should be such an agency, which may consist of a committee of employers, and a committee of employees, or outside experts in personnel work, but preferably the three agencies sympathetically cooperating. The scope of the activities of this agency should at least cover the working conditions, the health, the accident problems of the different departments, for they are the base of regularity and decreased labor turnover, and also because they may mean contentment, as well as the elimination of fatigue and worry, the latter being now a well recognized cause of accidents. The perspective of this fact finding agency, not being restricted by departmental limits, should be able to see the entire problem, and so viewing it, carefully analyze it, and make corrective suggestions before it is too late. By it and through its work the railway is provided with another important and powerful means of coordinating interdepartmental relations, for establishing standards of performance and procedures. This strong coordinating influence is bound to favorably affect your accident rate. This body will unravel the true facts and fix responsibility where it belongs. Where there is no such agency, matters may become hopelessly involved, "alibis" offered, sometimes accusations are made; and departments assume a defensive rather than an understanding attitude in their dealings with each other, and the result is very apt to be that preventable failures and accidents continue to happen. This fact finding agency, however, with mind unfettered, uninfluenced either by sentimental feelings or passion, may be expected to view the subject with the cool, calm eye of an analytical investigator, and courageously deal with causes, reason, and effects, rather than with details or circumstances which may be immaterial. One of its duties might well be to inquire into the physical condition of employees, by having a physical examination not only of the new employee, but a re-examination of others, to determine whether or not he has any physical defect which might seriously increase likelihood of an accident to himself or others.

We shall now consider briefly the educational phase of our problem. It should be remembered that the most valuable activity in behalf of interdepartmental cooperation for the prevention of accidents must take place in the educational field, and that there can never be too much of it. From every point of view, the overwhelming necessity and importance of educating employees and public in accident prevention and safety work is universally recognized.

Our educational work should not take the form of cramming, for it is a usual experience that if one tries to remember too much at once, one forgets more quickly. Nor should we depend too much on "outlines"—that sorry attempt to push camels through the eyes of needles and so administer a get-knowledge-quick course to the employee.

A recognized stimulus to memory is interest, therefore, everything reasonably possible must be done to educate employees and awaken their interest in all departments.

No matter what may be said to the contrary, the history of the accident prevention movement testifies without exception in any state, that the attempt to secure even an approximate reduction of accidents without invoking educational aids and methods is foredoomed almost to complete failure. Nowhere has it succeeded, nowhere can it succeed without the help of these important factors. So, as a final conclusion drawn from this fact, it may be stated that any scheme directed to secure interdepartmental cooperation in preventing accidents should have its base in educational effort.

The educational program must be designed to meet the needs of all concerned, and when so designed it results in harmonizing the interests of all departments and their employees, and hence promotes better interdepartmental interest and safety. Some central authority capable of appreciating the interests of all departments should devise the procedure and see that it is enforced. While your educational program may not always claim, or even require, psychological precision, it well merits general attention for it will make the employee think.

We are conscious how fantastic a thesis one would seem to be supporting who should claim that *all* accidents can be prevented. We now find, however, most of the larger industries including the railways, Government departments and commissions actively engaged in educational work having for its object the fullest blossoming of the safety bud, and where the dangers incidental to industry may be warded off by an ordered regime, common sense and constructive education.

During the past 25 years industry has made its greatest advances in science, and in safety to life, and the railway industry has taken part in this development. There is neither time nor space here to tell about the very large number of things that have been attempted by and for industry to prevent accidents, nor to describe the measure of their success. I shall only note the significant fact, which no thinker has failed to perceive, that there still exists a tremendous gap to be filled or explained, and the formidable leap across to the no-accident side requires the utmost of education and sincere cooperation for safe conduct. Disguise the requirements under any name you may, the clean-cut fact still confronts us, that the great chasm which exists, may be enduringly bridged only by and with the help of the educational and safety factors. Experience records that mechanical safety devices, of themselves, are insufficient. While I shall not burden you with a lot of statistics I wish to stress the fact that safety methods, no accident competitions, building up attitudes and habits of safety in the individual foreman and employee, reduce both the frequency and the severity of accidents.

Don't neglect to warn each individual employee of dangers which may not be apparent. Notices warning of dangers should be conspicuously placed about your shops and premises and, if necessary, should be printed in foreign languages so that your foreign employees may be able to understand them.

We but express a thought that has been worn threadbare from use, when we say that to interest the employees of the railway in the accident prevention movement is something worth working for; just as high farming increases the yield of an acre, so education will increase the yield of the employee in terms of interest and safety.

It has been stated that, "it is fundamental that each foreman should conscientiously recognize that it is part of his responsibility to teach his men to do their work more efficiently," and I wish to add, also to do it more safely. Hence we ask you: are you keeping pace with new developments in your line of work, new methods, new equipment? For new ideas are constantly being perfected. What was considered the "last word" in doing your job a year ago, perhaps is now out of date. The way to keep abreast of the times is to consult and study

the literature dealing with your specialty, attend the group conference meetings of your department, read your company bulletins and develop the habit and practice of keeping up to date. Then you can give maximum service by taking full advantage of all the benefits new safety and economic methods are bringing about.

Department heads should be held responsible for the workers' safety, therefore it follows that a high accident rate should count against the promotion of any executive or sub-executive as it indicates his failure properly to educate the men under him.

Instruct and educate your employees to realize that the absence of sudden shocks, jerks and sudden strains in doing work that requires heavy lifting or other considerable physical exertion will greatly reduce the chances of back injuries, hernias, abdominal wrenching, and any number of other bodily accidents or troubles entailing not only physical pain and disability, but mental anguish as well.

It is several years since our general manager, Edward Dana, pioneered into the field of educating the railway employees on this property, and today this work has become one of the great outlets of cooperative activity in all the departments of the railway. It is the hope and inspiration of all ambitious employees, who are attracted to it by the unusual opportunities it offers for broad self-improvement, for greater occupational information, and especially for increased knowledge of the technique of the railway business.

This sort of educational work is bound to spread and as a result we know that within the past few years there has been decidedly increased cooperation among interdepartmental groups through the medium of meetings, lectures, and varied entertainments, which has made the spread of interest and of good feeling more rapid and permanent, and which cannot but have a steadying effect and be a healthy stimulus toward accident prevention and general efficiency.

In undertaking this educational work the railway embarked upon a venture that has become increasingly popular each year. This simply means that the rising popularity of the educational program, as evidenced by the affirmative and enthusiastic response of the different departmental groups, has brought the railway face to face with the alternative of either continuing this mutually helpful work, or disappointing a very large number of ambitious and earnest employees—we have every hope and confidence that the former will be the course chosen by the railway which, in furtherance of its function as an educative agency for the employees, will include in its yearly educational program the more advanced phases of the transportation business.

Could we properly treat this subject without emphasizing both the necessity and the importance of cooperation? We think not.

We may accept as true the proposition that all departments must cooperate in eliminating accidents. Starting with this premise, it follows that we should understand what is meant by cooperation.

The adjective voluntary as applied to the cooperation of railway employees, or to the management of the affairs of the railway, must not be taken as implying that there is any very wide choice open in those matters, for such cooperation is really compulsory, since if it be foregone affairs will remain either unmanaged or inefficiently managed. It therefore follows that one has flatly no right to conduct one's self as his individual inclination dictates, if so conducting himself means doing what he pleases without regard to the interests of the railway, of one's fellow employees, and the public. This is both an economic and a natural law, for the violation of which, penalties are inevitable; hence we may be sure that necessity will make short work of our aspirations toward utter impunity.

Management and employees,—efficient, willing, intelligent, interested, both on their toes in reciprocal relationships—working with each other and together with dignity and integrity, and in a spirit of mutual helpfulness, and for the promotion

of the best interests of the railway: those are the factors which tend to promote and sustain constructive and safe interdepartmental activity, and in outline is what we understand cooperation to mean.

In connection with the factors thus explained careful consideration should also be given to the following important propositions:

a. The progressive electric railway company is not operating its property just to furnish work for its employees. Some of the things many employees do are so plainly against the interests of both the railway and themselves, however, that one often wonders how and why they act as they do. The success of any railway depends largely upon how well its employees perform their duty—honestly, courteously, without trouble and without accident.

b. If in any department coordination is lacking, if any department fails to properly function at the right time, it indicates a lack of the right kind of cooperation.

c. No matter how good the electric railway, how large the mileage, how great the number of passengers carried per car mile, the financial success of the railway is measured only by net corporate profit or loss. Profitless prosperity does not help either the railway or its employees very much. Finding a way to stop the leakages that prevent net profit or loss, whether this leakage is due to accidents or other causes, so that the fullest measure of net income may be available for the railways, should be a matter of great concern to each of us.

d. Learn to count men among your assets. It is their brains, their alert minds, their eyes, their hands, their efficient operation remaining throughout the work-day, which permits you to lower the cost of running your departments, and hence increase the net revenue.

Therefore, have an open mind—don't disregard, without giving it fair and full consideration, a suggestion made by an employee for the safe conduct or economic operation of your department. When necessary, be big enough to put aside the defense mechanism, by which the mind seeks to expel or repress unwelcome ideas.

A responsive stimulus to interdepartmental cooperation in accident prevention is the appeal to departmental pride to have,—(1.) the longest no accident record; and (2.) the best record for the number of hours worked without a lost time accident.

When the department or even the entire plant has found it possible to go month after month without a single lost time accident, the remaining appeal is to keep up this no-accident record as long as possible.

Such cooperation, such coordination, constructively dwelling in and practiced in a particular department, goes beyond the limits of the particular department to affect the thinking and the attitude of those in other departments. It develops new alertness and interest, and pride develops in the men in all departments, who like to feel that they are associated with the systematic effort and methods that such cooperation reflects.

The personal impressions of railway employees, their likes and dislikes, their naturally favorable reaction to a sense of fair treatment, and their feelings of resentment and their desire to retaliate in the face of sharp practice, all are bound to color their actions. Their personal equation is ever to be reckoned with in business, for no matter how utilitarian or impersonal the organization may seem, it derives its character and tone from the personalities of the individuals whose cooperation gives it life.

Avoid assuming an air of superiority, we must avoid the "highbrow" attitude, for you cannot interest your employees unless you are interested in them and sympathize with them, since behind their forehead is a human brain, and in their breast beats a human heart.

Be tactful, for it is a matter of common knowledge that the chief use of tact is in persuading others to accept one's opinions, and no doubt this accomplishment is as desirable for railway men as for others. Be careful of your criticism, since

when one is critical, one is not necessarily judicial or even logical. An unguarded remark to an employee has been said to be as bad as an unguarded gear. It is important to have your men in the right frame of mind, for what the men think is important to the safety of the whole organization, and to make them think the right things about their employer, is the employer's task—nor is it a small task.

Pretty generally, men work because they have to work; not because they seek excitement or need cigarette money, but because they must support themselves, their home, and those dependent upon them; it follows, therefore, that it is only in rare instances that it is impossible for men to see on which side their bread is buttered. Of course, against stupidity, even the "Gods" labor in vain.

War is not fought in kid gloves. Our war on accidents cannot be so fought, either. It is a never-ceasing fight, and so we plead with you to keep on the battle front, for the plea of the railways for interdepartmental cooperation is a plea to which all departments must listen. Whatever, then, may be one's position with the railway, he is doomed to failure unless he is willing to and does in fact, cooperate to promote the interests of the railway and to prevent accident. It is a principle to which all must subscribe, and upon the altar of which all must kneel.

We're born to duty, stern daughter of the voice of God, and try as we will, strive as we will, we can't shuffle it off. Therefore, those who are unwilling to do everything reasonably possible to promote the principles of interdepartmental cooperation, need feel no surprise if the official thunder clouds swiftly gather and burst with crushing violence on the offenders.

There are yet many things to be done, and many things to keep doing. We should strive to develop a force of employees on a high standard of integrity of character, who will have the devotion of any army and the loyalty born of a deep and sympathetic understanding of human values and human relations and who fully understand and appreciate the necessity, value, and advantages of cooperative methods.

It is more than likely that the next ten year period will see marked advances in the work of accident prevention. The development of any phase of this work is dependent upon the amount of constructive thought given to it and to the action taken upon this thought. The tendency toward better and more scientific personnel work is in itself an index which unquestionably reflects the industry's attitude in this important phase of its business.

The electric railway world has long experienced with dismay the ever present accident menace, with its seemingly inevitable increasing costs, both for industrial and public accidents. With this constantly increasing burden, we may see through the steadily increasing use of the automobile, the jaws of competition slowly closing about many electric railways. One may think that this is strong language. Well, it is strong language. But strong language is sometimes needed and, if it visualizes for us a situation which should be apparent, it may be helpful. The railways are not quite helpless yet, however, for there is a way out. One of those ways is to stop accidents which, it has been estimated, in 1926 cost the electric railways in the United States substantially \$45,000,000. Other economies can also be effected, although these are not for us to discuss at this time. Let us all make our work help instead of hindering, and have no "ducking" of responsibility. Do your job with precision and unfailing accuracy, then we will meet the rigid requirements of electric railway service. Make every factor a favorable factor. If you do it, you will find that it is possible to defeat the closing jaws of competition, pressing on you in your present situation. Unless you do it, although you may now be big and strong financially, you may find that the jaws are relentlessly closing.

This accident problem, in spite of all the changes that have come about, is still the same old problem. One need but study its history to be satisfied of this. Take

but a cursory view of the marvels of modern mechanics, of modern maintenance methods, of the ingenious and useful devices and contrivances designed for and intended to solve this problem—with automatic machines which are almost fool-proof—and then remember that, with safety incorporated in the design, construction and installation of industrial equipment, it is possible to prevent only about 25 percent of industrial accidents through mechanical means, and that for the prevention of the rest, we must turn to educational methods, better supervision and improved morale of employees, one may then realize why the solution of our problem depends so much upon education and the creation of a constant spirit of cooperative safety—why it is necessary to have the fullest possible cooperation between the several departments of the railway, all coordinating to stamp out thoughtlessness and carelessness.

The accident prevention movement, with its roots in the past 30 years of American history, has risen strongly in recent years and is surely, if slowly, leading the mind of the people to a better understanding of the place the movement really has in the hearts of the masses, and also to a clearer understanding of the part that safe conduct plays in human progress.

Cooperating earnestly with the railways, we find the National Safety Council. As the light of the sun is broken up into the beautiful tints of the rainbow, so the transcendent character of the work of the men and women who promote the cause of the National Safety Council is reflected in the safer life of our fellows, to whom we are drawn by one of the best and deepest impulses in our nature.

Worshippers at the shrine of accident prevention are beginning to realize, however, that devotion to the cause and efficacy of methods or volume of accomplishment, do not always go hand in hand. They are discovering, too, that the fight cannot be carried on with too little regard to the cost to certain properties of getting the best results.

Today, one of the most hopeful signs on the accident prevention horizon is the National Safety Council. This organization presents in permanent form the record of what has been done in the field of Safety and the methods by which it has been accomplished. Active membership in and sympathetic cooperation with the Council will not only cut down your expense for accident prevention work, but will also increase the efficiency of your standards.

On its humane side the Council may be said to be a collection of constructive, cooperative acts and records in the cause of a safer life. It is with constant advertency to these two facts that its work must be appraised and interpreted. One cannot say too much in commendation of this work. As a record of achievement, it stands out like torches lighting the way to a more interesting and safer life. From its reports and records there emerges, with critical perception and a humane understanding possessing all the force of life, a wealth of suggestions and analyses concerning a great many questions and practices which are vital to the successful operation and maintenance of the electric railways. In these records is the story of years of constructive endeavor, behind which always is the Council's resolute purpose, amounting to a sense of destiny, fulfilled only when the industrial life of the worker and the life of the public is made as nearly 100 percent safe as is consistent with modern conditions. Its work is unsurpassed in interest and importance. It is far in advance of all other agencies for safety, and it speaks with all the weight of a great authority.

In conclusion, to paraphrase a familiar biblical simile, "Let the heavens rejoice and the earth be glad, let the sea and its billows be roused, let the fields and all in them rejoice, that this fair land of ours has in it such an organization as the National Safety Council, whose work hath found the hearts of the people; and the mountains and hills shall sing praise before it, and all the trees of the land shall clap their hands in approval of its humane purpose and efforts."

CHAIRMAN KOEHLER: We thank you for this very generous contribution. Gentlemen, I must ask that we defer discussion on Mr. Reynold's paper in the interest of time. We still have the paper of Mr. D. A. Scanlon. Mr. Scanlon is the General Superintendent of Railways, Northern Ohio Power and Light Company, of Akron, Ohio.

One-Man Car Operation from a Safety Viewpoint

By D. A. SCANLON

General Superintendent of Railways, Northern Ohio Power and Light Company, Akron, Ohio

During the past decade, the cost of furnishing electric transportation has steadily increased and during this same period practically all operating companies have faced serious competition from both the independent bus and the individually owned automobile. Of the two competitors, probably the latter has been and still is the greater menace to the very life of the electric railway business.

Many railway companies have practically overcome bus competition through the acquisition of independent lines. This has been accomplished usually at a tremendous cost to the operating company, whether the lines were purchased from independent operators or established by the company. A very substantial investment was necessary to inaugurate bus service. New buildings, equipment and workmen were required to operate this new phase of transportation, which a few years ago appeared to be more or less of an experiment. However, at the present time, there appears to be no question as to the necessity or permanency of the bus as a transportation unit.

Regardless of the expense involved in overcoming bus competition in many localities, it has been accomplished; but competition presented by the privately owned automobile has not been overcome by transportation companies. Present indications are that it cannot be overcome. Not only have we suffered the loss of revenue from fewer passengers carried, but we have been seriously handicapped by the very instrument which has taken our business. Traffic congestion in many of the larger municipalities has become so acute that it is almost impossible to operate a passenger carrying vehicle, whether car or bus, with any degree of accuracy or efficiency. This is another feature over which the transportation organization has very little control. In this connection, I might say I am convinced that operating officials, and particularly safety engineers, should cooperate very closely with local safety councils, city officials and chambers of commerce, in regulating traffic to the best interests of all concerned. I regret to say we do not have a local safety council in Akron, however our company is represented, through our safety department, in all activities in this direction and our problems have received favorable consideration through this contact.

I have mentioned briefly some of the major factors, particularly decreased revenue, which, to my mind, were the principal reasons for many railway companies inaugurating one-man car operation. During the past five or six years, most railway companies have established one-man car service to some extent. In a few of the larger cities the one-man car is operated only in sparsely settled districts, where few passengers are carried and traffic is not congested; however, the one-man operated car is proving its efficiency to such an extent as to justify its exclusive use in some urban centers. Not only has the one-man car proved successful in urban service, it is now being used exclusively on some interurban lines with a marked degree of satisfaction. An example of such operation is the line from Buffalo, New York, to Erie, Pa.; from Alliance to Canton, Ohio; from Akron to Wadsworth, Ohio; and from Canton to Massillon, Ohio. The last mentioned line

maintains a fifteen minute schedule during an eighteen hour day and operates at high speed. Automatic spacing signals are used and during the three-year period this line has been operated with one-man cars, we have not experienced even the slightest car collision, in fact, accidents of all types have been fewer than when operated with two-man cars. The Stark Electric Railway company, operating from Alliance to Canton, Ohio, reports a similar experience since changing to one-man operation. I have not received a report of the success of the Buffalo and Erie operation; however, from observation, having had occasion to inspect this system, I am personally convinced it is entirely satisfactory from both a safety and efficiency standpoint.

The Pittsburgh Railway Company started to operate one-man cars in 1926 and has since steadily increased this service and, according to its report, experienced a slight increase in the number of accidents per 10,000 miles operated as compared to two-man operation; however, it is also stated the company experiences fewer serious accidents with the one-man cars than with the two.

During the first half of 1928, as compared to the last year, this company reports the percentage of accidents per 10,000 miles operated as 2.93 per cent on one-man cars and 2.79 per cent on two-man cars. This slight increase is accounted for by the fact that most one-man cars are operated by conductors, who, for a period at least, are not experienced motormen or operators.

A very interesting report of successful one-man operation was received from the Houston Electric Company, Houston, Texas, showing the per cent of accidents per 10,000 revenue car miles operated for a four year period—1924 to 1927 as follows:

	One-Man per cent	Two-Man per cent
1924	6.33	7.71
1925	7.18	9.67
1926	7.24	8.79
1927	5.62	6.96

This notation was attached to the above comparison:

"We are completely sold to the use of one-man cars on this property and our plans are for the elimination of two-man operation as soon as possible. It is our opinion that an operator on a one-man car is more apt to avoid accidents through being kept busy, than with two-man operation which does not require both men to be alert at all times."

The Kansas City Public Service Company, (Kansas City, Missouri), while not submitting comparative statistics, reports a very favorable experience in accident prevention since the adoption of one-man cars.

The Wisconsin Power & Light Company, (Fond Du Lac, Wisconsin), reports as follows:

"It has been our experience in operating one-man cars to find that our accidents have been decreased; has made better operators of our men and has built up better relations with the public, due to the fact that all operators come in contact with the traveling public. Like other utilities, we have found a few minor objections to one-man operation, but on the other hand the advantages of operating them off-set the disadvantages and are the winner by far."

The People's Railway Company, (Dayton, Ohio), submits the following summary of its experience in one-man operation:

"This summary includes figures from the City Railway, Peoples Railway, Oakwood Street Railway and D. & X., which are all of the local companies operating front entrance and rear exit one-man cars over various periods from January 1, 1922, to June 1, 1925. The accident figures were compiled for the periods that

these companies were operating two-man cars and then compared with the figures taken after the respective companies had inaugurated one-man operation. Over the period of two-man operation, the accidents were 413.502 per million car miles and 50.277 per million passengers. For the period of one-man operation, the accidents were 368.822 per million car miles and 48.817 per million passengers carried; showing a decrease of accidents in favor of the one-man car period of 10.8 per cent per million car miles and 2.91 per cent per million passengers."

The Gary Railway Company, (Gary, Indiana), reports as follows:

"Since the latter half of 1927, our property has been 100 per cent one-man operation and our number of accidents and incidents for the first six months of 1928 have been reduced over the similar period of 1927, with approximately 60 per cent one-man operation, from 479 to 315 accidents.

"It would hardly be fair to believe that this decrease is all due to one-man operation as we have constantly endeavored to reduce accidents by the installation of safety devices, safety programs and rigid safety discipline of trainmen.

"The important feature of one-man operation from a safety standpoint is that all one-man cars should be equipped with every known safety device. We know of no accidents on our property that can be attributed to the one-man operation of cars.

"We have also found that on an average, conductors make better one-man car operators than motormen.

"Operating at present 100 cars over 250,000 miles per month with an average of 5,180 miles per accident for the six months of 1928, it can safely be said that one-man operation has materially helped our accident record."

From the Virginia Electric and Power Company, (Richmond, Virginia), where a mixed service is maintained, came the following summary of the company's experience for the year 1927:

City of Richmond—Population 203,000

Total car miles operated.....	7,958,231
One-man miles operated.....	5,665,377
Per cent one-man miles operated.....	71.19%
Two-man miles operated.....	2,292,854
Per cent two-man miles operated.....	28.81%
Total number of accidents.....	3,106
Number of accidents one-man cars.....	2,141
Per cent of accidents one-man cars.....	68.93%
Number of accidents two-man cars.....	965
Per cent of accidents two-man cars.....	31.07%

City of Norfolk—Population 188,000

Total car miles operated.....	5,070,554
One-man miles operated.....	2,998,440
Per cent one-man miles operated.....	59.13%
Two-man miles operated.....	2,072,114
Per cent two-man miles operated.....	40.87%
Total number of accidents.....	2,517
Number of accidents one-man cars.....	1,414
Per cent of accidents one-man cars.....	56.18%
Number of accidents two-man cars.....	1,103
Per cent of accidents two-man cars.....	43.82%

"The conditions of operation are about the same for both one and two-man operation. All lines of importance in both cities enter or pass through the congested business area."

On the property I represent, we are operating one-man cars exclusively in three cities, namely, Akron, Canton and Massillon, and also on two suburban lines, serving an aggregate population of approximately 500,000, and generally speaking, we have found such operation advantageous from every viewpoint, particularly in the reduction of the number and seriousness of our accidents.

Many mechanical safety devices have appeared since the advent of one-man cars which have contributed to their safe operation. We have placed flood lights across the entire front ends of our equipment which have materially reduced head-on collisions with other vehicles. Ratchet gongs have been installed on all city type cars. This has proved an effective safety measure. All cars have been equipped with automatic treadle exit doors which lends greatly to maintaining schedules; in fact the treadle doors, which operate only when brakes are set and power off, have eliminated entirely the possibility of passengers falling from moving cars. With the two-man operation this class of accident presented serious possibilities. There is, however, some danger of passengers being caught in the automatic doors and we have found this a rather difficult hazard to overcome. Elderly and feeble persons are prone to cling to grab handles or door casings and are struck by the closing door. Women accompanied by small children are sometimes struck by the doors because they lift the child from the treadle after they have alighted. The weight being removed, the door closes *before* the child is clear. However, this condition can best be controlled by the operator, who is thoroughly instructed to watch the alighting passengers by means of the rear vision mirror, locking the door open whenever there appears to be danger of it closing on them. Our door accidents are continually decreasing as the car operators and the riding public become more familiar with the operation. I can not say we experienced an increase in accidents of this nature since operating one-man equipment as door accidents were more or less frequent before that time. All cars are equipped with automatic power and brake control so that they can not be moved while any doors remain open.

Following is a summary of accident experience in City service on the Northern Ohio Power and Light Company's property during the past two and one-half years—1926 to July 1, 1928—indicating car miles operated and passengers carried per accident. All occurrences reported, regardless of whether or not they involve the company in any respect, are included in this comparison:

	1926	1927	1928
Total car miles operated.....	5,649,518	4,918,739	2,461,314
Total number of accidents.....	3,165	2,208	843
Miles operated per accident.....	1,785	2,228	2,920
Percentage of accidents per 10,000 miles operated.....	5.60%	4.49%	3.43%
Total passengers carried.....	37,533,989	33,382,497	16,505,425
Passengers carried per accident.....	11,859	15,119	19,579
Percentage of accidents per 100,000 passengers carried.....	8.43%	6.61%	5.11%

The above compilation indicates our experience prior to and after the installation of one-man service. The greater per cent of all operation in the year of 1926 was two-man, as it was not until the latter part of that year a few short lines were changed over. In February of 1927, the system was entirely converted to one-man equipment. I do not contend that the operation of one-man cars has, by

any means, been entirely responsible for the progress we have made toward safe operation. It must be considered as a contributing factor, however. In this connection, I mention a few major activities on the property I represent which have also contributed to our safety records.

We have a full time safety organization, under the direction of Mr. Shaw, which has carried on a very effective accident prevention program during the last six years. One feature of our safety work which has proven very beneficial is the awarding of gold safety emblems to men who operate a period of one or more years without being involved in an accident of any nature. During the past four years the safety department has compiled individual accident records and during that time 195, or 26 per cent, of all the men employed in road service have received honor badges indicating one, two or three years of continuous service without an accident of any description.

In addition to our regular safety meetings, daily posting of accident records in car stations, and the display of safety bulletins, we have established permanent schools of training for all car and bus operators. Each school is under the supervision of a full time instructor who stresses every conceivable feature of the transportation business which leads in the direction of safe and efficient operation.

I trust I have not tired you in giving statistics or in drifting away from the subject assigned. In conclusion permit me to make the assertion that from the experience of other railway organizations mentioned, and from my own experience and observation, I am thoroughly convinced that one-man car operation is practical, economical, and a matter of good business from a safety viewpoint.

CHAIRMAN KOEHLER: Mr. Scanlon, we thank you very kindly for having brought out these very interesting facts. Gentlemen, we again must ask that discussion be deferred until some later time.

ADJOURNMENT

October 3, 1928

A. W. KOEHLER, Chairman

**The Milwaukee Electric Railway and Light Company
Milwaukee, Wis.**

The second session was called to order at ten o'clock by the chairman, A. W. Koehler.

CHAIRMAN KOEHLER: The subject which will be discussed for us this morning is one that is particularly timely, and one that is intensely interesting to every one of us. We are exceedingly fortunate in having as our principal speaker a man who is eminently well qualified by reason of his intimate contacts with electric railway properties all over the country, having himself been the operating head of a sizeable company.

It is a privilege and a pleasure to introduce Mr. Lucius S. Storrs, Managing Director of the American Electric Railway Association.

Reconciling Increased Speed with Safety

By LUCIUS S. STORRS

Managing Director, American Electric Railway Association, New York City

While it always is a pleasure to attend a meeting of the National Safety Council, this year I am especially proud to be here and speak for the local transportation industry of the United States. The reason for my particular feeling of gratification today is that the industry which I represent has made a remarkable record in accident preventions during the last year. The electric railway industry long has been an active member of the National Safety Council and in season and out of season has firmly believed in expounding the gospel of accident prevention. Even when safety work was regarded lightly by many and scoffed at as theoretical, our industry "stood pat." Now, with figures to prove that intelligent educational effort finds its reward in reduced accidents, we are more than pleased to proclaim the facts of our success to the world.

Briefly, the electric railway industry during the last year has reduced its fatal accidents to one person in every 155 million carried.

In other words, a total number of passengers approximating one and one-third times the total population of the United States is carried in safety to every single passenger fatally injured.

Now, the electric railway industry is embarking on a new field of endeavor. It believes, and tests conducted during the last year tend to confirm the soundness of its belief, that not only can passengers be carried in greater safety but that the speed at which they are carried can be materially increased without adding to their danger. Later I shall cite the experiences in a score or more of cities which will prove that this theory of speed with safety is entirely correct.

The present top speed of electric railway cars in many urban communities is not in excess of 12 miles per hour. The average probably ranges somewhere between 8 and 11 miles per hour. It is only fair to say that many more companies make an average speed of 8 miles per hour than make 11.

The local transportation industry firmly believes that if it could increase the speed of its cars to approximately 15 miles per hour it would relieve traffic congestion, decrease accidents appreciably and add greatly to its revenues.

There can be no question that increased speed of public transportation would cause owners of private automobiles to leave their cars in garages in increasing numbers. The chief complaint that the electric railway man today hears from private automobile owners is that street cars do not provide a quick ride. This

undoubtedly is a just complaint and the reason for it is two-fold. Primarily, street congestion is so bad that electric railway cars cannot possibly attain high speeds in urban centers. Secondly, engineers have not kept pace with the demand for increased speed. The city car which can make 15 miles per hour in safety and comfort is not yet developed. However, engineers are working on this problem and doubtless they will solve it some time before collateral problems of traffic congestion are solved. None will deny that if the speed of cars were increased to 15 miles per hour, which is the average now attained by private automobiles in cities, that many motor car owners would be only too happy to leave their automobiles in garages and patronize public service.

While there are a score of cities in the United States which are proving daily that both increased speed and safety can be accomplished, probably the outstanding one is Chicago. Traffic congestion relief has been effected, greater speed attained and accidents decreased there.

That you may have first-hand information about results accomplished in Chicago, I am going to take the liberty of quoting a few remarks from Mr. E. J. McIlraith of the Chicago Surface Lines, with whose remarkable traffic engineering record all of you are familiar. In describing the Chicago situation Mr. McIlraith recently said:

"We have an average speed of operation for the surface railways in Chicago of about 11.3 miles per hour at the present time. There is no other city with which I am familiar—and I think I know most of them—which can approach that speed. That speed is actually attained as an average between terminals throughout the day.

"Now, with an average speed of 11.3 miles per hour we have a very low accident record, and I think you will agree that we have as busy streets and as narrow streets on the average as any other large city has to contend with. It is true that in Philadelphia the streets are individually in the central section much narrower but when used as one-way streets the actual space for traffic in that one direction is greater than we have for one direction in each street in a city like Chicago, and, in fact, in most American cities.

"If the speed we have obtained permits us to operate in so large a city with comparatively few accidents something must have intervened to prevent accidents and to permit the trainmen to be able to operate with the intense street traffic without getting into trouble. More than half of the Surface Lines trainmen in Chicago were able to go through an entire year without a chargeable accident, not without an accident, but without a chargeable accident. If, somebody runs into the rear end of the street car with an automobile that is not necessarily the fault of the motorman or of the conductor of that particular car. Having carefully classified our accidents we find that more than half of our men have been able to go through a whole year without a chargeable accident. Where the streets are as intensely used as we have them in Chicago, that means the coupling of increasing speed and accident prevention; this may not be so difficult as many people think.

"Speed can be kept high, traffic can be kept moving and accidents may be prevented if the proper attention is given to the right things. Therein lies your problem namely, discovering what it is that prevents accidents and what it is that motormen and conductors should do on the streets. It calls for a careful analysis of the details of the management job, for getting down to the men's problems, knowing what they are doing, seeing that they understand what you expect of them and that they know what you expect them to do.

"Too many railways send out their operators, after training them for a week or two in a school and then dare them to learn how to be good motormen."

"A special survey of the industry which I have made to bring the facts for this paper up-to-date reveals that virtually every large company in the country is showing increased speed and decreased accidents. There are of course, exceptions to this rule, but in most cases there are special reasons for these unusual situations.

If you will bear with me, I shall deal in alphabetical order with reports from these various outstanding cities, giving you the high lights of what is being done in them toward furthering the increased speed and safety movement.

Over a five year period from 1923 to date, the speed of cars in Atlanta has increased about six-tenths of a mile per hour, or from 9.18 to 9.75, and accidents have been decreased approximately 25 per cent. It is notable that in 1926 the speed in Atlanta did not increase, but accidents increased appreciably. This was due to the introduction of a new type of car with which the motormen were unfamiliar.

"A man operating a fast schedule realizes that his entire and undivided attention is required and he is more on the alert and therefore more apt to anticipate traffic and other hazards of operation," says Frank H. Butler, vice-president of the company.

The Union Traction Company of Indiana, a high speed inter-city line, says that recent increases in speed have not caused increased accidents.

The Baltimore situation is most interesting on account of the highly congested, narrow streets of that city. While speed there has increased only slightly during the last year, the company has been able to decrease collisions between motor cars and traction cars by approximately 13 per cent. An interesting feature of this situation is that the inauguration of skip-stops was followed by a decrease in accidents at points where accidents had occurred before the skip-stop system was installed.

Birmingham, Alabama, has found it possible to increase speed from 9.6 per mile an hour to 10 miles an hour and, coincidentally decrease the cost of its accidents for its last fiscal year. This city shows an increase in the total number of accidents during the last year, but this is declared to be due to the fact that a number of minor accidents of a character previously ignored were reported. It is interesting to note that this company has not had a single fatality in recent years. Intensive safety work among the employees is credited with bringing about many favorable results.

The International Railway Company of Buffalo, rapidly is rolling up an enviable accident prevention record. During 1927 the company showed a reduction of 15 per cent in accidents of all kinds as compared with 1926. During the first six months of the present year the reduction over 1927 was in excess of 31 per cent. No material change has been made in speed on this company's lines owing to the fact that recently the type of car has been changed and the motormen have not been wholly familiar with the new equipment.

The Chicago, Aurora & Elgin inter-city lines maintain a speed of 45 miles per hour between terminals and yet in the face of this it has been able to decrease accidents recently. Its 1927 decrease was 5½ per cent. The greatest change was shown at crossings where decreases were brought about by the installation of better protection.

The Chicago, North Shore & Milwaukee line, winner of the electric traction speed contest in 1927 with a record of 41.8 miles per hour between Chicago and Milwaukee, has not had a single passenger fatality due to a collision in the last eleven years. The speed with which this company won the electric traction trophy was an increase of six miles per hour over 1920.

Likewise, the Chicago Rapid Transit Company, which operates the elevated lines, has not had a passenger fatality during the last five years. During this period the speed of express trains on the line have been increased from 16.6 miles per hour to 19.7 miles per hour.

I now want to make reference to another large city property without naming the city and for very peculiar reasons. The president of the company is superstitious regarding accidents. He believes that when you are making a good record you should keep quiet about it and that touching wood, consulting a voodoo doctor,

or carrying the left hind foot of a rabbit captured in a grave-yard in the dark of the moon, will not prevent accidents if you talk. However, he has permitted me to say that in his city, with a population of more than 500,000, he was able last year to decrease his accidents 10 per cent. This record also was made with an increased speed.

The Connecticut Company, operating practically all local transportation service by electric railway and bus lines in Connecticut, decreased its accidents approximately 5 per cent during the last year. Its greatest decrease came in collisions with motor vehicles. It had no passenger fatalities.

Speed on the Texas Electric Railway of Dallas, an inter-city line has been increased somewhat without increasing accidents. The Dallas Railway & Terminal Company increased its speed about one-third of a mile per hour during the last year. It had no fatalities to passengers and the cost of accidents in per cent of gross revenue was lowered appreciably.

Denver Tramways stands well out in front in this new movement. Over a seven year period cars have been speeded up approximately one and one-half miles per hour and accidents cut approximately 50 per cent despite a doubled registration of automobiles.

James P. Tritton, Superintendent of the Indianapolis Street Railway, joins Mr. Butler of Atlanta in declaring that he finds men who run cars at high speeds pay more attention to their duties than others. This company has increased the speed of its cars approximately one mile per hour during the last year.

Omaha cars have been speeded up approximately five per cent and accidents decreased during the last year. None of eight fatalities was attributable to increased speed.

Accidents have decreased steadily during the last five years on the Pacific Electric Company lines. In 1923 the total number was approximately 10,500 and this year a total number will not exceed 6,000 or a reduction of more than 40 per cent.

Los Angeles has found it very difficult to increase speed on account of the rapid growth of the city. Stops are becoming more frequent due to the development of outlying sections. Only limited train service, in the opinion of D. W. Pontius, General Manager, will make reduction in schedules possible.

The Louisville Railway Company, winner of the Anthony N. Brady accident prevention prize this year, reports the speed of its cars has been increased slightly during the year and fatalities decreased 300 per cent. Speed gradually is being increased on all lines and eventually faster schedules will be maintained throughout the city.

Public Service Coordinated Transport lines, of New Jersey, reports the introduction of a bonus system for employees has greatly reduced the number of accidents thus far this year over 1927. Public service territory is a particularly trying one owing to the vast increase in the number of automobiles used.

The local New York situation is one of the most interesting in the country both from the standpoint of speed and accident prevention. Surface lines in the greater city have made strenuous efforts to increase speed and decrease accidents. Brooklyn City Railroad has done stellar work by a bonus system for the men and safety talks. Companies on Manhattan Island have not been so successful. Congestion on this narrow strip of land is, of course, simply terrific and undoubtedly the time is not far distant when some radical measures must be adopted to relieve the chaotic situation. Meantime the Third Avenue Railway System is conducting a steady campaign against parking and other forms of traffic congestion and doing its utmost to decrease accidents. Undoubtedly in the long run this will have a good effect.

While we are on the subject of New York I want to say just a word regarding the safety of the subways. Unfortunately, in recent months, the Interborough

Rapid Transit Company had an accident during the rush hours. It was due to circumstances over which executives could not possibly have had any control. Despite this accident, which resulted fatally to eleven persons, the subways remain the safest railways in the world. It was interesting to note in connection with this unfortunate circumstance that most of New York's daily newspapers, which cannot always be called entirely friendly in their attitude toward the company, were extremely fair. They pointed out that such accidents are bound to happen on any common carrier and that they should in no way decrease public faith in subway travel.

Intensive safety work in Milwaukee has resulted in a decrease of 22 per cent in the number of persons injured during the last year. This company, like others, has not been able to increase its speed greatly on account of changing the type of cars. Greater speed undoubtedly will be shown as men become accustomed to the new form of equipment.

Analysis of the accident record of the New Orleans Public Service, Inc., shows the total number were decreased more than 15 per cent during 1927 and 1926. There were no passenger or employee fatalities during the entire year.

Providence is another city where traffic congestion seems to practically preclude increased speed for the present. However, the company through intensive and highly intelligent accident prevention work, has succeeded during the last five years in decreasing its annual number of accidents more than 40 per cent.

Washington, D. C., presents a peculiar situation. The capital of the nation has broad streets and many families containing several wage-earners. As a result, the average number of automobiles owned is exceedingly high and traffic congestion is as bad probably as in any city in the United States. In the face of this situation the achievement of the Washington Railway & Electric Company in increasing speed on its lines three-quarters of a mile per hour during the last year was remarkable. A slight increase in the number of accidents is shown, but a statement from the company says that these were not attributable in any way to the increased speed. The Capital Traction Company reports that it is hopeful of accident prevention work in Washington in the future, although the present does not show a great deal of change. A safety campaign early last year resulted in decreasing collisions between motor cars and the electric railway cars about 20 per cent.

Conditions are improving in St. Louis, and to anyone familiar with the local situation there, this is encouraging. Probably no city of its size in the United States needs an untangling of its traffic problem more than St. Louis. The downtown streets are narrow, parking is allowed for limited periods on many of them, and traffic control is poor indeed. A better lighting system and more officers to handle traffic are badly needed. In the face of this it is virtually impossible for any transportation company to increase speed. However, the company has shown that accidents can be decreased by intelligent work. During the last three years the total number of accidents per million car miles has been decreased from 429 to 410. In S. W. Greenland, general manager of the company, the safety movement has a firm and enthusiastic friend, however, and I am sure that if it is humanly possible for the speed and accident prevention record to be bettered during the next year, Mr. Greenland will bring it about.

A letter from C. V. Wood, president of the Springfield Street Railway Company, throws an interesting sidelight on what happens to speed when buses are substituted for high speed rail lines. He reports that the average speed of his cars decreased in 1927 due to the fact that most of the high speed interurban lines were discontinued and buses substituted. He finds that the new light-weight car, a notable addition to the Springfield service during the last year, can be operated through streets with greater speed and equal safety. This property has had no fatal accidents to passengers in recent years.

The higher speed movement is well in hand in San Francisco where the Market

Street Railway Company operates. Mr. M. McCants, vice-president in charge of transportation, recently wrote me that he was speeding up his entire service. He is an enthusiastic devotee of both increased speed and safety and believes that they go hand in hand.

I have given you, rather sketchily I fear, a cross-section of the speed and safety situation as it exists today in the electric railway field. To summarize it very briefly I should say that, with a few notable exceptions, local transportation companies generally are speeding up their cars and making better accident prevention records. I am hopeful that within the year such progress will be made in mechanical equipment that we can report to you that we have greatly increased our speed and decreased our accidents at the same time.

We in the electric railway field know where the chief credit for our great safety record belongs. It belongs distinctly in the ranks of our employees who are running our cars today with greater safety than ever before. Credit for arousing their enthusiasm in accident prevention should go, of course, to executives, but if the industry had not been possessed of a body of loyal, enthusiastic men, anxious to do their very best to prevent human suffering, this record never would have been achieved.

Many friends of our industry have said many kind things in recent years regarding our accident prevention work. We are appreciative of all this, but we want to assure all that merely because we have made a good record in the past and have done much toward carrying forward the movement, we have no intention whatever of resting on our oars. We want to be increasingly active in this great work and are ever ready to carry on our share of any assigned national or local task.

I want to say that several years ago, Mr. Nicholas F. Brady, son of Anthony M. Brady of traction fame, established, in memory of his father, an annual award to the electric railway that conducted its affairs with the greatest degree of safety during the preceding year. I know of no one thing that can do more to improve public relations in any particular community than the recognition of an industry at large of the outstanding accomplishment of that one particular property.

We have of necessity, for many, many years, had to tell our hard luck story to the public. We have tried to impress them with the problem. We got into the condition of being considered—not a yellow cur, but not a very highly esteemed citizen in the community. It got into our own organization. We were rather apologetic of our job at that time. Fortunately, that is long since passed, but the attitude of the public, the public mind hasn't entirely in many communities changed.

If, however, in any one of those particular communities, the company could by its achieved high record, obtain recognition national in its scope by such a thing as this Brady Award, it does do, I know positively, a very great deal toward changing the entire public situation. Fortunately, our properties were entered in the contest before the war, and received the Award. We made the maximum use of it in all of the cars in general throughout the county, didn't we, Mr. Jordan? The result was, it was the one thing from which we started a change in public attitude.

This Award was discontinued during the period of the war. In the meantime, Mr. Brady had become dissociated from the traction and of public utilities. He had gone into the power and lighting end, but I prevailed on him a year ago to reinstate the Award. Prior to that, there was one award given, a gold medal (a silver replica to the officers and a bronze replica to the employees). In order that it might be more inclusive and give more people the opportunity to accomplish something, he conceived the idea of dividing the companies into three classes; those of large cities with maximum vehicle mile operations, medium sized cities, and small cities with small vehicle mile operations; so that the smaller and medium sized cities might have as good an opportunity to get an Award as the larger cities.

The gold medal was to go to the large city, the silver medal to the medium sized city, and the bronze medal, to the small city.

That Award was granted this year, as of last year's operations. Much to my disappointment, only seven contestants appeared as claimants. They divided themselves between the three different classes. I told Mr. Brady, or conveyed word to him, that it was merely a starter and if we could continue, that I was quite sure he would find that the industry as a whole would recognize the opportunity he was affording. This year (and the contest was supposed to close October 1) four contestants entered, all of them in the one class.

Now, you are overlooking something. I hope very much that some of you may be able to prevail on your executives to wire in that you want to be a contestant in your particular class. I am quite sure we can prevail on Mr. Brady to extend the period of time for entrance up to October 15. The presentation of your claim is a very simple thing. It is taken care of entirely through the American Museum of Safety.

If you should not get the award, it perhaps adds a little bit more to your desire to improve your condition. Some man whom you hadn't thought of as being a little better than you, may get the award. The next time, you will try to be a little better than he, perhaps. I think that an industry that is doing so much in the matter of public safety ought to recognize this opportunity that exists right in their own communities. I feel very keenly about that and I wish there were some words I could use that would prevail on a larger group to enter the contest.

CHAIRMAN KOEHLER: We are exceedingly grateful to you Mr. Storrs, for having discussed for us this very vital problem on reconciling increased speed with safety. I know that in the majority of minds, there are many questions.

G. T. HELLMUTH (Chicago North Shore and Milwaukee R. R., Chicago, Ill.): I should like to ask Mr. Storrs whether the Award is open to electric interurban railways, or only to city railways?

MR. STORRS: Every kind of electric railway property in the world.

H. P. ASHWORTH (Pittsburgh Rys. Co., Pittsburgh, Pa.): Mr. Storrs made the statement that motormen are sometimes put on the job and then they trust to luck. I would like to ask how the men are trained—according to the ability they show, or are they given a certain fixed period of instruction.

MR. STORRS: I think that is an individual question, almost entirely. Some men can get their feet on the ground quicker and know what their problems are quicker than other men. There is a certain psychology about it. I think it is up to the man's immediate superior. I merely said a great many motormen are given cars and are dared to become good motormen.

MR. LYNCH (Director, Kansas City Safety Council, Kansas City, Mo.): When I have met Mr. Storrs previously in other gatherings, we have been friends. I told him this morning that friendship ceases, because he is here with his own gang, and that I would see if I couldn't start a battle right here in his own home-town.

This matter of speed and safety of the street railway is a very serious problem, I think. In the first place, I would like to say that I can see no reason from Mr. Storrs' presentation, why we should accept the conclusion that increased speed will make safer operation. Mr. Storrs brought out nothing which would indicate that there has been any change made which would make safer operation at higher speeds. In other words, what I mean is that these same properties, so far as I can see, would have had still better safety records had they not increased their speed. Mr. Storrs has given nothing to make us believe this increased speed has made it safer. He pointed out one property that has had a big reduction without increasing its speed. So, let's don't be confused in this issue here.

Now don't misunderstand me. I don't want to say that increased speed cannot be

obtained and still reduce our operating accidents per million car miles, or on whatever basis we care to establish our contest.

I do have considerable sympathy with the street car people as a safety man. If we can get more people to ride street cars than are riding motor cars at present, our record of accidents to street users will be better. The thing that I have in mind here this morning is, what has the street railway done particularly to make the operation of cars at higher speeds safer? I was hoping Mr. Storrs would tell us some of the things that he has done.

The training of the men naturally is a very important item for safe operation at any speed, if you please. The question of man failure, of course, can be found in industry. As a matter of fact, perhaps 70 per cent of the causes of accidents are due to man failure. Equipment failure also enters into it in industry. I can see no reason why equipment failure shouldn't enter into it as well in the street railway problem. I wonder if we shouldn't consider some of our operated equipment and see if it is as safe as it could possibly be made.

MR. LYNCH: I wonder if this matter of right of way is receiving the proper attention. Getting down to a concrete example, Mr. Fennell said yesterday, he wondered if the street car, by slowing down at intersections, wasn't really breeding a contempt of the street car at those intersections. I agree, perhaps that is so. I don't like to call it contempt. I think what actually is happening in the minds of the public is that you are developing (in the mind of the motor car driver) the fact that the street car can stop if the operator sees the motorist.

The psychology of it is this; the motor car operator, not ever having been a street railway motorman, doesn't know how far a street car has to go before it can stop. Motorists assume a street car can stop as quickly as they can after they see each other at the intersection. The motorist approaches the intersection, and he is in the habit of seeing the street car come up slowly in order to make sure to be able to stop. He then begins to assume that a street car can stop anyway.

Why don't we educate the public in the distances required for a street car to stop, at 20 miles per hour, for example? I tell you, they have no conception of the distance that it takes for a street car to stop. It takes a motor car going at 20 miles per hour with two wheel brakes, 27 feet to stop. They can do it with four wheel brakes in some 22 feet at 20 miles an hour. I believe it takes a street car at 20 miles per hour, some 140 feet to stop. I may be wrong on that. You street railway people all know what it is, I assume. I wonder how many of you do know how far it takes? I won't ask you individually, but the public should know about it.

This question of the right of way came up down at the Hoover Conference. Mr. Storrs will bear me out. I was pleading for the street car to have the right of way at intersections. They wrote it into the model municipal code that way, that the street car would have the right of way at the intersection. I went a step further and asked, "When does the street car enter the intersection?" I claim the street car entered it whenever it was close enough to the intersection to make it mechanically impossible to stop the car without going across the intersection.

The men said, "Well, when is that?"

I said, "140 feet back from the far side of the intersection, at the average running speed of 20 miles an hour."

Then, the automobile men and insurance men who were there threw their hands up and said, "What do you mean, the motorist must stop when he comes to a street railway track?"

I said, "I am only interested in safety on the streets."

My idea is that we must either make the motorist stop by legislation or we must educate him to such a point that he will stop, knowing the hazard he is facing when he approaches a street railway track at an intersection. It would be foolish to put the regulation into effect that an automobile must stop when approaching a

street car track, without some education. We have found for many years that unless an ordinance was apparently equitable, it was not self-enforceable, and if such a thing isn't possible, there is no need in writing it into the record.

The whole thing that I want to make a plea for here today is, that we study our equipment, make sure that the street cars are equipped for the safest possible operation. Then, conduct an educational campaign in your communities so that the people will realize the operating conditions of the street car, so that they will realize how far from the intersection braking power must be applied for a street car to stop. You might carry on a little campaign in your car cards as to how far it takes a motor car to stop going at 20, 30 and 40 miles, with two and four wheel brakes. Twenty-five out of thirty motorists think they can stop at those rates of speed with four wheel brakes within one car length of their motors. I have heard them testify in court that they could do it. We know it is absolutely impossible to do it. If they don't know anything about the motor car, they know much less about the street car.

Then, we should find out for ourselves what the street cars can do, taking them out and testing them. Take a loaded car and take a light car with your maximum air brake main reservoir pressure, or whatever you call it. See which gives the best brake, we will say. Then take that same car out, put a dead load in it with a minimum governor setting, and see what your distance is. Then see if those figures are what you want to tell the public. That motorman knows nothing about how far it takes to stop without counting his passengers and looking at his air pressure.

I say a lot can be done yet, inside the industry about the equipment, and through propaganda to the public in order to create the proper respect that the street car deserves upon the street. I say it deserves respect because it is limited in what it can do. Before we speed up, let's get that respect established by propaganda to the public.

T. G. BRABSTON (Birmingham Electric Company, Birmingham, Ala.): I am speaking as a representative of the street railway and as an ex-president of the local Safety Council, so that I am viewing this thing from two distinct angles. In the first place, this question of safety—the best proof of it, as with pudding is in the eating of it.

I have two twenty mile lines down there about which I would like to say something. This gentleman should take into consideration the fact that when we say "schedule speed," we don't mean free running speed, but we mean speed between terminals, including all service and passenger stops. On those lines I have a schedule speed of 13 miles an hour, and those lines have consistently run from 30 to 40 and 45 thousand miles per chargeable accident. I think that is one of the best indications of what a line can do that you can find. These lines are partially suburban, partially city. I have two other lines from which the schedule speed varies during the period of the day, from 11¾ to 12 miles an hour, and are mostly in traffic. Those lines, before the speed was increased, had about 9¾ to 10 miles per hour. Since that speed has been increased on those lines, the chargeable accidents on them have been reduced practically 50 per cent.

Of course, there is among our colored population down there, an exchange of comments on the operation of these cars. They are the 65,000 pound cars. They don't stop readily or easily. The colored folks say, "Boss, when you hears dem motor cars say 'peep peep' you better step on the brake, 'cause they ain't going to stop."

That doesn't mean these fellows are going to recklessly go down the line trying to hit everything. As the record shows, accidents have been reduced 50 per cent, but the public has learned, when a 65,000 pound unit is coming down the street at a fair rate of speed on a well defined rigid track, it isn't going to stop as quickly

as an automobile. Naturally, the weaker vehicle must pay some deference to the heavier one.

In respects to the matter of braking and stopping, I think the average street railway man will bear me out when I say that there is no car probably anywhere in the United States that has a 100 per cent braking efficiency from a mechanical standpoint. I don't mean by that, that they have defective brakes. No man who has run a car at a rapid rate of speed is going to complacently stand on the front end of the car and handle it if the brakes are no good. No operating official, no superintendent or no railway is going to permit a car to remain in service on which the brakes are not effective. I say if there are such institutions, that they are way behind the procession in maintaining the highest possible braking efficiency.

On the other hand, when you talk about stopping automobiles, brake tests conducted under the direction of the Safety Council, not only in Birmingham, Alabama, but in the average city, will develop the fact that from 60 per cent to 80 per cent of the automobiles on the streets are entirely without brakes, or with brakes working under such unequal braking effectiveness, that any record as to the distance in which they are going to stop is merely theoretical.

The greatest trouble we have in automobile collisions in Birmingham, is due to a beverage down there known as Shelby County Corn; and a mixture of that with gasoline and a nut at the wheel, usually results in a collision. That tells the story pretty generally all over the country. The great trouble with the street railway industry has been that they have apologized for their presence on the street and have not maintained the speeds and the preference to the heavier vehicle. They have perhaps emphasized the point of hitting no automobiles under any circumstances—the Alphonse and Gaston act when they came to a crossing. When you educate the public up to the knowledge that a car cannot stop, that it has a schedule to maintain and that it is going to pass on a rigid track, the automobile passenger or driver is going to give preference to the street car. That has been our experience, and we have endeavored to educate the public through the National Safety Council. As a result, we are reducing automobile accidents and collisions with street cars consistently day-by-day.

Just to give an idea of perhaps the psychological state of mind the people have down there: for the year up to date, we have had something like 990 automobiles sneak up behind street cars, slamming into them while they were either standing still or getting away from a stop. On the other hand, we have approximately the same number of collisions where motormen (accidents which we do not consider are chargeable to the motormen) collide because a car approaches from the rear of the street car and pulls out in front of it. We have those constantly.

I believe from my experience both as a director of the Safety Council and as an operator of 175 miles of railroad, that the necessity for educating the driver to the fact that the car is not always going to give him the right of way is a very important and potent factor in the prevention of accidents. The higher the speed, the greater respect the other is going to have. I don't mean we are ruthless in our instruction to motormen to hit automobiles or to have accidents, because they are taught to prevent them if it is humanly possible to do so. I pay a tribute to the man on the platform for his efforts in that respect. We have something like 40 men who have gone six and one-half years without having a chargeable accident during that time. More than 50 per cent of our 700 men have gone from 6 months to six and one-half without having chargeable accidents. Certainly that is a tribute to the man on the platform, who is doing the job.

DANIEL MAHONEY (Pittsburgh Ry. Co., Pittsburgh, Pa.): In regard to speed, we all recognize the necessity of speed. I believe that speed tells a man to be intensely on the job because of the hazard he is confronted with on account of speed. Now then, in order to carry on at this speed that we desire to have, cars should be equipped so that we can increase the speed going uphill. For, if we

have to depend on making our speed going downhill on narrow streets where automobiles are parked (sometimes within two or three inches from the track, where we merely pass them by a hair) it is extremely dangerous. If we have to depend on the grades downhill to make up our speed, speed is absolutely dangerous and it is criminal. If we wish to have speed, let the builders of the cars equip them so we can make this speed going uphill.

Our speed has increased in Pittsburgh just as in every other city. We are doing our best, and the men appreciate the fact that we must have speed. In the matter of braking equipment, we take a car out in the morning, and it is thoroughly satisfactory. Perhaps all you managers don't know this as well as the man who runs the car, but you can take a car out and work half a day, turning it over to the late man at four o'clock in the evening. The late man enters it. The emergency stops, naturally, have had an effect on the braking equipment. When I turn a car over to a man in the afternoon, he puts a trial or two on it, and his braking power has been reduced 50 per cent. I don't think there is any necessity for me to say any more, but what I advocate in speeding up the cars is to make the time in going up hill and not down hill where the cars are allowed to run recklessly in order to keep up with the schedule.

HENRY D. BAMBRICK (Pittsburgh Ry. Co., Pittsburgh, Pa.): Regarding speed, I know quite a lot about it, both on the railroad and in other places where speed is important. A great many motormen really don't know how to use air. When some motormen get into close quarters, they probably pick up 30 or 30 pounds of air without pulling sand. The consequences are, that the car is going to slide; by the time you have your air released and do what you should have done in the first place, the damage is done. I have been very fortunate myself with respect to freedom from accidents, because the barn foreman knows I will not operate a car unless it is perfectly right.

We have a great many one-man cars in Pittsburgh. Some of the cars have been converted. In the old days when they broke a man in, if he was not satisfactory after being placed on for a day with the early and late man, he would probably be given a job as a conductor. You can't take a conductor, and within three or four days, turn him into a first-class motorman. I want to say in all fairness to our own people, if more time and attention was given to training, they would get better results. I think it is to their own benefit to do so.

MR. POWELL (Louisville Railway Co., Louisville, Ky.): I would not have gotten up except for the benefit of Mr. Lynch. We have increased the speed in Louisville during the last two years. Two things Mr. Brabston didn't mention, and I want to speak of them for Mr. Lynch's benefit. One city line is 17 miles long to the round trip, all within a congested area, and it was having more accidents than any other line on our property, and I think that we are as safe as any body else. The Brady Award gives us that credit. I was chiefly concerned with this one line, so I increased the running time of 96 minutes to the round trip, to 90 minutes to the round trip. The accidents were cut in half the first month on that line, and we then increased the running time to 88 minutes for the trip, with still the same results. That line has been a winner of our monthly contest numerous times since. They are very proud of the fact that they carry the banner on their car house for about one-third of the months.

That is not all due to the increased speed at all, because before we increased that speed, we first started an educational campaign among the men in getting their support on what we were doing, and why. Then we put interlocking devices on all electric switches on that line, making it impossible for a man following to throw the electric switch under the car in front of him. We also saw that the intersections were repaired and put in good condition. Then we placed inspectors at the heavy loading points morning and evening to get the cars away quickly.

Another point I want to make is in the increased miles per hour. On our property we do not interfere with the present schedule time in the rush hours. We found by careful check-up and study of the line, with the decrease in riding in the daytime and at night which we experience in these periods, that it was possible to increase the speed considerably in the daytime and at night. We brought the miles per hour up to approximately 15 miles after eight p. m., which gave us a tremendous increase in the average miles per hour for the entire day. During the last six months, I have increased the speed to 15 miles per hour on five lines. The task I have as soon as I get home from this convention is to increase the speed on one of the major lines. I think we can cut the time down to 75 minutes and still get the Brady Award next year.

G. T. HELLMUTH (Chicago No. Shore & Milwaukee R. R., Chicago, Ill.): What about the use of the magnetic brake?

MR. POWELL: It would be a wonderful brake except for one reason—when the car goes over the switch a great many men use it and ruin it. Outside of that, it would be all right.

MR. SPECK (Pittsburgh Rys. Co., Pittsburgh, Pa.): In regard to increasing speed schedules, I would like to ask if they find it advisable to get out a crew of men to maintain a schedule or let the men operating those cars, see what they can do first? The reason I ask is, in Pittsburgh, we have a crew of men called "speed-up men." These men work a day now and then, and they might take chances where others wouldn't. I maintain that the man who is on the car under proper education with a proper knowledge of how to handle the car, will do better work than these so-called "speed-up men." I wonder what other properties are doing, whether they are picking their own men regardless of standing or anything else, and putting them on just for a day or for a trip. Do they ride along with them to find out what they are doing, or what? I claim it is more advisable to let the man on the car go ahead and see what he can do.

CHARLES GORDON (Electric Railway Journal, N. Y.): I don't like to see this discussion get into the minutes indicating the idea that electric railways are increasing speed with any inference that they are increasing the maximum running speed in city streets. That is not what we are doing, we are increasing the run-time. We can only do that in about three ways. First, through increased alertness on the part of the operator of the car; second, through starting the car quicker; and third, through stopping the car quicker.

Any of you men know that in city service, making seven or eight stops per mile, there is only one way in the world that you can increase the schedule speed outside of increased alertness on the part of the operator—either through starting or stopping quicker. I think Mr. Lynch's comment assumes, in a small measure at least, that we are talking about increasing the maximum speed of the electric railway operated on city streets. I think you will all agree that that is not what we are doing. I wanted to make sure that the minutes, at least indicate that thought.

E. HOLLIBAUGH (Pittsburgh Rys. Co., Pittsburgh, Pa.): I hear considerable discussion here of chargeable and non-chargeable accidents. I would like to know how they arrive at the decision in classifying accidents as chargeable and non-chargeable? We have not been able to settle that question in Pittsburgh. If we could just simply arrive at some sound conclusion and then analyze our situation, I think we would make a reasonably good showing there.

MR. HENRY (Pittsburgh Rys. Co., Pittsburgh, Pa.): That question Mr. Hollibaugh asks came up last year, and a committee was appointed to settle that.

CHAIRMAN KOEHLER: There are a number of companies who have adopted, I believe, the American Electric Railway Association's recommendation of designating chargeable and non-chargeable accidents. The Milwaukee Electric Railway, for one, has that system. The substance of it is this: the definition states that

any accident, which, by the exercise of reasonable forethought, foresight, skill, and diligence on the part of the operator, could have been avoided, is a chargeable accident. Please note the words "reasonable care, forethought, skill," et cetera. By the same token, any accident which, through the exercise of reasonable skill, forethought, and so on, could not have been avoided, will be called a non-chargeable accident. That leaves an opportunity for argument. You have to judge an accident on its merit. Every accident is just a little bit different. There are some accidents that are on the borderline. It wouldn't hurt our conscience to call them chargeable or non-chargeable. That type of accident falls within a class which we are bending our efforts to avoid. It is an accident perhaps that could conceivably have been avoided, so we let it fall into the chargeable class.

MR. HENRY: In other words, there ought to be a uniform standard.

CHAIRMAN KOEHLER: Yes. We went a step further than that in Milwaukee by establishing what we called a Reviewing Committee, composed of the assistant superintendent of transportation, general claim agent, and the safety director. Later, there were invited to these meetings, all of the division superintendents. All of the accidents in which there was any doubt were discussed so that everyone might have a word to say about them and so that there might develop that uniformity of judgment that is necessary to make that system a success. After that committee had functioned for about a year, it was discharged because there was no longer any need for it. Uniformity of judgment had been established. Consequently, the matter of chargeable and non-chargeable accidents, at least so far as Milwaukee is concerned (there are representatives here who will bear me out), is no longer a serious problem. We understand that what is chargeable in one division is chargeable in another. Any difference of opinion that may have existed is now gone.

H. O. ALLISON (Pittsburgh Rys. Co., Pittsburgh, Pa.): I am in a peculiar position. I have some twenty men here with me. In Pittsburgh, we have recently started to re-arrange our schedules in over-all running time. I didn't believe that Mike Lynch would start anything like that after he met me yesterday. I don't believe Mike has been long in the railway service, have you, Mike?

MR. LYNCH: I served as foreman of the carbarn under the superintendent of shops.

MR. ALLISON: That helps a lot. Anyway, we are good friends. I want to make reference to the Service Betterment report of the American Electric Railway Association. With the permission of Mr. Storrs and Mr. Lynch on that, I shall refer to what Mr. D. L. Fennell, General Superintendent of Transportation, Kansas City Public Service Co., Kansas City, Missouri, says in this report: "In increasing the over-all speed of street cars . . . it would also automatically speed up the flow of all vehicular traffic and thus make possible the still faster street car operation."

Again it says here, "In order to make this speech, we make these recommendations:

1. "By increasing the proportion of car-running time during which cars can move at maximum free running speed, and by making full use of such time.
2. "By reducing the time spent at stops.
3. "By installing superior mechanical equipment.
4. "By training car operators to utilize to the full, opportunities for increasing speed."

He says also, "lines of increasing time during which cars can move at maximum free running speeds:

"Reduction in number of passenger stops.

"Continuous motion at top speed (I think that is what Mr. Lynch referred to) between terminals is neither a practical nor a desirable idea, but reduction in the

number of passenger stops is not only feasible but is an important means of increasing speed of operation.

"In eliminating stops in congested areas, however, it must in all cases be remembered that here the short rider is found, and that if forced to walk in search of a stop he may continue walking to his destination.

"Stops to take on passengers can be reduced in number in two ways, (1) directly, by eliminating stopping points, and, (2) indirectly, by increasing service."

In the eliminating of stops and relocation of stops, it naturally means that all traffic can move more freely. Congestion is the problem of today. There is the skip-stop plan, stagger skip-stop, express street car and local bus operation, express street car and local street car operation, and also the reduction of stops by increasing the service. We have in mind the improvement of traffic conditions in the Service Betterment Report. You can improve the conditions if your car can run a greater distance freely.

I think probably that some operators get the idea that the thought is now, "You must maintain this speed of so many miles per hour continuously from the starting point to the destination." That is not so. It is in over-all running time. Our increase in speed in Pittsburgh does not amount to half a mile an hour. We are operating at some 9.02 miles per hour.

The greatest problem in the operation of street cars, of course, has come about through the use of the automobile. I think that these directors of local Safety Councils can help to reduce accidents and can help to relieve congested places if they will exert some effort to bring about a thought on the part of the automobile owner that the street car can be operated only upon the track, and if you will get the operator of the automobile to permit us to use the track when we are coming along there rapidly. Instead of doing that, they will park in front of us, alongside of us, cut alongside of us and then pull in head of us. In our educational work in Pittsburgh, we are endeavoring to bring about traffic regulations that will lead ultimately to that end. If we move freely, all traffic is also able to move freely.

Our men know that I do not object to what they say here or any other place on any subject that is brought up. These men do think for themselves, and they know exactly what they want to say when they get up on the floor to say it. They handle these things from their angle.

If we could bring about a situation or an understanding that will give all the operators the idea that speeding up is not going to mean reckless speeds in congested districts, but proper speeds in the over-all running, we will get the proper results. There are places where an automobile can move safely at 50 miles an hour. There are other places where it can only proceed safely at 10 miles an hour. In that manner, we want to increase speed. To refer to it as "speeding up" is entirely wrong.

I think too, that we have been the under dog. I would go so far as almost to echo what Mr. Storrs didn't want to say when he referred to the yellow dog. They have been taking care of automobiles and pedestrians at all points, even in the middle of the squares and intersections. We have been taking care of them too.

Now about the education of the personnel. We say to the operator of the street car, "If you see a motor vehicle approaching an intersection and you are in it, don't look toward him but go ahead, and then for his own self-protection, the automobile will not keep on coming." If the motorman looks toward the operator of a motor vehicle, nine chances out of ten, the motor vehicle will keep on coming and they will get into an accident.

We have the usual number of motor vehicles running into the rear ends of stopped cars and into the sides of cars, yes, even into the front ends. They do that frequently. There was a fatality on the Beaver Valley Line just last Satur-

day. A man drove right into the front end of a lighted street car. That may have been a mixture of "White Mule."

Two men who are with me are the chairmen of the safety committees of the various car houses. We have started one-man car operation more generally, and we started with what you have been referring to as "speeding-up." There has been a considerable amount of discussion on our property in that connection. It has been thought that it would increase accidents. As a matter of fact, minor accidents have increased, but as a matter of severity, they have *decreased*. That was with the first month of the operation. They are now on the decrease, all of them. I think if we do gain some little respect from the automobile driver on the speed problem instead of being kept back in the horse-drawn vehicle class, we will speed up all traffic. We will relieve congestion and we will bring about better operating conditions for the automobile driver and for the street car, and in that manner, we will reduce accidents. Free-flowing traffic does not have accidents. I don't think Mr. Lynch could dispute that. It is congestion that brings about the greater portion of accidents.

CHAIRMAN KOEHLER: I wish that the discussion might go on, but Mr. Storrs must get away. I am going to ask if he will summarize the discussion.

MR. STORRS: We didn't think we were going to start quite so much when Mr. Lynch and I framed this. I didn't intend to go into the particular mechanical details. I assumed everybody knew them. It is unthinkable that any organization would try a program of getting the cars operating at a less over-all time without going through three steps. In the first place, they have got to have the equipment so it will accelerate more rapidly.

(Mr. Storrs requested that his discussion be omitted from the record at this point.)

MR. STORRS: Equipment, then, is the prime essential. It is unthinkable that anyone would try a program without having that equipment so designed that it would accelerate and decelerate more rapidly. The main thing, of course, is the intensive training of the men who operate the cars. They must understand that the car is a new piece of machinery that they can't take out unless they have had the preliminary education that is so essential. Above all is the education or publicity given to the public of what it is all about, that free-moving traffic is what you are after. I think Mr. Lynch has been thoroughly answered, and the next time he gets into a row, he will, as usual, succeed in getting the answer for it.

CHAIRMAN KOEHLER: Gentlemen, our next subject is The Shop Employee's Contribution to a Safe Railway. This subject is going to be discussed for us by Mr. Harry Cordell, Master Mechanic, Chicago, North Shore & Milwaukee R. R. Company. I take great pleasure in introducing Mr. Cordell!

The Shop Employee's Contribution to a Safe Railway

By H. CORDELL

Master Mechanic, Chicago North Shore & Milwaukee R. R. Co.

The main spring of the complex industrial world of today is mechanics. Every industry, irrespective of what the product is, relies on mechanical engineering to find ways and means for greater, safer, and more economical operation. The railroad industry is no exception—here, if any place, is required super-intelligence, skill, foresight, quick thinking, accurate judgment, team work, and above all, the right mental attitude toward the safety of others.

Such being the case, the shop or mechanical department employees, contribute more toward the safe operation of a railroad than any other factor,

be that factor an individual or a department as a whole. Things and thoughts have changed. The shop department, or (let's be up to date) the mechanical department, was not considered a very important institution some decades back.

Most anybody could tinker around the old-time steam engine, with its simple construction as compared with the super-locomotive or the complicated electric car of today, or putter around the horsedrawn street car.

The transportation department in that era could and did reign supreme. The mechanical and electrical geniuses, however, could foresee the need of improved methods and more efficient and complex equipment was proposed and gladly accepted.

Being of a generous mind and aware of their limitations, the transportation men readily transferred the responsibility to maintain the equipment, to an organization whose personnel was especially trained along mechanical and electrical lines.

Another reason why the shop employees were, and perhaps are yet in some places, considered of minor importance is their lack of contact with the public.

We admit that there is nothing spectacular in our work or position. Hidden away from the glamour and refinement in which other departments work, being dressed in overalls against broadcloth and brass buttons, dirt, oil and grease, against immaculately clean hands and face, we still faithfully and uncomplainingly carry on, unmindful of the praise and compliments which are showered so bountifully on the men in blue when their passengers reach the end of the journey safe and on time.

You have seen the grape juice advertisement, "Don't thank me, thank Welch." This could be changed to a slogan something like this: "Don't thank me, thank the shop department," and be used in the trainman's reply to the patrons.

Sometimes our men, growing tired of the placid, uneventful life of the shop, venture forth and seek employment in the transportation department, taking with them the training and ability to observe and act, thereby greatly enhancing their new associates. But why paint the lily!

For fear of being considered an egotist, blowing my own as well as my department's horn too loud and long, I want to say that I appreciate the fact that all branches of work which go to make up a railroad organization, whether it be the transportation, track, overhead, traffic or mechanical department, have grown so complex, so interrelated, so interdependent, that safety and efficiency can only be obtained through complete unity in thought and action. This coordination is brought about by study, personal contact and observation.

Every employee on a railroad must feel and shoulder responsibility and consider his or her job as the all important one, on which depends the safety and welfare of not only himself, but his fellow employee, the traveling public, the company, and the commonwealth served.

The shop employee is particularly involved in this requisite. To foster such an attitude among the employees, leadership must be considered first. The foreman will show by his sincerity, his every act and order, well defined principles based on the predominating factor—safety.

He is not only a boss, but an instructor. His orders carry with them detailed plans which will carry the work through in a safe, speedy, and therefore economical way. Such a foreman meets his men with a cheery "good morning," starting the day right. The task completed, a word of praise, a compliment for work well done, thereby creating a desire for greater effort. This is our ideal foreman.

But what about this one? His orders carry an air of superiority and aloofness, which is not pleasing nor inspiring to his men. He assumes that everybody knows what is to be done. His short and tart reply to information asked is repelling to the men, who, rather than be admonished for apparent stupidity, proceed along wrong channels, where danger, waste and cost run amuck. Good men are held down because they might prove too conspicuous. No credit for work well done. Enter into a conversation with him regarding his work and you will find his store of knowledge is just as limited as is his capacity for leadership. The fallacy of retaining such a man in a supervisory capacity is self-evident.

The greatest good or evil comes from the inspiration the men receive from the foreman. As is the head, so is the foot!

The men under the ideal foreman will help each other by action and word of mouth. The older hands will show the new men the short cuts, the danger spots, and the way to become welded into the organization.

Will the men under the other foreman do this? No. They are copying their leader, afraid to show the new men the way, being themselves uncertain as to right or wrong.

In which of the two organizations will we find the minimum of accidents? Do you believe that the two above extremes will reflect into the equipment? Most certainly.

In no work that I can think of is willingness to instruct, help and counsel, of greater importance than in and around the railroad shop. We are all subject to that old bugaboo, man failure, and an omission of a cotter key, a nut, a pin, or other trivial part of the car, would, after the wreck, could it be clearly defined, answer many a surmised reason, forwarded by wiseacres, as to how it all happened.

Forgetfulness and carelessness are two of failure's jesting aids that always play pranks on folks. Forgetfulness sneaks around and stoops behind a fellow and carelessness walks right up in front and pushes him backward, while failure stands back and snickers.

Dare I say that many a man, due to lack of a friendly feeling toward his fellow co-worker, notices an omission or mistake and neglects to act? Yes, that is unfortunately true, and may exist to a marked degree, upon close analysis, in your own shop. What would cause that condition, you ask? There are many causes. It may be religious, political, racial, or just down-right cursedness and indifference, as to what may happen to the other fellow, the company, himself, or those whom we strive to serve and please; our customers.

Does a man of this caliber attend safety meetings unless held on company time? No. He has no time except for his own indulgence. Why does he work among men? Why is he not "stung" out by his fellow employees?

He is under foreman No. 1, where pollution is not tolerated, but thrives under foreman No. 2, polluting and putrefying the entire organization.

The esteem in which the operating department holds the shop employees depends entirely upon results, and is of the greatest importance. The public demand for unfailing service can be given only by the closest attention and inspection of the equipment.

The engineer or motorman must feel certain and at ease, implicitly depending on the apparatus to function unerringly. Starting with this feeling, promoted by past experiences, is it any wonder that the train is on time, customers satisfied and sold on the service? In order to obtain this enviable record a sound mind in a sound body is necessary.

Safety, the keynote to successful operation, must be the medicine freely dispensed by the attending physician (the safety engineer) and his assistant

(the master mechanic). The dispensary (safety meeting) must be well stocked with safety talks, pictures of operating hazards, experiences and suggestions, and large bottles of open and free discussions.

I will now mention a few of the diseases that play havoc with our safety body. I will also take the liberty of suggesting some remedies which may be found helpful.

Gout:

This dreaded disease finds an easy victim in the supervisory force.

Its first symptoms manifest themselves by stiffness in the joints, evidently making it impossible for the patient to find time to attend safety meetings.

Remedy: Send patient to the chief surgeon immediately (the general manager) for his diagnosis. If his findings show an acute state, an immediate operation may be necessary for the purpose of removing false mucus membranes (wrong attitude) after which the patient should rapidly recover.

Flat Feet and Fallen Arches:

Some master mechanics suffer from this ailment. It is an insidious disease which develops slowly.

The most pronounced characteristics of this ailment appear when things are going along nicely. The "old man" ceases to pry into details and lets good enough alone. Small defects, to all appearances of no importance, cause no indentation on the tranquillity of his mind. Gradual stagnation follows, which unless stopped, may prove fatal.

Treatment: The chief surgeon (general manager) may analyze this case as a bad case of self-satisfaction. For this he may prescribe the cure all, work. He may also prescribe trips of inspection to other properties, attending conventions, reading of magazines and journals pertaining to the maintenance work.

The antidotes mentioned should, unless disease has progressed too far, raise the patient out of the lethargy and to a realization that as long as the wheels turn progressiveness and initiative are required.

Tetanus or Lock Jaw:

This disease affects the attendance at safety meetings. It seems to assume the proportion of a pestilence in large groups. The most versatile among the men before or after a safety meeting, will be found stricken with the disease as soon as the meeting is called to order.

Treatment: A mild enema in the form of coaching, from the chairman may effect relief. A good story may act on the restricted area and bring about an abundant flow of saliva which may loosen the jaw. Once relieved, care must be taken that patient is kept in good humor and encouraged and complimented for his contribution.

Neurasthenia:

Long dull safety sessions bring about a bodily unrest which seriously interferes with the effectiveness of the meeting. This malady may affect even the best safety men, and is first noticed by shuffling of feet and chairs. As the trouble progresses, yawning and stretching follows.

Remedy: A real chairman who knows how to conduct a meeting. Live subjects and interesting talks—not the long monotone kind. A cigar or two lends a charm to the occasion. Diversified programs, and a little (not too much) entertainment to keep up the spirit of the patient, will affect an improvement and final cure.

Odema or Dropsy:

This is a serious affliction, and appears mostly while men are at work. For some unknown reason tools and material are permitted to fall causing injuries. Then again, it becomes chronic, and is evidenced by dropping material removed any old place, forming tripping hazards and it results in a general bodily disorder commonly known as "poor housekeeping."

The disease, unless checked, will become contagious and spread to the car equipment—bolts, nuts, brake rigging, motor parts, covers over electrical units, etc., will drop off the car, causing great hazards and delay to service.

Remedy: As this is a mental disease, the master mechanic should be the

attending physician, rather than the safety engineer. A consultation with the interne (department foreman) of the ward where patient works is first in order. It may be found that the trouble rests with the foreman rather than with the man. If this is the fact, a stimulus may be applied in the form of a good plain talk. This will act as a tonic and a general improvement will be noticed.

Again, it may be necessary to lecture on hygiene to the entire department. Isolated cases will call for individual dispensation, and if remedies applied have no effect, an amputation must be resorted to. This generally cures the disease.

Hoof and Mouth Disease:

This most dreaded disorder attacks the safety engineer, as well as the men. It is a serious sickness as it interferes with the routine of work, and the sufferer neglects to do his part. The most of us can only do one thing at a time and do it well. Concentration is impossible when a bedlam of voices is piercing the air.

The other counterpart of the disease is walking. Visiting from one department to the other affects the morale as well as the output. The close schedule

in which car equipment is inspected and maintained, calls for attention to business and that only.

I feel, without fear of contradiction, that hoof and mouth disease (walking and talking) can well be assigned to political demagogues and other non-producing individuals.

Treatment: The medicine applied to Odema or Dropsy will affect a cure as far as shopmen are concerned.

Medical science has not, as yet, discovered a serum that has caused even a slight improvement, when the disease attacks the safety engineer. As this scourge is spreading, I hope some one finds a way to at least check it.

In conclusion, may I just say that we in the shop department realize the important part we play and that our contribution to a safe railway, in a condensed table, consists of the following ingredients:

Knowledge of work	50 Parts
Cooperation	25 Parts
Constant Vigilance	25 Parts
Total	100% Safety

CHAIRMAN KOEHLER: Mr. Cordell, I am sure we are all impressed by your display of knowledge of the medical profession. We knew you were an able master mechanic, but I don't believe any of us were aware of all this latent talent which you possess. I know there will be a great deal of discussion, but there is not sufficient time to give justice to it in the few minutes that remain. We want to hear the report of the Nominating Committee.

I am going to ask Mr. Hellmuth now if he will present the report of the Nominating Committee, of which he is chairman.

Report of Nominating Committee

G. T. HELLMUTH (Chicago, North Shore & Milwaukee R. R., Chicago, Ill.): Mr. Chairman and Fellow Members of the Section, the Nominating Committee consisted of Mr. R. W. Emerson of Cleveland, Mr. W. H. Boyce of Pittsburgh, and myself. We made up a list of officers of the section, and our considerations were based on their service to the section and on their ability to serve the section. We have given this matter very careful consideration, and now have this ticket to present to you:

Chairman, E. K. Eastham, St. Louis Public Service Company, St. Louis, Mo.

Vice Chairman, H. K. Bennett, Manager, Providence Safety Council, Providence, R. I.

Vice Chairman, Melvin W. Bridges, Chicago Rapid Transit Company, Chicago, Ill.

Vice Chairman, Glenn H. Shaw, Northern Ohio Power & Light Co., Akron, Ohio.

Now, Mr. Chairman, if there are no other nominations, I shall move that the nominations be closed.

H. O. ALLISON (Pittsburgh Rys. Co., Pittsburgh, Pa.): I second the motion.

CHAIRMAN KOEHLER: The motion has been made and seconded. What is your pleasure, gentlemen?

(The question was called for.)

CHAIRMAN KOEHLER: All in favor of accepting the report as read will signify by saying "aye"; contrary-minded by a like sign. It is carried.

MR. HELLMUTH: I shall therefore move you, Mr. Chairman, that the secretary be instructed to cast one ballot for the election of these officers.

MR. HODGES: I second the motion.

CHAIRMAN KOEHLER: The motion has been moved and seconded that the secretary cast one ballot to elect these gentlemen to office. All in favor will signify by saying "aye"; contrary-minded by a like sign. The secretary will cast such a ballot.

Now, gentlemen, just a word. This is the occasion for your present chairman to retire from office. Before I ask Mr. Bennett to conduct your new chairman to the platform, I want to take occasion to express my deep appreciation for the very loyal cooperation that has been extended me by the vice-chairmen, officers and committee chairmen and members of the executive committee, members of

the staff of the National Safety Council as well as those members of the section who have so generously contributed of their time and thought, and who have made my administration a pleasure indeed.

We held but a very few meetings, but those meetings were very well attended. At our first meeting held in Chicago, I believe we had almost 100 per cent attendance. You can appreciate what that means when you know that these men came from long distances, leaving their work for a period of a day or two in coming and going, and remained away from their offices the greater part of a week. That has meant a great deal. Our deliberations have been interesting. There has been shown a genuine spirit of concern for the welfare of the Electric Railway Section. We have been mindful of the responsibility that has rested upon us, and we have tried to discharge our duties to the best of our ability. How well we have succeeded, I leave with you.

I am not going to take up any more time. I want to give you an opportunity to look into the face of your new chairman, and to greet him. I simply want to say now as Mr. Bennett conducts him to the platform that I wish for Mr. Eastham

the greatest success, and the very same kind of cooperation that was extended me. I want to assure you, Mr. Eastham and members of the Section, of my continued interest and support. Anything at all that I may be able to do during the coming year, I will do cheerfully.

(Chairman-Elect Eastham was escorted to the chair.)

CHAIRMAN EASTHAM: Gentlemen, I am deeply appreciative of this honor. However, like most honors, there is a corresponding responsibility involved. In accepting the honor, I say to you I accept the responsibility and will meet it to the best of my ability. It would appear that our section may be faced with certain rather serious difficulties in the years immediately before us. These difficulties are related to those which face the electric railway industry as a whole—decreasing revenues and lightened finances. I fear that some managements, sorely beset, will, in the general effort to curtail expenses, make the mistake, as I view it, of cutting down on their accident prevention organizations. Some reflection of this is found in the net loss of memberships in our section for the past year as shown by Mr. Boyce's report. In the interest of accident prevention work as a whole we should meet this problem boldly and convince management by argument and results achieved that now more than ever is the time for increased activity in accident prevention. The sound reasons are: That the cost of accidents is the largest item of useless expense in any company's budget; that sincere accident prevention work is one of the best avenues to public and passenger good-will; that accident prevention work, while an integral part of efficient operation, yet has such important tie-ups with employee and public relationship as to deserve and require trained direction and leadership.

I have a further conviction that for those of us who are safety workers and for our industry as a whole, we should spend increasingly more time and effort toward reaching and educating the general public on all matters affecting public accidents. This can best be done, it is my belief, through closer cooperation with all other agencies working toward that end, particularly local safety councils, the public and parochial schools, police departments, citizens' traffic committees and state and national conferences for uniform, well-worked-out traffic laws.

My message to you for the next year, as safety workers, whether as manager or motorman, is this: Cultivate a code of ethics as high as our basic aim of saving human life and limb. Stand up and be counted always for those policies which in your judgement will best conserve the life, liberty and happiness of your American fellow-citizens, yes, and of your fellow-man the world over.

That our Section may start its activities promptly and energetically, I am setting the precedent of naming our committee chairmen at this time as follows:

Membership: Samuel H. Reid, Bureau of Safety, Chicago, as Chairman. Vice Chairman, Mr. Arthur Gaboury, of Quebec, Canada.

Publicity and News Letter Editor, the man who served us so faithfully and so well during the past year. Mr. Buell W. Nutt, of the Safety Equipment Service Company, Cleveland, O.

Poster and Slide, Mr. L. R. Brown, of the New York State Railways, Rochester, N. Y.

Program Committee, Mr. T. G. Brabston, of Birmingham, Alabama.

Engineering and Statistics, Mr. Edward Maltz, of the Cleveland Railways, Cleveland, Ohio.

Members-at-Large, Mr. R. W. Emerson, G. T. Hellmuth, and Daniel Fennell.

Those gentlemen, the committee chairmen, plus the members-at-large, plus the officers of the Section just elected, will constitute the Executive Committee. I am going to ask all of those gentlemen who are here (and I hope you will pass the word along to those who are not) to meet with me in my room this afternoon for a very brief session so that we can get our sectional activities started promptly.

Now, gentlemen, just one other word, the success of the work of this section for the next year depends fully as much, if not more, on the cooperation of you individual members, you representatives of your companies than it does on the officers and the committee chairmen. The report that was made from the Poster Committee, that on a request last year sent to 50 companies for assistance, only one answered, I think we should improve upon during the coming year. The same has to do with getting out our *News Letter*. Mr. Nutt is going to take the time to do this work from his own business, and he certainly deserves the help of all of us. I want the help of every one of you. I feel that your officers should be entitled to that. I expect it and I believe that I will get it. I want to say that tomorrow morning's session will open (if there is only one man there) promptly at nine-thirty o'clock. We have a good deal in the way of discussion. We have left room for that on the program for tomorrow, and I know we want to start on time. The program for tomorrow is most interesting, embracing a playlet and picture given through the courtesy of the Public Service Company of New Jersey. I am going to ask you all to be there promptly at nine-thirty. When we come here to these meetings, the benefit comes from us all attending and in discussing the matters that come up.

S. H. REID (Bureau of Safety, Chicago, Ill.): I don't think there is a man in this Section that fails to appreciate the splendid service that our retiring chairman has rendered during the past year. He has shown unusual ability as a leader, as is evidenced by the attendance at the various executive meetings which he has held during the year. I therefore think it proper at this time that we should extend a rising vote of thanks to Mr. Koehler for his splendid services.

(The members arose and applauded.)

ADJOURNMENT.

October 4, 1928**E. K. EASTHAM, Chairman****Safety Director, The St. Louis Public Service Company
St. Louis, Mo.**

The third session was called to order at nine-forty o'clock by the chairman, E. K. Eastham.

CHAIRMAN EASTHAM: Now, gentlemen, I trust we won't have any great amount of disorder today, because if I hit this table too hard, it is going to bust. We have sent out for some question cards which will be placed at your disposal, because we have more time left today for discussion than at any of the other meetings. When the cards are passed around, if any of you gentlemen have any matters that you want brought up under the head of the general discussion, aside from the discussion left from the previous sessions, put them on the cards and we will cover just as many of them as possible.

The first paper on the program this morning is by Mr. Arthur T. Warner, General Manager of Traffic, Public Service Coordinated Transport, Public Service Corporation of New Jersey, Newark, N. J. I think it should be very interesting to us all because the bus is coming to play an increasingly important part in most of our transportation systems. I understand that Mr. Warner will be a few minutes late. We have had some very interesting programs in the last two or three days, and due to lack of time, it has been necessary to forego discussion. Is there any point with reference to the papers that we have already had, or any other point that the delegates would like to bring up at this time?

MR. HAUGHT (Pittsburgh Rys. Co., Pittsburgh, Pa.): I would like to ask the man from Chicago how they arrive at the conclusion in the accident percentage of 70 per cent human failure and 30 per cent mechanical failure. How is that arrived at?

MR. GORDON (Bureau of Safety, Chicago, Ill.): Naturally, we keep records. Otherwise, we wouldn't know where we were, and over a period of years, you will find that 90 per cent instead of 70 per cent of the accidents are caused by man failure. Just as an evidence of that, we had a stenographer in our office whose duties it was to recopy or to make cards from accident reports. She had a great many of them. In commenting upon them, she said, "It looks to me as though nearly all these things are caused because somebody didn't do something he should have done, and he should have known it was wrong."

I said, "Well, our statistics show that the big majority of our accidents are caused by man failure." At that time, 75 per cent was quoted.

"Why," she said, "it looks to me more nearly like 100 per cent."

That was a stenographer's viewpoint from going over the accidents that came into our office. We are backed up on that statement because of our own records.

E. HOLLIBAUGH (Pittsburgh Rys. Co., Pittsburgh, Pa.): I feel that that stenographer was right because I don't think we can examine an accident without being able to trace some mistake along the line where someone was negligent. That is where the human element enters. If it is a mechanical failure, it might be the result of improper tests. I don't believe we can have an accident without in some way, being able to trace it to the human element. Just where we are going to stop, I think, is the general attitude in mind.

S. H. REID (Bureau of Safety, Chicago): In 1925 we began keeping fairly accurate statistics of accidents with a view of determining the cause over a period of five years, beginning with 1924, it was. We found that about 78 per cent of the employee accidents were due to what is generally called "man failure." The

second period changed that somewhat by reason of improvements that were made in the mechanical conditions. The obvious physical hazards were reduced. Consequently, the number of accidents due to physical conditions of the property over which the injured might have not had any control, are decreased. At the end of the second period, that percentage was about 58. At the present time, it is 49 per cent. That, of course, is by reason of the improvements that were made in the physical conditions of the property.

So far as fatal accidents are concerned, we find that almost all of them have happened because somebody disobeyed a rule or failed to use some safety appliance that had been provided. We have those statistics, Mr. Chairman, covering the accidents to the public. I am speaking purely of employee accidents. I think the figure of 90 per cent or even higher, due to man failure, is very conservative.

WILLIAM WILSON (Pittsburgh Rys. Co., Pittsburgh, Pa.): In behalf of my brother trainman here, I think that he has the wrong idea in this way: We are trainmen. You men are officials. He has the idea that you are trying to put the responsibility for all the accidents upon the trainman. Some of us might take the stand that you are wrong on your percentage. In my activities in the safety movement, I have found out, as Mr. Hollibaugh says, that you can trace accidents back to man power. Contributory negligence is one of the greatest accident hazards that we have to contend with. I think the National Safety Council traced several accidents back to man power in this manner: There was a man operating a car with a man sitting up close to him, talking to him. A man stepped out from the corner, who was knocked down and his arm was broken. The report was made out by the motorman, but the National Safety Council went a little bit further.

They interviewed the man who was talking to the motorman. "When you were talking to the motorman," they said, "what were you talking about?"

"Well, he had a little trouble at home, a few nasty words with his wife, and he didn't see the man when he stepped out from the curb because he had his head toward me, talking." Perhaps Mr. Hollibaugh had that in his mind.

MR. SPECK (Pittsburgh Rys. Co., Pittsburgh, Pa.): Speaking of the 75 or 80 per cent man failure, where are you putting it, on the employee or the man in the street? Let us differentiate between the two. The way it appears now, all the responsibility is on the trainman. Mr. Wilson spoke of a man being hit by the street car. The man on the street had as much right to see the car as the trainman had to see the man on the street. The man on the street had a larger thing to see.

Are we putting it all on the trainman in determining that percentage and not on the man in the street, or the vehicle? I think we should deliberate on that.

MR. GORDON (Chicago Bureau of Safety, Chicago, Ill.): We have to place this accident prevention matter on the individual, be he motorman, engineer, clerk, or pedestrian. When we say man failure, we mean the fellow who leaves the monkey wrench on top of his step ladder so that when he steps off to move it, it falls and hits him on the head. That is man failure. We also mean when a motorman stands with his hand on the controller or air valve handle and deliberately bumps into an express wagon that can be seen for a mile in broad day light, with nobody around him, that it is man failure.

We must always say that it is man failure on the part of the operator on the front end of a street car when he talks to a passenger in violation of his company's rules. Let the passenger talk, but the motorman doesn't need to talk. Neither does he have to look around at the fellow while he is talking to him. Therefore, it is man failure. Then it goes back to the company in violation of a rule, where the company's officials knowingly permit a violation of that rule.

It then becomes a habit and a practice, and the first thing you know some fellow doesn't know about the practice and he disobeys his book of rules. In the case I have in mind, that same thing happened and seven people were killed. The company was censured for that accident, not the man on the front end of the car.

CHAIRMAN EASTHAM: Mr. Warner is now here, and the balance of this very interesting discussion can go over.

Mr. Warner, I have already introduced you. Without any further introduction, I will call upon you now.

Bus Operation from a Railway Man's Point of View

By **ARTHUR T. WARNER**

General Manager in Charge of Traffic, Public Service Coordinated Transport, Newark, N. J.

I come from an organization located in New Jersey, that is today operating some 1,700 buses and 1,500 trolley cars and furnishing a complete system of local transportation to approximately 90 per cent of the population of that state.

I would rather, therefore, change the subject as I start to discuss it, because the transportation organizations that today are operating both cars and buses are not railway men. They are adapting all the best elements of all the means available to them to supply their communities with the necessary local transportation. Consequently the railway man of the past, as such, is rapidly disappearing, and in his place we have the transportation man.

Times, mental attitudes and points of view, have changed somewhat to the railway man in the last ten years. Way back in 1914, just prior to the start of the World war, we in the east heard many tales of points in Texas, California and other places throughout the southwest, where people were running automobiles for a nickel a ride. We rather laughed at it, and thought it was another California publicity stunt and like the perpetual sunshine, roses, oranges, etc.

About six months or a year later, however, the first laugh had changed to a frown and we were beginning to realize what it meant to go up against jitney buses that flooded our streets in this section. They settled upon our lucrative business areas like swarms of 17 year locusts. They picked out the spots where the business was the thickest and skimmed the cream. Without permanency, stability, reliability or regulation they established themselves, and lived on business that the local railway organizations had taken decades to build up and establish. All sorts of prophecies were made that these old jitneys were simply a fad of the moment, that they were economic monstrosities, and that people would not long stand for such plainly illegitimate operation and that the jitney would die of its own weight. But somehow or other they continued to exist. Of course, regulation in some form began to develop shortly, but by the time regulation did come, buses were fairly well established and a bus riding habit had been only too well formed.

At the end of the war we in New Jersey found between 1,200 and 1,500 buses in direct competition with our street car lines and threatening our very existence,—and New Jersey was no exception, other states were exactly similar to ours. Up to that time the railway industry had looked upon the motor bus as an enemy, which it must fight to death, but the time was arriving at which the larger and more aggressive railway organizations were beginning to experiment with the bus, to accept it as an ally, to see its possibilities, as well as its shortcomings and to make use of its good points, to fix for it a place in the transportation field.

I am reminded of a story of a traveler motoring through the sunny south, who stopped at the side of a field, wherein a small boy was hoeing potatoes.

Some conversation took place and finally the traveler said, "Son, what do you get for hoeing?" The youngster replied, "Nothing if I do, and hell if I don't." This unfortunately illustrates only too well the way some of our railway officials viewed the bus situation. They felt that there was nothing in it for them if they engaged in bus operation, but that they would be in hot water if they didn't. Thus it has taken between 10 and 15 years to turn the local transportation agencies to a point where they are ready to accept the bus and bus operation as part of their job. Since 1923 or 1924 this change has been under way very rapidly and we find now that practically all of the larger local transportation agencies are giving at least a portion of their service with buses.

I have been advised that I should dwell upon the safety element in bus operation. I hardly need to say that operation, to anybody raised in the railway business, is always *safe* operation. With us *safety* has been the first element of service. Every railway slogan has had safety in it somewhere. Safety always; safety first; safety, service and efficiency; safety, courtesy and loyalty. There are dozens and dozens of them, but safety appears in each. So when we started to consider the bus as a vehicle with which to carry our patrons, as a means by which we could furnish a service such as we were accustomed to give with our trolley cars, we looked at the high, light, single tire, often brakeless, vehicles and wondered what elements of safety they contained,—and we set about to develop what in the first place, was a safer vehicle.

Changes in design which have always catered to safety, have been marvelous throughout the last ten years. In 1918 the buses were then made-over truck chasses, with high frame, three or four steps to climb, low roofs, no lights, no ventilation, no heat for winter operation, single tires in the rear,—consequently skiddy, uncertain brakes. In short, certainly not a safe vehicle from the point of view of street railway operators. I think that I may say without contradiction that the rapid development of the bus from that stage to today has been due to the fact that railway organizations have seriously taken over bus operation and have materially assisted the manufacturer and designer so that the bus of today is the answer. I doubt if independent operation could have developed the bus anywhere nearly as rapidly as the efficient and experienced organizations that have been serving for years local transportation to their communities.

I will not go into a long technical discussion describing the various stages in the development of the bus of 10 years ago to the vehicle of today. Let it be sufficient to say that the modern bus is a safer, more comfortable and more dependable vehicle from all points of view. Chasses have been lowered, which has brought down the center of gravity; we find dual wheels on the rear, which has done away with skidding; four wheel air brakes are now in order; buses are now well lighted; good ventilation exists; all of which, in brief, gives the patrons a ride which will compare favorably indeed with that in an expensive limousine.

Various regulatory bodies have done much to increase safety provisions in bus design by adopting specifications making it necessary to have all vehicles equipped with elementary safety devices. Our New Jersey Commission, for instance, in its specifications requires the following details which are certainly a part of any safety program: Window guards, partition behind the driver, emergency door, grab handles and railing, ventilating system, heating system, gas tanks properly located and protected, mirrors, fire extinguisher, lights, in addition to specifications requiring a certain strength of chassis frame and other mechanical details.

My own company is one of those which is strongly in favor of the gas-electric drive, which by the elimination of the transmission and all gear shifting has, we

believe, additional safety features. The operator's hands, being free from gear shifting are just that much more available for other duties. The lack of gear shifting also gives freer acceleration, eliminates the jerking of the passengers, which comes from sudden gear shifting and consequently gives a safer and more comfortable ride.

Of course, all my observations are based largely upon my own experiences in New Jersey. Five years ago today we had less than a dozen buses running on two short country lines. Today we have over 1,700 buses which will operate over 55,000,000 bus miles this year and carry over 325,000,000 passengers. So you can see we have certainly opened our arms to the bus as a means of modern transportation within the last five years, and today the system in London is the only one in the world that surpasses us in size.

Certain factors in bus operation have an immediate appeal from a safety point of view. The first of these is, I think, the factor of pick up and delivery at the curb. With municipal street traffic in its present state in any of our larger communities, a vehicle that is able to take the passenger at the sidewalk and deliver him at the other end of his journey also at the sidewalk, has a distinct safety appeal. Today an excursion into a metropolitan street is fraught with considerable danger. A man takes his life in his hands and one realizes that the apostle must have had a picture of modern conditions when he wrote of the "quick and the dead." The next element wherein bus operation differs from car operation from a safety point of view is that the bus, being dirigible and not operating over a fixed track, has a flexibility impossible with a street car. This tends, I believe, to the safer use of the highway. A bus is not tied up for long because the vehicle ahead of it breaks down. Traffic jams will, therefore, not be caused in bus operation to the same extent that they are in car operation.

We have found in the development of an operating personnel, that the same intensive methods of training are necessary with bus operators that we have always used with our car platform men, except that, as a rule, a would-be bus operator comes to us with a driver's license and some bad habits of driving, which he must unlearn before he can become a first class bus operator. Our schools of instruction are flooded with ex-truck drivers and ex-taxi cab men and we find that our first duties are to make these men overcome bad habits that they have acquired in the earlier employment. This is something we never had to do with the trolley operator. Of course, the car operator is running on a fixed rail, has only one place to go, and other vehicles using the highway know this. They can regulate their own movements accordingly and consequently the car operator is never subjected to the accusation of being a road hog the way the bus operator is. The very dirigibility of the bus gives it an element of uncertainty as far as other vehicles go, that is absent in the street car.

I want to digress from the strict discussion of safety to give you a brief picture of the different ways in which we are using buses in New Jersey at this moment. In our larger communities such as Newark, Jersey City, etc., the trolley system is still carrying the backbone of our mass transportation. We have inherited sizable bus operations that parallel these car lines and we use this bus service coordinated with the car service in such places. We are rerouting these bus lines to adjacent parallel thoroughfares so that there will not be a duplication of service on the same street and the bus will be placed on a highway not occupied by car tracks so that it may develop to some extent a territory of its own.

In other municipalities, such as Paterson, Plainfield, New Brunswick, etc., we have discontinued our street car service and replaced it with bus service. These have been on lines of comparatively light traffic, where street car operation

was over single track with turn-outs and where the flexibility of bus operation has been developed to its fullest extent. We have installed new bus lines as feeders, crosstown routes, extensions into new developments and to open up new territory.

We have also placed in operation a considerable number of so-called "Deluxe" bus lines. We call them "Super Service" lines. These are vehicles specially designed for greater comfort and interior attractiveness. They differ from the regular bus in the same way that the parlor car differs from a day coach. There are individual seats, well upholstered, and extremely comfortable, there are curtains in the windows, mirrors in the panels, interior finish of a pleasing design. These vehicles furnish the patron as comfortable a ride as in his own limousine. We charge a higher fare for this service and it is furnished on a basis of a seat for every passenger. Routes such as these, chosen so as to serve neighborhoods that would naturally patronize more expensive and higher class service, are developing rapidly in our territory and give evidence of having great future possibilities. This is a field for the bus that the street car never had.

Another service developed which is distinctively bus as it grows, is the longer special trip touring parties, chartered or special buses. This business is growing by leaps and bounds. On July 4th of this year, we had 221 buses engaged in taking private parties to various points all over the east. We have sent buses from New Jersey to Florida, to Canada, to Chicago, in fact all over the eastern part of this country, and most of these parties come in for repeat orders. Last summer we handled the annual excursion of one of our larger insurance companies taking 3,000 of their employees in 90 odd buses from Newark to the Jersey shore and return. This trip formerly had always been handled by special trains on the steam road. Their committee asked this year if we could furnish them buses. The rate we quoted was 20 per cent higher than that offered by the steam road, but they decided to try it with buses this year because of the pick up nearer home, the delivery at the beach, and the relief from train schedules. On their return the committee in charge informed us that they were converted to buses and would not voluntarily return to trains.

I have just cited a few of these cases to show that the bus has and is creating more and more a distinct appeal of its own with the traveling public. There are small elements in bus service that the trolley cannot give, that the steam road cannot give, and if the local transportation agencies are to meet the competition which the privately owned automobile is giving today, they must go to the buses, because the bus gives the service which approaches more nearly that of the private car.

The bus has now reached the point where it must be and is accepted as a part of the transportation industry. The vehicle is being developed rapidly. It is being continually improved in design to give greater safety, greater comfort and a wider range to its use. Its adoption by so many transportation agencies has led to the use of modern operating methods, of operating forces trained for their work, and continually under the eye of executives who have been brought up with safety as their watchword.

I would, however, be lax indeed, if I allowed this occasion to pass without an appeal for greater cooperation in our safety campaigns from those who have, after all, the greatest power to produce safety results. All our states, all our larger municipalities, all governmental agencies that exist, have passed and now have in force laws, ordinances and regulations governing the use of highways in the interest of safety. These laws should be uniformly enforced. I refer not only to speed regulations but to parking ordinances, jaywalking, the elimination

of left hand turns, in fact every kind of so-called traffic rule. The work of the Hoover conference has been a great step to bring about a uniform system of traffic control and regulation. We in New Jersey are now enjoying the first fruits of this conference. Our legislature within the last three months has passed a uniform traffic act. We have, we feel, enough laws and regulations and the thing remaining for us to do is to enforce, uniformly, justly and fully the laws we now have, so that the bus, the car and private automobile may each use the public highways so that each may travel with the greatest possible safety.

CHAIRMAN EASTHAM: I greatly appreciated the talk made by Mr. Warner. I don't know of anything that will be of greater importance to our industry, as time runs on, than this subject. The industry must have a thorough understanding of the place of the bus. Of course, with us as safety men, we are interested in the safety features in that connection. We have some time for discussion of this particular paper while Mr. Warner is here.

G. T. HELLMUTH (Chicago, North Shore & Milwaukee R. R., Chicago): There are two questions I would like to ask Mr. Warner. First on your gas-electric cars, you mentioned the use of electric brakes. You mean you stop on reverse in emergency?

MR. WARNER: There are two motors in opposition so that the motors are bucking each other in that case, so the power acts as a brake.

MR. HELLMUTH: That is a good deal like the reverse on a car?

MR. WARNER: Somewhat.

MR. HELLMUTH: Then, secondly, do you find your claim cost in operation of motor coaches less than the claim cost in operation of street cars?

MR. WARNER: Mr. Brown, our claim agent is here, and he can give you that information better than I can.

MR. BROWN (Public Service Corporation of New Jersey, Newark, N. J.): Mr. Warner explained we started operation in 1923 and gradually added to the units during these years, so we are constantly taking on new buses, new units. Of course, you all know that claim expenditures reach a peak gradually over a period of five, six, or seven years. For instance, if you take on a brand new proposition, there is nothing due for the first year. I would say that half of your expenditures are made on an old proposition, where you have been operating for years. About half of the expenditures during a given year would be on the current accidents. So, gradually that is built up until a peak is reached. We haven't reached the peak yet because of the addition of units.

I think from my observation, taking into consideration the improvement in mechanical devices, operation, and so on, that the claim operation on the buses will cost slightly less than on the railroad. Of course, the bus has many advantages, as Mr. Warner has outlined. The very fact that the bus can deviate from its course in given situations, which is impossible for the trolley, is important. Then too, if you are figuring your results on percentage of gross expenditure, the bus has very much less carrying capacity, which also comes into play. I think on the gross revenue basis, that the bus is going to cost (for all city operations) less than the railway when it reaches its peak.

MR. WARNER: There is one point there I would like to explain. We have a bonus system in effect this year. It was started last year. This year it has been modified to some extent as a result of our experience last year. We set up three bonus periods a year, of four months each. We have practically set up \$20 for each man. If he runs for four months with no accidents, he gets \$20 at the end of four months. For the first accident he has, \$1 comes off; for the second accident, \$1.50 comes off; for the third accident, \$2.50. If he has more than three accidents, he is out of the picture. So, he either gets \$15, \$17.50, \$19, or \$20.

In addition to that, each garage has a garage prize based on the number of improvements made this year over last year on a mileage basis. On that basis, the small garage has the same opportunity as the large garage. That means if a man has his three accidents, he is still eligible (if he belongs to a careful garage) to come in on the average prize. It also means that everybody in the garage is interested in the record of every other man in the garage.

As I say, a change was made this year as a result of our experience last year. We wanted to make it so that every operator would have an interest in the accident record of every other operator in addition to his own. The result of that is a reduction (while running more miles and more vehicles this year) of some 1200 accidents this year compared to last year. Whether those 1200 accidents will enable us to save enough to pay that full bonus or not, I can't answer you. I don't believe anybody else can answer you, because it is actually more than 1200 accidents. The tendency is to go up. We have not only started the upward trend, but we have now established the downward trend. There is 1200 plus whatever the normal increase would be. The more vehicles you get on the street, the more accidents you are going to have. There are more vehicles on the street this year than last year.

G. T. BRABSTON (Birmingham Electric Company, Birmingham, Ala.): I would like to ask a question in respect to that bonus system. What has been the effect on the unreported accidents? I am sure from all of our experiences under a system of that kind, we find a certain tendency on the part of the operator (which is a natural human bent) to be lenient with himself on an accident he doesn't think is serious, but that same accident may cause a great deal of trouble with the Claim Department at a future date.

MR. BROWN (Public Service Corporation of New Jersey, Newark, N. J.): The unreported accidents were not increased. I found that accident reports decreased very materially, but they used good judgment in discriminating, so the actual result was, that there was not an increase in unreported accidents. With that bonus in the back of their heads, they did not report as many trivial matters as before.

MR. BRABSTON: Isn't it your experience that it is the usual practice and custom of the person that wishes to magnify one of these trivial accidents, to wait five or six months before he presents a claim? That is a delayed situation rather than an immediate one.

MR. BROWN: That is sometimes so, but I don't think it is generally so. I am taking the results over a long period.

MR. HELLMUTH: I should like to answer Mr. Brabston's question, because that bonus award business is my pet. I arranged a lot of data and communicated with many properties. It is just as Mr. Brown said. Last year, his company was operating 1,500 buses?

MR. BROWN: Mr. Warner said about 1,700 at this time.

MR. HELLMUTH: One-fourth of all the bus business being done by electric railways was done by the Public Service Railway of New Jersey a year or two ago. Their volume of experience therefore, is so large that it pretty well represents the correct average. If that isn't enough, let me say that with the street railway companies and other bus companies, that the experience has been almost universal in that unreported accidents have not increased. Of course, in one way that is due to a number of the companies making a penalty of two accidents as a charge for every unreported accident against the man who doesn't report it and it afterwards turns up.

MR. BROWN: Our discipline is quite severe. That also covers our street railway operation of how many cars?

MR. WARNER: About 1,400.

MR. DONNELLY (Pittsburgh Rys. Co., Pittsburgh, Pa.): I would like to ask Mr. Warner if he has any sand equipment on those buses for bad weather to keep them from skidding and causing accidents.

MR. WARNER: You mean chains?

MR. DONNELLY: Don't you use sand at all?

MR. WARNER: Sand and ashes; ashes more than sand. We put a mixture of ashes and sand on all bad grades with spreaders. That is done as soon as any ice condition appears, but only on a very few places do we use chains.

MR. STOUT (Altoona, Pennsylvania): I want to ask Mr. Warner if he has anything to designate bus stops along the highways, especially out in the outlying districts where other fast-moving traffic might be following the bus? We have had the experience that they sometimes run into the rear end of the bus because they weren't expecting the bus to stop. Do you have designated stops?

MR. WARNER: We use the same system as on the trolleys. Bus stops are trolley stops except at places where bus stops are designated where there are no trolleys. Out in the open country near side corners, the stops are usually marked with markers on the poles. That is the usual system, although I guess most of the drivers stop right in front of any farm house.

E. HOLLIBAUGH (Pittsburgh Rys. Co., Pittsburgh, Pa.): We have been afraid of the individual bonus for several different reasons. Unreported accidents was one reason. Another was the way of arranging this bonus so that the individual men who participated would have no hard feelings. One man might have an the non-chargeable accidents and he might be afraid he would get into hot water. Then, we also thought that the bonus might eventually play out and we would have to get something to take its place after a while.

I can see where this bonus that goes to car houses would eliminate the element of individual controversy. We had a little prize last year for men who went a certain period of time without an accident. Then they wanted to make it an accident of any kind. Finally, in awarding the prize, we discovered it was going to create a great deal of hard feeling within the district. Some of the car houses gave the buttons out indiscriminately to the poor devils who had accidents, the same as to the rest to avoid any hard feelings.

MR. ALLISON (Pittsburgh Rys. Co., Pittsburgh, Pa.): Mr. Brown, what is the average cost per accident on the coaches?

MR. BROWN: I haven't figured that, but it is about 5½ per cent of gross revenue.

MR. ALLISON: You don't have the cost per accident?

MR. BROWN: You mean all accidents reported?

MR. ALLISON: No.

MR. BROWN: I could readily do it.

MR. ALLISON: The second question would have no value in this case, probably. Have you made any estimate of the cost of the bonus system in comparison to the cost of accidents to see which is costing the most?

MR. BROWN: I don't know as there is any way in the world to determine just what effect the bonus would have. After all, the money is what you are after.

MR. WARNER: I think I can say this, if it were possible at the end of this year to segregate the cost of accidents and not have any of the claims run over, that at the end of the year the bonus would pay for itself, and more.

MR. BROWN: This will give you a rough idea: Our claims were about 20 per cent this year.

MR. ALLISON: That will help a lot.

MR. BAMBRICK (Pittsburgh Rys. Co., Pittsburgh, Pa.): In 1903, the Pittsburgh Railways Company paid a penny an hour for every hour operated free from

accident for six months. Many of the men got prizes. I got quite a large one myself, but that plan caused a lot of dissension. Some of the trivial and unreported accidents later turned out to be severe accidents. Last year the question was brought up in trying to devise a bonus plan.

MR. WARNER: I will tell you one way in the detailed operation of the plan that we have tried to eliminate that. We established a so-called appeal list. If a man was sick on the car, it was an accident. The operator called that accident appealable. If a car was standing still and an automobile came up and bumped into the rear of the car, that would be an appealable accident. There were other similar cases. That worked out in this way: If an operator had an accident that he thought was appealable, he filed an application for appeal. The division manager and division claim agent sat as a committee on that appeal. If the accident came within the appealable list and he could prove that it was subject to appeal, they granted the appeal, and that accident was not charged to him.

S. H. REID (Bureau of Safety, Chicago, Ill.): I think one very important question in connection with the bus operation of which Mr. Warner spoke, is the question of training operators. I should like to have Mr. Warner tell us just what his procedure is in training an operator from the time the man is employed until he is allowed to take a bus out on the street or highway alone.

MR. WARNER: A man goes to school for instruction. In the first place he must have a state driver's license. He goes to school and spends from three days up there working on a stripped chassis and learning how to drive all the different makes that we use, our operating methods, reports, fare collections, and so on. I say three days—it is more than three days. The time usually runs from five days to a week. He then goes to the garage to which he is assigned and is sent out with an operator there for instruction and practice on the line on which he is to work. He learns the stop streets, dead stops, heavy traffic points and so forth. After another week or more there, he goes back to the school of instruction for final instruction and examination. The whole instruction course, I would say, takes sometimes from twelve days to three weeks.

MR. REID: Is he allowed to operate these buses over the lines without passengers?

MR. WARNER: No, he operates with a regular driver. It is left to the driver's discretion as to whether or not he should operate for a mile or so. If, at the end of the mile, he is all right, he is allowed to drive more into the heavier traffic. He picks up the regular operation in that way.

MR. REID: How about medical examination?

MR. WARNER: He takes a medical examination first, before he is given any instruction at all.

MR. REID: Then do you have periodic re-examination after that?

MR. WARNER: No, we have the instructors doing follow-up work all the time.

MR. HELLMUTH: Can he get the state driver's license as a result of the instruction you give him without examination on the part of the state?

MR. WARNER: He must have that before he comes to us.

MR. HELLMUTH: You want a man who has already learned to drive?

MR. WARNER: He has to know; we don't want to, but we have to. It is a state law.

MR. HELLMUTH: Could he get a license as a result of what you have taught him?

MR. WARNER: Yes.

MR. HELLMUTH: You prefer a man who is new?

MR. WARNER: I would rather take a green driver.

MR. ALLISON: Is he paid for the training period?

MR. WARNER: Yes.

MR. ALLISON: How much?

MR. WARNER: One dollar and a half a day.

MR. SPENCER (Providence, R. I.): Your men come from street railways?

MR. WARNER: Most of them, I believe, come from outside. We have, though, had a large number of men transferred from cars. We have a great many men that are operating both cars and buses today. We have a number of operating stations where both buses and cars are run. The men on the extra list particularly, are operating both. A man may run a car in the morning and a bus in the afternoon.

MR. REID: Are there any rule books covering bus operation?

MR. WARNER: I think we do have one.

GEORGE MCGAFFIN (3rd Avenue Railway System, N. Y.): If a man presents a chauffeur's license when applying for a position, would that qualify him to drive a bus?

MR. WARNER: No, sir; not until he goes through our instruction.

MR. MCGAFFIN: Would it qualify him to drive the bus with instruction?

MR. WARNER: Yes.

MR. MCGAFFIN: If a man presents a chauffeur's license, can he drive a street car also?

MR. WARNER: Our state driver's license is issued to drive an automobile.

MR. MCGAFFIN: Suppose a man had never driven anything except a three-speed commercial car and applied to you as a bus driver?

MR. WARNER: A man can't drive any motor vehicle in New Jersey unless he has a state driver's license.

MR. MCGAFFIN: Yes, but suppose he has never driven anything but a three speed commercial car and he gets onto a bus with four speeds?

MR. WARNER: He must forget about that and learn how to drive the bus.

MR. MCGAFFIN: Yes, but does he take passengers on the first time out?

MR. WARNER: He goes to school for a week or more.

MR. OLMSTEAD (Wisconsin Power & Light Co., Milwaukee, Wis.): On our property, we have consistently kept away from bonuses and prizes, and we have a wonderful accident record on bus operation. I think our education of the driver is a good deal more extensive than Mr. Warner gives. I should like to ask him if he didn't have the bonus, would he have had more accidents?

MR. WARNER: I believe we would.

MR. ALLISON: That is only belief.

MR. WARNER: Only belief, my judgment. I don't see how you can avoid it.

MR. OLDHAM: We are avoiding accidents, and we don't have a bonus or prizes.

HARRY CORDELL (Chicago, North Shore & Milwaukee R. R., Chicago, Ill.): I am not a bus man, but I have been thinking, however, judging from what we read in the papers about private automobiles in the garages backing out and running over people (we had 34 cases in Chicago), that we have that very condition on buses. The bus driver may back up without calling the pedestrian's, garage man's, or anybody else's attention to it.

Wouldn't it be well for us to consider an automatic noise-making device, so that when the bus is in reverse, it would automatically signal the people in the rear of the bus that it was backing up?

MR. ALLISON: That is a good suggestion.

CHAIRMAN EASTHAM: Gentlemen, we have a trained and high-priced cast of actors backstage here. You probably saw them going in there in droves. This discussion is most interesting, but I am afraid we can't keep on the bonus proposition. I have heard more discussion on that in the five years I have been associated with the section than anything else. There never has been a unanimous

opinion reached along that line. However, we can take it up again after the playlet is completed.

This is a play, "Whose Fault," presented by the Public Service Company of New Jersey, through the courtesy of Mr. A. J. Van Brunt, Director of Safety Education. After that, the balance of our time will be given over to discussion along this same line or other lines.

"Whose Fault?"

A PLAYLET IN ONE ACT

By JOHN M. ORTS

Assistant to Director of Safety Education

and ROBT. A. McARTHUR

Superintendent Employment-Instruction

Public Service Coordinated Transport

Directed and Staged by Mr. McArthur

CAST OF CHARACTERS

STENOGRAPHER.....	Miss Florence McQuirk
DIVISION MANAGER.....	Mr. Robert A. McArthur
CLAIM AGENT.....	Mr. William Schnable
SUPERVISOR.....	Mr. W. B. Graham
DIRECTOR SAFETY EDUCATION.....	Mr. John M. Orts
SUPERVISOR OF INSTRUCTION.....	Mr. W. E. Rice
TONY THE TRACKMAN.....	Mr. James Barnstable
AN INSPECTOR.....	Mr. William Dannenberg
A CAR OPERATOR.....	Mr. Edward Ryan
A BUS OPERATOR.....	Mr. Orrin Harrison
A BUS PATRON.....	Miss Elizabeth Clark

*Curtain rises. Stenographer seated at desk typing a letter
Telephone rings*

STENOGRAPHER: Manager's office. No, Mr. McArthur has not come in yet. Who is this, please? Yes. Can I do anything for you? Mr. Warner? Yes. Yes, why that report was signed and sent in yesterday afternoon. It should be in your office now. Very well. Thank you. Good-bye. *Telephone again rings.*

STENOGRAPHER: Manager's office. No, but I expect him any minute now. Is there anything I can do for you? Yes sir, *(pause)* I see. *(pause)* Yes sir, *(pause)* All right, I'll tell him as soon as he comes in. Yes sir, Good-bye. *(Makes note of the call and resumes typing.)*

MANAGER: *(Entering)* Good morning, Miss McGuirk. What's new this morning?

STENOGRAPHER: Mr. Schnable dropped in about twenty minutes ago to see you and said he would be back. Mr. Van Brunt telephoned a few minutes ago to remind you of the meeting of the Safety Committee at eleven o'clock and is anxious to have you attend it if at all possible.

MANAGER: Oh, yes, I remember about that meeting and I intend to be there. This is the morning we set for the investigation of that bad accident.

STENOGRAPHER: Yes sir, Mr. Graham said he would have the operators, the trackman and the inspector here at ten o'clock and he would be here himself.

MANAGER: Did you notify Mr. Orts and Mr. Rice also?

STENOGRAPHER: Yes sir, they will also be here at ten.

MANAGER: Very well. *(Starts looking over papers)* *(Claim Agent enters.)*

CLAIM AGENT: Good morning Mr. McArthur.

MANAGER: Good morning, Mr. Schnable. I'm very glad you dropped in. How do you account for that bad verdict the jury gave yesterday in the Wilson case?

CLAIM AGENT: Yes sir, that was a bad verdict. Here are the facts in a few words. In the first place it was an unreported case. We finally located Operator Henry, No. 4114 who was in charge of the car, and got his story which was the old one; "This lady fell after she left the car, I followed her to the sidewalk to get her name and she said she was not hurt, so I didn't bother getting the witnesses or making a report." They put the Operator on the stand yesterday and tried to prove that he opened the doors before the car had come to a full stop, and on cross-examinations he lost his head entirely and didn't know anything about speed—miles per hour—how far it would take him to stop his car going at a certain rate of speed, etc. In fact he proved by his own testimony that this lady might have fallen from the sky for all he knew; went all to pieces and shoved twenty-five hundred dollars into the waste basket.

MANAGER: I am very sorry to hear that, this fellow is a good operator and has a remarkably good record.

CLAIM AGENT: True, but without any witnesses to back up his story and left alone with the burden, he went blank.

MANAGER: I believe Section IV of the new Traffic Law is going to help us in these unreported accidents. God knows we drill our men enough in the importance of getting witnesses.

CLAIM AGENT: *(Getting up to go)* That's the answer to the whole problem.

MANAGER: Are you in a hurry to get away, Schnable?

CLAIM AGENT: Well, I have a call or two to make—Why?

MANAGER: I have arranged a conference this morning to discuss that bad crash at last Tuesday. The others will soon be here and I would like to have you sit in.

CLAIM AGENT: That's fine. I can spare the time. *(Sitting)* *(Stenographer exit.)*

MANAGER: Schnable, that accident has me greatly upset. We have been having a few of the same type recently and we must adopt some means to prevent them. I've spent a lot of time just trying to figure out how a collision such as this really could occur. Here is that car, operated by one of our oldest men. A man who has been travelling up and down that street for years, knows every alley and corner where danger is likely to exist. Then we have the bus operator, a good driver and a fellow who is never known to lose his head in any kind of traffic. Both the car and the bus reach the corner about the same time and both stop to discharge and pick up passengers. Both evidently start up about the same time and we have that awful crash. How they could come together with sufficient force to crush the life out of one poor fellow, injure two others badly to say nothing of the damage to both the bus and car, is beyond me and I am sure the discussion this morning will give us something to work on.

STENOGRAPHER: *(Entering)* Mr. Graham, Mr. Orts and Mr. Rice are here.

MANAGER: Show them in. *(Graham, Orts and Rice enter with greetings, etc.)*

" *(To Graham)* Are your men here, Mr. Graham?

GRAHAM: Yes sir, both operators, the Inspector and trackman.

MANAGER: Fine. We'll hear the trackman first. *(To Stenographer)* Call Tony in. *(Tony enters.)*

MANAGER: Good morning, Tony. Take a seat.

TONY: Gooda morn, boss. (*Bows and sits.*)

MANAGER: Where were you Tony when this accident happened last Tuesday afternoon. Just tell us, what did you see and what did you do?

TONY: Wella Boss—I was standing at de track, justa like did, (*standing and waves arms*) when all a once dis a bus comma outa dis street; den one beeg crash—I looka and see de bus he turna disa way round, OH! I says mabie one, two or twenty-five killed. I run justa lika hell to telephone. Key no fit; can't open box. Den I run to de store on de corner. Oder man usa de telephone. Den I run to de car barn.

MANAGER: Ran to the car barn? That was six blocks—In the name of common sense, what for?

TONY: Maybe tella dem do something?

MANAGER: Well the car barn was a long way was it not Tony?

TONY: Yes, Boss I all excita. I wanta do someding.

MANAGER: What did you do then, Tony?

TONY: I tella dem at car barn; dey know it ahead. Den I come back, everything all gone; justa littla glass in da street, I clean up. Dotsa all, Boss.

MANAGER: So that's all you know about it, Tony?

TONY: Yes, Boss.

MANAGER: Well, the next time you are around when an accident occurs, you let someone else do the telephoning and you help get things moving.

TONY: Yes, Boss.

MANAGER: All right, Tony, that's all. That testimony will be a great help to us (*laughing*) (*Tony exits*)

MANAGER: Mr. Graham, explain to me just where and how this accident happened.

GRAHAM: Operator Ryan, in charge of the eastbound _____ car claims he stopped on the near side of the intersection and picked up about ten or twelve passengers. Some did not have the correct change. When all had boarded, he closed his car and made change for the passengers on the platform.

MANAGER: Yes, I see. But we have a rule prohibiting making change while operating.

GRAHAM: Yes sir, we have.

MANAGER: Then Ryan's at fault for disobeying that rule.

GRAHAM: Yes sir, he is.

MANAGER: All right, go ahead.

GRAHAM: Bus Operator Harrison, in charge of the _____ bus, southbound also claims he stopped to discharge and pick up some passengers, and then started across _____ while the trolley was still standing. The trolley operator claims the bus was still standing when he started. Anyway the left front corner of the car caught the front part of the bus, fatally injuring a passenger who was standing on the step of the bus and hurting two others inside.

MANAGER: Were the doors open on the bus?

GRAHAM: Harrison states he was just closing the doors when the accident happened.

MANAGER: Well, he must have started with them open for a passenger to be on the step.

GRAHAM: That's the way I see it.

MANAGER: And that negligence resulted in the death of one person and serious injuries to two others. How much damage was done to the equipment?

GRAHAM: Very little to the car. The bus had the upright corner, door and first panel caved in. The driver of the bus swerved with the car or the damage would have been greater.

- MANAGER: I see. *(To Claim Agent)* We are spending a lot of money for this type of accident, are we not, Mr. Schmale?
- CLAIM AGENT: Yes, we are, and this one is going to cost plenty.
- MANAGER: *(To Graham)* Who was the Inspector at that accident? *(Stenographer rises and goes to door.)*
- GRAHAM: Inspector Dannenberg.
- MANAGER: *(To Stenographer)* Have him come in. *(Inspector enters.)*
- MANAGER: Good morning, Dannenberg. *(Motions to a chair.)*
- INSPECTOR: Good morning, Mr. McArthur. *(A general good morning.)*
- MANAGER: Dannenberg, what time did you arrive at the scene of that accident at ——— last Tuesday afternoon?
- INSPECTOR: 4:22 p. m., the ambulance was just pulling away.
- MANAGER: I see—and what did you find in general? How was the crowd talking, etc.?
- INSPECTOR: Well, as far as I could learn, some of the bystanders seemed to think it was the trolley operator's fault and some thought otherwise. But I secured several names and turned them in with my report.
- MANAGER: Did you hear anyone say how the trolley car was being operated?
- INSPECTOR: A number of the same people said the Operator did the best he could and made a very good stop.
- MANAGER: Any comment about making change while in motion?
- INSPECTOR: No sir.
- MANAGER: We are having a number of this type of accident, that is with vehicles coming from the left or from a blind side as it is called, are we not, Dannenberg?
- INSPECTOR: Yes sir, we are.
- MANAGER: Can you think of any plan or means in which this type of accident can be reduced?
- INSPECTOR: A general campaign of instruction and a bulletin posted in the Car House may help.
- MANAGER: That's a good idea. *(Making note of same.)* All right Dannenberg, that's all, thank you. *(Dannenberg exits.)*
- MANAGER: *(Turning to Instructor)* Mr. Rice, have you a question on your examination sheet regarding the making of change while car is in motion?
- INSTRUCTOR: Yes sir, I have a sheet with me. *(Hands sheet to Manager.)*
- MANAGER: *(Reads sheet)* I see, that's very good. Do you talk personally to the men about using care in approaching intersections, making change and starting from a standstill without looking to the left?
- INSTRUCTOR: Yes sir, both on preliminary and on final examination. The Instructor on the school car also—
- MANAGER: I see—that's fine. Well keep at it and have all your instructors follow this up closely every day.
- INSTRUCTOR: Yes sir, I'll start a special drive on this.
- MANAGER: *(Addressing all in office)* My object in calling you gentlemen here this morning is to see if something can't be done to put an end to this type of accident, which is reaching an alarming stage. I want you to hear the statements of both operators in this particular case and then determine just where the blame should be placed.
- (To Stenographer)* We'll hear the car operator first. *(Stenographer exits.)*
- DIRECTOR SAFETY EDUCATION: Is there not a rule in the rule book covering these subjects also?
- MANAGER: *(Producing rule book from desk)* Yes, Mr. Orts, both subjects are fully covered here—*(designating rule in book)* *(hands open book to Orts).*
- (Operator enters with Stenographer.)*
- MANAGER: Good morning—take a chair.

OPERATOR: Good morning, Mr. McArthur. (*Sits.*)

(*Cast talks about accident.*)

MANAGER: Now, Mr. Ryan, I want you to feel right at home and to understand that I did not bring you here to discipline or discharge you, but that was a very bad accident and I want you to tell us all you can about it—just how it happened and the cause—Just a minute—How long have you been operating a car?

OPERATOR: Seventeen years, sir.

MANAGER: That's a long time. How long have you been operating a one man car?

OPERATOR: About four years, sir.

MANAGER: I see. Were you a motorman before operating one man cars?

OPERATOR: Yes sir.

MANAGER: Are you a married man?

OPERATOR: Yes sir.

MANAGER: Have you any children?

OPERATOR: Yes sir—six.

MANAGER: How do you like to operate a one-man car?

OPERATOR: Better than two. Most of the conductors were nothing more than excess baggage.

MANAGER: Now tell us in your own way just how this accident was caused.

OPERATOR: I made a stop at _____ Street and picked up about a dozen passengers, started my car—

MANAGER: With doors open?

OPERATOR: No sir, I always close my doors before I start.

MANAGER: I see. Go ahead.

OPERATOR: Some of the passengers did not have the right change and I was making change, when—

MANAGER: Just a minute. This intersection is usually a pretty busy place, is it not?

OPERATOR: Yes sir.

MANAGER: And in this instance you were making change as your car started across this busy intersection? Surely you know careless work such as this is a violation of the safety rule—

OPERATOR: I know that rule, sir, and always try to observe it, I never take a chance expect when necessary, and this time I thought it necessary.

MANAGER: (*After pause*) Well, go ahead with your story—

OPERATOR: As I was saying, I had just started my car, when the bus shot out of the side street, the front left corner of my car caught the right front corner of the bus turning it around.

MANAGER: How near to your car was the bus when you first saw it?

OPERATOR: Well it just shot out of the street and was there that quick—(*snap fingers*).

MANAGER: I see—now don't you think this accident might have been avoided if you had given more attention to the operator?

OPERATOR: I hardly think so—I have had them come at me in every direction many times; these bus operators think they own the streets. I did my best.

MANAGER: You did your best. Well, killing one man and sending two to the hospital, smashing up a bus and a car doesn't look very good does it?

OPERATOR: No sir, it does not.

MANAGER: What was the condition of your car, as to brakes and sand, etc.?

OPERATOR: The brakes were good—sand wasn't working.

MANAGER: (*All attention*) Sand not working, why?

OPERATOR: Well I was late pulling out and did not get a chance to try it.

MANAGER: Then your sand did not work at the time of the accident.

OPERATOR: No sir.

MANAGER: If the sand had been working, wouldn't it help?

OPERATOR: It may have helped a little, but this accident couldn't be avoided—the bus was too close.

MANAGER: Did you look to the left before starting your car?

OPERATOR: Yes sir.

MANAGER: Do you always look to the left before starting your car?

OPERATOR: Well I think so.

MANAGER: *(To Stenographer)* You may call in the bus operator. *(Exit Stenographer.)*

MANAGER: *(To Operator)* The habit of making change while the car is in motion and starting a car without looking to the left is getting to be a serious neglect on the part of our operators. It has reached a point where a large percentage of front end collisions occur just from this neglect and they are always bad ones.

(Bus operator enters with cap on side of head but after looking around sheepishly removes same.)

(Stenographer enters and goes to desk.)

BUS OPERATOR: Good morning.

MANAGER: Good morning. Let's see, your name it—

BUS OPERATOR: Harrison is my name. *(Cocky.)*

MANAGER: Oh yes, Harrison. That was a bad accident you fellows had last Tuesday.

BUS OPERATOR: Well it was a pretty bad accident but I don't think I was to blame.

MANAGER: No?

BUS OPERATOR: No, the trolley car was standing still when I started across the street, then he started up and—

OPERATOR: That isn't so—I started my car when—

BUS OPERATOR: Aw, what are you talking about, don't you suppose I—

OPERATOR: Yes I know just what you did, you pulled out right in front.

BUS OPERATOR: That's all bunk. *(Heatedly.)*

MANAGER: Wait a minute—wait a minute—we are not going to get anywhere with you boys arguing. Now let him tell his story. *(Pointing to the Bus Operator.)*

BUS OPERATOR: As I was saying before the cloud burst—

OPERATOR: Yes you're a cloud burst too—

MANAGER: Now, now, *(directing both hands at operators)* *(to Operator)* sit down.

BUS OPERATOR: The trolley was standing when I started my bus across—just as I got to the eastbound track he started up and hit the side of my bus. I tried to swing with the trolley when I saw him coming at me but couldn't make it—

MANAGER: Did you have your doors closed?

BUS OPERATOR: Well, I was closing my doors as I started up.

MANAGER: Passengers on the step?

BUS OPERATOR: Well, the last passenger was just pushing in.

MANAGER: Isn't it a fact that you started your bus with the doors open and passengers on the step?

BUS OPERATOR: Well, I only went a little ways.

MANAGER: Yes, and that brings out the fact that your view to the right was obstructed when you started in that manner with passengers on your step? Had you allowed all your passengers to get inside and then closed your doors before starting, that poor fellow would be alive today—just think that over. *(After pause)* Do you attend the safety meetings held at the car house?

BUS OPERATOR: Some of them—

MANAGER: What do you mean by some of them?

BUS OPERATOR: Well, whenever I get up in time. I got a pretty late run.

MANAGER: What sort of a program do they have at those meetings?

BUS OPERATOR: I don't know. They do a lot of talking.

MANAGER: Have you ever offered any suggestions as to how the meetings should be conducted?

BUS OPERATOR: I sent in a recommendation once and then I quit. They said something about it at one of the meetings but I wasn't there.

MANAGER: Then apparently you take about as much interest in safety work on the property as you do in the safe operation of your bus. I mean as far as the education of your part of the work is concerned.

BUS OPERATOR: They want you to go to safety meetings, union meetings, all there is—is meetings.

MANAGER: Do you realize the question of human life is involved in this discussion?

BUS OPERATOR: Yes sir.

MANAGER: Then you say a safety meeting is not interesting?

BUS OPERATOR: I've been to some that were and others that weren't.

MANAGER: Is that the reason you don't take an interest in the safety movement?

BUS OPERATOR: They want you to go on your own time. Why don't they pay us if they want us to be at every one?

MANAGER: Aren't the meetings for your own benefit?

BUS OPERATOR: Partly yes. It isn't all one sided.

MANAGER: Do you think you could contribute in some way to the promotion of safety?

BUS OPERATOR: Well, I think after this accident that I will attend more meetings and jump into some of the discussion that they talk about.

MANAGER: That's very good, Harrison, I'm mighty glad to hear you say that.

(To both Operators) I want you men to think over your mistakes in this case, for you both are at fault for the accident. Get your heads together so that it won't occur again. Don't be so quick to place the blame on the other fellow; be more careful and do your individual part to prevent accidents. You may both go now. I shall probably want to see you again later on and I'll send for you. And by the way, (as both operators rise to go) when you boys get outside, shake hands and realize that we are all working together and we can't have any bad feelings toward anyone if we want to make a success of our job. That's all—good day.

(Stenographer shows both operators out.)

SCHNABLE: I think that was very good advice and I am sure they will profit by it.

MANAGER: I do hope so. A closer spirit of cooperation among our men is bound to show up in accident reduction.

STENOGRAPHER: (Entering) A Miss Brown is very anxious to see you. I told her you were busy but she seems all excited and insists on seeing you at once.

MANAGER: Show the lady in.

STENOGRAPHER: (At open door) Step this way, please.

MISS B.: (Entering and rushing up to the Manager's desk) Am I speaking to the Manager?

MANAGER: Yes, madam, what can I do for you?

MISS B.: Well I just want to know what you intend doing about the service we are getting on the ——— line. Are those bus drivers out there to pick up passengers or are they running the buses for a joy ride. I never saw anything like it in all my life. And when you do get on a bus (which is seldom) you have to put up with the worst kind of abuse. Your men are far from being gentlemen and don't even know the meaning of courtesy. And such riding, after you do get on; why, you are thrown all over the bus by the rough starting and stopping. You are always preaching Safety First, you should have the buses padded on the inside.

MANAGER: Madam, I am indeed very sorry to hear you criticize our men and our service in this manner. Won't you kindly give me your name and tell me your complaint and I can assure you it will receive proper attention.

MISS B.: My name is Brown—Miss Priscilla Brown.

MANAGER: And your address, please?

MISS B.: 917 Park Avenue.

MANAGER: Thank you, Miss Brown. Now tell me just what happened?

MISS B.: I was standing right on the corner of _____ Street just a little while ago—

MANAGER: What was the time, please?

MISS B.: Oh, about an hour ago. Bus No. 68

MANAGER: Which way was the bus going?

MISS B.: Which way was the bus going? Why endways.

MANAGER: Yes, yes, I know, our buses always go endways.

MISS B.: Oh, no they don't, with some of these reckless drivers they go sideways quite often.

MANAGER: Yes, yes, but in this case, which direction was the bus going?

MISS B.: Why, coming down, down, this way (*showing directions with her hands*). And he never looked up or made any attempt to stop.

MANAGER: And you were standing right on the corner?

MISS B.: Certainly, I hope you wouldn't expect a person to stand out in the street especially with those wild Indians you have running the buses.

MANAGER: Is it possible he could not have seen you?

MISS B.: See me? If I had been one of those young flappers with skirts above my knees, he would have seen me. That is all they do see. They would run their buses right up to the front porch for them.

MANAGER: Very well, Miss Brown, I will take this up with the Supervisor and—

MISS B.: That isn't all. The next bus No. 152 came along, operated by a Mr. Percy Smith, No. 6,040—at least that is what it said in the front. Well, for a wonder he stopped, and when I boarded the bus he was very impolite and gave me an argument about the other bus not stopping.

MANAGER: Now, Miss Brown, how did Operator Smith know that the other bus did not stop for you?

MISS B.: Why I told him.

MANAGER: You say he was discourteous—just what did Smith say?

MISS B.: Oh, he said the same as you, that perhaps the other driver did not see me. Well, I politely told him I did not want any of his back talk or I would report him.

MANAGER: What other remarks did Smith make that you considered discourteous?

MISS B.: (*Hesitating*) Well, he didn't say much more.

MANAGER: Miss Brown, just what did Operator Smith say?

MISS B.: Well, when I told him that I had been standing on that corner for twenty minutes and the bus ahead of him drove right on by me without stopping, he said the bus should have stopped if the driver saw me—and—

MANAGER: Yes—go on—

MISS B.: He asked if the bus was crowded and I told him no, it was not—and he said then there was no reason why it should not stop.

MANAGER: Quite so; Miss Brown you wouldn't consider Smith very discourteous with those remarks?

MISS B.: Well I was quite provoked, especially when that bus did not stop.

MANAGER: Did Smith do or say anything to hurt your feelings?

MISS B.: (*Slowly*) Well—no.

MANAGER: Miss Brown, how often do you use the buses?

MISS B.: I generally come downtown every day when the weather's nice.

MANAGER: And how do you find the majority of our operators?

MISS B.: Oh some of them are polite.

MANAGER: Some of them? Is that all?

MISS B.: Well I guess I could say the majority of them are courteous. *(Slowly.)*

MANAGER: Thank you. But it is the minority that we want to know about. The thoughtless fellows who forget their actions are usually the cause for complaint of poor service. We welcome complaints that are just and in every case we endeavor to correct the cause for such complaints. I can assure you that the failure of that bus to stop, will be investigated and proper steps will be taken to prevent any further cases of this kind.

MISS B.: I believe you are sincere and I ~~thank~~ I was too hasty in my criticism. I am glad I came in and I shall tell my friends of the kindly manner in which I was received. Please don't ~~discuss~~ that bus driver, he may have been late or had some trouble and I lost my patience. Good day.

MANAGER: Good day, Miss Brown. *(Miss Brown exits.) (To group)* I only wish these thoughtless fellows would come to their senses and make things more pleasant for everybody. Well gentlemen, you heard that lady's complaint. What is your thought?

DIRECTOR SAFETY EDUCATION: I have tried to observe and figure out; a bus driver has many things to think about and while it is very aggravating to be passed up on the street, yet there may have been a good reason for this operator's seeming neglect.

GRAHAM: That is true to a certain extent, but had this fellow been on the job he would have seen that this lady wanted his bus. Selling transportation is our business and it can't be done that way. There is never a day goes by without a complaint of running by passengers, and my men will certainly hear from me about it.

MANAGER: Well, gentlemen, I feel this discussion has aided us in bringing out the facts in this case. As I see it, I feel the trolley operator should bear the blame for not having been certain that nothing was approaching from his left at an intersecting street and also for making change while his car was in motion particularly at such an extremely dangerous place. I feel the bus operator was lax in not closing his doors before starting and permitting passengers to remain on the step with his bus in motion, thereby obstructing his vision. And I feel that the blame of both these men will be placed by the general public on every one connected with the Transportation Safety Department, all the way from Tony to myself. *(Pauses and pounds desk)* Accidents must be cut down and it's up to us to do it.

I want to thank you all for coming in this morning and I hope it will be a long time before it will be necessary for us to get together on an accident as serious as this. That is all, gentlemen. *(All but the Stenographer rise.)*

STENOGRAPHER: You are not forgetting about the safety meeting?

MANAGER: *(Looks at watch)* That's right. Gentlemen, I am going to the safety meeting now.

GRAHAM, RICE, ORTS, SCHNABLE: That's where we are bound for too. *(Moving to door.)*

MANAGER: Glad to hear it. Then let us go together. *(Getting coat and hat.)*

GRAHAM, ORTS, RICE, SCHNABLE: Fine, yes, that's bully. We'll just about make it.

MANAGER: *(To Stenographer)* You'd better come and bring your note book, Miss McQuirk. I am sure there will be many good things brought out that we will want to refer to later.

(All exit.)

(A motion picture produced by the Public Service Corporation of New Jersey on the subject of safety was then shown.)

CHAIRMAN EASTHAM: Gentlemen, I think we owe a vote of thanks to Mr. Van Brunt of the Public Service Corporation of New Jersey for this very splendid playlet and picture. I don't know when I have seen the subject brought up so clearly, these things that we as street car men, safety men, have to contend with and that the claim departments have to contend with also.

I would like for that to be shown on the minutes of this meeting, that we do extend that vote of thanks. Now, we have about half an hour remaining, and if any of you have written out cards on the matter you would like to have discussed, I wish you would bring them up here and we will cover as many of them as possible. I would simply like to ask this, we have such a limited time left that we make the discussion as brief and to the point as possible.

The first card that was turned in, I think, brings up a very interesting point. It says, "What are companies doing to protect their curve cleaners?" Has any gentleman here anything to give us along that line?

MR. POWELL (Louisville Ry. Co., Louisville, Ky.): About three or four years ago, we had two deaths due to automobiles running over our curve cleaners. There is a white coat and white cap which the company furnishes those men. They are required to wear them now, and they are very effective.

M. W. BRIDGES (Chicago Rapid Transit Co., Chicago, Ill.): I had a letter from somebody in Pittsburgh or Philadelphia about a month ago, asking what we were doing to protect our curve greasers, curve cleaners, and so on? It happens that we are operating over our own private right of way and have but a few crossings. I wrote back to the gentleman explaining that, and immediately got an answer. They had adopted a white belt with a white cross belt which had not seemed to fulfill its purpose. In addition to that, they were using a four-candle power lamp on a storage battery. This lamp was placed on the back of the cross belt, and the storage battery was put in the man's pocket. I give you that simply as a matter of information. I don't know how it works out or anything else. I think it was Pittsburgh that did that.

MR. GALLAGHER (Pittsburgh Rys. Co., Pittsburgh, Pa.): Yes. I brought that up about having a light for the sand men and curve cleaners at night. At that time I suggested a battery lamp to be worn on their caps with a light in front and back. Down there it gets pretty dark in the morning, and a white belt is of no use at all to a fellow sanding those hills. I think a light on the hat would be a better protection than a belt, because they could use it more in the morning and evening when it gets dark. Anybody will respect a red light, but they won't a white belt.

CHAIRMAN EASTHAM: Let me remind this gathering that we started a question box in the *News Letter* last year. Mr. Nutt had several questions in the last issue or two. There are many of these things that we can't solve in a few minutes' time. If any of you have had experiences and have found things worth while on this matter or any other matter with reference to safety in car or bus operation, take the time to sit down and write Mr. Nutt and tell him what you are doing, that information will appear in the *News Letter*.

With reference to the *News Letter*, I don't think we have secured a wide enough distribution. We are going to try to work out a plan whereby the member-companies will be asked how many issues of that *News Letter* they can profitably use. I believe ordinarily it goes to the safety man in charge of the particular company, but I think in many cases if there were a dozen of those *News Letters* that could be sent to different department heads, it would help materially.

We have here a question: "Mr. Fennell of Kansas City, Missouri, referred to the use of yellow lines on streets. Do the autos and other traffic observe and obey those lines? If not, what is done to the offender?" That is asked by Mr. Allen, of the Pittsburgh Railways.

MR. ALLEN (Pittsburgh Rys. Co., Pittsburgh, Pa.): I ask that question because we use outlines in Pittsburgh, and find that about 90 per cent of the automobiles and other traffic practically ignore those lines. That is the reason I asked whether or not there could be something better adopted so that it would attract attention in some way, which would cause people to obey those regulations.

CHAIRMAN EASTHAM: Mr. Fennell isn't here, but I think the chairman might say a word or two on that, because in St. Louis we have gone farther in the painting of yellow lines than most any other large city I know of. We paint them on curves, paint them to designate loading zones, paint them from time to time at the curb, designating the point where all the automobiles should park in order to allow the cars to pass at the curve; and we have found it a very splendid means of indicating to the general public and to other traffic on the

streets what they should do. Not all of them do that, like anything else that you might attempt, but it has a good effect with a sufficient number of them, so that we have found it extremely efficacious. We have found it has helped to reduce accidents and it has helped to get the cars over the line. There is no law behind it. If an automobile, truck or pedestrian disregards the lines, there is nothing that can be done to the offender. We simply have permission from the city of St. Louis to do this work. Some of it, the cities themselves should do, in my judgment, and there should be penalties for violations. But since the city doesn't do it, we have done a great deal of it and find it is very worth while.

W. J. ROUNTREE (Georgia Power Company, Atlanta, Ga.): We find in Atlanta that the general public observes the lines we put on the streets a great deal more than the lines that the city puts on the streets for parking purposes. We think too, that the clearance lines along straight track (where the clearance is just enough for an automobile when it is right up against the curb) have proven of real value to us.

T. G. BRABSTON (Birmingham Electric Co., Birmingham, Ala.): I might say we are more fortunate than our sister city of Atlanta, Georgia, in the matter of the width of our streets, which are practically all 100 feet. We are more fortunate in the matter of lines because the head of the traffic department of the police have these line making machines. They will put lines anywhere and everywhere that we ask them to put the lines. In the downtown district, the streets naturally resemble very much a crossword puzzle. The pedestrians and automobilists sometimes get bewildered trying to stay on the right side and not on the wrong side of a line. The loading zones, cross walks and curbs are all marked by the police department. I think that makes a considerable contribution to the safe progress of traffic. In addition to that, on some of our main boulevards, the police department has very cheerfully met our request in putting a line along the middle of the street to prevent automobiles, in their eagerness to pass each other, from getting too far over on the other side of the street, or on the opposing track.

There is a violation of the law in going against the prescribed regulations in going through, across and along these lines. While it is like a great many traffic police regulations, being not very rigidly enforced, when the revenue of the police department runs low, some of the traffic squad go out and pick up enough to bring the average up.

CHAIRMAN EASTHAM: I think that is a matter that can well be kept in mind by all of you on your properties. Of course, the particular city and what the city is doing, would have something to do with it, but it is well worth your consideration.

Here is a question that I am very much interested in myself: "On one-man cars, how are we to get away from passengers talking to operators?" I think it could be broadened to include cars of any kind. What is being done on the different properties to prevent passengers, and to prevent other employees (let me add) from talking to the operator?

A. T. WARNER (Public Service Corp. of N. J., Newark, N. J.): In one-man operation, I guess the only way out of it is inspection on the street and discipline for it. It is up to the individual operator. Some of them talk too much, and some don't talk enough. Some are too curt with their answers. It is a question of individual judgment, but the line can be pretty sharply drawn where there is too much talking. The only way to do it is through incessant inspection and discipline.

MR. WILSON (Pittsburgh Rys. Co., Pittsburgh, Pa.): I put that question in. We are adopting one-man cars on our lines. I haven't in mind now the city passenger, but the man from out of town. He comes in, goes up to the operator and asks him for a direction. I would suggest in all one-man cars, that a street guide be supplied. All of the cars in Pittsburgh have destination numbers on them, for example. In the street guides, the destination number could be given. That passenger could refer to the street guide to find out what car to take, the transfer points, and so forth.

CHAIRMAN EASTHAM: I might say in St. Louis, most of the operation is two-men cars. Some time ago permanent signs were put up, "Please do not talk to the Motorman." Some of the other properties perhaps don't like to do that, but I think it has some good effect. It doesn't stop talking to the motorman or operator but I do believe it has some good effect.

G. C. COBB (Supervisor of Safety, Georgia Power Co., Atlanta, Ga.): In regard to talking to operators while they are in the discharge of their duties, I would like to say that we have in Atlanta, a street car directory which all the men carry. The passengers can get them from the company or in public places where they are sold. We would be glad to mail this particular guide to any of you who are interested in this information. It goes to tell the streets that the cars proceed on,

the streets that they cross, and the number at which they cross a street. It is a very valuable guide for medium sized-cities.

MR. OLMSTEAD (Wisconsin Power & Light Co., Milwaukee, Wis.): I don't think it is possible to do away entirely with talking by the operator of a street car because there are questions which a passenger will ask that the operator has to answer. We do the same as our Chairman said, his company had done. We have a permanent sign in front of the operator. We have had some intense education for operators, which I think has done a great deal to decrease conversation. That, I think, is the only thing you can do, gentlemen, because there are some questions they have to answer, there is no doubt about that.

W. T. HANNA (Pittsburgh Rys. Co., Pittsburgh, Pa.): In Pittsburgh, our company furnished us with a pocket guide. Oftentimes on my car, there will be

an agent, a stranger who will come into the city. When he wants to find out some of the streets (as a general thing I know about all of the streets) I reach into my pocket, hand him this book, and tell him to sit down and read it. It gives the streets in alphabetical order. I then tell him how to get to his destination and what car to take. I am often congratulated on having the book and for being a help in directing people to different places.

In regard to talking on the cars, a man can talk with safety from one end of the road to the other, with a passenger, but the trouble lies in turning around to talk to the passenger. If you school yourself into operating your car and tending to your business, you can answer all these questions and look straight ahead. You will notice that some fellows always have to turn around and look at a passenger in order to answer him.

MR. MAHONEY (Pittsburgh Rys. Co., Pittsburgh, Pa.): I would like to know if the various managers of the companies that are operating one-man cars are making any effort to discourage the practice of operators making change, issuing transfers, and giving information to passengers while the car is in motion through heavy traffic.

A. L. HODGES (Brooklyn City Railroad Co., Brooklyn, N. Y.): We have issued orders to our men (which we enforce to the best extent possible) that passengers boarding the cars shall be taken care of, given change, transfers, or any other transaction that must take place between the operator and the passengers, *before* the car is started. That works out so that it does not delay the service. We have one-man operation down in the congested territory of Brooklyn on Fulton Street, right along, and it does not disturb the service.

In regard to talking to the operator (Brooklyn being closely associated with New York) we have a great many visitors, and I want to say that I agree with the gentleman who discussed that question. It is a matter of discipline. For every stranger that asks an operator a question on a one-man car, there are three firemen or policemen or employees who get up there on the front-end talking to the operator. That is something we must break up. The only way to do it is through discipline. The odd thing about it is, if you have an accident, those fellows up on the front-end, the policemen or firemen, never see a thing!

MR. HENRY (Pittsburgh Rys. Co., Pittsburgh, Pa.): Do you enforce that rule on your men, not to make change while in motion?

MR. HODGES: We do, to every extent possible whenever it is seen by the supervisory officials.

MR. ROUNTREE: We have just gone through an experience down in Atlanta that bears very closely on that question. In fact, we are working on the matter now. We are trying very hard to break up by other means than discipline, the habit of making change (doing conductor's work in other words) while the car is in motion. We find that the objection of the men on the platform to it is that it makes it more difficult for them to operate according to schedule. We think that by getting the men on the cars to try it out, we are proving to them that it doesn't. If the conductor's work is properly done, make their schedule requirements any more difficult to meet. The company is trying to enforce that rule.

With reference to talking on the platform, I don't think anything is going to penetrate that situation quite as much as the one-man car. Down there, we are running two-man and one-man cars, and the man on the one-man car is too busy to do much talking.

MR. WARNER: One thing about change making that seems to me to help a lot is to eliminate the necessity of making change, on the part of the operator, by impressing on the passenger the idea of keeping the proper change handy. Another idea is to place change makers at your heavy traffic points. We have the five cent short zone, with no transfers at all, so the operator has no paper to handle. We have nothing but five cents, a single coin, a nickel, to collect. We find that 83 per cent of our people are now carrying the proper change, without any outside assistance at all. That was brought about by a series of educational campaigns. We had posters in the cars "Keep your nickel for carfare," and in our little pamphlet that we get out every two weeks, we put in cards for passengers to read. That point has been strongly stressed. Consequently, we have raised the percentage of passengers who have their exact change, considerably. All that helps the operator

Then, put a man on the heavy loading platform; points of heavy traffic origin, with a lot of nickels. Let him ask the passengers while waiting for a car, "Have you your change?" He helps that operator by providing passengers with the right change and impressing upon the passengers the idea that they should have extra change. That helps the operator a great deal before the passengers even get onto the platform of the car.

CHAIRMAN EASTHAM: It might interest this gathering (those of you who use tokens) that along that line of helping the conductor or the operator through the people having their change ready, whether it is a token or otherwise, that in St. Louis, where the fare is eight cents, probably the worst (next to nine cents) single fare that there is to be collected and handled, we recently bought 50,000

token holders and gave those to our passengers who bought ten tokens, eighty cents' worth of tokens. The supply of token holders was exhausted in the first two days that they were put out. We have ordered another 100,000 of them. They are simply little metal containers, and they fit in the vest pocket. They have already increased the percentage of our passengers using tokens over those requiring change, tremendously. I think today, the number using tokens is something like 88 per cent of the total number of fares collected.

MR. OLMSTEAD: We did the same thing in Wisconsin last Christmas. Token holders reduced our delays to a great extent. Regarding transfers, those transfers are given the passengers when they get on the car. On each route we have different transfer points. Those are the only places where transfers are given.

MR. BAMBRICK (Pittsburgh Rys. Co., Pittsburgh, Pa.): I find that operators, in giving out transfers, selling tokens and making change while the car is in motion, operate at a much slower speed than they would if they did all that before they start the car. An operator will go along with two or three notches in that way, and he doesn't make the time that he could if he did all that work before he started. He could then move along with full power. I have seen that many times. If they did the change making and so on before they started up, the schedules could be maintained.

CHAIRMAN EASTHAM: Now, gentlemen, there are two questions here which, unfortunately, we will not be able to take up, although both deserve consideration. "What effect has traffic regulation on the speed of trolley cars in congested districts; and what is the best way to overcome this?" And the other: "What is the proper braking pressure on a 65,000 pound car; also on a 45,000 pound car?"

We have only a minute or two left and I don't believe we will get anywhere in that time in taking up either of those questions.

I feel that the start that was made a few years ago of giving time for discussion at these meetings is the best thing that we have ever done toward increasing

interest in the meetings. I will recommend to our Program Committee for next year that that be considered and taken care of as fully as possible, so that the papers may be given thorough discussion. I think more comes out of the discussion than the mere reading of even the best prepared papers.

There is one other thing I would like to say to this group, that is, to congratulate the Pittsburgh Railways Company and the Pittsburgh men here for having brought so many of their platform men to this meeting. This may not meet with universal approval, but I have felt, from the time when certain companies started bringing a number of their platform men to the Congresses, that it has tremendously livened up the proceedings. Those men actually operating the cars have been able to ask questions and bring out points that the balance of us might fail to do. For two or three years in the past, I have brought a group of men from St. Louis. This year, on account of the long distance to travel and some other factors, I wasn't able to do it. I hope to see that custom readopted. I would like you to consider that. It is only a personal matter with each company and each management, but I would like you to consider it and take it up with your managements. I don't know yet where next year's Congress will be held, but if it is possible, bring one or more of your platform men, not alone with the idea of filling up the hall, but of bringing out the real, essential points and factors that we want to disclose at these meetings. I think it means as much to us as safety men, whatever our titles may be, and as much to the managers that come to these meetings, to get those contributions from the men operating the cars as anything else that could possibly be done.

I believe that we have had a very interesting Electric Railway program at this Congress. I hope that we will be able to arrange an equally interesting one for you at the next Congress. I trust that you not only will attend the next Congress, but that you will come through on the plea that I made yesterday of cooperating throughout the year with the editor of your *News Letter* in any and every way that you can. When some chairman writes a letter to you requesting information, asking for suggestions, or inviting you to prepare a paper, do that, because it is by that kind of cooperation and that kind *only* that this Section can achieve its fullest success during the coming year.

MR. ALLISON: May I say one thing to you? I believe unless you bar us from your next Congress, there will be 22 safety chairmen from Pittsburgh Railways present.

CHAIRMAN EASTHAM: Fine!

H. K. BENNETT (Providence Safety Council, Providence, R. I.): May I make one suggestion, if the Section's *News Letter* is continued another year (we all hope it will and have no reason to think it will not be) may I call attention to the QUESTION BOX, and offer a suggestion that the two questions that we didn't have time to discuss, be sent to Mr. Nutt, to be placed in the first issue after the Congress?

While I am on my feet may I say that the columns of that *News Letter* are open for suggestions and questions from every member of the Electric Railway Section. I hope you take advantage of that and see that the questions come in. The answers will come forward probably in the issue following.

MR. WILSON (Pittsburgh Rys. Co., Pittsburgh, Pa.): If I am not out of order (I don't want to embarrass our Program Committee) but we men from Pittsburgh and the men from St. Louis attend these meetings and hear papers read by officials. May I suggest that you ask some trainman to prepare a paper for the next Congress?

CHAIRMAN EASTHAM: I think it is a splendid suggestion. We did, at the last Congress in Chicago (if you will remember) have a paper from a man who may not now be considered a trainman, but a member of your Amalgamated Association—Mr P. G. McGrath. I believe it was.

We haven't in any way tried to slight you. The fact is, we haven't in the past been able to know in advance just what companies expected to bring men. There has been a little difficulty from that standpoint. If Mr. Brabston will make note of that suggestion, I am very sure he and his Program Committee will carefully consider that and they will see if it can be worked in for the next Congress.

ADJOURNMENT

Joint Luncheon Public Utilities and Electric Railway Sections

October 3, 1928

T. G. BRABSTON, Chairman

**Superintendent of Transportation, Birmingham Electric Company
Birmingham, Ala.**

The joint luncheon session of the Public Utilities and Electric Railway Sections at the Seventeenth Annual Safety Congress, was called to order at one-thirty o'clock by the chairman, T. G. Brabston, Superintendent of Transportation, Birmingham Electric Company, Birmingham, Alabama.

CHAIRMAN BRABSTON: Gentlemen, we are going to be very happy at this time. We are going to be entertained by some gentlemen representing the world's greatest railroad.

(A quartet representing the Pennsylvania Railroad rendered four compositions.)

CHAIRMAN BRABSTON: I am sure we all realize now after hearing these songs, why the Pennsylvania Railroad is so distinguished for its courteous and efficient service, and I am sure I reflect your sentiment when I say to this quartet that we are greatly appreciative for their contribution.

We have at this time a rather interesting event on the program. There is constantly a rivalry between departments and companies in establishing successful records. And that reminds me of the man that came up to my town from somewhere, and said to the waiter who was a darky, "If you will wait on us now satisfactorily I will reward you with the proper sort of tip. By the way, I have never been down here before, what is the average tip?" "Well, boss, ah'll tell yo', the average tip hits a dollar." "That is perfectly all right. You wait on us properly and I will give you an average tip." When he got through, the darky asked if the service was all right and the man said "Yes," and handed him a dollar. The darky said "I thank you. I have been working here close on to three years and you am the first man what come up to the average."

We have 23 companies here who have a distinction that have certainly come up to the average. There are three trophies which are to be awarded to those companies who have established themselves in having records worthy of recognition and outstanding in the industry, and the first of these is presented by Mr. Floyd W. Parsons, Editorial Director, Gas-Age Record, New York City. I think it is a wonderful incentive and spirit that has prompted the offer of this trophy. At this time it is my pleasure to present Mr. Parsons who will make this presentation on behalf of that publication.

Presentation of Trophy

By FLOYD W. PARSONS

Editorial Director, "Gas-Age Record," New York City

In the words of the horsethief who was about to be hung and asked to speak on that occasion, I am the one most interested in this part of the performance and the least enthusiastic about it. If any of you play golf and play a blind hole and the caddy says, "It is just over the hill," and you shoot over and you find the ball is way off—that is just about the position that I am in today. First I did not believe

I could use my vocal chords. We editors dictate from seven to ten hours a day. We really work, and so I only expected to say a word.

I understand it is intended that I speak for just a few moments and then present this trophy. I visited a throat man this morning, so after leaving the throat man I went down to see my dentist and he put something in my mouth. He said, "What can you do for fifteen minutes?" I said, "If you will give me that package I will write a speech that I am going to make in about thirty minutes." So I did that. I have never been to one of your meetings. I have written stories and syndicated them and put some in the *Saturday Evening Post* and helped the movement along as best I could.

My experience with accidents started when I was six. They were building a new jail in our town. They left one of the cells outside. I was the prisoner. I had to escape. I fell off and cut my head and still have the scar. Later I jumped on a freight train and was thrown between the platforms of two cars; and the wheels went around and knocked me around until twenty cars had passed. I was still alive. That gave me a positive indication that there must be a good God that saves us. Later, I was a mining engineer and I went in with twenty-seven men to try to rescue a lot of men caught in the drainage. We organized our party and three came out. The other twenty-four came out some days later pretty stiff and dead—so that I have some acquaintance with what accident prevention means. When I first went into the mines in 1902 we shoved off and lit gas feeders and then took our coats and beat them out. That was when we talked about safety lamps, so that I have seen the development of industry, of accident prevention, for twenty-five years or more and have carried my little part in this movement in an editorial way in the big magazines.

There was a timid old lady who went to cross a ferry, and after starting she became a bit nervous and said to the darky boatman, "Has anybody ever been lost in crossing here?" The darky replied, "No ma'am, no ma'am; my brother was drowned last week but we found him the next day." So it is almost entirely a question of the point of view.

Today we are bothered with a lot of bunk and half truths. "Did you know that Harry made \$5,000 a week," said Abe to Solomon. "I don't believe it" said Solomon. Abe said "I will prove it. Did not Harry make \$5,000 in Washington?" "Yes, that is right" said Solomon "but wrong in four places. First, it was not Washington, it was Cincinnati. Second, he did not make it in a week but in a year. Third, it was not \$5,000 it was \$500; and fourth, he did not win it, he lost it."

Today we are perjuring in industry and life generally and we get a number of falsities. We believe guinea-pigs come from Guinea; lead pencils have lead in them; the staff of life is bread, the worst thing that nine out of ten can get; and that fish is brain food, but it is nothing of the kind. That the ocean is flat—nothing of the sort; it is a gently sloping hill. We take histories and fill them with exaggerated tales about the early hero. If you will examine our forefathers and what they did you will find they were a pretty tough bunch. Tremendous changes come along and cause great hazards to arise. We are always fooling with things we know little about. Radium has killed a lot of people. Radium, which you read about, is doing a lot of damage. The aeroplane—all these and other new things—are taking toll in life, but that is the only way we can improve life and relieve the over-carrying of the burdens that we shouldered under the old methods. The automobile is a great thing but the carbon monoxide from them as they roll along the streets goes into the lower parts of buildings, up the stairs and in the remote office and helps to give us a new problem in polluted atmosphere. Accidents,—the kind of taxi drivers we have—and that reminds me of a story.

A lady got into a taxi and told the man where she wanted to go. The taxi started off with a terrible jerk and the driver dodged everything on the road. When she arrived at her destination and wanted to get out she said, "This is the first time I ever rode in a taxicab and it is terrible." "That's nothing" said the driver; "this is the first time I ever drove one."

People who invest their monies in companies do not see the reports of minor accidents that cause delay and loss of time and reduction in production. The general plan we have in facing life is filled with so many inconsistencies. We go to an extreme in saving along one line and wasting along the other. That reminds me of the ducky who was going fishing, and he met an older boy along the road and he said, "What's the matter with your cheek, it's all swelled up? What have you got in your mouth?" "Well," replied the little ducky, "I'm going fishing." "Well, what have you got in your mouth?" "Worms!" The old boy said "Worms? Why don't you put them in your pocket?" "Put them in my pocket? Do you think I'm going to put them in my pocket with my lunch?"

Gases have quite a black eye. In fact the gas industry which has just awakened is about to play a dirty trick upon a lot of people who want an easy way to get out of the world. We are well along in our research to make it impossible to commit suicide with gas in comfort. The research men tell us they are well on with the experiment and when you try to take a little gas to end it all you get so damn sick before you die that your purpose is entirely defeated. Also we find that our ordinary radium gas fire is the nearest thing to sunlight. There is quite a craze around about ultra violet light. If you don't get it you can't absorb phosphium in your system. We also have discovered that in our ordinary radium fire we have ultra violet rays. The use of gas will become more prevalent because fellows will strip off nowadays and the rest of the family get the ultra violet ray for nothing. It shows how things are changing nowadays but there are new days coming on.

The utilities, I will say, have gone a long way. One hundred thirteen units were in the contest just held this year and these employed 72,000 men. Out of the 113, 93 made complete returns. Fourteen of these units came through this contest without a single lost time accident, and when you consider that the accidents in the gas industry extend from traffic conditions to fitting and on through all of the other operations of building, chemical departments and all, that is really quite some record. In this contest the unit of the Southwestern Gas and Electric Company, the unit situated in Dallas, Texas, has won first honors. They employ 105 men and they worked 181,710 man-hours, and I want to present this cup to Mr. J. Allen Read, Safety Director of this particular company. Is Mr. Read here?

Accepting First Honors

J. ALLEN READ (Safety Director, Southwestern Gas and Electric Company, Dallas, Texas): The Chairman tells me to make my remarks snappy so I am going to. This is, indeed, a surprise to me. I have not even seen our last month's report. I thought it was hopeless. I felt that the small gas portion of our company had no chance at all. I want to thank the *Gas-Age Record* for this cup and thank the section; and I am sure we will duplicate this record not only when we have a contest but also when we have not.

I want to pay a little tribute to the company that won this cup. This was not won by any individual. It was won by every employee of the Southwestern Gas and Electric Company. They operate in some 80 or 90 towns from Mississippi to Arkansas and from Mississippi to Texas. Three hundred fifty to 400 employees have just completed a year with but one lost time accident, and that happened when a negro boy threw a stone in one of the fellow's eyes. This is only the gas section but all our sections are endeavoring to prevent accidents. I thank all of you. I am just so surprised and thrilled that I can't say anything.

CHAIRMAN BRABSTON: That is fine. At this time we are going to have the presentation to this other group who have so singularly distinguished themselves. Mr. Ernest W. Beck, Vice-President of the National Safety Council, will now make his presentation.

Presentation of Trophies

By ERNEST W. BECK

**Vice-President, National Safety Council; U. S. Rubber Company,
New York City**

Mr. Chairman, I feel very much out of place here, not being affiliated with a public utility. I am pleased however to come here and encourage the proposition of a no-accident contest. The previous speaker who presented the trophy spoke of the number of contestants. I noticed one or two gentlemen making a few notes regarding the number of units without a lost time accident. I want you to know that improvement as a result of this no-accident contest is equal to 280 per cent. In other words, the persons employed to no lost time accidents were 37 to 1, compared with the record of two years ago of 12 to 1. That is wonderful.

I have been quite tied up with these contests because I am convinced that this element has accomplished a great deal. I say that from experience. My company has shown an improvement each year for the last five years over the average of the last three years. These things don't just happen. The gentleman when he accepted that trophy gave credit to where it belonged—each and every one of the organization. He knows and I know that there must be somebody at the top who is giving the contest his approval, who is approving the expense account, making out the budget, believing it is good from a financial point of view and an humanitarian point of view. The expense is infinitesimal with the enormous savings it represents.

Your contest was started in March 1928 and was operated six months and showed the good results. You have six groups, gas, electricity, combination of gas and electricity, telephone, telegraph and water. I am surprised you did not get enough in your water group to contest for a cup, especially under the Eighteenth Amendment. You, have, however, been successful in getting 113. I believe you can get more and in another year the National Safety Council will be able to report many more in the contest, and the reason is because of the success this contest has had.

Any man who turns down a sound no-accident proposition I cannot understand. He cannot be sold on safety. It is a very, very essential part of a properly organized safety program. I have been asked to present this trophy to the group known as the electric group. In this group there were seven companies who operated without lost time accidents. Competition must have been very keen. That is a wonderful record. Is Mr. Watts in the room? Mr. Watts, in behalf of the National Safety Council, it gives me great pleasure to present this trophy and I hope you and your organization will be successful in winning another next year.

Acceptance by the Electric Group

MR. WATTS (Southern, O. Pub. Service Co., Zanesville, Ohio): When an occasion like this arises, a fellow is more or less swept off his feet. We did not, until a few minutes ago, know we won it. I suppose you men want to know where Zanesville, Ohio, is located. It is midway between Columbus and Wheeling, West Virginia. Our company employs something like 135 employees actually engaged in the manufacture and distribution of electric energy. We have found by experience that the safety director cannot sit behind his desk and preach safety. He must

Joint Luncheon Public Utilities and Electric Railway Sections 1043

get out on the firing line. As late as last Saturday we had occasion to put in a two and three quarter mile emergency line and had to employ something like 35 men. I took it upon myself to go with them to see that they got by with it. I want to take this occasion on behalf of my company and myself to thank the National Safety Council for this trophy.

MR. BECK: The losers win. I know of no factory, even if they showed red figures but what have felt that they really were better off than if they had not joined so I am going to mention as honorable the others who have operated without lost time accidents: San Antonio Public Service Company, Citizens Gas and Electric Company, Wisconsin Electric Company, Superior Water Works, and Wisconsin Power Company.

Our next group is combination gas and electric. It is a large group and the plant winning a prize is a plant working a large number of man-hours. The winner of the combination gas and electric group is the Lake Superior District Power Company, at Ashland, Wisconsin. They serve 36 companies in Michigan and Wisconsin, having a total population of 65,000 members. All companies are rendering electric service and one town served with gas and one town operates street railways. We are extremely fortunate today in having the vice-president and general manager of that organization with us. I have checked up on him and I have a wonderful record of the work he has been doing for safety. I know he must have it. You must meet the man and talk with him and you will know that he is a safety enthusiast. He is here today and it is a pleasure to have him with us. I will now present the trophy to Mr. G. W. Hodgkins.

Speaking for the Gas and Electric Group

G. W. HODGKINS (Vice-President and General Manager, Lake Superior District Power Company, Ashland, Wisconsin): Mr. Chairman, gentlemen: I am a long way from home and I want to tell you where I come from so you will live with me for a few moments in my home.

A year ago I was at a meeting and the gentleman that introduced me said that we build only nine hole golf courses in our section of the country because the summers are so short we cannot get all the way round the course. We live on Lake Superior at the western end. I have heard your safety directors talk. I have heard the men most interested expound their different ideas on safety practice but I am convinced of one thing and that is that first there must be some background to tie to. I know it is easy to issue bulletins for boards and put up your safety signs on your boards around your plants but I also know this: You men all know Abe Lincoln. You probably have all heard the story of the time Staunton wanted to do something and Lincoln said not to do it and the men went back to Lincoln and reported Staunton as having said "Lincoln's a damn fool" and Lincoln said "Staunton's usually right." You understand that Lincoln was President of the United States. A man whose every wish, every order, could have been fulfilled. Yet, he said, "Staunton is usually right."

From that attitude of mind, Lincoln developed a personal following from his bitterest enemies until today he comes to us through history almost a Christ.

In any industry you have got to develop the thing that Lincoln developed to achieve the highest degree of work, whether it be safety work or some other kind of work in your organization and when I say that, I don't mean loyalty to me—I mean loyalty to every man who has men responsible to him and men that look to him for their welfare.

If I were to wish for success, the greatest success that could come to me, it would be to have the feeling that the men who work under me believe in me and I want the men who are responsible to me to have the whole work under them of

the men responsible to them believe in them because nothing in the world runs as counterfeit as insincerity.

You can follow out a set of rules and orders because they are given you. The men that work for you know as well as you when the men to whom you are responsible are insincere. Men get wrought up and some one will criticise some man in his organization, but this is also true. You can criticise the men in your own organization but when it comes from somebody outside or somebody above in your organization you know that you will fight for every man in it who is depending on you for his welfare.

I spoke of Lincoln. It was my good fortune to be in Washington when Colonel Lindbergh came home, and I would not have missed that trip. I would not have missed seeing the things I did see for anything. I sometimes wish that some of the people back home who are sending some of the representatives down to Washington could go down and see some of the things that I saw.

You know that this country was not built in a minute or a day. It meant the sacrifice of years and sacrifice on the part of the greatest men of the nation, and that is what we mean when we talk about patriotism. You can't expect a man to come to this country off a boat and understand all the pictures that have gone before, pictures that our native born American can absorb. Yes, I went down to see the Statue of Liberty. It stands, a metal piece, and perhaps to some people it means just that. To me it meant more than that. It meant that the time of discord with France was over and we have an anchor out in the harbor, a present made to us by France; and those of us here and those of us there know what the Statue of Liberty stands for.

Gentlemen, I only cite these historical things to have you believe that the thing which will make industry prosper, which will make safety work more effective, is the loyalty which is born of association, respect and regard for the men you work for and with, and success can only come in that way.

I don't take any personal credit for this wonderful trophy I am taking home with me, and a few moments ago as they were singing their song, I wished it were possible for those back home, all of them who are associated with me, to be here today to get some of the inspiration that I will fail to take back.

You know the public utilities today are occupying so much of newspaper space. I wonder sometimes if the men who are writing these articles know men in utility business. Sometimes I doubt that they do because as I go around the country and look into the faces of such as are gathered here today, I don't believe it is possible for us to be such a damnable lot as some of the newspapers represent us to be. We all have to work. I don't believe any other industry furnishes men who are more sincerely and conscientiously trying to do the thing they should do, more than the men in the utility industry.

I want to add this, Gentlemen: I believe it was just our good fortune to have first prize. I don't believe we did any more than other organizations represented here today. We have all sincerely tried to do our best. Next year it will be some other company and I will be just as glad for you as I am for our own company.

As I go about the country I have pride in knowing the men engaged in the industry. I think this is true: generally speaking, we go back to the question of loyalty and I think the companies that have the least turnover have the greatest loyalty, and the companies that have the greatest loyalty have the fewest accidents; and I believe, the companies that have the fewest accidents have the best records in earnings.

Our Safety Director, Mr. Jule, gave me some records of accidents but I won't take up your time with those.

We should develop a sense of responsibility and gather about us younger men. It has been my good fortune to be associated with a company small enough so that I know the men.

Joint Luncheon Public Utilities and Electric Railway Sections 1045

Many of the boys are sons of fathers who are either on pension or are getting old. If there is any one accomplishment that I feel more proud of than any other, it is the fact that I have been able to gather about me young men whom I have known all my life and who have known me all their lives. We work together and it is just as easy to get into my office as it is to get into any other office on my property.

I am going home to my property with a thrill that comes to an organization in a thing of this kind. I want Mr. Jule to stand on his feet to show you the man on the property. He has not taken the prize himself but has been with the men throughout the territory. Mr. Jule!

(Mr. Jule stood up for a second.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Employees' Benefit Associations Section

New Section Officers

General Chairman—GEORGE W. VARY, Bethlehem Steel Company, Bethlehem, Pa.

Vice-Chairman—DR. OTTO P. GEIER, Cincinnati Milling Machine Company, Cincinnati, Ohio.

Secretary—J. W. RIDDLE, The Youngstown Sheet and Tube Company, Youngstown, Ohio.

Program Committee Chairman—R. E. McEWEN, Western Electric Co., Hawthorne Station, Chicago, Ill.

Service Committee Chairman—DR. DEAN K. BRUNDAGE, United States Public Health Service, Washington, D. C.

Retiring Officers

Chairman, R. E. McEWEN, Western Electric Company, Inc., Hawthorne Station, Chicago, Ill.; *Vice-Chairman*, JOHN BAILEY, The Bell Telephone Company of Pennsylvania, Philadelphia, Pa.; *Secretary*, GEORGE W. VARY, Bethlehem Steel Company, Bethlehem, Pa.

October 3, 1928

R. E. McEWEN, Chairman

Employees' Service Division, Western Electric Company
Chicago

The first session of the Employees' Benefit Associations Section at the Seventeenth Annual Safety Congress was called to order at two o'clock by the chairman, R. E. McEwen, Western Electric Company, Chicago, Ill.

CHAIRMAN McEWEN: I think that there is enough business before this meeting to take the whole afternoon without any lengthy remarks from one who has been styled "chairman." Those who have printed the program have given me the responsibility of discussing the past, the present, and the future of the E. B. A.

The past of the Association is somewhat brief, the first meeting being held in 1916. The reason for its being grew out of the fact that each year at the National Safety Council there were found a large group of men interested in benefit fund matters, and they were always getting together and discussing their mutual problems. From that nucleus the Council decided it would be advisable to set up a

separate section where they might get together and exchange experiences. I have recently reviewed the programs of the various sessions held since the organization of the section.

The early meetings were largely given up to a discussion of the mechanics of benefit fund associations. Discussion was had on such subjects as, "How much shall the member in the benefit association contribute?" Other matters of mutual advantage were much discussed. I think we all agree that we should adopt some broader policy than the mere mechanics of a benefit fund association. There is a wider field here for the benefit association. We are gradually growing away from the theory that the National Safety Council should do the work of accident prevention and the Benefit Fund should pay the bill. We have found that we are a great force, not only in meeting benefit requirements, but also in disability prevention.

With that idea uppermost in our minds, this year we have drafted the first section of our program along the lines of health protection. We feel that here is a big field which we can work very much to the benefit of the members of the association and to the industry in which they operate.

As previously stated we ought not to get away from doing all we can to improve the mechanics of the benefit fund, but I think we can do something more in the prevention field, and my study of the programs over past years leads me to this conclusion—that we have been doing a rather hit or miss job in this section. The programs differ, covering certain subjects many of us are interested in, at the same time we have never seemed to have a definite forward-looking purpose, or object, toward which to work.

As chairman of the Association I wish to offer the suggestion that we adopt some means in this section to run through our meetings and our activities, some line of endeavor, some line that will hook-up the loose ends and all to the purpose of having some definite object in view in years to come. Perhaps, one of the most effective means of doing that would be to enlarge the duties of our program committee.

It is a difficult thing for a program committee to be appointed here today with little or no knowledge of the activities of the section, and draft a good program for the succeeding year. The men may not know the talent we have present in the meeting, or the far reaching objects of the association; and it seems to me if our chairman would appoint one new member and allow two of the old members to stay on the committee for another year, we would then establish a line of connection which would help us to reach a more definite result. I would be glad to know the sentiment of this meeting along that line. I don't know of a better time to ask about that than right now. Has anyone anything to say, or any suggestion to offer? I would be glad to hear from some of the old line men.

DR. OTTO P. GEIER (Cincinnati Milling Machine Company, Cincinnati, Ohio): I move that it is the sense of this meeting that your suggestion be followed now and that the officers be instructed to that end.

CHAIRMAN McEWEN: If there is no objection we will appoint one member to serve for three years, one for two years, and one for one year.

I have talked about the past of the association; the present is here with us. Mr. Vary, who has very efficiently acted as secretary this year, is going to say a few words about the future of the organization before our program officially begins.

GEORGE W. VARY (Bethlehem Steel Company, Bethlehem, Pa.): As I see it, the function of the Relief Association is more than to collect contributions and to pay benefits. It should also function in such a way as to prevent sickness.

The first step in this direction, in my opinion, is to compile uniform statistics

so that proper comparisons can be made, not only in industries of a like character but also in industry as a whole.

When the Bethlehem Relief Plan was inaugurated in 1926 all reports were formulated with the view that the data obtained would be of such a nature as to coincide with the reports of the United States Public Health Service following the Manual of the International List of Causes of Death.

It seems to me that with this kind of information available, in conjunction with periodic physical examination, a step in the right direction can be taken to reduce the amount of lost time due to sickness.

The problem in industry today is to get the maximum effectiveness and efficiency out of the worker and it is to the benefit of the employee as well as the company that an effort be made to reduce the lost time due to sickness and accidents.

When you consider that the lost time due to sickness is six to eight times that from accidents, and that the death rate from sickness is at least ten times that from accidents, it is obvious that sickness prevention is the larger problem.

I recommend to this meeting that the chairman be authorized to appoint a committee to submit to the members of this section a uniform method of reporting and tabulating by causes the lost time and deaths due to sickness.

CHAIRMAN McEWEN: Mr. Vary has suggested some sort of an organization which can carry on this statistical work. I wonder if that committee might not function in some other respects. I think everyone who has ever served as an officer of this group has found that during the year a great many inquiries are made as to the method of building and operating benefit funds. It is hardly fair that the chairman should assume all the responsibility of answering all questions of the group; it seems to me that in connection with this committee's work, we can appoint, not a statistical committee alone, but a service committee that will function in both respects, compiling the statistics as suggested, taking care of the inquiries that are presented to the section, and gathering the best data available to answer those inquiries and assume the responsibility of giving the Section's opinion on these matters. I think that would be better done by a committee than by an individual.

So we are again faced with the proposition of having some sort of a "Service Committee" to function during the year under the direction of the chairman. I believe that Dr. Sappington, who is head of the Health Service Division of the Council, should be added as ex officio member.

As I have previously stated, our program is majored today on the subject of health. I am going to take this occasion to present Mr. F. W. Willard, Personnel Director of the Western Electric Company, New York City.

Some Thoughts on a Program of Health Education for Industrial Workers

By F. W. WILLARD

Personnel Director, Western Electric Company, Inc., New York City

It is well within the memory of many of us that a responsible executive of a private industry proposing to spend some of the corporate funds for the education of the industry's employees in the rules of health and the prevention of disease would have been examined by an alienist. Yet at that very time influences in industrial management were preparing the foundation upon which today private corporate funds are being expended for that very purpose without specific and concrete proof that the expenditure of those funds will certainly bring profit to the industry. Yet no executive or group of executives who have set their faces

definitely toward this goal have serious doubts in their minds concerning the ultimate profit to be derived by the corporation.

There must be some background in the experience of present-day executives which supports this confidence. It is my guess that industry's experience of the last twenty years in the protection of employees from bodily injury, and education in habits of safety is the support. There are of course other compelling reasons for the development of health education in industry, but I believe that the profits derived from reduction of industrial accidents are the most persuasive.

With few notable exceptions, the preceding generation of industrial leaders were reluctantly interested in the provision of safe tools and safe working environment for their employees. I think that speaking for industry as a whole, it is well to admit frankly that social pressure through agencies of government compelled in the first instance the attention of industrial executives to the need for accident elimination. Even then, not a few industrial executives looked upon the problem as an expense forced upon them by unjust legislation.

A few years of experience, however, indicated to them that this thing which they detested as an encroachment upon their individual liberties by government was actually bringing new profits to the industry. Today no intelligent executive will spare any expenditure necessary to prevent an industrial accident.

There is not available complete statistics on industrial accident experience during the past two decades. Such as are available indicate that while there has been an increase in trend of accident frequency there has probably been a substantial over-all decrease in accident severity.

If, however, we study those industries which have kept records during that period and whose managements have during that period made more or less consistent and continuous effort to reduce accidents, we find very substantial improvements. Probably the best records available for any one industry as a whole are those of the Interstate Commerce Commission on the experience of the railroads of the country. These indicate a substantial reduction in severity and some reduction in frequency up to the beginning of the World War.

The disorganization of the war resulted in a serious relapse, particularly with respect to severity but since 1920 the commission's records indicate a severity and frequency rate distinctly better than the best years preceding 1914.

A study of individual industries reported by the American Engineering Council shows very distinctly the substantial results obtained where definite and aggressive safety campaigns were conducted.

The important characteristic of the experience of industry in its successful efforts to reduce industrial hazards is in my judgment that mechanical protection of the worker proved in and of itself to be only a partial solution of the accident hazard problem, and by no means a major part. Quite generally in the earlier campaigns for reduction of accidents, expenditures by industry were directed to the modification of plant equipment to make it impossible for the workmen to be injured. The result of this effort and expenditure was unquestionably profitable, because it removed from a rapidly mechanizing industry some of the exposure to the most distressing and seriously disabling types of injury.

Nearly thirty years ago my first employment in industry was on one of the great railroad systems of the country, where I came in personal contact with a generation of older railway train service employees who had not labored under the protection of the automatic coupler and the air brake. I recall very vividly the distressingly large number of those men who bore the scars of battle with the hand coupler. The train service man in that generation who had all his fingers was the lucky one. Rare indeed today is the train service man who hasn't all his fingers.

After a few years of effort on the part of industrial management to reduce the mechanical hazards by improvement of their equipment, discovery was made that there was something lacking in this effort. While severity of accidents was declin-

ing, the frequency did not seem to follow. In fact in some industries which had gone to extremes in mechanical protection, the frequency rate of accidents among their employees actually went up.

Then it was that the campaign for education of all the people began. The results of this campaign of education, particularly to the benefit of factory employees and to the profit of factory managements, have already gone beyond the most optimistic estimates. It is this experience in my judgment that is impelling forward-looking executives today to tackle the problem of education of all industrial workers, in both management and employee groups, in the simple and proved rule: of the preservation of human health.

Absenteeism on account of sickness disability among industrial employees is estimated to average seven days* per capita per year. The direct loss in dollars involved in the payment of wages or its equivalent in disability benefits amounts to \$100,000,000** per year; and the indirect loss, which of course can only be roughly estimated, is placed by another authority at \$2,250,000,000* per year in the United States. This does not take into account the indirect loss to industry by lowered production due to lowered physical vitality, and interrupted production due to interruption of the productive work of the individual.

This is a big pool of potential profit to industry, but an ocean of potential happiness and prosperity to society. Like the accident prevention project, it offers to the managements of private industry a profit incentive which is awakening the consciousness of this generation of industrial managers to the necessity of observing all of their social obligations if they are to build a permanent industrial structure.

Although my subject relates specifically to the health problem in industry, I cannot omit to acknowledge the social agencies which have in the past quarter century contributed so effectively to the solution of the problems of public health. Without the constructive work of these agencies, industrial managers today out of current income could not hope effectively to carry on a program of health education. We undertake to teach to industrial workers the simple and accepted rules of health preservation and disease prevention with confidence because these other agencies have placed in our hands proved, scientific facts, many of which twenty-five years ago were undiscovered. In fact it is more than probable that effective health education could not be carried on today without this new background of knowledge.

First among these agencies is the medical profession, supported in no little measure by the industrial profits of a generation past. They have diligently and with admirable social consciousness applied the methods and the discoveries of physical science to their art, until today they are rapidly bringing the cure and prevention of human diseases into the laboratory of exact understanding.

Beginning with the elimination of smallpox as the great scourge of civilized peoples, the means of absolute prevention of yellow fever, typhus, diphtheria and typhoid fever have been scientifically established and proved. Tuberculosis among the civilized peoples is on the rout. Treatment of children's diseases has been so far developed and infant mortality so substantially lowered that the average expectation of life has been materially increased. The average span of life in New York City in 1880 was forty years; in 1925 it was fifty-five years. The death rate in New York City in 1875 was 28.3 per thousand population and in 1925 it was 11.5 per thousand.

The people at large are being progressively indoctrinated with the proved results of medical research through municipal, state and federal public health agencies. Nevertheless, it is estimated that the total expenditure of public funds for this

* Louis I. Dublin, Statistician, Metropolitan Life Insurance Company in "Health and Wealth."
** Estimate based on average wage of \$4 per day—J. D. Hackett in "Health Maintenance and Industry."

work is less than fifty cents per capita annually. It is further estimated that an expenditure of five times this amount annually would further reduce the death rate, and increase the expectation of life from five to seven years; but it is also estimated that the American people are spending a billion dollars a year in some form of medical service, principally curative rather than preventive. Probably 2 per cent of the population of the United States are at all times so ill as to require some sort of medical curative service.

Along with the public agencies for health education, the public press is rendering useful service in its daily talks on disease prevention and cure, and its service of answering the questions of readers relative thereto. It has still a large potential field for operation in public health education, as well as in the protection of the public through the censorship of its advertising. There is growing an insidious fear psychology in the advertising of certain merchandise useful or necessary to the health of the individual. In some respects it is not less harmful than the brazen advertising of the patent medicine nostrums of more than two decades ago. The press cooperated in the elimination of such advertising at that time. They can do much to redirect present trends.

A fourth important public agency is the American Red Cross. Their work in connection with education for the prevention and cure of tuberculosis is well-known. It has probably been one of the most effective agencies in the education of the people resulting in a marked decline in the incidence of that disease. Its nation-wide educational campaign in first aid, both in accident and sickness, is beginning to show tangible results.

The medical profession, through its extensive endowments for research, is tackling vigorously those dread diseases of middle age, particularly cancer and heart disease, which, apparently because of the extension of life expectation due to the reduction of infant and youth diseases, has been increasing in incidence relatively.

Viewed in the light of all these developments, which have demonstrated their usefulness in the last quarter century, it is not surprising that intelligent stewards of industry should take advantage of the potentialities of their rapidly improving relations with their employee groups to augment the process of public education in health principles, having obviously a direct object in improving the profits of the industry and consolidating the confidence of the community in industry as a constructive social instrumentality.

How is it being done? First, progressive managements are pushing their efforts to complete the job of physical protection of employees against health hazards in their working environment. No inconsiderable number of employers have gone a long way on this road, but there still remains much more to be done than originally anticipated. It isn't sufficient to provide pure drinking water, adequate lighting and ventilation, and sanitary buildings. Each and every manufacturing process needs to be studied from the viewpoint of its effect upon the health of the worker. For example, the study of stools to correct bad posture; the study of fatigue and nourishment; the elimination of all sorts of contaminations of factory atmosphere, whether they be gases, or solids in the form of dust suspensions, are vitally essential to the foundation of an effective program of health education. An employer's good faith is quickly open to suspicion if he attempts to teach his employees the principles of health preservation and yet asks some of them to perform their daily tasks in an environment which is plainly injurious to health.

Along with the safety movement of fifteen and twenty years ago, the grosser of these industrial conditions were vigorously attacked, both by public and private agencies. The National Safety Council presents an admirable record of accomplishment in this phase of prevention. But our rapidly developing methods of manufacturing are presenting new problems every day, and the progressive manager

cannot safely overlook the hazards to workers' health which may be involved in these new methods.

The time to prevent the introduction of any processes injurious to the health of the workers is during the development of the process, and the engineering forces of progressive manufacturers today are quite properly considering this as an important part of their process development. However, the engineer cannot do this alone; management must provide for his service adequate medical supervision, with proper equipment and facilities.

With this medical supervision, physical examinations as a condition of employment have become essential. As a service to employees who are awakened from their traditional fatalism, periodic physical examination of the individual is an important step in this industrial program.

What is perhaps of most importance, particularly to industries who are beginning to attack this problem, is an effective indoctrinating of the responsible supervisory forces with the reasons for, and advantages of health education. The supervisors must have the principles of health preservation well learned and effectively practiced upon themselves, if they are to wield the necessary influence upon the people entrusted to their supervision. This education of the supervisors is no small task. Presumably, the fact of selection of a man to supervise the work of others indicates a higher level of intelligence for the individual. Undoubtedly this is true with respect to the personal and technical qualifications of the individual, but it does not follow that, with respect to the problem of individual health, the supervisor is necessarily more intelligent than the supervised. In fact there is some evidence to indicate that he is not. Some of the most intelligent people are the most flagrant violators of the simple rules of health, because of their heritage of ignorance and fatalism.

This fact makes the education of the supervisory force in health principles an essential preliminary to a general health education program. In an organization where the management and the general forces have effected harmonious working relations; where mutual confidence and cooperation generally rule, the personal influence, through personal habits, practices and conduct of the supervisory employees is the most powerful instrumentality in the education of the general forces. A supervisor who has the respect of his associates under his supervision can by his own habits and practices nullify the efforts of the management in a program of education of this kind.

These are most commonplace remarks; it borders on offense to your intelligence to mention them, but the principles are so essential to an effective accomplishment of any program of education that they cannot be omitted in a discussion of this kind.

Another important instrumentality in this project is the maintenance of some sort of a sickness benefit plan, either mutual or non-contributory, as the conditions of the industry may seem to justify, so as to help lift the burden of worry from the individual when he is disabled on account of sickness.

It goes without saying that with the proper medical supervision, physical examination of applicants, periodic physical examinations of employees, and training and indoctrinating of the supervisors, an adequate system of records of experience is necessary in order to be in a position ultimately to determine sources and causes of illness, and to enable management effectively to measure results as their work proceeds.

We stand in the position today, as far as experience in health education among industrial workers is concerned, of not being able to present a concrete statement of experience upon which to predict the probable profits to be expected from the expenditures in health education; but we cannot continue these expenditures without at some time taking a reckoning on the books. Therefore an adequate system of records must be built up with the program. Causes and effects are so

easily confused in studies of human health that even with the most meticulous accuracy of record, we cannot always be sure of correct conclusions. As we gain more experience in the carrying out of this program, we shall undoubtedly find other essential tasks of which we are now ignorant, just as we found that the mechanical protection against accident was not the whole answer to accident prevention.

We are finding that we as a people do not know very much about effective teaching. The teaching of health principles certainly is not easier than teaching the classical subjects in our formal educational institutions. Precept in the written and the spoken word is rapidly going out of use as a teaching agency. Practice and example are looming large. The conference method is rapidly gaining ground, but the most effective teaching will come through the realization by the individual of the personal benefits which he has derived, just as we have found in our program of thrift education that the accomplishment of individuals in the practice of thrift principles has become the most effective propaganda in the education of the others. If we are to receive the returns which we confidently expect, management must give a lot of hard work and study to their methods of teaching.

What then may industrial employers expect to receive for their money expenditures and their effort in the education of the general forces of employees in the principles of health preservation?

We confidently expect an increase in average productive efficiency. This can be expected directly to contribute to reduction of unit costs of production.

We can also reasonably expect a reduction in our present current expenditures of wages and salaries for absenteeism on account of sickness disability, whether through the payroll or the benefit association. These will be returns of direct money profits to the industry.

Indirectly the reduction of sickness absenteeism will substantially supplement the results of thrift education and further the effort toward making each employee economically independent.

We may expect a return in the form of increased length of service of competent employees on whom expenditures for specific training in the business constitute a part of the industry's investment.

Improvements in morale which are incidental to these returns will be reflected in the industry's reputation in the community in which it operates. This reputation is so essential to the renewal of inevitable personnel losses from the better elements of the community, that its importance can at no time be under-estimated.

It is hazardous to predict what money return may be expected. Certainly I could not predict it for the industry with which I happen to be connected; but viewing the estimated losses which industry now carries on account of sickness disability, and the losses which the public carries on the same account, it is not unreasonable that with thorough and effective health education through the principal industries of the United States, it might return to those industries in the next two decades a saving of half of the present estimated losses.

The social returns to the public at large will be greater. Such effects on the entire social structure cannot be predicted in definitive terms.

CHAIRMAN McEWEN: We certainly thank you for your fine paper, but we are not going to excuse you. A little later we may have some questions to ask you; but at present we have a matter of business on hand which is the election of new officers and we will hear from the Nominating Committee on that subject.

The chairman of the Nominating Committee has given me this report to present in which it is offered to this section that we elect as our officers for the next year:

Mr. George W. Vary, as Chairman.

Vice-Chairman, Dr. Otto P. Geier.

Secretary, Mr. J. W. Riddell.

If there is no objection the nominations will stand as read.

Now since Dr. Geier is slated to be the next vice-chairman of the Association I think that it would be a good idea if we found out what sort of a man he is before we let him take it. We have a wonderful chance to discover this for Dr. Geier is now going to give us his paper and I am sure we will all be greatly interested in what he is going to say to us.

Sickness Insurance Through Benefit Plans vs. State Insurance

By DR. OTTO P. GEIER

Director, Employees Service Dept., The Cincinnati Milling Machine Co.,
Cincinnati, O.

In order that we may have a fairly clear concept of compulsory sickness insurance, let me briefly review the results of the International Labor Conference on compulsory sickness insurance, held in Geneva in 1927. (*International Labor Review*, December, 1927.)

First, however, let us interpolate the fact that compulsory sickness insurance for the industrial worker was established by Bismarck in Germany in 1883; in 1885 the commerce workers were added to this insurance plan. The next year the agricultural workers were added.

In the years 1888 and 1891 Austria and Hungary established a system, Norway in 1909, Great Britain in 1911, Roumania and Russia in 1912, Czecho-Slovakia in 1919, Poland in 1920, Japan and Chile in 1922, Bulgaria and Italy in 1924. France, after a discussion of 4 years, is about to establish compulsory insurance against sickness, invalidity, old age and death. Denmark and Switzerland each enjoys voluntary systems of insurance wherein a greater percentage of the workers are covered than in the compulsory schemes of the other European states.

Germany, the oldest country in point of experience, has 32 per cent of the total population insured, but 62 per cent of the "occupied" or working population. In England 35 per cent of the total population is insured, but 77 per cent of the "occupied population" is in the fund.

The 1927 International Labor Conference reached the following agreements: That the waiting period shall be three days; that the benefits shall extend for 26 weeks. (In this conference the workers' representatives insisted that the benefits shall begin the first day.) It was also determined that agricultural workers shall be included in any scheme; that benefits shall include venereal disease, illness occurring from wilful misconduct, brawls, etc.

It was further agreed that the general tendency shows that "the function of compensation for illness was gradually giving way to restoration." Another trend in the discussion was that "workers' families should be included in the medical benefits."

It was recognized by the conference that the organization of the medical service raises many difficult problems, such as—Who is to organize the same, the sickness fund or some outside agency? Shall the free choice of doctors be allowed the insured? Shall the physicians work on a fixed salary, on a fee for every person insured, or for a fee for every sick person, or on a fee based on actual attendance? The conference did not consider it expedient to draw detailed regulations for the organization of the medical service. This is undoubtedly one of the bug-bears, or the weak spot, of any compulsory sickness insurance plan.

Likewise the conference could not reach a conclusion as to how costs are to be borne, i.e., what per cent by the insured?—by the employer?—by the state? It did recognize the necessity of establishing courts or tribunals for appeal by the

insured against the decision of the management of the fund. It also recognized the impossibility of organizing medical service in certain rural districts. The conference could not agree on what the minimum cash benefits should be. The report closed with a statement that "The conference is evidence of striking international support of social insurance." To us it will appear striking that although the experience of some of these states covered a period from 17 to 45 years they were unwilling to commit themselves to so many of the strikingly important fundamental working arrangements of their sickness insurance plans.

We should also be interested in the extensive discussion of this subject by Andreas Grieser, director of the Federal Ministry of Labor, of Berlin, appearing in the *International Labor Review* of June, 1927, in which he claims that "*social insurance makes for the creation of a new productive capacity*," in that it "*maintains a sick person at his standard of living*." "Restoration," says he, "rather than compensation is the principal function of social insurance." "It should provide benefits in kind, medical service, drugs, hospital service, specialists, dentists, maternity and prenatal care; care for the convalescents and medical aid to the family." Again he says "Sickness insurance has become the principal instrument of the health policy for the masses." He further states—"The idea of the responsibility of the employer that holds in industrial accident insurance does not afford a sufficient basis for the employer to share in the cost of illness."

Mr. Grieser then gives certain supporting data for Germany's experience, stating that in 1924 benefits consumed 32 per cent, medical service 21 per cent, hospitalization 13 per cent, drugs and appliances 11 per cent, and administration 7 per cent, of the fund's expenditures. He adds that since 1885, benefits have tripled, medical service has increased seven fold, hospital service six fold, along with other assistance and convalescence. It appears that 10 per cent to 12 per cent of the insured become entitled to invalidity insurance, after having exhausted their 26 weeks of benefits. He adds that accidents occur to 60 out of every 1,000 workers per year, and that one in 10 of these lose time and draw benefits.

Mr. Grieser further states "Experience has shown that for every 100 workers insured, 45 to 50 cases of illness result and that these illnesses average 24 days lost time from work. That is, every worker is ill on the average every 2 years and loses 24 days."

Assuming that Mr. Grieser's figures are based on 300 working days, it seems that they have an average sickness in Germany today of 4 per cent (12 days in a year), whereas the most active proponents of social insurance in this country have never claimed more than 3 per cent absence in this country. The industry with which I am associated has an average sickness rate of 1.8. My former associate, Dr. Ferguson, by introducing medical supervision in a considerably larger group than ours reduced the absence from sickness from 4.2 to 1.5 per cent. Whereas Mr. Grieser claims that 50 per cent of the insured suffer illness lasting on the average 24 days, the figures in our establishment and others indicate that but 13 per cent of the workers are affected by illness in the course of a year, and that their average lost time is 26.31 days.

In Germany 71 per cent of the insured belong to territorial funds, 24 per cent to trade union funds, 5 per cent to mutual aid funds; in England 46½ per cent of the insured belong to friendly societies, 42 per cent to industrial assurance approved societies, 9.9 per cent to trade unions, and .8 per cent to employers' provident funds.

Mr. Grieser explains this division of the insured by stating that when compulsory insurance is introduced, it comes into being by compromise and that certain existing institutions are entrusted to carry out the provisions of the compulsory sickness insurance plan in addition to establishing state funds for those not so covered. He concludes with this comprehensive statement: "Compulsory sickness insurance as a creator of security, health, well being, and productive capacity and

as an instrument of education, is an element both important and necessary in the proper economic and social organization of communities."

The foregoing abstracts indicate an almost unanimous opinion in Europe of the advisability of such insurance, Denmark and Switzerland standing alone in Europe for the voluntary insurance system.

One cannot but give heed to European history and experience. Many of our well-meaning economists and social workers however have been so influenced by the trend of opinion that they are enthusiastic propagandists for the introduction of social insurance in this country.

I wonder whether these afore-mentioned propagandists have ever seriously analyzed the forces that are at work in this country on health plans different from the European system, which are tending to secure perhaps not as wide spread a cash benefit to the sick, but which are evidently going away beyond the European system in creating "*security, health, well being and productive capacity*" including the "instrument of education." Putting aside the question of cash benefits, it would be interesting to compare the per capita expenditures on medical service, hospitalization, drugs and appliances in this country to similar expenditures for the insured under the compulsory scheme. For finally, the fundamental purpose of any health promotion scheme should be to secure to the individual the maximum amount of remedial measures—medical service, hospitalization, etc. From a recent study made by Homer Folks of New York, we note that \$2,364,925,396 are here spent annually for health, hospital and medical care, which means that the per capita expenditure for these purposes in the United States is over \$200.00. To this must be added millions of dollars that are being expended by insurance companies in the care and prevention of illness, untold sums by industries in the protection of the worker against disease and accident, unknown sums by the individual in his effort to protect his health. Who is there today who can say what percentage of our population is already covered by sickness insurance through fraternal organizations, insurance companies, lodges, and the benefit societies connected with industry?

What we can talk about with a fair certainty is the general health level of the average worker in this country and to note whether it does not bear most favorable comparison with Germany, for instance, which has had compulsory sickness insurance for nearly 40 years. The real measure of a social system is its results. According to the facts already quoted, we enjoy one-third less lost time from illness than they do in Germany. Is there not perhaps a fundamental factor at work in our voluntary system which is more productive of positive health and well-being than that which comes out of the compulsory systems abroad?

The proponents of constructive health programs in this country, as no where else, have stressed the value of preventive medicine. Those abroad have leaned heavily upon the dole, or cash benefit side of the insurance system. It is most evident in our experience with workmen's compensation acts, that it is almost impossible, once having established a cash benefit scheme for those injured, to have any considerable attention paid to the prevention of accidents by the state. After 16 years of activity on the part of the workmen's compensation act in Ohio, with an annual expenditure of \$16,000,000.00 (one third of which goes to medical and hospital service) it has finally been possible to secure the expenditure of 1 per cent of the annual fund for preventive safety work. You can readily make a fine sob story to secure the establishment of a fund to pay injured workers for being injured, but you can make very little headway in securing state controlled funds for the prevention of deaths, dismemberment, widowhood, orphanhood, which should finally be our real consideration.

From the experience of European nations one can see how painfully slow has been the progress of securing money from the insurance funds to prevent disease, and how difficult it apparently is, under state-wide benefit funds, to compel any

feeling of personal responsibility on the part of the insured towards keeping well. Of the compulsory insurance plans found abroad the one in the Canton of Basle, Switzerland, where only the most extensive medical surgical hospital pre-natal service is extended with no cash benefits has its best appeal to me.

Let us refer once more to the concluding paragraph of Mr. Grieser's article on compulsory insurance, where he holds that this social insurance is "*a creator of security, health, well-being, and productive capacity.*" In making a comparison between these factors of the average European as against the same factors in the average American, can we not say with full assurance that we have more security, health, well-being and productive capacity in the average American citizen than obtain in the citizens of the European nations? If he refers to financial security, we need not argue that point. His own figures show that the German citizen is not as healthy.

What about "well-being and productive capacity"? Let us take the testimony from three professors of Engineering and Social Economics from one of the largest universities in Germany, who recently visited me. They are in this country on a three months study-tour, being sent here by the German government. One of these gentlemen made a four months study of industrial, social and economic conditions in this country four years ago, and it is because of what he reported that the German government sent these three this year. Here is what he said in effect: "If Germany wishes to reconstruct herself economically and socially, she must adopt the methods of management, and the methods of industrial relations of America. Failure to do so will mean her inability to cope with the competition of the United States." These gentlemen were deeply impressed with the "feeling of security, the health and the well-being and the productive capacity" of the average American workmen. They stressed the happiness of our workers compared to theirs.

Let us take the testimony of another of this endless succession of visitors from abroad who are trying to sense what America is doing to make her so productive, to give such a generally high level of health and well-being, that affords the average workman such a high standard of living compared to theirs. This man was the directing head of all social effort in his state—workmen's compensation for accidents, sickness insurance, health and hygiene, and conciliation in labor disputes. Among other things, he said our 8-hour law is not a law for the limitation of labor. It is a health measure. "Our workers earn as much in a day as your men earn in an hour. Our men cannot gain sufficient strength from the food they can afford to buy to be strong enough to work more than 8 hours." "What need have we," I asked him, "for compulsory insurance?" "None," he quickly answered; "don't ever make the fatal mistake of introducing it. It is out of harmony with the American system of individualism, initiative, independence. Hold fast to what you have. That has made you great and strong."

I can understand how in these European countries and in Japan and China, that a dole system by any name should be absolutely necessary. Let us think of the girl operator in the silk industry in Japan, who averages 38 cents a day, who works 7 days a week, and who has but 2 off days a month. Any system, under any name, that will come to the assistance of this girl when she is sick should be welcomed, and is a social necessity.

Nothing that I have said should lead anyone to believe that I am personally against any intelligent plan that distributes the cost of illness particularly to these costs. We are far on our way in this country to do it, and yet it devolves upon more employers to recognize the necessity of establishing beneficial funds within their organization, to be used however chiefly for raising the standards of health, to act as an "instrument of education"—to teach the value of preventive medicine, physical examination, to wean the worker away from the use of patent medicines, the advertising quack, the advertising dentist, and other professional fakirs. The

money so wasted by the American people represents the tidy sum of about \$120,000,000.

I recognize fully the millions—yes, billions—of annual waste in this country from ill-health, but I see no hope of appreciably reducing that waste through compulsory insurance. The same creative energy, the same initiative, the spirit of adventure, the willingness to expend huge sums, the extreme individualism that has made American industry dominant throughout the world, should not be ham-strung by compulsory legislative enactments in imitation of poor Europe. This same American spirit should be led to see the enormous economic accomplishments possible within the field of preventive medical service. Do this, and our country will be setting standards of longevity, of vital working capacity, of productiveness, of health and well-being, happiness and contentment, such as the world has never known.

That great American, Herbert Hoover was the first great Federal officer who summarized for industry and the country at large our extravagant wastefulness of human life. Many others have contributed to this discussion. No group of men have such a large responsibility towards the creation of a public sentiment in favor of the more general adoption by industry of more intensive health work, than this group assembled here today. You have no right to be satisfied with so conducting your benefit societies that the members thereof secure only cash returns in case of illness. It is your job, specifically, to develop health services within your organizations by the employment of medical, dental X-ray and diagnostic services, to the end that your members may be forced to endure the least possible number of days of illness and suffering. Instead of insurance they most need *assurance* against illness to the end that they may produce more, earn more, live more happily and die less early.

Ours is the duty not to allow ourselves to engage in controversy with those who would apply mis-fit European social systems to us. Ours is to work, think, create, energize our fellow workers, our managements, our public health officials, our private organizations, to an extensive study of life at its best, abundant health, pleasure in work, which means increased earning capacity, which means well-being and productive capacity, which means readiness to accept "education," all of which, summed up, brings security.

This is not jingoism or a "spread-eagle" speech. I have travelled sufficiently in Europe, studying the health of communities, the safety of the worker, his living conditions—to know that they have much to learn, much to attain. The word "sanitation" has found its fullest meaning on this side of the water. They are still ladling out milk on the streets of London, 20 years after such filthy habits have been prohibited in my home city. The dogs in Belgium and Holland are still dragging the milk cans through the streets. In some places in Italy the milk goats are still making their house to house deliveries.

Let us be a little careful how we overload our state governments with new duties. They are making a pretty poor job of what they are doing now. The State and municipal governments are almost the worst thing we do in America and until that time comes when our statecraft is responsible, when its efficiency gets on a par with private organization, we had better hesitate to choke down its throat any more indigestibles.

I hope that the American Association for Labor Legislation, and other proponents for social insurance, will keep up an almost irresistible demand for social insurance, for they thereby will furnish good reason why the thinking executive should be constantly at work, elaborating and perfecting health machinery within his organization, as well as that of the community. Next it becomes the duty of every upstanding, intelligent person, who has any appreciation of the enormous economic waste chargeable to ill-health, to so conscientiously study the health measures that we have on hand, that we may have an awakened public conscience.

That the interest of the medical and allied professions may be secured toward working out sound social economic schemes, all to the end that the average man may have accessible to him the best that the medical sciences have provided. The value of positive health is immeasurable. Its securement is worth our country's best effort. It is within us not to follow, but to lead the world in new health standards.

CHAIRMAN MCEWEN: We have heard from Mr. Willard some of the advantages of a health program; we have heard from Dr. Geier some of the disadvantages of state insurance, they both point in the same direction. We should do more in our own organization to increase the number of members under the benefit fund protection and save the health of those people.

It is our particular privilege today to have Mr. Harold A. Ley, the President of the Life Extension Institute of New York City and he is going to offer a remedy for our problem—Mr. Ley.

Using Benefit Associations for Better Cooperation in Safety, Health and Other Employee Activities

By **HAROLD A. LEY**

President, Life Extension Institute, New York City

The tendency of state legislation is to increase the weekly compensation to the injured workman and also to broaden the laws to include occupational diseases. Both these suggestions are in the right direction; but as you include them you are confronted with the simple fact that it is impossible to differentiate between occupational diseases and ordinary diseases. For instance, hernia certainly isn't an occupational disease; still, when a man with a hernia lifts a heavy box and suffers from strangulation he claims compensation for that hernia—and gets it. The same is true of heart disease, vertigo, infections, and other ailments. Clear up these conditions and you have fewer accidents.

The next step will be legislation compelling employers to pay for lost time due to any kind of sickness.

A careful scientific study by the Life Extension Institute brought out the fact (since confirmed by studies of the United States Public Health Service) that 42,000,000 gainfully employed lose 350,000,000 days from illness disabilities and non-occupational accidents annually. At present there is seven to nine times as much time lost through sickness as through accidents.

This brings us up to the problem as to what steps industry can take to protect itself from these impaired risks. This protection is also required for consumers, who, in the long run, have to meet increased industrial costs in the prices they pay for finished merchandise. If industry doesn't work out this problem in a manner satisfactory to labor, the politicians will settle it through state legislation, with all its accompanying evils.

When the time comes that workmen are paid for lost time while sick it is vital that they be interested in the net cost of this sickness; because it is much easier to put in an unwarranted claim for sickness than it is for an accident. Unfortunately, there are many employees who would rather loaf on two-thirds pay than work for full pay. No one objects to a man's receiving whatever is just for a legitimate claim, but no one is in favor of paying employees for loafing when they should be at work. If the employees are interested in the net cost they will make it their business to stop malingering and false claims.

The report made by the Life Extension Institute to the Hoover Committee on the Elimination of Waste in Industry, brought out certain facts in regard to health conditions in industry, which have since been amply confirmed.

It was there stated that the annual economic loss in this country from preventable diseases and death is over \$3,000,000,000; and that \$1,800,000,000 of this loss is among the gainfully employed.

Twenty-five millions in the working classes have defective vision requiring correction.

There are more than one million with some form of tuberculosis.

There are more than eight million with flat feet.

There are more than six million with organic diseases resulting mostly from infection.

There are more than one million five hundred thousand with venereal infection.

Five hundred thousand working people die annually.

At least one-half of this death loss and disability rate is preventable and postponable by proper medical supervision, periodic medical examination, health education and community hygiene. In other words, approximately one billion dollars could be saved in industry every year by improving the health of the working man. When consideration is taken of what this loss means when translated into misery and suffering—the bulk of which is the result of ignorance and thoughtlessness—it is apparent that there is a big opportunity for service in preventive work. What is the answer? The periodic health examination!

The Metropolitan Life publishes the statement that there has been a 50 per cent reduction in mortality among their policyholders examined between the ages of 50 and 60, and 18 per cent on the entire group examined. They claim that this represents a profit of two dollars for every dollar they have spent.

The Guardian Life reports 23 per cent reduction in mortality among policyholders examined by the Life Extension Institute.

This is cold-blooded testimony based on more than ten years experience given by insurance companies which have the best medical and actuarial advisers that money can engage.

Improving the health of the working man is a problem that deserves the consideration of everybody interested in national affairs; but though it is a national problem, it is also by its very nature a most personal problem.

Every employer should be interested in the health of his employees because he is in business to make money. The amount of money he makes depends on the productivity of his employees, and their productivity depends on their health and their attitude toward their employer. No employer ever made any money out of a sick man or a grouch.

What is the use of spending \$100 a year on a machine to keep it in good condition and then assigning a man to run it who can get only 50 percent of its efficiency because of his condition? Unlimited amounts have been spent for inspecting factories, machines, boilers, and automobiles and keeping them as nearly 100 per cent perfect as possible; while the men who run the machines have been only 50, 60 or 70 per cent efficient. What good is the 100 per cent perfect machine if the man who is supposed to operate it is at home sick? The employer not only loses money on this man but he may be losing money on a dozen other men whose work is affected by the absence of the sick man.

After the employer has done everything he can to reduce sickness absence and abolish malingering there is still much that can be accomplished by enlisting the interest and cooperation of the employees.

Anything that will improve the health of the employees and, at the same time, increase their good will toward the firm is something for which every employer should be glad to pay something, especially if he can be assured that he will get back two dollars for every dollar he spends. I claim he can afford to pay one and one-half per cent of his payroll if it will result in all of his people taking an interest in improving not only their own health but the health of every other

employee. An employer should contribute to such a fund for the same reason that leads him to make any profitable investment.

Take a payroll of \$1,000,000 a year on a thousand men. One and one-half per cent equals \$15,000. Isn't it reasonable to expect that a thousand men really interested in improving their health will increase their efficiency enough to cut that payroll \$15,000 especially if the request to contribute this amount comes from the employees under an agreement that they are going to contribute a like amount? Any employer who is asked by his employees to join them in paying for a thing on a fifty-fifty basis is overlooking a big opportunity if he doesn't join with them, even if he cannot see any direct benefit for himself from what they want. On the other hand, if he *can* see where he can make more money by agreeing to join with them, and then doesn't do it, he ought to have a thorough mental examination. If he does agree, he ought to tell his people he is doing it merely because he can see where he can make more money, I'll defy any agitator to make trouble for the employer on account of that statement. An employer has often given the agitators the very ammunition they needed when he has come out some morning and told his people he has decided to *give* them something. No matter what he had decided to give them, every one of them said to himself (even if he didn't tell his boss): "If he has any money to give away why doesn't he put it in our pay envelopes?" They want and are entitled to every cent the employer has to spend on them. I know of no "God given right" that entitles an employer to decide what his employees want. If there is any doubt in your mind as to whether your employees want a thing, ask them to help pay for it and make it optional whether they do or not. That is the acid test. Think of the millions spent by well-meaning employers in the last 20 years, that not only could have been saved but probably did more harm than good.

Above everything else, it is the great hope and great desire of all of us to continue to live. It is not mere extra years of life that we want but extra years of health, extra years of working power and usefulness. The employee's health is his greatest asset.

In order to improve the health of the working man it is necessary, first, to find out what condition he is in and how he lives; and then, to instruct him as to what medical treatment he should receive to improve his physical condition and what he can do himself in correcting the errors in diet and hygiene which in many cases are directly responsible for ill health. This all necessitates, first, a complete physical examination; but most work of this kind has failed because the average man thinks himself perfectly well and, therefore, not in need of an examination.

"An examination," he says, "is all right for Bill who has tuberculosis or John who has heart disease, but why should I take one when I've never been sick and haven't an ache or pain?"

The trouble is that most people measure their health by pain, and pain is a very poor yard-stick to depend on. There is no pain in the early stages of tuberculosis, Bright's disease, heart disease, cancer, or anemia. If you wait until the pain period arrives it may be too late to do anything. The only way to detect these troubles in the early stages is by a complete physical examination, and the problem is: How can you get the employees to submit to annual examinations and also to be anxious to take steps to correct the impairments that are found?

Simply taking an examination never did anyone any good. If it does not result in the individual's doing something to correct his faulty living habits or his physical impairments the time and money have been wasted.

Any self-respecting man resents being told how he must live. He is perfectly willing to learn what is the best way to live but he wants and insists on the right to decide for himself what living habits he will adopt. That is why it is almost obligatory—if we are to get anywhere in this health work—to have the

cordial interest of the employee himself in any plan that has for its object, the changing of his living habits. There is a way to get employees to take a real interest in this problem; and that is through a mutual benefit association (controlled entirely by the employees) which gives adequate sickness and death benefits and a periodic health examination; the cost of these benefits to be borne jointly by employer and employees.

Now let us see if it will be possible to interest the employee in paying one and one-half per cent of his wages into a mutual benefit association provided his membership entitles him to:

1. Life Insurance equalling one and one-half times his annual salary, payable in case of death or total disability. (No insurance to amount to over \$10,000.)
2. Two-thirds pay for 26 weeks in case of sickness or accidents not covered by the Workmen's Compensation Laws.
3. Annual physical examination.

Every employee wants to make as much money as he can and he also wants to provide for himself and his family in case of sickness and death.

Under this plan he receives at extremely low cost (through the co-operation of the employer) life insurance protection for his family in case of death, and adequate protection for time lost on account of sickness or non-occupational accidents.

Experience has shown that the older employees having dependents are interested in life insurance and health insurance while the younger ones are interested simply in health insurance. The older employees (who are incidentally the most influential) get the benefit of cheap insurance under a group policy; as the rate is dependent on the average age. This, of course, makes them boosters for the plan, and when they are told that it is necessary to have 75 per cent of the employees before they can get a group policy, they go out and use all their influence to induce the younger employees to join.

Take a man 40 years old earning \$2,000 a year. His dues would equal one and one-half per cent or \$30 a year. He would receive \$3,000 of life insurance in case of death or total disability and two-thirds pay, or \$26 a week, for 26 weeks in case of sickness. Think of what it would mean to this country if every employee received two-thirds pay when sick.

While these insurance features are a great help in relieving the employees of some of the worries and anxieties that come with sickness, the examination feature is also extremely important. The employer can very properly agree to contribute his share toward the plan provided the employees will agree to insist that every person who joins the mutual benefit association take a physical examination every year.

That is the only condition he needs to insist on, but that is important; otherwise, they won't take the examination because, as I said, they don't think they need it. When they have had an examination they find out for the first time in their lives their true condition. This is of advantage to the employee as well as to the firm because the workman's wages are directly influenced by his physical condition.

Give these men the opportunity to have their physical impairments pointed out to them under the right conditions and they will welcome the chance, but if they think the information disclosed by the examination is going to be on record or will be used against them in any way, they simply refuse to take the examinations. If they are convinced that this information is treated confidentially, all opposition disappears. That is why it is so important that all this medical work be handled directly by the mutual benefit association and not by the employer.

This does not mean that the employer should not introduce the examining of new employees; for I believe he should, not only for his own protection but for the protection of the mutual benefit association. If a company has a generous benefit plan in operation, it does not want to leave the door wide open for every

sick person in town to come in and be taken care of at the expense of the company and its employees. But don't think you have done very much when you have examined a man looking for a job. The diseases discovered then are often only those that are so far advanced that they can be detected without any help from the individual. A man doesn't volunteer any information about himself if it is going to prevent him from getting a job. When the member of the mutual benefit association comes up for an examination the purpose of which is to prolong his life, however, he will tell the doctor all the things he suspects about himself as well as all he knows. Every doctor doing this work will agree that he needs all the information available from all sources to do a good job and it is impossible to do a good job without 100 per cent cooperation of the person being examined.

Neither do I mean that the company should not have a medical department of its own to treat accidents and sickness arising in the plant. A mutual benefit association such as I have described will increase the work of such a medical department tremendously.

If you are going to have a mutual benefit association of this kind it is very important that everyone in the organization should join. I am speaking now especially of the most important members of the organization. If these people, who are generally paid full wages when sick, have to look to the mutual benefit association for two-thirds of their wages and to the company for the other third, they will take an interest in seeing that the mutual benefit association is properly run. Many mutual benefit associations have such inadequate benefits that no one is particularly interested in seeing that they are conducted along the proper lines.

It is proper for the company to make a marked distinction between those who join the association and those who do not when it comes to deciding what it will do in the case of sickness. Some companies pay the man who does not join one week's salary when he is sick and then stop, regardless of his position. These companies feel that they have done their duty when they have made it possible for every person to be protected in case of sickness or death at a small expense. It is optional for each person to join the association. When he decides not to join, then the companies feel that they are relieved of all responsibility. As a result, very few employees fail to join.

A mutual benefit association such as I have described lays the foundation for an interest in preventive work. You have employer and employees working together for a common purpose.

When it comes to deciding what a physical examination should consist of you have a problem that is very little understood. Just how far each individual association will go in giving its older and more responsible members a more thorough examination depends on how much the company is willing to do toward paying the additional expense. Fifteen years' experience has taught the Life Extension Institute that the minimum examination should take an hour and be just as thorough as a doctor trained in this particular kind of medical work can make it with the instruments that he can carry around with him, but after he has done as good a job as possible there is much additional work to be done by the laboratory, X-ray, electrocardiograph, etc. A moment's thought will convince anyone that the superintendent of a plant earning \$30,000 a year should have a more thorough examination than the office boy earning \$500. There are plenty of office boys, but superintendents and other important men in the organization simply cannot be replaced and it is worth almost anything to the company to keep these men in good shape for as many years as possible.

If the employer tells the association that he is willing to pay his contribution into their treasury and that they can pay the cost of the life insurance, sickness insurance, and examinations and can have whatever is left over at the end of

the year, he at once interests all the members in the health of each member. They can then do things that no employer can do. If every time one of their members is out sick they have to dig down into their treasury for his wages, they soon become interested in seeing that everything possible is done to get him back on the job and they then see if they can induce the individual to do the things he should do, so that he won't be out again in a short time with the same trouble and costing them more money. This is just what the employer wants, because he cannot make any money out of a man except when he is on his job working to the best of his ability.

The three per cent contributed by the company and the employees will not only be sufficient to pay for the benefits I have described but will leave a saving of 20 to 40 per cent, if the association is properly run. If this saving is left to accumulate in the treasury of the association and is used by the members to help take care of the thousand and one things that come up in every organization during the year that are not covered by the regular benefits, it is a very valuable adjunct in solving a lot of problems that are not paid for by the company. The company would rather pay in many cases (even though it does not feel morally obligated) than have the employees feel that the firm is "stingy."

The following cases which occurred in my own construction company illustrate this point:

The president of the association came to me one day and told me he thought the association had saved the life of one of our men. It seems that this man had double pneumonia and his wife and baby both had influenza. He had spent all his money and needed additional medical and nursing assistance. The officers of the association called the executive committee together and voted to spend \$200 on this case. Then they made it their business to go out and get the additional help needed. They were gratified when the man was on the road to recovery to have the doctors tell them that if it had not been for this additional assistance the man never would have lived. He was so grateful that he said that as soon as he was "back on his feet" he was going to pay back in \$5 instalments the money they had spent. This had all been done without the knowledge of any of the officers of the company and was all over before we knew about it. Needless to say, we were very much pleased.

This case occurred a few months after the association was formed, and several of the clerks who had not joined up to that time signified a desire to join when they heard about this case.

One of our men in Virginia was in a bad way. He had been losing flesh very rapidly and both he and his wife were very much worried. I sent word to have him come to New York and have a thorough examination.

He was at the Life Extension Institute for four or five days, having a physical examination with all kinds of X-ray tests. His trouble was diagnosed as ulcer of the stomach. He was told what to do and two weeks later I received a letter from him telling me how much better he was feeling and enclosing the bill for the X-ray examinations he had received while in New York. (Membership in the association entitled him to a complete physical examination, but not to these extra tests.) He stated that he had been under a great deal of expense and wondered whether Fred T. Ley & Company would pay this bill. I wrote him and told him that the association had funds in its treasury for just such things and referred his letter to the association.

The president of the association told me he didn't think the association should pay this bill, as he felt the man himself was well able to pay it. He was drawing a good salary and had only his wife and himself to support. I said that it was a matter for the association to decide. The president sent the member a letter asking him certain pertinent questions in regard to his financial condition and stating that before the association could pay this bill the answers to these ques-

tions would have to be considered by the executive committee. The member replied: "If you fellows expect me to answer all these questions, I'll pay the bill myself." If it hadn't been for the association, the firm would have paid the bill.

In the third case two men on a job in Worcester had been found with hernias and the doctor recommended operations in both cases. The men agreed to go to the hospital together and have the operations performed at the same time. One was a foreman and the other a superintendent. The foreman had joined the association, but the superintendent had not.

The president of the association came to me one day and said he had received word from the superintendent that he had wanted to join the association but that the executive committee had turned him down. I asked him why they had taken such action and he said that the superintendent had had a chance to join the association, but hadn't done so. They sent word to him that they would be glad to have him join after he came out of the hospital. They could see no reason why he should draw five or six weeks' compensation (and in that way reduce their dividend).

The most striking example I can give is the case of one of our vice presidents who died.

Five years previous to his death he had had an examination. His blood pressure was found to be 155 and there was a marked trace of albumin in the urine. He was a young man 36 years old, weighing about 150 pounds. He was an important man in the organization and the firm could not very well insist on his taking an annual examination. He didn't take another examination for five years and during that period he rather ridiculed the idea of other men being examined. At the end of five years he was feeling bad and decided he would be examined. The examiner found him to be in a serious condition; his urine was full of sugar and his blood pressure was over 200. He was willing to do anything then to regain his health; but it was too late. Four months later he was buried.

His death cost the insurance company carrying the risk \$5,000, and spoiled the association's chances of earning a dividend that year. On the day after his funeral the executive committee of the mutual benefit association held a meeting and voted that in the future every member of their association would be obliged to take an examination annually or forfeit his membership. They felt that this death was unnecessary and that if this man had had yearly examinations he would never have allowed himself to get into such a serious condition. This vote of the executive committee was resented by some of the members but the committee stood firm.

One of the members who objected, finally decided that he would rather take an examination than lose the insurance benefits. He thought he was suffering from a little bronchial trouble at the time but on taking an examination at the Life Extension Institute he was advised to go home and go to bed as his temperature was over 103. Under the rules of the association a member had to visit this man within four days. He came back from the visit and told the executive committee that they had better do something and do it quickly or they would have another death, as this man had failed very rapidly in the four days he had been home and his family did not seem to know what was the matter with him. The executive committee called one of the best diagnosticians in New York City. He diagnosed the trouble as sleeping sickness and told the family he didn't think the doctor who had been treating the man knew what the trouble was, because the treatment he had been giving was the worst thing in the world for the patient. The diagnostician gave the family the names of four doctors, any one of whom, he said, was competent to handle the case. They changed doctors and in three weeks he was back at the office and, with tears in his eyes, was telling the fellows that they had saved his life.

We believe that all these results have been obtained simply because we have a plan that is working along the right lines.

CHAIRMAN MCEWEN: I am sure we owe a great deal in thanks to Mr. Ley for his fine presentation of an interesting subject. Now we must have some discussion on these various subjects and I am going to begin by asking Mr. Ashe if he will not start a little discussion on the latter paper.

S. W. ASHE (Pittsfield, Mass.): I think, first of all, we ought to congratulate the officers this year on the very able papers that they had presented and I know that if this afternoon's session is any indication of what you are going to get during the next year, you are going to get a great deal that is worth while.

I am always glad to hear Dr. Geier; he always gives you a real good story. And when it comes to the last speaker, Mr. Ley, I think you are very fortunate because there is no one who has made more of a study of the benefit idea and matters of physical fitness than he.

I believe that many of us who have been handling the Mutual Benefit Fund Associations for years do not realize their possibilities. If you can get the men interested in an organization like this it cannot only help you in everything you want to do, but it is a great stabilizer in regard to labor. That has been our experience; and in order to get that you have got to frame your own association in such a way that you can watch the finances, because the employees have got to practically run the concern.

The important thing is to get the men interested, to have them hold their own meetings and bring up their own problems. It is remarkable what you can do if you get it functioning right. I know of no organization that can put the thing over the way the Benefit Fund Association can. I am glad that Mr. Ley has investigated the idea of this fifty-fifty proposition.

A good many years ago our manager, who is now a vice-president, conceived the idea that if the employees wanted to do anything badly enough they would pay half, if the company would pay the other half. There are any number of things employees want to do that will involve the expenditure of money. You may wonder how many really want to do this, but enough usually do or they could not raise half the money to do it. If you make them realize that they want the thing badly enough they will be willing to help in financing it, if you show that you are ready to lend your cooperation. The same thing might be said of insurance.

Mr. Ley has worked out a very complete plan, which is the result of years of patient study, and what I like about it is that it is simple; but the statistics are very nearly right. He has gotten hold of statistics that really mean something. If you are going to formulate a plan of this sort, which will stand the test of unusual situations, you have got to have it based on real concrete experience; such as the way big insurance companies decide how much they are going to charge you. That is built up from experience and one of the difficulties with our associations is that we have not kept accurate statistics.

In our particular plant the cost of taking out insurance is paid by the company and the employees pay the sickness costs.

CHAIRMAN MCEWEN: There is a lot to be thought of and talked about in this meeting and I am sure there are some impatient people who have something on their mind they want to get off. Let's have some questions.

R. P. SAMUELS (United States Finishing Company, Providence, Rhode Island): I am interested to know what type of doctor—I mean by type, a surgeon or so called medical man—is preferable in connection with a health program outside of the plant and in the home where the Mutual Benefit Fund sees fit to act?

DR. GEIER: I think a physician is better than a surgeon for the reason that you have the need for a more socially minded factor which you find in the physician.

The medical type of man would be better outside the plant for the surgeon is more specialized, and is not liable to afford the best contact. Of course there are some exceptions, but in the main that holds true, and I believe it will work out to the best advantage.

CHAIRMAN MCEWEN: That has been my experience.

DR. E. C. McCULLOCK (Procter and Gamble, Staten Island, N. Y.): I think this question of sickness insurance is the biggest question before the American people at the present time. It is a question we ought to think about and decide how we are going to deal with it.

The accident insurance compensation was a big thing and has been pretty satisfactorily handled, on the whole. In accident work we have some objective since there is a physical evidence of injury that helps to decide. In sickness this is often lacking and we are depending on outside symptoms of the patient. Whether or not a man is able to work is a question that comes up hundreds of times and we have to decide it. Very often the doctors differ as to whether a man is able to work or not. Very frequently the company's doctor will take the stand that the man is able to work and he goes to his family doctor and brings back a certificate that he is unable to work. My company usually sustains me, but this is a proposition that has got to be reckoned with. Our Benefit Association requires a certificate from some doctor before the man draws his benefit.

There are artificial methods of keeping down the sick list. A doctor can make up his mind that when a Benefit Fund man comes in that he is going to make him keep on working. I know of a physician in the army that ordered a man on duty who had a broken leg. You can do the same thing with lost time accidents, but surely many of the men would be better off home than on the job.

The trouble with most of these associations is that they were originally framed without any regard at all for the family doctor's point of view. The family doctor is expected to treat the injured at home and is expected to make out all the reports the company may require, and he is expected to send him back to work when he is fit to work, and he is expected to do all sorts of things; and when he has done all this the family doctor can whistle for his bill, because all the benefit money will have been used up.

In regard to the cash benefit, I think that two-thirds of a man's normal pay is sufficient. I do not favor giving a man full pay when he is off the job because of sickness or injury, for I feel that it tends to lengthen the period of sickness. Of course, I believe that sufficient money should be spent on the doctor, but I believe that two-thirds of the man's pay is enough from the benefit.

There is the question, also, of what is to be done with the people who are subject to certain diseases. I had one man tell me he was liable to have fits. He could not get a job anywhere and he had a wife and children. These people are deserving of statutory aid and there is a lot of good work they could do, but it is better to have them in an environment that is arranged for them.

MR. JOHNSON (The Hoover Company): I presume that all here are interested in insurance and I was wondering if we could find out how many had their insurance for their employees paid by the company, and how many had the workers contribute?

CHAIRMAN MCEWEN: I think we could find that out. How many here have Benefit Associations, of one kind or another?

(About twenty-five raised their hands.)

CHAIRMAN MCEWEN: How many of those associations are carried on entirely by the employees?

(About twelve raised their hands.)

CHAIRMAN MCEWEN: Now the question is how many work on a fifty-fifty basis, where the employer contributes a portion. How many have that?

(About twelve raised their hands.)

CHAIRMAN McEWEN: There is still the question of how many of these are carried on entirely by the employer?

(About four raised their hands.)

CHAIRMAN McEWEN: That gives a fair idea of the situation. Now, is there any further discussion, or questions?

J. P. JACKSON (New York Edison Company): I was over in the Executive Meeting and I heard the statement made that there was something like one billion dollars a year lost through accidents. The figures for accidents are really astounding, but the figures for sickness are just as large. As soon as a man begins to get sick he can only do a quarter of a man's work and the company

is going to lose real money. I think the lesson Mr. Ley has given us is one which we all ought to follow.

CHAIRMAN McEWEN: I think we all appreciate the problem.

MR. McCULLOCK: I believe that a large amount of the insurance placed by the Benefit Associations has been taken over by the insurance companies. Now I have no fault to find with the insurance program and Mr. Ley's paper suggests that all small companies of underwriters are analyzing the situation. It is hard for me to understand why a great corporation like the General Motors would let an insurance company handle all the business of the mortality, etc., rather than doing it themselves. According to the program as outlined I believe that sickness insurance is a major part of it and even though this entails much risk, it is a risk that has to be taken.

DR. GEIER: In my paper I spoke of the fact that the company had the right to run its own business and decide whether it would pass this over to a corporation on the outside. I can consider nothing more dangerous to our Benefit Fund Associations, for the outside company will be running the business the employees

are supposed to be running. You lose many of the bonds of sympathy that would be brought into play with the employer. I hope I am not misunderstood and you think I am taking any exception to insurance companies. We owe them a great deal because they have helped many to spread their loss. But when we are faced in the near future, as we are bound to be faced, with problems of compulsion, the only hope we have of staying the hands of the politicians is to show that industrial management has looked ahead far enough so that they have sufficient power to run these sickness and other benefits alone, and not have to call in outside aid and admit they know nothing about it. I think it is pretty apparent that the fellow who takes out insurance is going to be careful. I believe that in the motor car industry insurance is going to be compulsory, but I hope we in industry are going to learn how to handle our affairs without any aid and we can say that we know how to run our business, and we will be intelligent enough to see that we afford protection.

ADJOURNMENT

October 4, 1928

R. E. McEWEN, Chairman

**Employees' Service Division, Western Electric Company
Chicago**

The second session was called to order at 9:30 by the chairman, Mr. R. E. McEwen.

CHAIRMAN McEWEN: The meeting will come to order. We have a very long program this morning and I think there will be a lot of discussion, so I will at once call upon Mr. Grant, who has come all the way from Los Angeles. He is with the Union Oil Company and will tell us something about his views on the Benefit Fund.

Hospital and Surgical Benefits As a Part of Relief Plans

By W. S. GRANT

Assistant Manager Insurance & Personnel, Union Oil Company of California

The past few years have brought about many radical changes in the industrial world—industry demanding more from employees, and in turn employees requiring and receiving more attention than ever before from industrial management. Savings plans, welfare funds, athletic and social programs, etc., have been arranged for employees' betterment, both physically and financially. Directors of industry have long realized the necessity of competent help, if operation and production are to be efficiently handled, and with this in view one of the most important developments in recent years has been the establishment of proper hospital, medical and surgical treatment for employees.

We speak of efficiency in man power. Regardless of our positions in industry, we have all at times turned this problem over in our minds, and when selecting an employee, education, previous experience, age, appearance, physical condition, etc., are taken into consideration. Too much stress cannot be placed upon "physical condition." If a man is not physically sound, it is unreasonable to expect complete efficiency from his efforts—it is only natural to expect that his efficiency will be affected in accordance with the degree of physical impairment.

This deficiency might appear in many forms, the most prevalent being carelessness—causing the breaking down of mechanical equipment and resulting in many injuries, not only to the one physically below normal but to co-workers as well. Statistics show that certain employees are continually having accidents. A further analyzation will often prove the cause to be really physical, a condition of which possibly the individual is not aware and not noticeable to his co-workers, but which would have been discovered had the employee been required to pass a physical examination.

A man to be mentally alert must be physically sound in every respect. If not, there are times when his efficiency will be materially impaired.

Much stress is laid upon the purchase of high grade mechanical equipment—great care being taken in the selection and installation—while in selecting the men to operate this machinery often not much attention is paid to the physical condition of the applicant; and it is probable that the first one who seems to have the rudimentary intelligence necessary to keep the machinery in operation is employed. It is not possible for a piece of mechanical equipment to operate to its maximum capacity unless the operator is efficient both physically and

mentally. It is reasonable to expect that one who is physically fit produces more than one who is physically impaired, and in order to get the maximum production out of a piece of perfect mechanical equipment it is essential that the operator should be, as nearly as possible, in as perfect running order as the machine he is to operate.

Nearly all of our states require medical and surgical attention and hospitalization to be given an employee in the case of injury. The management of our company heartily agrees and goes a step further: not only is that given which is required by the state (we carry our own compensation liability) but care is taken to select the best specialists in all lines of the medical profession to rehabilitate our injured employees. The initial cost, of course, is higher when specialists are consulted, but, from the standpoint of efficiency of the employee, it is much more satisfactory to pay the surgeon for a perfect result than to pay the injured employee for permanent disability which will never allow him to function up to his usual maximum capacity.

Industrial accident commissions are demanding more of industry than ever before, and the burden is placed on us of restoring injured employees to perfect condition, regardless of what disabilities were present when the injury occurred. For instance, we frequently find it necessary to extract abscessed teeth and clear up other infections before the injured can be pronounced as physically fit for work. In such cases the value of continued attention to employees' physical condition is forcibly brought home, it being obvious that in case of injury the rapidity and completeness of recovery would depend to a great extent on the employee's general health.

In many cases the efficient handling of "Human" repair work will produce complete recovery, whereas if handled by a general physician partial disability might remain, and the increased cost of competent surgical attention in effecting a complete recovery would be more than offset by the liberal award of compensation for permanent disability usually allowed in such cases by the state authorities. The employee who realizes that he has been given the best medical attention available naturally has a kindly reaction toward his employer and his loyalty to the corporation is thereby considerably augmented; on the other hand, if an employee meets with a serious accident and through inefficient medical attention carries with him a permanent disability for the rest of his life, his loyalty and efficiency are both impaired. His employer feels morally obligated to make a place for him on the payroll and, in addition to paying for inefficiency, has a disgruntled employee.

If such procedure is beneficial and essential in the case of accidents while "on duty," it is only reasonable to believe that like procedure should be equally beneficial in "off duty" accidents, as well as all forms of physical disabilities involving the employee's efficiency. Our company and probably all other large industrial concerns spend many thousands of dollars in the upkeep and maintenance of their mechanical equipment in order to secure maximum production. How much more important it should be to industry to keep the human machinery in perfect running order through periodical inspection by capable human mechanics and have repairs made when necessary. When a piece of equipment gets beyond repair it is placed on the scrap heap, and, unfortunately, this system has been followed to a certain extent by some industrial concerns with their man power.

All leading industries of the nation at the present time are coming more and more to realize that with an employee they have a more or less permanent investment and are taking the necessary steps to keep the human machine in proper working order until such time as the employee through the natural course of events becomes too old to perform his duties efficiently, when he is placed

on a pension sufficient to keep him in comfort for the rest of his life. Our company has had in effect since October 1, 1915, what is known as the Employees' Benefit Fund. All employees are eligible for membership, which is compulsory, upon the completion of one year's service, at a cost of \$1.00 per month. This contribution assures them medical, surgical and hospital attention for any one illness or accident off duty up to \$250, and in the case of death provides insurance for their beneficiaries ranging from \$500 to \$2,000, based on length of service of the employee. These life insurance benefits are payable in event of death from any cause and are in addition to any death benefits payable under the workmen's compensation law of the various states. Should the cost of medical attention in any one case exceed \$250, the excess is taken care of by the company and charged to the employee's account, allowing repayment by monthly payroll deductions, or by direct payment, if desired. If it so happens that the employee dies, the over-expenditure is covered by the insurance money paid the beneficiary. Since the inception of this fund the company has collected from the employees \$845,593.85 and has paid out for medical, surgical and hospital care \$1,074,126.46, plus \$525,582.20 insurance, a net cost to the company of \$754,114.81.

However, the increase in efficiency and morale of the organization has repaid the company many times over, and this asset, although intangible, does, we feel, justify the large expense involved.

In most cases where benefit plans have been inaugurated it has also been found necessary to have all employees pass a physical examination as a condition of employment. Many industrial concerns have adopted a plan of yearly physical examinations—a general examination for the average employee and a more thorough physical examination for the officials of the company, in whom, of course, the organization has a much greater investment. The cost of such examination is usually absorbed by the concern itself. Severe illness, loss of time from active duty, is often prevented by adopting this policy and securing corrective treatment before the disabilities become serious. The average man takes for granted that he is well and pays but little attention to his physical condition. As we grow older these so-called minor ailments become more and more difficult to eliminate, often becoming serious before we are aware of their existence. After a few years' service an industrial concern has a vital interest in an employee—labor turnover costs are high. The higher the position affected the greater the loss to the company.

The selection of doctors seems to be a great problem at first, and in reality it is a problem. However, it is one that can be solved satisfactorily, like any other problem that is of vital importance to an average group of men. Years of experience have proven that it is not the best policy to allow the selection of medical attention to remain in the hands of the employee.

Often in the case of sickness the family physician is called in, he in all probability being fairly well posted on general medical procedure, but very likely incapable of making other than a general diagnosis, often not willing to admit his own limitations. Therefore, the best results are naturally not secured. The patient in time realizes this and goes out shopping for new medical advice, obtaining this from a neighbor or a co-worker, and usually being given the information by the latter that his family doctor had attended a member of his family or a friend very efficiently. Irrespective of the fact that the ailments in both cases were entirely different, the advice is heartily accepted, a change of doctors brought about and the same procedure gone through again.

Many such cases were brought to our attention previous to the adoption of our present medical plan. Often an employee seeking medical attention for himself, before obtaining the desired results, had called in several doctors on

a comparatively simple case. Had the correct diagnosis been made and treatment given at the inception of the illness the patient would have recovered and been able to return to work in a much shorter time, the cost accordingly being a great deal less. It can be easily seen that if it can be so arranged to have medical and surgical attention directed by a competent head—one who is interested both in the industry as well as the employee—more satisfactory results would naturally follow.

We have at the head of our medical panel nationally known surgeons and physicians. It was thought at first that these men would not be willing to participate in our medical program. However, when the case was placed clearly before them they were only too glad to comply with our request. The fact was pointed out that in our industry at least the medical profession was receiving very unfavorable criticism, inferior work being performed in many instances resulting in loss of life or permanent disfigurement.

Naturally those highest in the profession resented this attitude and, when it was brought to their attention, were glad to assist in rectifying it. This they have accomplished to the betterment of their profession, to our employees individually and to our standing as an organization.

To further assure ourselves of competent medical service throughout all districts where we operate our chief surgical advisor and chief medical advisor have personally suggested and passed on all doctors before they were placed on our medical panel. The cooperation thus secured has been of inestimable value.

All of these doctors are very well satisfied with their connection with us and are only too pleased to perform the duties required of them. It was pointed out when placing them on our panel that during their general practice approximately 50 per cent of their work was charity, either from necessity or from inability to collect from their patients. It was upon this basis that our fee schedule was arranged, our argument being that all services authorized by our company would be chargeable to us and would be paid immediately upon receipt of bill. Further, if the expense of the treatment exceeded that which we allow our employees, the overexpenditure would be absorbed by our organization as heretofore outlined (we taking the responsibility of collecting from the employee), the physician taking no risk whatever. This program has been heartily accepted, and upon that basis we are operating today.

Medical and surgical men are rapidly becoming interested in industrial medicine and surgery. A short time ago it would probably have been considered unprofessional for a physician to become openly connected with an industrial concern, but now they find that such affiliations are a good advertisement for them and in addition greatly enlarge their clientele through contact with the various employees. For this reason even the highest in the medical profession gladly accept a place on our panel.

To sum up, there is no doubt from the experience of our company but that medical, surgical and hospital benefits should be a part of all relief plans. Such a medical plan as ours makes available to the employee first class treatment at a nominal cost, whereas similar treatment, if it had to be arranged for privately, could not ordinarily be obtained, due to the amount of expense involved. This is a day of cooperation and efficiency, and such an arrangement is just one more step towards complete harmony in industry.

CHAIRMAN McEWEN: I would like to know a little more about the mechanics of selecting these doctors. Do you select medical men from a panel you keep, or do your employees select anyone from the panel you furnish.

MR. GRANT: We furnish the panel man. We do not allow them to go to anyone who is not on the list.

J. W. MYERS (Standard Oil Company of New Jersey): Do you allow the employee to select the type of hospital service? Can he go in a private ward?

MR. GRANT: No, we select the hospital.

MR. MYERS: I was wondering how you managed to control that, and how you avoid having very expensive treatment?

MR. GRANT: We found it necessary to control the situation and made them attend a doctor who was in the panel.

MR. MYERS: What is the ratio of your medical cost to your compensation paid on account of sickness and not on industrial accidents?

MR. GRANT: Apparently you are running in the hole when you work this along this basis, and the ratio is not exactly easy to determine. I believe we use about sixty cents out of a dollar for insurance and that leaves forty cents for medical care. We are going in the hole but we feel it is worth it.

CHAIRMAN McEWEN: I am going to rather hurry through the formal program and leave time for more detailed discussion at the end.

We have Dr. Ferguson of the Shelby Shoe Company, Portsmouth, Ohio, here and he is going to tell us what he thinks about giving assistance to members whose Benefit Fund allowance is exhausted.

What Further Assistance, if Any, Should Be Given to Disabled Members Who Have Exhausted Their Benefits, and What Is a Fair Measure of Disability Qualifying for Benefits?

By C. L. FERGUSON, M. D.

Personnel Director, Selby Shoe Co., Portsmouth, Ohio

The question of additional help, after all benefits have been paid, is a problem which inevitably confronts everyone dealing with long disabled members of Employees' Benefit Associations. This is especially true when benefits terminate at a fifteen, twenty-six or fifty-two weeks period.

Beyond all doubt, members who have exhausted their benefits should be given all of the assistance we can secure for them, and this can be done in many different ways. But, I do believe that an extension of financial aid should not be offered by the Benefit Association unless there are provisions for such in the constitution.

Many times a committee representing the Association becomes very liberal-minded. It will propose the granting of large donations to some particularly deserving cases, but they seem to forget that there are others just as deserving and that there will be many more in the future. I firmly believe in making no exceptions. I more firmly believe in the strict adherence to the constitution, and most strenuously in cases of exhausted compensation. If further financial assistance is granted, it should originate from some other source.

In some long protracted cases, the strained financial condition of the family is very pronounced. The welfare of the sick member is not the only one involved. Our sympathy goes out to the worried wife and to the undernourished little children. We are our brother's keeper. We cannot let people endure hardship and suffering simply because of exhausted benefits. In outstanding cases of this sort, the company is always willing to give assistance. I have known cases when the company has matched or doubled donations of fifty, one hundred or two hundred dollars collected by interested co-workers. Money is often loaned without

interest to the disabled employee. A mutual arrangement is made whereby he can pay this back at a specified weekly amount when he is able to return.

In these days of group insurance, it is a common occurrence for the loan to be secured through the life insurance. In cases where proven permanent, total disability exists, the insurance company through its disability feature, will pay the principal in a lump sum or in monthly installments.

In securing assistance for unfortunate Benefit Association members, one should not forget the various charitable organizations in the community. Their services embrace a variety of valuable activities. They give nursing care, financial assistance, work out a budget system, obtain work for one or more members of the household, probably move the family into a house of cheaper rent, secure admittance into a hospital or sanatorium for the patient, communicate with relatives who are able to help in the family's support, or get the aid of the county commissioners whose budgets contain funds for emergency cases.

I recall the case of a young man who was the victim of T. B. He refused sanatorium treatment and utilized all of his benefits. He lived with his mother who was very poor. By selling her furniture she had enough money to take her son to a little farm in the Kentucky hills. This, apparently, was a hopeless, fruitless case. Three years later the man came back, and in a far worse condition, but he had a change of heart and then wanted to enter a T. B. sanatorium. The Bureau of Community Service was notified; the T. B. nurse made an investigation and reported back to me that the boy had five brothers who could contribute five dollars a week, a sufficient amount to secure sanatorium treatment for him. Here was a problem totally solved. This meant some effort and assistance, but now the boy is recovering and is just as well satisfied as if he had a periodical income from the Benefit Association.

Just recently we had a case of a man and wife who had received all of the benefits to which they were entitled. His, he had drawn because of T. B., and she because of an operation. During a later period of the husband's disability, arrangements were made with the county commissioners to send him to a county T. B. sanatorium. Previous to leaving he said he had to have fifty dollars to pay a debt, and unless he got that paid, he would not go to the sanatorium. The company loaned him the money to pay the debt. He went to the sanatorium, stayed one day and left. Shortly after, the wife developed incipient T. B. The problem then was, what further assistance can be given to these two unfortunates whose only possession was a second-hand Ford? How can they get the proper attention and care?

An appeal was made to charitable organizations again. The problem disappeared. The wife was admitted into the Ohio State sanatorium. The husband, who is an ex-soldier, went to the Dayton Soldiers' Home and later was sent to a sanatorium in Denver. What more do they need? Nothing except suitable work when they are able to return.

Just recently I read an article about an employee who had been disabled for one year. During that time his company sent his wife his entire wages every week. When the employee was able to return to work, he was greeted by the general manager, who said, "Bill, you certainly have had a tough time, you have been a brave boy; if I can do anything more for you in the future, don't hesitate to let me know." Bill suddenly realized that he had no job. He was looking for assistance in the future; he needed and wanted work. So the securing of work is an assistance we should be ever mindful of. Place the man or woman in some kind of work just as soon as they are able to return. If they are not able to do their regular work, place them at something suitable if possible.

Since we are interested in the type of assistance we can give after the benefits are exhausted let us consider, before closing this discussion, what assistance the Benefit Association should be giving during convalescence in order to eliminate to a minimum, cases which cover long periods of time.

I would like to suggest to those who do not have this provision incorporated in their constitutions, that the Benefit Association pay for diagnostic facilities when necessary and when ordered by the medical director. In other words, make it possible for the family physician and the disabled member to get X-ray, laboratory or consultation service. In many instances the writer can recall the beneficial results derived from the expenditure of five, ten or fifteen dollars during the first few weeks of disability. For example: Is this a case of bronchitis or T. B? Has the cause of that rheumatic case been discovered? Is the cause of this woman's nervousness due to factory work, as is often stated, or is it really due to toxic goiter. Is the next case which is diagnosed as indigestion, really stomach ulcer, duodenal ulcer or cancer? Often we are confronted with the so-called nervous breakdown cases which the family physician says is due to overwork, but, after some diligent search, the teeth, tonsils, sinuses, appendix, gall bladder or some other foci of infection are found responsible. These are a few examples and many more could be given. What assistance can the Benefit Association give that is better than to provide a means of making an early definite diagnosis so that the member will get the proper treatment early. This is not a "cure-all" for every case, but it is a big factor in reducing the number of disabled employees.

What Is a Fair Measure of Disability Qualifying for Benefits?

With industry's steadily increasing desire to render "Service," and its striving for the regeneration of society, too much emphasis cannot be placed upon the ordinary virtues—justice and honesty. Every man can discern between truth and falsehood, honesty and dishonesty; and although the element of dishonesty is one of importance in the operation of a Benefit Association, I believe we are more concerned about the impartial and unprejudiced relations we have and should have toward one another.

We, upon whom is fixed the responsibility of making final decisions on cases questionable, desirable and undesirable, are ever mindful of the question, what "is" just to all concerned? Being in cooperation with and desiring to mutually benefit all parties, we keenly appreciate the necessity of fairness. To render the greatest possible amount of good with the money entrusted to us should be our uppermost desire.

With this urge constantly before us, we are continually confronted with situations which make us ask, what is a fair measure of disability qualifying for benefits? Irregularities and misunderstandings are the most prevalent factors which foster these situations. It is the case of a questionable cause of disability or questionable disability itself that present the problems.

I recall numerous cases which had legitimate beginnings and were free of suspicion, but in time they taxed one's ingenuity, tact and investigating abilities to justify compensation.

Gossip is usually the instigator of situations of this kind. One hears many remarks—"This person is trying to put something over;" "That fellow is a crook;" "She isn't sick because I saw her on the street or at a show or in an auto;" "This man isn't sick because he made the statement that work was slack and he had decided to draw benefits." Many similar remarks come to our ears, which, if accepted for truth, would keep us in a constantly unsettled state of mind.

I know nothing that will arouse question about the integrity of an employee who is as readily as a borderline disability. Evidently, it is a common practice to look upon these truly unfortunates with suspicion. This is often practiced by the foreman, floor ladies and fellow-workers, and wholly because they fail to grasp the necessity of securing all of the facts in the case.

Many times unfair accusations are made about various patients' physicians, and aims to the effect that the doctors have been bribed to write certificates per-

mitting the alleged patient to draw benefits. A misconstrued remark from the disabled employee, or a misquoted doctor's statement often arouses suspicion, and the unavoidable question arises, is that individual deserving of benefits? Let me state before I am misunderstood, that now and then there is evidence of a certain amount of malingering, and that occasionally favoritism is shown by attending physicians, but I have found the percentages to be so small that it isn't worthy of our consideration. Also, I have observed that accusations often fade into oblivion if the accusers are requested to present sufficient proof to substantiate their claims.

I learn from corresponding with the officers of your section that the following questions have been raised:

How far should one go in paying out relief benefits? Should persons who have no specific illnesses, but who are simply old and worn out be entitled to relief benefits, or should benefits be limited entirely to specific maladies under the care of a regular, licensed physician? Are hay fever patients disabled? Is the employee who is working, but who is on the verge of a so-called nervous breakdown entitled to benefits if ordered to rest? These cases seem to present difficulties to some from the very outset.

Since we are interested in concrete examples of what is a fair measure of disability qualifying for benefits, it occurs to me that it is futile to attempt to describe such cases and to render a decision. However, it does appear to be imperative that provisions for a plan be suggested whereby we can more accurately and easily decide upon questionable cases. The real problem is one of indecision, therefore the plan which will reduce unfairness to an inconsequential minimum is that which we are seeking.

This question is an interesting one, and it can be approached from many angles, but I fail to see the occasion for many complexities providing we have a workable plan. Before drawing up the rules for the constitution of a Benefit Association, it is essential to make a study of numerous Benefit Associations' plans, then try to incorporate as many of the good points in your plan as possible. In this carefully selected constitution will be found rules definitely stating the certain number of weeks for which benefits shall be paid in cases of disability, and it will also contain concise information regarding the nature and causes of disabilities for which compensation will not be paid.

We are searching for a definite means by which we can determine qualifying and disqualifying measures of disability, therefore, in lieu of this fact, who is to judge whether or not a person is disabled? There is no one better qualified than one of the medical profession; the family physician should be the first to pass on a case. If one is seriously enough disabled to draw benefits, he is in need of a physician. A report from the attending physician should be received before compensation is paid, and, thereafter, as long as the term of disability continues, a weekly report should be filled out by the physician. This report, when completely and properly filled out, will furnish information pertaining to diagnosis, prognosis, estimated date of the patient's return to work, date of last visit and whether or not the patient is carrying out instructions.

It appears to me that the person most fittingly qualified to finally decide upon these reports is a physician who is the medical director of the Benefit Association. If he is the physician for the company employing these unfortunates, and they are members of the Benefit Association, his numerous contacts and his accumulated medical records will often help in evaluating the report of the doctor in charge.

The greater majority of the industrial concerns today employ a visiting nurse. Her report is a valuable factor in determining the validity of claims, and in addition, there are often visiting committees which make thorough investigations and reports.

Therefore, the report of the family physician, that of the visiting nurse, the

committee's reports, and these along with the Medical Director's personnel information, leave a very small doubtful remainder. The question may arise—suppose the nurse and visiting committee do not agree with the family physician? There is but one conclusion, and that is an attempt to prove which is right.

There is no doubt but that a lay executive will frequently be put to a pronounced disadvantage in attempting to decide what is a fair measure of disability qualifying for benefits. We should not quibble about legitimate cases of disability, or about cases which we cannot disprove. The phase which should monopolize our concern is—do we have sufficient personnel capable of obtaining necessary information about these cases.

I most clearly realize that there are some cases of hay fever that disable their victims greatly, and these undeniably qualify for benefits. If old people are partially or totally disabled, they are deserving of compensation; where pension systems for the aged do not exist, I know of no better plan than to pay the full allowance of benefits. They deserve it. I consider it advantageous to take the man or woman on the verge of the so-called nervous breakdown off the job and pay them benefits. Most often these patients recover entirely in four to six weeks, then enjoying a change of scenery and climate. This quick recovery, however, does not lessen the degree of their disability.

The fact that a patient is not confined to his bed, home or wheel chair proves nothing.

To conduct a Benefit Association smoothly and effectually one should abide by evidence, facts, rules and make no exceptions. When one looks for exceptions and makes exceptions, there is an unbelievable amount of trouble that follows.

What is a fair measure of disability qualifying for benefits? It is a satisfactory proof of total disability.

CHAIRMAN MCEWEN: Thank you; that was very interesting. We have a lot to discuss today. The first question that has been brought up is the question of what we are going to do after the benefit has expired?

S. W. ASHE (Pittsfield, Mass): I think, judging from the discussion we had last year's session of the Mutual Benefit, that this paper offers a vital thing for our consideration. The author of the paper has been willing to go one hundred per cent, and the paper is so important that I think copies should be made and sent out to all those who are here today. What you need more than anything else are concrete and specific experiences in handling this problem.

I have always felt, and I have been handling this for a good many years, that the working out of a problem is best taken care of by the citing of examples. We have been favored with some illustrations of help given to men who were out for two and three weeks. I do not believe that is comparable to the help that should be given to a man out ten weeks. Nevertheless, you must give help at the start when it is needed.

In the development of our association at Pittsfield we did it along those lines—give help at the stage when it was most needed. It is a very difficult thing to set up an association with regular weekly benefits, to provide protection, and to take care of these cases which are at the beginning stage. We created what we called a special reserve fund. This was built on the profit from shows and carnivals. We could take a couple of thousand dollars every time and put it in this fund and it was built up that way. With the fund we take care of the man who has tuberculosis and has to go away, and we will pay it from the fund so that he can be doctored out in the air where he can have a chance to recover. We found a great number of these cases and it grew to be rather expensive and we conceived the idea that every year we would take something out of the general fund and add to it, and it was done in such a way that we did not feel it.

There are several things I would like to talk about but I will just tell you one

more thing. We had four executives during the past year who were a little run down. We took those four men and sent them out on a trip to a convalescence hospital and gave them treatment for a few months. They were all men who had become fatigued with the strain of the business. They would have all been serious cases if we had not taken care of them and put them under rigid hospital care. As it was they were all restored to normal.

I think that this idea of getting hold of a man in the early stages of his trouble is worth a lot of attention, and that is why I think it is such a valuable paper along these lines that we heard this morning. I have never heard a paper of this sort at any of our meetings before.

CHAIRMAN McEWEN: In handling that kind of a case we try to anticipate an employee's breakdown. If he is in a tubercular condition we must realize in the beginning that we are going to have to carry him for a long time. So in the very beginning you have a definite problem that ought to be thought of. Most of these disabled people can carry on a short time with their benefit, living at home and caring for themselves or possibly securing hospital attention if it is needed, but when you have to look at the future of a case there is another problem, and especially in a tubercular case.

There are charitable cases taken care of by the State and if we see that an employee is not going to complete a cure before the benefit has expired we urge him to go to a charitable institution. I think every one of us can study that sort of case with a great deal of profit. I am sure there is other discussion on this subject.

MEMBER: It appears to me that as a case approaches the twentieth or thirtieth day we should begin to look toward the future of that case because the benefit will probably be about exhausted. We should re-grade the benefit and give a little less each day; in other words, a day or two added from a waiting period would increase the life of the benefit.

CHAIRMAN McEWEN: Is there anyone else who would like to talk about this? If not we will come back to the subject later and proceed now. Our next item is on the value of statistics in preventing sickness. This subject will be discussed by Dean Brundage of the United States Public Health Service, Washington, D. C.

The Value of Uniform Statistics in Preventing Sickness

By DEAN K. BRUNDAGE

Assistant Statistician, U. S. Public Health Service

In discussing the value of uniform statistics in the work of attempting to prevent sickness among industrial employees, I should like to review very briefly some of the statistical data that have already been made available, through the cooperation of sick-benefit associations. When this has been done, we shall be in a better position to pass judgment on their value.

During the past seven years a group of about 35 employee benefit associations which now have a combined membership of about 175,000 persons have sent monthly reports of their cases and average number of members to the United States Public Health Service. We have analyzed the data contained in these reports for the purpose (a) of affording information concerning the frequency and nature of disability in sample groups of the industrially employed population, and, (b) of ascertaining the normal expectancy of sickness, especially the average rates for specific diseases, as a basis for judging whether certain causes of disability in any given group of workers were occurring at normal or excessive frequency.

These statistics have been valuable to us in our studies of the dusty trades

of other occupations suspected of causing damage to health. Without these facts there is no question that we would be seriously handicapped in our work some of the health hazards of industry. But aside from this use of the data by government research organization, of what value are the statistics to the sick-benefit associations themselves?

The Principal Causes of Disability

It is important, surely, that the officers of an industrial relief association should have a clear picture of the comparative frequency of the different diseases and conditions causing disability among their members. The diseases which affect the greatest number of persons, which most frequently necessitate disbursements for medical relief suggest the proper point of attack, for it is obvious that even a small degree of success in controlling the diseases which are most prevalent would reduce the number of payable cases far more than would result from the complete elimination of certain diseases which rarely occur.

During the six year period extending from January, 1921, to January, 1927, the reports from sick-benefit associations having a waiting period of one week showed that the respiratory diseases were responsible for many more payable cases than other disease group. About 43 per cent of all the claims during this six-year period were on account of diseases of the respiratory system.

Within the respiratory group, one disease was outstanding on account of its high prevalence. It was responsible for nearly 50 per cent of the respiratory disease claims, and for about 20 per cent of the claims for all causes. This disease, influenza or grippe which in a period relatively free from serious epidemics the disease was, nevertheless, the greatest single cause of claims for relief. Even in non-epidemic years the cost of this disease to American wage earners as a whole must reach a staggering total. The second most frequent cause of disability within the respiratory group were diseases of the pharynx and tonsils (chiefly tonsillitis). Bronchitis ranked third in frequency and pneumonia fourth.

Of the broad disease groups, the second most important from the standpoint of number of payable cases are diseases of the digestive system. Within this group the largest number of claims during the six-year period were for diseases of the stomach, and the second largest for appendicitis, the frequency of which was about the same as that of pneumonia (all forms). Diarrhea and enteritis occupied third place within the digestive group.

Another important group of cases were the non-industrial injuries which accounted for nearly 10 per cent of the claims for sickness benefits. Among the non-respiratory, non-digestive diseases the most frequent were rheumatism (acute and chronic), diseases of the nervous system.

If we add together the number of disabilities from the five most important groups, we find that they cover 48 per cent of the cases. In other words, nearly half of the claims resulted from only five different diseases or conditions. These five were: (1) influenza or grippe; (2) non-industrial accidents; (3) tonsillitis and other diseases of the tonsils and pharynx; (4) rheumatism—acute and chronic; and (5) bronchitis. It will be observed that three of the five major groups are respiratory diseases. The epidemic and infectious diseases against which health work is so largely directed caused less than 3 per cent of the cases.

The epidemic and infectious diseases which are mostly the diseases of childhood have been brought under control to a gratifying extent. It appears that our next objective in public health work might well be the prevention of those diseases to which the adult population is most susceptible.

Factors Which Affect the Rate of Sickness

In additoin to this morbidity picture which the reports from industrial relief associations have given us, they have enabled us to measure and evaluate the influence of several important factors affecting the sickness rate. One of these factors is sex. The frequency of disability lasting more than one week was found to be about 44 per cent greater among female than among male members of the reporting associations. The female rate was more than twice that of the male rate for diseases of the nervous system, diseases of the pharynx and tonsils, and appendicitis. On the other hand, females experienced only about one-half as many disabilities as men from pneumonia, rheumatism, and from lumbago and other diseases of the organs of locomotion. Hernia was reported as the cause of disability among women about one-fifth as often as among men. For most diseases, however, the female rate was higher than the male rate. The frequency of non-industrial injuries was about the same for either sex. It is apparent from these results that the larger the proportion of women in a sick-benefit association, the higher is the rate of claims to be expected.

The age distribution of the members also affects the rate of sickness. The days lost per person per year increases much more rapidly with age than does the frequency of cases. This indicates a tendency toward a gradual decrease from age 30 to about age 45 in ability to recover rapidly from disease, and a much more marked lessening of recuperative ability after age 50. The records also show that members under 25 years of age generally experience disability more frequently than those between the ages of 25 and 45.

The incidence rate of sickness was found also to vary widely from industry to industry. In general low sickness rates occurred in the heavy industries, and high sickness rates in the industries in which the work was less difficult from a physical standpoint. From this it may be assumed that workers tend to select the industries for which they are best fitted physically, the stronger, sturdier individuals going into the heavier industries such as iron and steel manufacturing, while the physically inferior tend to seek the industries which have the light, sedentary jobs. The frequency of sickness was especially low in the iron and steel industry.

A fourth factor is the effect of occupation upon health. In several instances high rates for certain diseases have suggested the possibility of occupational health hazards. The Public Health Service is now making a special study of what appears to be an important hazard to health in one of our basic industries. The reporting associations in this industry have rendered a great service to their members by helping to make possible the discovery and investigation of a situation probably involving a health hazard which might otherwise have gone unrecognized for years.

Is the Frequency of Sickness Decreasing?

With uniform statistics of sickness one can also throw light upon the question whether the industrial population is experiencing more or less sickness than in the past. For this purpose we tabulated all the cases of disability according to their duration as reported by 15 associations which sent their reports continuously throughout the last six years. The sickness curve for the three years 1922 to 1924 inclusive was compared with the curve for the three years from 1925 through 1927. In the latter period there were fewer cases lasting from 8 to 20 days than in the preceding three years, but more cases lasting 8 weeks and longer. No measurable progress therefore appears to have been made during the rather brief period 1925-27.

Essentials of Uniform Statistics of Sickness

In comparing the morbidity experience of one association with another, it is necessary, of course, that the waiting period, i. e., the number of days which must elapse before the patient begins to draw benefits, be the same. Probably a majority of industrial mutual associations in this country have a waiting period of seven calendar days, benefits beginning on the eighth consecutive day of disability. Associations with a waiting period of less than one week may be included if all the cases lasting less than eight days are omitted in the statistics, but there is no satisfactory way of including associations which have waiting periods longer than days. Theoretically they could be put into separate groups, but practically there

TABLE 1

Frequency of Different Diseases Which Caused Disability for More Than One Week Among Approximately 95,000 Male Industrial Workers in a Diversified List of Industries, 1921 to 1926 Inclusive

Number of cases, 1921-1926	Annual No. of cases per 1,000 male members	Diseases causing disability
57,554	100.6	Sickness and non-industrial accidents.....
24,549	43.1	Respiratory diseases.....
11,869	20.8	Influenza and grippe.....
3,619	6.4	Diseases of the pharynx and tonsils.....
3,238	5.7	Bronchitis.....
1,884	3.3	Pneumonia—all forms.....
837	1.5	Tuberculosis of the respiratory system.....
3,102	5.4	Other diseases of the respiratory system.....
7,701	13.5	Digestive diseases.....
2,637	4.6	Diseases of the stomach, cancer excepted.....
1,911	3.4	Appendicitis.....
1,031	1.8	Diarrhea and enteritis.....
855	1.5	Hernia.....
1,267	2.2	Other diseases of the digestive system.....
19,573	34.3	All other diseases.....
3,271	5.7	Rheumatism—acute and chronic.....
2,493	4.4	Diseases of the nervous system.....
2,232	3.9	Diseases of the circulatory system.....
2,026	3.6	Diseases of the skin.....
1,857	3.3	Lumbago and other diseases of the organs of locomotion.....
1,591	2.8	Epidemic and infectious diseases.....
1,507	2.6	Non-venereal diseases of the genito-urinary system and annexa.....
930	1.6	Diseases of the eyes and ears.....
589	1.0	Diseases of the bones and joints.....
349	.6	Cancer—all forms.....
2,728	4.6	Other non-respiratory, non-digestive diseases.....
5,531	9.7	Non-industrial accidents.....
		Number of years of life under observation 570,042

are not enough of them to warrant the collection of special sets of statistics for associations with the longer waiting periods.

The length of the benefit period, i. e., the maximum duration of payments for disability, does not affect the sickness incidence or frequency rate, but when comparisons are made of the amount of time lost or of the duration of disability, it is obvious that only those associations should be included which have the same benefit period, unless one wishes to reduce the time lost in each association to the common denominator of the association having the shortest benefit period.

Most employee benefit associations keep reliable records of sickness, but it is

TABLE 2

Relative Frequency Among Males and Females of Different Diseases Causing Disability for More Than One Week in a Group of Industrial Workers, 1921 to 1924 Inclusive

Diseases and conditions causing disability	Annual number of cases per 1,000—		Per Cent of male rate
	Males	Females	
Sickness and non-industrial accidents.....	94.8	136.4	144
Respiratory diseases.....	40.1	58.6	146
Influenza and grippe.....	16.4	20.2	110
Diseases of the pharynx and tonsils.....	5.9	15.7	266
Bronchitis.....	5.3	6.6	125
Pneumonia—all form.....	3.3	1.4	42
Tuberculosis of the respiratory system.....	1.5	1.7	113
Other diseases of the respiratory system.....	5.7	13.0	228
Digestive diseases.....	12.7	17.7	139
Diseases of the stomach, cancer excepted.....	4.2	4.4	105
Appendicitis.....	3.1	7.5	242
Diarrhea and enteritis.....	1.9	1.8	95
Hernia.....	1.5	.3	20
Other diseases of the digestive system.....	2.0	3.7	185
Non-respiratory, non-digestive diseases.....	33.2	51.2	154
Rheumatism, acute and chronic.....	5.5	3.1	56
Diseases of the nervous system.....	4.2	11.2	267
Diseases of the circulatory system.....	3.6	3.3	92
Diseases of the skin.....	3.5	3.2	91
Lumbago and other diseases of the organs of locomotion.....	3.1	1.4	45
Epidemic and infectious diseases.....	2.7	3.0	111
Non-venereal diseases of the genito-urinary system and annexa.....	2.5	4.4	176
Diseases of the eyes and ears.....	1.5	2.5	167
Diseases of the bones and joints.....	1.3	1.0	77
Cancer—all forms.....	.6	.9	150
Other non-respiratory, non-digestive diseases.....	4.7	17.2	366
[Non-industrial] accidents.....	8.8	8.9	101

Number of years of life under observation: males, 336,525; females, 39,967.

TABLE 3

Frequency of Cases of Sickness Including Non-Industrial Accidents Which Resulted in Disability for More Than One Week, and Number of Days Lost From Work on Account of Such Cases, by Age, Among Male Members of the Employees Benefit Association of a Farm Implement Company. Experience of Employees at Three Plants of the Company, 1916 to 1920 Inclusive.

Age Group	Number of years of life under observation	Number of cases	Number of days lost from work on account of those cases	Annual number of cases per 1,000 males	Annual number of days lost per person on account of these cases
Under 25	38,672	6,949	208,061	179.7	5.381
25 to 34	5,578	1,059	22,946	189.9	4.114

" 15		57,525	3,290	57.2
" 16		37,895	2,142	56.5

sometimes found that there is no common basis for comparison on account of the diverse methods and practices employed in the classification of ailments causing disability. In classifying the nature of the illnesses as diagnosed by physicians, the Manual of the International List of the Causes of Death, third revision, Paris, 1920, should be used in accordance with the recommendation of the committee on industrial morbidity statistics called together in 1925 under the auspices of the National Industrial Conference Board.¹

TABLE 5

Frequency of Cases of Sickness (Including Non-Industrial Injuries), of Specified Duration in 1925-1927 Inclusive Compared With 1922-1924 Inclusive.

Experience of Male Members of 15 Sick-Benefit Associations Which Reported Their Cases to the Public Health Service Throughout Both Periods.

Duration of disability in calendar days	Annual number of cases per 1,000 men		Number of cases

Number of years of life under observation			181,238	158,279

For a group of associations having the same waiting and benefit periods and using the same disease classification, the requirements for current knowledge of disease prevalence are few, as indicated below:

- The average number of members each month who are entitled to benefits when sick, classified according to sex.
- The number of male and number of female cases which began during the month, classified according to a condensed list of the diseases causing disability.
- The number of days lost during the month, classified in the same way as the cases.
- The number of payable cases per 1,000 males and per 1,000 females, and the number of days lost per 1,000 from each of the diseases in the condensed list.

A monthly morbidity report containing substantially this information is in operation in all plants of the Bethlehem Steel Corporation. If more associations would prepare such reports for their own use, and forward a copy each month to the Public Health Service, we could publish more promptly the monthly analyses of sick-benefit association reports which we plan to inaugurate soon in addition to our annual review of the data.

¹The Manual of the International List of the Causes of Death, third revision, Paris, 1920, may be procured from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 70 cents per copy.

this brief discussion I hope I may have conveyed the impression that there are some glimmerings of sense in the attempt to collect uniform statistics of sickness and that the statistical method may be employed to good advantage in the study of health problems in industry. The facts of sickness are especially desired by those who hold the vision of employee sick-benefit associations of the future powerful organizations working for the prevention of disability among their members.

CHAIRMAN McEWEN: I think we were all very much interested in Dean Brunson's talk. Is there any discussion?

MR. SCHOUTY (Bethlehem Steel Corporation): Mr. Vary is the man who got interested in all this. You know, you never know where you are going unless you have a guide, and statistics are a pretty good guide. Nowhere are the hazards of sickness in abundance than in the steel industry. There must be some way of cutting down, not only the accidents, but the sickness, and I believe that the first step is the compiling of uniform statistics in all branches of industry.

we would make a more serious effort to really try to assemble the facts we need to be making a beginning. Try to see if the health problem will not be helped by the collection of statistics. See if it will not help in your own industry.

MR. JOHNSON (Hoover Company): I was just wondering if it would be in order if we suggested that each member here be sent a blank on which he could write all the necessary information; then also it could be used to put down questions that might be answered at the next meeting or possibly our Service Committee could answer them; and this would give those men who come from great distances a chance to have presented beforehand the questions that are on their minds; and in this way we would be sure of having them brought before the meeting.

CHAIRMAN McEWEN: I think I have a satisfactory answer to that, because Dean Brunson is to be chairman of this committee next year.

Now we will go on with our program and the next speaker will be Mr. Henry Jackson, of the Social Engineering Institute, New York City.

Should Pension Plans and Relief Plans Be Combined for Greater Economy and Effectiveness?

By HENRY E. JACKSON

President, Social Engineering Institute, New York City

It was a significant remark of Robert Louis Stevenson in which he said: "We are not blamed for doing wrong; we are blamed for not doing right." The difference is great. It is all the difference between plus and minus.

An employer is not to be blamed for operating a Relief Plan separate from his Pension Plan. He is to be blamed, in my judgment, for not combining it with his Pension Plan. Therefore, if I had formulated the question assigned me for discussion I would not have said, "Should pension and relief plans be combined?" but rather, "Should relief and pension plans ever be separated?"

Instead of asking, "Should a man's arm be combined with his body?" we would more properly ask "why a man's arm should never be separated from his body." The answer is that a man's arm is more useful when united to his body.

The illustration of a man and his arm to suggest my conviction that Disability Insurance and Life Insurance are organically related to a Pension Plan is that a man's arm is related to his body, and that what economic necessity has put together industrial corporations ought not to put asunder.

For the sake of clarity in this discussion let us define our terms. Sick benefits, usually covered by what is called Relief Plans, should be called Health Insurance, just as a death benefit is called Life Insurance, and which our prevention work is now beginning to make Life Insurance in fact. By a Pension Plan I do not mean a charity or dole but what I prefer to call an Economic Independence Plan based on annuities guaranteed by a reserve, an honest cooperative plan on a 50-50 basis; a plan that is contractual and supported by insurance, the employer's share of the cost regarded as a necessary operating expense and a proper charge against the depreciation of human machinery. This is quite different from the usual type of pension plan. In fact it is not a pension plan at all but something very much better and it is inexpensive.

I assume then that in regard to the three great hazards that all men face in common, death, disability and dependence in old age, our aim is to antidote these hazards with life, health and independence. I can most briefly indicate my opinion that these three programs are organically related by using a little word picture. The conception of a unified plan on the independence instead of the pension basis may be indicated as follows:

A fairly long road is winding up hill all the way. At the end of the road is a modest little cottage, with a woman standing in the doorway and a grandchild by her side. The name given to the cottage is "Economic Independence." At a turn of the road on one side is a dark clump of trees, out of which is peering a highwayman called "Death." At a turn of the road on the other side is a forbidding forest, in which is lurking another robber called "Disability." Where the road starts stands a fine type of artisan, intelligent enough to be thinking of the day after tomorrow. He is in the attitude of beginning the journey over this road. By his side and shaking the workman's hand is his employer in the attitude of giving him a fair start. He hands him a document like a passport to the journey—it may be an Independence Bond or an Insurance Policy—something to shield him from the dangers he may meet on the way. It is the workman who is taking the journey; the employer is assisting him to make its achievement possible. The suggestion is that the aim of the employer is to stimulate his employees to set their feet on a purpose road leading to a big goal and is willing not only to open the road to economic independence but also assist them to walk in it.

This conception clearly implies that the two protections against death and disability should be attached as temporary provisions to the retirement plan and discontinued when their temporary purpose has been served, that is, when the workman arrives at his desired goal.

The illustration of a workman traveling towards a reasonable degree or at least minimum degree of economic independence after a life-time of work with the cooperation of his employer makes sufficiently clear the general principle that economic and efficient reasons require a unified plan and that relief plans and pension plans naturally belong together. But the economic and moral advantage of a unified and related program may be still further exhibited by a Bill of Particulars, such as the following:

Pension Plans On Scientific Basis

1. Pension plans are, or are beginning to be, scientifically calculated on a sound actuarial basis. Relief plans are not. If the two plans were united, relief plans could more likely be put on a sound financial basis, which is a universal and vital need. Recently we analyzed the relief department of a large industrial concern. It had a balance of more than \$200,000 in its treasury. It was thought to be sound. As a matter of fact it was bankrupt with a deficit conservatively estimated to be one and a quarter million dollars. That is, if the relief department closed

business now and settled its accounts, it would require over a million dollars to meet the estimated obligations to which it is committed. If the estimate proved to be twice too high the deficit would be bad enough. Such a situation may involve a heavy loss. After a workman has contributed his dues to the Disability Fund during several years without drawing anything from it and then becomes disabled it is only a matter of paramount importance but is a moral requirement that he should have the guarantee that there is enough reserve in the fund to furnish him the promised benefits during his disability. The failure of a relief plan at this time is ethical bankruptcy.

By organizing all three benefits into a unified plan we give to each its relative importance. Of the three hazards, sickness is preventable, death may or may not be an

age, but dependence in old age is certain humiliation. Protection against dependence in old age, therefore, is the Hamlet of the play and deserves the most consideration. The other two benefits should be treated as secondary and temporary attachments to the pension plan. In organizing a relief plan it makes no difference in the world whether we put pension benefits in the first or in the second place.

If all three protections were organized into a unified program, it makes possible the suggestion that the disability protection should cover an employee's working life and his disability benefit should last until his pension benefit begins. This is as it should be. Disability from sickness or accident may occur at any time during his working life.

If we make the disability benefit cease when the pension benefit begins we naturally eliminate the distinction between temporary and permanent disability. This also is as it should be. As a matter of fact it is a distinction without

a difference. It is not possible to say what disability is temporary and what is permanent. If an employee were sick three months and recovered, his disability is temporary. If he were sick three years and recovered, his disability is likewise temporary. The only disability which properly may be pronounced permanent is death. Therefore it seems logical to treat all disability as one thing and cover it with a protection during the time when employees are exposed to the hazard, making the disability benefits cease when the pension benefit begins, at which time such protection is no longer needed.

5. Life insurance should be a provision attached to the Retirement System because life insurance and annuities are exact opposites and antidote each other. If John Doe dies you lose on the Life Insurance and gain on the annuities; if he lives you lose on the annuities and gain on the life insurance.

6. Disability protection should be attached as a provision to the pension plan, because it is the most troublesome part of the program and can be handled most effectively as part of a unified program. Life insurance is the simplest and least complicated part. Annuities while complex are not difficult to calculate; they are based on the purchase of future annuity dollars, distributed by a predetermined schedule. But disability protection involves so many local uncertain elements, that it requires a prevention program in which employee participation is enlisted to make it a financial success, and inasmuch as most pension plans in American industries are operated by employers themselves, so likewise disability or relief programs can be operated more efficiently by employers and employees cooperatively than by any outside underwriter.

7. Assuming that an industry has a large enough number of employees so that it can safely pool its own risk and safeguard itself against a catastrophic hazard, it can operate its own plan on the trustee basis and save itself a very considerable amount of money. In this case it will be a particular advantage to unify the three parts of its program setting up all three reserves as one reserve. This will greatly outtress the security and protection back of each part of the program. A poor experience in one part of the program will be covered by a surplus reserve in the other two parts.

Inasmuch as the above brief bill of particulars exhibits the obvious advantages of organizing all parts of a relief plan into a unified program, there must be some reason why such a policy has not hitherto been generally adopted. I venture to think that the chief reason is the prevailing impression that a scientific pension plan is expensive and therefore cannot be united with so called relief plans. Therefore, if the advantages of a unified program are to be made available, it is essential to correct this impression, which I regard as false. At least no employer is in position to say whether or not a scientific pension plan is expensive until he knows what his present pension cost is and almost no employer anywhere now knows what his present pension cost is.

Artemus Ward made a wise remark when he said, "It isn't the people's ignorance that makes the trouble but that they know so many things that aren't so." The greatest stumbling block in the way of sound and effective retirement systems is that employers know so many things about pensions that aren't so. For example, one of the widely held opinions which I regard as mistaken are as follows:

1. That a scientific pension plan requires a large outlay of money.
This is not the fact.
2. That the cost of such a plan increases indefinitely in the future.
This is not the fact.

That such a plan commits an employer permanently to an unknown obligation. This is not the fact.

That such a plan always means a large increased expense over his present cost. This is not the fact.

necessary to eliminate false ideas before we can adopt true ideas. We are led to demonstrate to the point of mathematical certainty that these four long accepted opinions about pensions are contrary to fact. It can be shown that the only type of plan which American industries are willing to consider "liability" as commonly understood is a myth; that the maximum cost for many years can be definitely determined and budgeted; that the actual cost that the net cost can be exhibited every thirty days.

have recently made such a demonstration for a large concern with 40,000 employees, for which we drafted a unified program such as we are discussing in this paper. The benefits provided are: A monthly retirement income on the average at one-half of an employee's wage; Life insurance coverage ranging from \$5 to \$45 per week, lasting as long as the disability lasts and ceasing only when the pension benefits begin, which is an unusual and generous provision.

annual cost to the employer for this program is: Life insurance $\frac{3}{4}$ of 1 per cent of payroll; Health insurance $\frac{4}{10}$ of 1 per cent; Pensions 1 per cent.

low cost of a scientific pension plan is so important for our discussion that I assist your memory to bear it in mind by the use of an illustration. Professor Huxley, in one of his college examinations, asked a student, "What is a lobster?" The student answered, "It is a red fish that moves backwards." To this Huxley replied, "Your answer is entirely correct except for three things; it is not a fish, it is not red, and it does not move backward." The trouble with this student was that he knew so many things that aren't so. If many employers were asked what a pension plan is they would probably answer, "It is an expensive charity that increases annually in cost." This prevailing opinion is correct, except for three things; it is not a charity, it is not expensive, and it does not increase annually.

my conviction that a permanent scientific and inexpensive solution of the pension problem is now available, so that the way is open for the unification of our protection program as recommended in this paper. I believe the "Relief" and "Pensions" should be discarded in order to eliminate the idea of charity which is distasteful to self-respecting American workmen and employers alike both to the benefactor and beneficiary. We should adopt some form as an "Economic Independence Plan," which we have persuaded one industry to adopt.

organization of such a unified program is primarily more of an engineering problem than an actuarial proposition, important as the actuarial calculation is. It is a task of social engineering, which is engineering applied to human machinery. We have organized such a unified program and coupled with it a prevention education program, then it is exhibited for what it really is, a big thing and not a little thing, a program which can be utilized as a natural channel inside the industry itself, to eliminate waste, prevent sickness and accident, enlarge production, increase profits, promote the partnership spirit, practice reciprocity. It is helpfully the most vital and creative factor in any industrial enterprise and the most expensive item on its budget. It is not only the right method but it is the right methods always pay in the long run.

CHAIRMAN McEWEN: I am sorry that we cannot discuss this, but the time is very short and we must soon adjourn. We will hear from Mr. G. F. Close, who will tell us what he thinks we should accomplish during the next year.

What Should Be the Burden of the Employees' Benefit Association Section's Program for 1929?

By GILBERT F. CLOSE

Commonwealth Steel Co., Granite City, Ill.

I suppose this question could be interpreted in two ways. First, "What subjects should be considered on the program of this Section at its meeting in 1929"—or, second, "What in general should the Employees' Benefit Association Section strive to accomplish next year." I have chosen the broader interpretation of the subject because, of course, the question as first interpreted would be no more nor less than the work of the next year's program committee.

To supplement and confirm my own ideas, I wrote to some of the officials of the National Safety Council and to some of the men who have been active in the Employees' Benefit Association Section in recent years and asked their opinions. What I shall say is based in part upon the ideas of those who have been most actively connected with the Association, and I wish to acknowledge the advice and assistance which they have given me.

I don't think we have yet come to realize fully the importance of a sane and constructive health program in industry. For many years we have been seeking to promote safety and reduce or eliminate accidents in industry, but it is only since the recent development of Employees' Benefit Associations that we have come to realize at all what a tremendous field there is in promoting the individual health of men and women in industrial life.

One company that perhaps I know more about than any other, had the experience in 1927 of having 3,361 days lost from work because of injuries to its men. During the same period, the same company, through its Benefit Association, discovered that 13,143 days had been lost on account of sickness, and this last figure doesn't include any lost time on account of illnesses which were less than seven days in length. It is, I think, very conservative to say that for every day lost on account of industrial accidents, seven or eight days are lost on account of sickness. On the basis of these comparative figures, we can all appreciate what an important problem the health of our employees is:

In my opinion, this one matter of seeking to safeguard the health of our employees should be the real burden of this Section of the National Safety Congress for next year. It is not enough for Employees' Benefit Associations to pay benefits to its members when they become sick. That is more or less of a routine matter. The real problem is to devise ways and means of conserving their health.

It has been the feeling of several men who have been active in the Employees' Benefit Association Section, that this Section has lacked continuity and that there has been very little to keep the Section and its problems before its members during the intervals between the annual meetings. In other words, a small group of men get together before the annual meeting and prepare a program which may or may not be adequate, and after the annual meeting is over, the Section goes into a state of coma, to awaken in time for another spurt before the next annual meeting.

I believe our Section would render a very much greater service if its activities could be continued throughout the year and from year to year.

It has been my fortune to be the chairman of the Employees' Publication Section for the past year, and so I am quite familiar with its activities. What success that

on has had has been due largely to the fact that we have had an excellent *Letter* from month to month, a well-written article each month on Employees' cation problems in the *National Safety News*; we have had for several years ze contest for the best publication, we have also held at least one sectional ng during the year, and in these and other ways have kept a very considerable er of editors interested and active in the work of the Section throughout ear.

n wondering whether the burden of the Employees' Benefit Association Sec- program for 1929 should not be the problem of keeping the work of the ation going throughout the year and rendering service to our various benefit ations with a more complete and varied winter program.

now, for example, that the *National Safety News* would be very glad to e a page to Employees' Benefit Associations if we could secure someone of members to write such a page in which up-to-the-minute discussion of Em- s' Benefit Association problems could be presented.

ow of no better way to keep up the interest than by the establishment of the ly *News Letter*. Many sections of the council have found this a very useful o render valuable service, and if we had a medium through which our various : association officers could discuss their problems, ask questions which could wered, and present their experiences for each other's benefit, it would surely itself to be most worth while and would tend to keep the Employees' Benefit ation Section active during the whole year.

a wondering also whether it would not be feasible for this Section to hold al meetings during the winter, perhaps one in the East and one in the middle where officials of the benefit associations could get together without so much e as is involved in attending a National meeting, and hear important prob- issussed, which would help them in their work. It has been the experience Employees' Publication Section that regional meetings are very much worth f they are not overdone, because they do make it possible for a great many nen to get together for exchange of ideas, for helpful discussion, and for tions toward better work.

e could have a monthly *News Letter* to provide a channel for the exchange ormation, we as a Section, might very properly appoint several committees e studies of different problems connected with Benefit Association work. ample, we might have a committee collect and analyze data, which would e something as to methods of doing business in Employees' Benefit Associa- and the costs of doing business. Another committee might be appointed to . serious study of some one health problem, as for example, tuberculosis, means of combating this disease. Another committee might work out some ing data on the problem of the employee who is still disabled and unable to fter his benefit period has lapsed. In many associations, this is a very problem. In this connection, the problem also comes up of hospital expenses er unusual expenses which cannot be taken care of from the usual weekly . There are a thousand such questions which it would be well to consider ich would make very interesting material for a series of News Letters, ne of them might very well be published in pamphlet form like the Safe s Pamphlets of the National Safety Council.

one considers the largeness of the problems involved, one is almost tempted whether the problem of preventing sickness and conserving health in industry t as important as the problem of safety itself, and whether the Employees' Association Section should not function actively from the Headquarters of onal Safety Council more or less on a par with the safety program itself.

the work of Employees' Benefit Associations may not technically be classed y work, it is closely allied with it, and there are certainly great advantages affiliated with such a strong, well established, and progressive organization

as the National Safety Council. And the annual meeting of this Section as a unit of the National Safety Council, gives many men interested in benefit association problems, the advantage of combining attendance at this Section with meetings of other sections in which many of them are actively interested.

However, as mentioned above, there is a distinct advantage in Sectional meetings, and in this connection, it is interesting to note that Mr. Harold A. Ley, president of the Life Extension Institute, is endeavoring to bring about a National Employees' Benefit Association conference once each year. This Section might very well keep in touch with the movement and develop a spirit of cooperation between the two organizations.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Employees' Publication Section

New Section Officers

- Chairman*—C. E. KANE, Illinois Central System, Chicago, Ill.
Chairman, Railroads—THOMAS OWEN, Louisville & Nashville Railroad Company, Louisville, Ky.
Chairman, Petroleum—C. A. WARD, The Pure Oil Company, Columbus, O.
Chairman, Automotive—FRANK CHIVERTON, Olds Motor Works, Lansing, Mich.
Chairman, Public Utilities—RAY GILLAN, Bureau of Safety, Inc., Chicago, Ill.
Secretary—RUTH E. CADE, A. E. Staley Manufacturing Company, Decatur, Ill.
Committee Chairman—L. H. McREYNOLDS, The Jeffrey Manufacturing Company, Columbus, O.
Committee Chairman—G. IRWIN, Illinois Bell Telephone Company, Chicago, Ill.
Committee Chairman—W. LIDDLE, Commonwealth Edison Company, Chicago, Ill.
Committee Chairman—V. H. KUPFERER, The Studebaker Corporation, South Bend, Ind.
Committee Chairman—L. Sisson, The Pennsylvania Railroad Company, Pittsburgh, Pa.
Committee Chairman—E. SMITH, Chicago Bridge and Iron Works, Chicago, Ill.
Committee Chairman—R. G. CONOVER, Yale and Towne Manufacturing Company, Stamford, Conn.
Committee Chairman—D. SUTTON, Postum Company, Inc., Battle Creek, Mich.
Committee Chairman—J. SHATTUCK, Kimberly-Clark Company, Neenah, Wis.
Committee Chairman—J. G. BRANDT, J. L. Clark Manufacturing Company, Springfield, Ill.
Committee Chairman—WYSE, Bucyrus-Erie Company, South Milwaukee, Wis.
Committee Chairman—NOLAN, Jewel Tea Company, Chicago, Ill.
Committee Chairman—H. P. DUTTON, McGraw-Shaw Company, Chicago.
Committee Chairman—BERT F. CLOSE, Commonwealth Steel Company, Granite City, Ill.
Committee Chairman—WILKINS, General Electric Company, Schenectady, N. Y.

Retiring Officers

- Chairman*, G. F. CLOSE, Commonwealth Steel Company, Granite City, Ill.;
Vice-Chairman—Railroads, L. B. Sisson, The Pennsylvania Railroad Company, Pittsburgh, Pa.; *Vice-Chairman—Petroleum*, C. A. WARD, The Pure Oil Company, Columbus, Ohio; *Vice-Chairman—Automotive*, V. H. KUPFERER, The Studebaker Corporation, South Bend, Ind.

Corporation, South Bend, Ind.; *Secretary*, RUTH E. CADE, A. E. Staley Manufacturing Company, Decatur, Ill.; *Program Committee Chairman*, C. E. KANE, Illinois Central System, Chicago, Ill.; *Publicity Committee Chairman*, C. WALTER SIEBEL, Oscar Heineman Corporation, Chicago, Ill.; *Membership Committee Chairman*, RUTH E. CADE, A. E. Staley Manufacturing Company, Decatur, Ill.; *Service Committee Chairman*, L. H. McREYNOLDS, Jeffrey Manufacturing Company, Columbus, Ohio; *Judges' Committee Chairman*, H. P. DUTTON, "Factory," Chicago. *Executive Committee*: THE OFFICERS AND ERNEST AUGUSTUS, Mead Pulp and Paper Co., Chillicothe, Ohio; R. H. FERGUSON, Bureau of Safety, Chicago; MARGARET T. STEVENS, The Baltimore and Ohio Railroad Company, Baltimore, Md.

October 3, 1928

GILBERT F. CLOSE, Chairman

Editor "The Commonwealther," Commonwealth Steel Co.
Granite City, Ill.

The first session of the Employees' Publication Section at the Seventeenth Annual Safety Congress was called to order at two o'clock by the chairman, Gilbert F. Close, Commonwealth Steel Company, Granite City, Illinois.

CHAIRMAN CLOSE: As chairman of the section for the past year, I want to make a brief report on our activities. Those of you who attended the meeting in Chicago a year ago will remember that the gentleman who was elected chairman of the section was Mr. R. H. Ferguson, and that I had the honor, as well as the pleasure, of being elected general vice-chairman. It seemed to me at that time that I had had a very delightful office thrust upon me, with a pretty good sounding title and no work, and everything was lovely. But about a month or so after the meeting Mr. Ferguson wrote me a letter and said that he was very much afraid he would have to give up the chairmanship of the section, and he called a meeting of the Executive Committee, and I found myself, with a job that really had some work connected with it.

We had a regional meeting last March in Saint Louis which was attended by 50 editors and at that time we had a very interesting and successful meeting. The papers presented and the discussions held were considered extremely helpful by those who attended. Altogether it was one of the best regional meetings which this section has held.

During this year we have had an unusually successful series of news letters gotten out by our Service Committee under the chairmanship of Mr. L. H. McReynolds, and I think all the members of this section owe Mr. McReynolds a vote of thanks for the fine way in which he has conducted this part of our section's activities. Mr. McReynolds, I think, did a good deal of the work himself, but he showed a magnanimous spirit and invited the other members of the section to edit letters for him or in his place, and two of the letters during the past year were edited by others. One letter by Mr. J. G. Brandt, of the J. L. Clark Manufacturing Company, of Rockford, Illinois, and the other letter was edited by Mr. F. O. Wyse, of the Bucyrus Erie Co., Milwaukee, and a group of Wyse editors. So in the *News Letter* the past year we have had a variety. We have sent very helpful, interesting, and worth while communications every month to our members.

In this connection, too, I want to say a word about the work of Miss Anne W. Buffum, of the Hooker Electrochemical Company. Miss Buffum undertook the difficult task of volunteer critic. She took various magazines from time to time

criticized them, publishing the criticisms in the *News Letter*. I think her criticisms were always kindly and also helpful. If she found anything she didn't like she didn't hesitate to say so, but she conducted that rather unique work in a very interesting and a very fine way. We are hoping that she will tell us something about it during our meeting.

I want to mention, too, another piece of work which was carried on by the section this year, by one of our committees but chiefly by Mr. R. G. Conover, of the Hale and Towne Manufacturing Company. Mr. Conover sent out questionnaires to something over 300 editors and gained some very valuable information, and we are going to ask him to tell us a little about it during our meeting. This was all done voluntarily and to send out circulars and to classify the replies received from a large number of editors, is a pretty big job.

I think I should also mention the work of our Judges' Committee. You know we have a prize contest, and we have judges who classify the publications of our members who enter the contest, and it is some job to pick the winners, and our Judges' Committee this year has done a big job, and we are grateful to them.

After all, one of the really important jobs of the section is the job of the Program Committee, and I cannot stop this little eulogy without saying a word of appreciation to Mr. Kane, of the Illinois Central, and his associates on the Program Committee, for the painstaking and conscientious work, and intelligent work they have put forth in arranging our program at our meeting in Saint Louis, particularly the work which they have done in arranging our program for the meetings.

I want at this time to express our appreciation and pleasure that so many of you are here today to attend this meeting. We hope you are going to get real education and help from the papers and from the discussions and we hope that you will all continue to be connected with this section. There are several hundred, perhaps there are a thousand employees' publications of one kind or another in different industrial and railroad and other organizations, and we haven't counted anything like the complete number. I hope that as time goes on this section will extend its influence and will reach out so that it will touch all of the employees' publications throughout the whole field.

We are going to begin our regular program this afternoon by a paper on the "Make-Up and Art in Employees' Publications," by Mr. Ernest Reidel, an artist and writer of New York City.

Make-Up and Art in Employees' Publications

By ERNEST C. RIEDEL

and Promotion Director for The Stillson Press, Inc., of New York City

It might be possible to view cross-sections of the minds of those planning the piece of printed matter, they would be as dissimilar as the print-estimates that are figuring on the same "printed matter." They are expected to have their readers' interest uppermost in their minds. They are buyers whose ideas are always acknowledged by the printer. Why, then, the buyers know more than anyone else what will hold their interest!

The printer is inveigled into the fog of the buyer's problems. He "works him;" he is careful not to rub the hair the wrong way; he tries to keep the buyer purring. Now the job is off the press—and everybody is satisfied.

But, after many such experiences, we kick off our traces and, in groping the progressive direction to follow, we ask ourselves what it is all

about: These editors and planners of printed publicity are all highly intelligent, well-trained, wide-awake men who recognize the science of having their efforts look interesting, in order to capture a broader audience.

They all have the same formula, haven't they? Well, hardly. And here is how we prove it—specifically—and the demonstration applies to any line of business, any kind of advertising.

A demonstration applied to a direct-mail piece is difficult to find, for the reason that the advertiser lays out his material once—and generally prints it but once. Surely no advertiser ever treated the same text in twenty-six different ways. However, a demonstration of how the minds of various planners of printed material work is afforded by the twenty-six magazines of the Bell System.

The telephone business has practically the same class of workers throughout the land. Yet, in considering the whetting of readers' appetites by the style of approach, every editor had a different opinion of how it should be done. Of the twenty-six magazines issued by as many different telephone companies in the United States, no two employed similar methods of attracting the reader when all of them printed the same text. Each took a different angle, a different aim. The same condition applies to the advertising of any business. Perhaps this mass of divergent ideas of how to capture reader-interest is a healthy condition. We hear "contrast," "variety" mentioned. Now the vital question is, which comes closest to being one hundred per cent correct?

We read many theories. In some cases the expounders of these theories do not apply them to the very printed message which contains their "theories." So we gasp and "blunder on," hoping for the millennium.

You give the reader meat, proven nourishment based on facts that make him remember you. You have him eating—but, to create that appetite you had to appeal to his eye. So, therefore, friends, we know that the layout is the ingredient that can make or mar the entire menu. The appalling neglect of this vital factor in printed salesmanship is a crime that is daily committed.

The arrangement of cuts is given too little real thought. Yet it has a great bearing upon its chances for compelling reader-interest. With the same identical cuts a real book-architect can produce an entirely different and more attractive book. Like a cook with the same ingredients, or an architect with the same building materials, the method of handling is what produces the best result.

Always consider every two pages as one and make them balance. Avoid spottiness, which bewilders the reader. Do not use too many trick shapes upon a pair of pages. Consider the heading, its arrangement and size, in conjunction with cuts upon the same page and its opposite.

The treatment of the heading is another contributing factor in clinching reader-interest, which is too often overlooked.

You have a carefully worded interest-arousing heading. You believe its intrigue sells the story, and that it will lead the reader into the story to find the answer to the question in his mind which the heading has aroused. The heading contains or implies a "how," a "why," a "when," a "where," a "which" or a "who." It does not begin with that interest-dampener "the," which often leads to betrayal in the heading of the subject of the story.

Very good! Now one good turn certainly deserves another. The importance of the heading's layout is too often overlooked. The life of the story's interest is staked on it. The first impression, the introduction, decides whether or not the reader will give his time to the text.

Give the heading air! Have it narrower than the width of the text, no matter how long the heading is. Let its shape be symmetrical, so that it lead the reader into the text. Above all, do not let the last line be so long that it abruptly separates the heading from the text. Let it be of equal length, or preferably shorter than the balance of the lines in the ding.

Do not use too many caps. They become tiresome and difficult to read, they run together unless widely leaded. For main headings, caps lend more dignity than lower case. They form a smoother, more decorative type than the jumpy uprights above and below a line caused by lower-case letters. This applies to main headings of a few words only. For the lengthier headings or sub-headings, lower case is more legible and saves space.

If a heading is to be at the top of a page, sink it to gain white space; lead the lines, and be not afraid to take depth for the heading above and below it.

If a cut is also used with the heading, put it above the heading. There should be no depressing ceiling above the picture unless its size is sufficiently strong to support a heading above it. A picture gains more value in repose if, like a painting, it is hung in the niche it deserves, with no ding above it to grudge the space the picture occupies.

Never allow the running head to appear above the main heading. Its punctatory use has sometimes caused it to read itself into the main heading under it.

The omission adds white space above the main heading and sets it off. Running heads are barnacles whose monotonous repetition unconsciously kills reader-interest. Put them where they do no harm—on solid pages of body-type or pages where cuts are not at the top of the page.

The initial letter at the beginning of an article should never be smaller than the caps of the main heading—generally larger. Ornamental, elaborate initials are dangerous if cuts appear on the same or opposite page. They emphasize the spottiness of a page. Their purpose, that of adding life to page of type, is overdone if cuts are also used upon the same page.

The value of proper margins is also often overlooked.

Of the twenty-six magazines previously referred to, all dealing with the same general subjects and appealing to the same general class of audience, two have the courage to take enough margin. It need not be extravagant. As little as an eighth of an inch more white space around a page of type makes a greater difference than one would suspect. Try it. The frame of white space is astonishingly potent in the relief it gives a page. Yet it is distressing to note so few planners of printing who set off pages and do not crowd pages with so simple a treatment.

It is further astonishing to note the many advertisers who are overlooking "little things" mentioned in this article.

As they are little things, but after they are recognized, established, and put into use they soon prove their bigness, their value and place in the process of selling by the printed word.

Let us see a more established use of these "little things"!

AIRMAN CLOSE: Mr. Reidel, we certainly appreciate the straight-forward and useful, practical suggestions which you have given us in this important part of the program.

Very likely some of you have some specific questions you would like to ask Mr. Reidel, or perhaps there are some matters that he discussed that you would like further information on.

MR. MARSHALL (Firestone Tire and Rubber Company, Akron, Ohio): I don't know whether this can be termed a question or discussion. Mr. Reidel confined his remarks very largely to the employees' magazines.

My experience in a great number of publications that come to my desk is that there is an increasing number of organizations who have their magazines more along the line of newspapers. I particularly have in mind the Pennsylvania Railroad. Their publication is entirely newspaper style, an eight column paper, and I recall others, our own publication the *Firestone Non-skid*, as some of you may have seen, and such publications as the Hoover which is rather smaller than a newspaper but still made up in newspaper style.

This occurs to me because Mr. Reidel spoke of the headings not telling the story. In house publications the great point of resistance is that you give them away. That is to say you have to make them interesting enough for the employee to take them. We have column headings that attract the eye on the stand. Our papers are in racks to be drawn from, and the very same psychology applies as in the case of the newspaper which has a vastly greater circulation than most magazines because they catch the eye with their headlines, and that has been in a way the basis, I think, of making up the different forms of these types instead of the magazine type.

Is Mr. Reidel inclined to give his thought on whether the newspaper style is better than the magazine style?

MR. REIDEL: Magazines come every month and the reader is supposed to be receptive and sit back and take it home by the fire and read it. But the newspaper comes out every day. There may be some that come out every month, but if here are I don't know about them.

The object of it looking like a newspaper primarily is that it is newsy and interesting, and it is in a different category entirely than the magazine. Its object is to be a perfect newsy magazine. There may be some last minute news items in it, marriages, births, and those things, but generally speaking they are articles that can be used from one month to another. They may be seasonable at best, but they are not news items.

A newspaper has to be gotten out very quickly, and I am reminded that several company publications in the past have contested for the best looking newspapers. Some newspaper in the West got this prize. I remember it well, as it was simply the old story brought out in a new form.

Don't make your stuff, even though it is a newspaper, look like it was dumped here. You can in a few more minutes, with scissors and paste arrange your page with balance. The main head up here, streamer, sub-heads, cut, cut, cut, and balance them. Newspapers should balance singly, of course. You cannot in the case that it is gotten out and size, have two pages that balance. One doesn't look at a newspaper as one page, but you do a smaller magazine. Plan a single page, however, and put it on a center line. Let both sides balance, and then you have a pleasing page. Not too many different styles of type, either, and you have to tell the subject of your story because you have a lot on a page.

If you asked a lot of questions, it wouldn't be clear, but you have got to have something on that one page that is going to interest that individual reader. You don't want to know whether all or none is interesting to the reader, and the only way you will get him to feel that unconsciously it is interesting is by balance and white space and nothing that is going to jar his sensitiveness, even though you may think he hasn't any. The crudest laborer has.

In the case of this one magazine that I referred to before, when I pointed out to the editor that he had a brutal, heavy caption here that was supposed to be for a picture, but really belonged to that one, it was a little confusing. Why don't you arrange them even, and make it easy for him. You are even requiring more

gence for this farmer to follow you than the other magazines that have gent audiences and are planning it with good taste.

M. WAGNER (General Electric Company, Schenectady, New York): I am glad been brought up, because it brings out a distinction I have never seen brought efore, and that is that there are two different functions to most employees' zines. The first is the news function, which none of us can avoid even h most of us come out once a month.

instance, if the company announces some new pension scheme or something at kind, it has got to come out in the employees' magazine and there is no in disguising the nature of the story in the head, because it is absolutely ative to get as much in the headline as possible as there are always a few will not read the story. We all know that none of our papers are read by one to whom they are given, and those people have got to find out about articular point.

t is a new pension scheme, they have to be told the essential things of the n scheme in as few words as possible and then those who are interested in it on and read the article, and it will gradually seep out, and then of course is another type of story which the informative headline is not good for. is the surprising story.

pose Bill Jones eats 45 fried eggs some noon. The nature of that story is hat you are going to word your headline so that people will wonder who nes is and what he is, and then they will read the rest of the story.

n there are those headlines which Mr. Reidel spoke of, and I don't believe are enough of those used. Most of your magazines are, in addition to their functioning, informative in a general way, and that is the type that Mr.

is speaking of mostly. We don't seem to have clearly in mind the fact e are trying to do two things at once in the magazine. If more attention is to the point that we have our news side and also our informative side, I we will have better results.

. FISH (*National Safety News*, Chicago): I have two cuts to put on one Would you put the larger or the smaller one at the top?

REIDEL: I would put the larger one at the top, but it depends a great deal he color of the cut. That is, whether it is a dark or light one. If it is very t will dominate the little one at the bottom and fight him. If it is a light I would put it at the top, or if it is a dark one, at the bottom. I go by ue of the picture as a whole. That is a good point, and I am glad you ned it.

etimes I have a nice soft half-tone on one page and I have got to put a line r here. It is full of heavy black lines and is going to hurt this picture, so I em as far apart as I can, and I tone some of them and get a pleasing pair.

LAABS (Seaman Moody Corporation, Milwaukee, Wisconsin): I would ask Mr. Reidel if he prefers sprinkling the cuts through the book or having ges of them or both?

is a discussion we have had many times on employees' publications and we settle the question. Some prefer it one way and some another.

REIDEL: You cannot sprinkle a lot of different cuts all the way through k. If there is one article it depends upon the length of the story, and you all your ammunition. If you group them all on one page, you have two or ages of type.

uld get balance all the way through. I try to have at least one subject on depending, as I say, upon the nature of the story.

LAAB: That is the trouble we have. Most of them are employees' publi- and we don't use stories. They are just news items. We get perhaps two hundred snap shots of men in the plant. They have no relation to s, but they want their pictures printed. One person will group them on

one page or full spread, and another person will put them in between the news items.

We tried to stereotype our work, and we have taken one magazine each month and dissected it in the meetings, and this is one question I was requested to ask. I am the official representative of the group.

MR. REIDEL: Balance; always get them to balance every few pages. You must sprinkle them all the way through. Let each two pages be as one. Whatever you put on both of those facing pages, make them balance.

CHAIRMAN CLOSE: Our next order of business is to give those who are present an opportunity to write down any question which they would like to have discussed at the round table meeting tomorrow. We have a number of blanks here, and I am going to ask Mr. Pulcipher to distribute them. If any of you have any questions to ask, not necessarily in connection with a paper, just any problem that you want answered, write it on this card and somebody in the crowd will no doubt have an answer for you tomorrow.

Our next order of business is the election of officers for the next year. Mr. Boswell is chairman of our Nominating Committee, and I will ask him to at this time present the report of the Nominating Committee.

Report of the Nominating Committee

By FORREST W. BOSWELL

Chairman

The other two members of this committee are Ernest Augustus and Mr. L. H. McReynolds. There was a meeting of the Executive Committee which Mr. Close held today noon at luncheon and some substitutions had to be made.

We endeavored to set up this slate so that we might have those represented who would be active and interested, particularly in this section. We also endeavored, as far as possible, to take into consideration geographical locations. In some cases we could not do that, but we endeavored to work it out so that the committee would not have to travel too far for the purpose of getting together.

The name of the chairman that we wish to present to this Section for next year is Charles E. Kane. He is editor of the *Illinois Central Magazine*. His location is Chicago and he was the chairman of our Program Committee for this past year.

Vice Chairman, Railroads: Thomas E. Owens, Louisville and Nashville Railroad, Louisville, Ky.

Vice Chairman, Petroleum: C. A. Ward, Pure Oil Co., Columbus, Ohio.

Vice Chairman, Automotive: Frank Chiverton, Olds Motor Co., Lansing, Michigan.

Vice Chairman, Public Utilities: Ray Gillan, Bureau of Safety, Chicago, Ill.

I would like to say with reference to having so many vice chairmen, that I think it was three years ago that this plan of having a vice chairman for each of these respective groups was presented. Perhaps this past year these vice chairmen have not functioned as they should. In some instances they did not function at all. The original idea of this set up was that the vice chairmen of these particular groups should promote the matters relating to our Section, The Employees' Publication Section, among the members of that particular group. In some cases they do not have employees' publications, and they are in a better position, perhaps, to recommend and urge why they should be represented as members of this section.

We nominated Miss Anne W. Buffum as the secretary for this ensuing year. She has declined to serve and so we are presenting the name of Miss Ruth E. Cade, of the Staley Mfg. Co., Decatur, Ill., again for the ensuing year.

for the Program Committee, L. H. McReynolds, of the Jeffrey Mfg. Co., Columbus, Ohio, who has rendered such excellent service as head of the Service Committee for the past year. To be associated with him R. W. Liddle, of the Commonwealth Edison Co., Chicago, Ill., and A. T. Irwin, of the Illinois Bell Telephone Co., Chicago, Ill.

Publicity Committee: Chairman, Jack Dempster, Canadian Cement Co., Port Colborne, Ont.; V. H. Kupferer, Studebaker Corp., South Bend, Ind.; L. B. Sisson, Pennsylvania Railroad Co., Pittsburgh, Pa.

Membership Committee: Chairman, S. F. Shattuck, Kimberly Clark Co., Neenah, Wis.; R. G. Conover, Yale & Towne Mfg. Co., Stamford, Conn.; Vern D. Sutton, Postum Cereal Co., Battle Creek, Mich.

Service Committee: Chairman, F. O. Wyse, Bucyrus Erie Co., Milwaukee, Wis.; J. G. Brandt, J. L. Clark Mfg. Co., Rockford, Ill.; J. N. Nolan, Jewel Tea Co., Chicago, Ill.

Advisory Committee: H. P. Dutton. I have shown his connection as the A. W. R. Company, Chicago, Ill. He only devotes a portion of his time in the editorial work of that company. He is on the faculty of Northwestern University.

We have also appointed C. T. Fish, editor of the *National Safety News*, who was a member of that committee this present year. And Gilbert F. Close, of the Commonwealth Steel Co., Granite City, Ill. The committee held a meeting just before this meeting and decided to make him the third member of the Committee.

At the Executive Committee meeting today noon, it was proposed that the past General Chairmen of this Section, comprise the Executive Committee for the ensuing year, to cooperate with the new chairman elect. They will consequently be Forrest W. Boswell, G. A. Doeller, and Gilbert F. Close.

They respectfully submit these names and move their election providing there are no other substitutes.

MR. BOSWELL: You have heard the report of the Nominating Committee. I want to say that I think that committee is a very disobedient and unobedient committee. We had a little conference just before lunch and the question of the membership of that committee for the judging was discussed, and I thought I would give the chairman of the committee very definite instructions as to the name of the third member of the committee, and he comes in and I find that the last word to have a word seems to have the prevailing word and I find myself stuck.

MR. BOSWELL: He suggested Mr. Augustus as the other member, and as Mr. Augustus happened to be one of the members of the Nominating Committee, we didn't agree and we substituted Mr. Close's name.

MR. BOSWELL: Mr. Boswell has moved the acceptance of the report and election of the nominees. Is that motion seconded?

MR. BOSWELL: Are there any other nominations for any of these offices? If anyone wishes to make any nominations from the floor, they are welcome to do it. If there are no further nominations, the chair will put the motion. (The report of the Nominating Committee was accepted.)

MR. BOSWELL: I think we would all like to at least have a look at our new chairman, and I am going to ask Mr. Kane to stand up and smile.

The next order of business reverts to the serious part of our program, namely, reports, and we are to have at this time a paper by Miss Anne W. Buffum.

As you will remember that I said that she had undertaken the job of volunteer critic and criticized some of our various publications in a very interesting and helpful way, and the criticisms were published in the *News Letter*. Miss Buffum is on the program at this time to read a paper entitled, "A Volunteer Critic's Conclusion Concerning the Editorial Content of Employees' Publications."

MISS ANNE W. BUFFUM (Hooker Electrochemical Company, Niagara Falls, York): Mr. Chairman and Fellow Editors and Friends of the Employees'

Publication Section: I think I am perhaps sailing under false colors so far as the program is concerned, since I am listed as a member of the Personnel Department, of the Hooker Electrochemical Company, Niagara Falls, New York.

My resignation from that company took effect last week, when I sought newer, bigger, but not better worlds to conquer. I hope you will pardon me, if, until another connection claims my loyalty, I still refer to our organization and how we do it, as a very small appreciation of four years connection with a friendly and fine company.

A Volunteer Critic's Conclusions Concerning the Editorial Content of Employees' Publications

By ANNE W. BUFFUM

Personnel Department, Hooper Electrochemical Co., Niagara Falls, N. Y.

Editorials are the bane of my existence. I would rather pitch hay than force my flickering intelligence to concentrate upon paragraphs light enough to be read and heavy enough to "mould opinion" as editorials are privileged to do—if they are able. I suspect that at least 50 per cent of the editors here represented would be honest in the confession that a brief editorial causes them deeper and more furrows between their eyes than, say, four pages of "personals." Such at any rate is my frank confession, so I am tarred with the same brush with which I shall decorate my fellow-editors, and must be forgiven for talking to myself.

My first conclusion in making a special investigation for this occasion was that we are a lazy set of thinkers. We will climb chimneys, freight cars, steel girders to get an unusual picture or a novel idea for a story; but when the time comes to concentrate our honest thought upon a single issue, we are prone to fall back on the sage of East Aurora or Dr. Frank Crane or syndicate material for which we pay precious cash from our publication budget.

I have found from study of a most practical survey made for me by the National Industrial Conference Board that of forty-six publications, representing 1,342 pages, about one-twentieth of the material printed was of an editorial nature. Figured accurately it comes to a little under 5 per cent of all the printed matter. That is not much. But, says the *House Organ Review*, "editorials are the keynote of the whole publication," and I am inclined to agree with the definition. It becomes important at once to make the keynote as true in tone quality as any other part of the paper.

No employees' publication is printed just for fun. Back of it, whether the idealist editor is willing to admit it or not, is the same practical purpose which urges the purchase of a new and expensive piece of machinery, though a fairly good job is being done without it. That purpose is profit. Most editors of employees' publications have pattern phrases which are very precious to them: "citizenship," "one big family," "the boss is human, too," "it's your company," and so forth. But under the pattern is the fabric of *business* and the problem of making money. The editor who appreciates his responsibility to his management, without letting it cloud the idealism of this opportunity, is a good editor. The editor who weakens a sentimental rhapsody or hectoring sermon—as some do—is untrue to the purpose back of his paper, and sacrifices an opportunity to earn the confidence and respect of his readers.

Mr. H. F. Browne, manager of the Industrial Relations Department of the National Industrial Conference Board, has this to say: "The employee magazine as a rule is quite carefully read. The editor has the opportunity, if he be intelligent and capable, to present subjects upon which the average employee needs infor-

and can tell them in a manner so that the employee can obtain a fair standing of the subject whether that be some product of the company or question of social justice. If the editor shows by his treatment of company news that he is merely currying favor with the powers that be, his opportunity for constructive usefulness is gone. If, on the other hand, he can cultivate in the minds of his readers the belief that he is fair, thoughtful and highly intelligent, his usefulness to the company and to the employees is boundless." This is a safety conference, which brings us naturally to a primary discussion of how this important subject is handled in our employees' publications.

Hundreds of us use "The Safety Valve" offered monthly by the National Safety Council. This service is necessarily general in its application, but is—as so many who claim the title are not—a genuine service, not operated for profit, but intended to help the advancement of safety in the United States. I therefore commend it to all editors who use it without regard to its application in the solution of their own safety problem. I have not happened upon one publication using the "valve" which did not print it verbatim, without troubling to fit the cap to particular readers whom it was intended to help. I have been lazy enough to do so myself, but my conscience told me each time that I was "passing the buck."

I venture to say that nearly every one of the cartoons sent out to editors by the National Safety Council each month has a positive application to a situation which can make the message of safety more personal, hence more effective. It is only a matter of sleuthing, but we are easily satisfied.

One case in point is a recent cartoon cautioning against hasty crossing in front of trolley engines. It happened that one of our people had met a freight train on the Erie in the material sent by the National Safety Council with the "Crossings Cautiously" cartoon. The man's name was not mentioned, but it was difficult for his acquaintances to take the warning on very personal terms. The local application is not so easy, but it is, I have found, worth the trouble.

Perhaps I misinterpret the spirit of this National Safety Council service, but I think it is intended to assist the editor to do his best in a national problem, not to shift to him the burden of editorial responsibility.

An impression in looking over many publications is that some editors feel safety material is a necessary evil; they check over their columns and count the inches of safety material lovingly, feeling rather virtuous than otherwise if they have squeezed in a little extra amount. I blush to admit this weakness, though I know perfectly well that a minimum of safety material, well planned, can accomplish more good than columns of longwinded "shoulds" and "shouldn'ts." On the other hand, the editor who thinks safety material is an employees publication is "the bunk" is short-sighted. The question is not one of how much or how little safety material should be used: it is how well it is handled. As Albert Chevalier's song used to sing, "It's not so much wot 'e says as the nasty way 'e says it!"

How sanguine to believe a safety consciousness may be developed in an editor. For example, the ability to write good headings may be acquired? I did not know how to write headings when I began to edit a paper, but I was fortunate to have a friend who not only knew how to write them, but understood the special viewpoint must be developed and practised. It seems to me that a special viewpoint in presenting safety material through our columns must be developed to save us from boring or, worse, annoying our readers.

A booklet, "Making, Maintaining and Measuring Interest in the Employee," published by the Metropolitan Life Insurance Company, Earl Morgan Curtis Publishing Company says: "I don't believe you would even build up interest let alone maintain it, with an article, *Be Careful With Your Feet—Safety*

First—Avoid Foot Injuries. But I do believe you would by showing a very badly worn and broken-out pair of shoes, almost pathetic in their appearance, with a caption, *These Shoes Would Be Fine to Hurl at a Bridal Couple, but—*and then following, “you wouldn’t throw them at a man to wear in the pressroom,” and very simply describe what injuries might occur due to lack of adequate shoe protection.” The message is identical in the captions given by Mr. Morgan, but the viewpoint makes the difference between boredom and interest.

I have learned that use of the two, three or four-line editorial is a pithy way to make the editorial page chatty and readable, from the standpoint of typographical pattern or makeup as well as that of potent thought. Various devices are used. Sometimes the company product is worked in to point the paragraphs. One of the major products of our organization, for example, is caustic soda. A special intimacy, therefore, is given our publication’s stock phrase, “Says Caustic Chris” and we put into the old man’s dialect homely bits of wisdom and sarcastic observation that have an edge of humor but no flavor of personal malice. “Caustic Chris” is a *person* in our factory and is quoted by the men; incidentally they look for his remarks and read them with good-humored recognition of their truth.

A paper company uses a department called, “Ned’s Straight Edge.” A powder manufacturing company prints “The Musings of Powder Keg Jim,” and so on. These homely sages may discuss anything from the boss’ weaknesses to the fine job certain men did on certain work. Their dry and biting sarcasm lends itself to safety propaganda, politics, horseplay, health, waste, thrift, economics, signs of the times, etc.; their downrightness makes an honest setting for the sentiment of Christmas spirit, good will, cooperation, pride in company achievement, loyalty and all the abstractions that tremble on the verge of preaching.

I do not mean that every employee publication should include such a department. Every editor must be his own judge of what is taste for his particular paper. It is obvious that many publications could not suitably use so informal an editorial. The example is cited only as a symbol of the possibilities of editorial achievement. I doubt if any work of the editor is more important than accident prevention. And to do it well requires originality, and understanding of human beings. For that matter, originality and understanding of human beings are required in any branch of editorial work.

Several experts on employee publications were consulted in verification of a volunteer critic’s opinion, among them Miss Thelma Walker of the Metropolitan Life Insurance Company, Mr. H. F. Browne of National Industrial Conference Board, Inc., Mr. C. T. Fish of the *National Safety News*, Mr. J. Douglas Brown of the Industrial Relations Section, Princeton University, Mr. S. Douglas Malcolm of the American Express Company, and *The House Organ Review*. Miss Margaret Stevens of the B & O Magazine was unfortunately, due to illness, unable to assist me. I should like to express here my gratitude for the promptness and thoughtfulness with which these busy people showed their friendly interest in the subject which at present engages us.

Almost all of these experts took the opportunity to express their recommendation that editors refrain from “preaching.” “Let editors not ‘write down’ to readers—let the readers ‘read up’—the best is none too good,” says Miss Walker. “Style does not mean much—human nature does. Make the reader feel that you feel—the Colonel’s Lady and Judy O’Grady are really sisters,” is Mr. Malcolm’s comment. “Make the editorials essentially from employee to employee, rather than from employer to employee,” urges the *House Organ Review*, and adds, “A great many editorials are merely clever but not helpful or inspiring. However, a cleverly written editorial with a spiritual value is priceless.”

“Loyalty” was named as the most popular subject for editorials, with “Safety” and “Cooperation” in second place. Loyalty and cooperation are the most valuable—and volatile—of all qualities in an organization: hardest to establish and

siest to destroy. My intuition would be that to harp on these qualities editorially is to arouse suspicion. But again it is the *how*, not the *how much*, that counts. In brief, a volunteer critic's conclusions concerning the editorial content of employees' publications (and never did I have so high-sounding and magnificent a subject handed me for discussion!) is that the majority of editors do not take full advantage of their opportunities upon the editorial page; we are verbose; we are shy; we refuse to accept responsibility; we are rather easily satisfied—in fact a smug; we do not think directly; we are unoriginal.

Of course there are exceptions to every rule, and I confess my enjoyment of not one or two but of many editorial columns. If I have trodden heavily in these few minutes, it is because so many of the papers are good enough to be worthy of perfection, and while I do not advocate sacrificing the *good* for the *best*, I do urge that we keep the best well in view and strive toward it.

CHAIRMAN CLOSE: Miss Buffum certainly told us what we are in a very frank and straight-forward way, and I am sure we all appreciate the picture which she has given us of the average plant employees' publication editor, I am sure what she has said has been helpful to us.

We want to have a discussion on this extremely interesting paper, and the discussion is going to be led by Mr. L. H. McReynolds, who is also quite some one in our line of work. We all know that he is a good editor, because we have been reading his monthly letter. Mr. McReynolds, we will be glad to hear what he has to say about this paper.

Discussion of Miss Buffum's Paper

By L. H. McREYNOLDS

Jeffery Manufacturing Company, Columbus, O.

Before I go ahead with my subject, I want to thank Miss Buffum on behalf of the Service Committee for the task she assumed last year. It took a lot of courage to start something like that.

Right along that line, I was over in our engineering department about six months ago and some man not connected with the editorial work, stopped me and said, "Who is this Anne Buffum?" Knowing that he had no connection with the editorial work, I said, "What do you want to know for?"

Of course, he had a friend who was editor and the editor had been talking to him and evidently this editor's magazine had been panned by Miss Buffum. I won't mention any names, but he is in Columbus and was a little bit riled up about Miss Buffum and her criticism.

I stood up for Miss Buffum and told him that was just one person's viewpoint; that I hope you all look at it that way, because criticisms do not hurt. I tell everybody in the Jeffery Manufacturing Co. to come right out and take a swat at us; that we will appreciate it if each one will give us their criticisms because we cannot progress without it.

I received this paper, however, and went over it rather hastily and set down a few things.

When Miss Buffum compares pitching hay with writing editorials, it seems to me that she is giving the farmer the best of the deal. Personally, I'll take the writer's limp from using the pen rather than the sore back from using the pitchfork.

Where a good many editors have trouble in starting an editorial, I confess that similar hesitation would come upon me were I offered a pitchfork and a load of hay. Editorials, of course, are the hard part of your job as magazine editor. A good

many editors have trouble in starting editorials. The saying, "Rome wasn't built in a day," is applicable to editorials. I don't know how you start to get your ideas or start writing editorials, but no idea is new and if you get an idea, jot it down no matter where you are or where you happen to be. Jot down your idea. Carry cards along with you.

You can see good ideas in walking up the avenue here. In fact, I got two ideas last night that will make good editorials. There are a lot of different things that you can work up.

If you see somebody put a paper in front of a man and he reaches down and signs his name without reading it over and knowing what he is doing, you have an idea for an editorial, and that editorial I would head, "Did You Ever See A Man Sign A Paper Blind Folded?" and you can work that right up as far as you like.

I find that by jotting down your ideas and then putting it in your drawer, perhaps you have one or two paragraphs written, and the next day you feel a little better. Your mind is a little more settled, and you reach down and pull out this sheet and perhaps write another paragraph, and maybe it takes two or three weeks to complete the editorial. Then you go over and over it, because a great number of people will read it and will criticize.

Our good friend Webster tells us that an editor is one who edits a book, newspaper, etc., and secondarily, also one who writes editorials. I think one of the first requisites is to write editorials. I don't know how you feel about it, but it seems to me that every writer who puts out a paper should have a page or column or two for his own use, as editorial to convey certain things to the men in the shop. Perhaps the majority of us make the task look or seem more difficult than it really is.

Why do you have trouble in writing serious matter? Good writing is nothing more than having something to say and saying it naturally. There's a good point—be natural. The average man has intelligence enough to know when you are making lavish statements and saying something that he cannot understand. I think plain language in your editorials will do more than trying to use flowery language and looking in a dictionary for big words and writing so that only a college professor would be able to read it. I would rather stick to the shopman's talk, because he is the man you are writing for—the shopman.

Yes, the editorials should be the keynote of the publication, by all means. They should be productive of the best that's in you. Most magazines were established with the thought in mind that they would be producers. You have a wonderful chance through your editorials to promote that efficiency which every company wants. The editorials are agencies through which the editor can work wonders with his personnel. There is the chance to make employees think, and when you have them thinking, you have accomplished much. Of course, you know that, but I read *The Houghton Line* by Carpenter. I suppose quite a few of you read it.

In one issue in particular, he had a lot of criticism which was very frank, and a man asked him why he wrote the editorial. He replied, "I write them to make people think;" and when you have your employees thinking, you have them satisfied.

You are working for a common purpose and when the different elements in any organization establish among themselves a relationship whereby their activities aid and supplement each other for the accomplishment of that common purpose, the institution thus formed may be called an ideal organization.

Personally, I don't mind writing editorials. They give one a chance to broaden out, to develop, to grow bigger, to speak a higher grade of language—but do not get away from the shopman's talk. Now I say most of the 800 or 900 publications in the United States are poorly edited and a great majority have no editorial policy whatsoever. I get about 400 publications myself. I don't review them like Miss Buffum did, of course, but I look them over and get ideas, as much for

out as for special articles like re-writes, and everything like that; and some of them don't make any provision at all for an editorial page.

Of course, that is their personal lookout, but there is one thing I will say for a newspaper type of magazine, and that is I'll venture to say that the majority of them have more editorial policy than some of the better magazines which have more money.

If you will pick up the *Firestone Non-skid* or the *Pennsylvania News*, you will notice that on a certain specified page, they have two or three short editorials, and they are written in the shopman's language and not flowery language.

In most cases, there is a part-time editor, and I suppose as he doesn't put in a lot of his time he doesn't have time to sit down and give serious thought to the editorial; and it does take time.

It is up to the editor himself to train his readers to read the editorials. Make them good enough to read.

The editor has a chance to mould; he can work wonders through his writings. He can bring about a welcome condition in any plant—that of convincing the employee that he is a member of a big family, which entails responsibilities not to be avoided. Single individuals can't do much, but as a big happy and contented family much can be accomplished. Family standards can be changed as well as a community and social life. The making of others is the paramount thing.

We try to get away from using syndicate material whatsoever. In other words, as Miss Buffum emphasized, when we see an article we will try to re-write it in our own words. We will give the idea to a shop man or any man in the personnel and let him re-write it in his own words, and he doesn't have to think up the idea himself. We either give him a subject or another article and let him write it. Safety material is a big problem. At the Jeffery Manufacturing Company, we have a safety director who writes, month after month, along the same lines, which employees are bound to get sick and tired of—same kind of language, the same column or whatever is necessary. For safety material I would advise pictures every time.

I venture to say that when one picks up a Jeffery Manufacturing Company magazine, he first glances at the cover, of course, then goes through and looks at the half-tones, and the safety page is passed by quickly. I have observed that when you have pictures they will stop and look at them. In this last issue of our paper particularly, we had these half-tones on one form. We run two forms, eight pages to the form, and as I was handing them out, one man said, "I like that. I got a lot of pictures in it and I will be able to read it;" and most of them do once through and look at the half-tones. If you will check up you will find that the first thing they do is to look at the pictures, because pictures tell a story. That is the only way you are going to get safety over; and as I say, if one man writing the personnel is bound to become tired of it, and it is tiresome to them because it is not going over.

Of course, the editor can help the safety director, but not all editors are safety directors. I know that Mr. Augustus is; he handles his own safety work and also the magazine. In my case we have a safety director and often he comes down to me and wants to know if I will take his page and write it for him. He gives me an idea and asks me to write it so that it will be somewhat varied.

I was going into a lengthy discussion on the first line or the heading and the first paragraph of the editorial, but I think Mr. Reidel covered that very nicely. The main point is making your heading readable and having an appeal in it. In all articles regardless of whether it is a special article or editorial, it is the heading that gets the attention. It must be catching.

First the heading and then in the first paragraph, I suppose, are where you have most of your troubles. Get a catchy heading and first paragraph, and take your time on it. Get your idea fixed in your mind and then write it over and over

again. Maybe you cannot do it in a day, or in a week. Last year, I wrote two editorials a month, and I don't suppose that one out of the twenty-four was written in less than a week, that is, in its entirety. It is hard to do it, and you must remember that a number of people are going to read it. You have got to go over it from the other man's standpoint, and you know that he is bound to be critical.

My idea coincides with that of the *House Organ Review* when it says that cleverly written editorials with a spiritual value are priceless. The subject for an editorial will vary every month according to that particular point you wish to get over. They should all hinge upon and be built around the common purpose of the company and its employees.

After all, you may have no special endowments, no decided evidence of being a genius in any certain line, but if you have plain common sense and if you are fair minded, you are in possession of the fundamental and basic qualities which go to make good editorials, and a great help to your fellow man through those editorials. In the final analysis it should be remembered that a man's work will not tower above his character.

I have jotted down here some points which you might keep in your mind:

1. Good writing is nothing more than having something to say and saying it naturally.
2. Many of us are over-conscious of the fact that we are writing.
3. Be natural.
4. Do not strive for effect.
5. Do not over-state or over-estimate. That is an undesirable habit and leads one into embarrassing situations.
6. The average man with ordinary intelligence is able to distinguish between lavish statements and real facts.
7. A magazine should be a producer. Keep that end in view always.
8. Promote efficiency through your editorials. Efficiency takes the frenzy out of business.
9. Use horse sense.
10. Fair mindedness and plain common sense are important as basic qualities of a writer.
11. Heading and first paragraph important. Must have appeal.
12. Use names employees are familiar with—no flowery language.
13. Don't brag; be sincere. Let readers know you are trying to help them.
14. Comparisons help to get editorials over. By that I mean start off with an article and use something they know about. If you compare something and work your editorial out that way it is going to have a punch and they are going to recognize something and will read it.
15. Shorter editorials are read more. I don't know how you feel about that, but I don't believe many people will sit down and read a long editorial. It gets burdensome and heavy and they are going to tire before they get through. So I prefer two or three short ones to one long one.
16. Find out the reader's reactions to your editorials; candid opinion.
17. Editorial board—three or four—vary the editorials each month. All write but take turns.
18. Jot down an idea, write it and rewrite it, and lay it aside. It may take weeks, but one is better fitted one day than the next.
19. Get ideas from employees.
20. Give them something they want.
21. Keep everyone on even keel.
22. Magazine is tonic to keep nervous system in shape.
23. Promote efficiency.

Those I have jotted down just as a summary.

While I was talking to the boss, I said, "Why wouldn't it be a good idea to go out and see some of the men and find out what their reaction is to our editorials?" Of course, he came back and said, "You ought to do that anyway." So I started out. I saw the general foreman and about ten or twelve shopmen. The general foreman told me his candid opinion, and said that was about all he did read.

Another man said the novelty had worn off.

The man who starts a magazine certainly has a cinch over somebody else. The paper is new in the plant and they will all look for it and read every line, but after you have gone for fourteen or fifteen years, then it becomes a settled fact that they glance through and pick out the parts they want.

Lack of time, of course, has something to do with reading a magazine. They are discouraged and they don't want to have anything to do with it.

If there is anything you want to discuss here about what Miss Buffum has said in her paper, I will be glad to take it up, or any question about editorials.

HARLES E. KANE (Illinois Central Railway System, Chicago, Ill.): As chairman of the Program Committee, I think I ought to say that both Miss Buffum and Mr. McReynolds were put on because we thought we should make them personally known to all the members attending this convention.

The *News Letter* is the life blood of this organization. I think it has done us a world of good in the last year, and I think one of the best things that ever happened to us was when Miss Buffum undertook to criticize some of these magazines. She very cleverly backed up Mr. McReynolds' work and I only hope that whatever she gets into at this time she will keep in contact with this organization.

J. G. CONOVER (Yale and Towne Manufacturing Company, Stamford, Connecticut): During Miss Buffum's and Mr. McReynolds' talks I made two or three memoranda, and I would like to say with regard to Miss Buffum's talk that I think the honor last year in Chicago of delivering a brief address to this body, in which I emphasized the very facts that she brings out: that fundamentally employees' publications are printed to make money for the company that employs the editor and if you will only keep that in mind you won't go very far wrong in material for editorials.

A great many of us have been in the habit of wanting to turn out something of high literary value. I turn out a paper on the first and fifteenth; and we are prone to think that because we turn out a sheet, something with type in it, heads and everything like that, that we have done our work. The question to yourself is this: Is this the kind of a publication that is calculated to make money for my employers?

We say, up in Stamford, that the function of the paper is in the way of making money for Yale and Towne Manufacturing Company, in the lessening of labor turnover. If you can lessen turnover you have made money, because it is said up here that it costs fifty dollars to bring a new man to the employ of the Yale and Towne Manufacturing Company and assign him to his particular work.

Therefore, if you can put something in the paper that makes the employee believe that Yale and Towne are good employers and that Stamford is a fine place to live and there is no use of moving on, you have in that sense made money for Yale and Towne.

So in reference to what Miss Buffum said about our being lazy, I wonder whether you have ever watched a chap lolling around in the grass who was called by his father and mother and it was said they couldn't get him to do anything. Finally you see him go through nine innings of a baseball game and shine, or run in a football game. He wasn't lazy at all.

Now, as far as I am personally concerned I have not in six years paid a penny for syndicate stuff for my paper or used a shears to put something in the *Yale*

Panel, and for this reason: I begin at the top of our offices and I call the roll. I go into Mr. Allen, the president, and say, "You are about due. I want a column from you."

He may say, "I haven't got time," but I come back and ask him what he is going to do about it and that he preaches cooperation. Then I go to the first vice-president, and the second vice-president, and I go all around; and they have all got to put something in on holidays. But in addition to that they must come across with a special article every once in a while.

When Mr. Reidel was talking I seemed to smell now and then a long acquaintance with newspapers. I had twenty years with them, and I was very much interested in the remarks about the heads. I wonder if Mr. Reidel has ever heard the statement that a good head can carry through a bad story, but a bad head can damn a good story? That is a newspaper axiom.

Mr. McReynolds spoke about these long editorials. That is what we are all proud to do. When you write a letter if you get in trim it flows right along.

It was Charles A. Dana who said, "Any damn fool can write a long editorial, but to write a short one that is a gem and has a pull in it, that seems to be a lost art, and one cannot always do it."

I was very much interested in listening to Miss Buffum, and I think she hit a keynote in her remarks about why we are editors. I cannot emphasize too often that when you get down to it, editors are to help make money for their employers.

CHAIRMAN CLOSE: I am inclined to think that the proper place for the good head we have been talking about is on the shoulders of the editor. I think if we have a good head we will probably get along with the rest of it all right.

MR. AUGUSTUS: I would like to ask Miss Buffum's opinion on one thing, about which I have had some disagreements with other editors.

Do you think that an editorial should ever deal with matters outside of your own immediate organization? For instance if you are in a small community where there may be the question of a community chest, or some bond issue for a worthy purpose, something that concerns the community at large, do you think it should have a place in employees' magazine if your company is backing the project and it is for the good of the community? Is it wise to editorialize that to your employees?

MISS ANNE W. BUFFUM: I feel that any subject which intimately concerns your employee is a fit subject for editorial, and your question would be whether your people are benefited by the community chest you suggested. If they take part in it as individuals and members of the community, as well as of the company, then they are interested in it, and it is perfectly good material for editorials. I think your question would be whether it was their business or not.

MR. AUGUSTUS: I might have gone one step further, by explaining that sometimes on these things that are of community interest, there may be a difference of opinion on the part of certain people in the community.

Our manager has taken the attitude that where there is a difference of opinion, even though he feels that the cause is just and should be supported, he doesn't feel that it is the part of the Mead Paper Co., to take sides and print in our magazine that we are for or against some particular project, or ask our employees to support it.

MISS BUFFUM: I think that is the right attitude to take. It is a personal matter rather than company or management.

CHAIRMAN CLOSE: It seems to me in connection with Mr. Augustus' point, that many of us would make a mistake if we took sides on controversial matters in our papers. If you stir up antagonisms you are not going to get very much good from it.

K. D. PULCIPHER (Pennsylvania News, Chicago, Illinois): In connection with Mr. Augustus' question, the editor who doesn't know what to do on the policy

ter of his company needs to get straightened out for his own personal benefit as well as that of the employee, and it seems to me that the editor hired by the company and the publication representing the company should follow strictly the company's policy.

R. AUGUSTUS: May I say just a word more? I think Mr. Pulcifer has misunderstood me. For the sake of argument I can very easily see where you are forming a real service by taking sides on certain controversial subjects.

One of the purposes of any employee magazine is to help form opinions, the same as a newspaper helps mould public opinion. Now then you may have a worthy cause in your community, something that sides have been taken on, which you think is a good thing for the community, and will benefit your company or your organization.

I cannot see—I am saying this for argument—why it isn't all right to take sides on that, and state your reasons why you think it is a worthy cause and why it should be supported, and try to help mould that public opinion insofar as the personnel of your company is part of the community.

Of course I agree with Mr. Pulcifer that you have to abide by the management's decision. If the management is not in sympathy with the particular project, you want to keep your job, you had better keep still. But where the management is in sympathy with the project, isn't it good policy to try to sell your argument on the idea that they should come out and make a statement on those issues and publicly support them? They do it through newspapers.

I know of one instance where a certain matter came up where our management came out publicly in the newspaper and in a written statement and by liberal cash donation helped a certain cause; but the manager of our plant didn't think it was wise to say a word about it in our magazine, although it was known all over the community.

R. PULCIPHER: There is only one answer to that. No company should be allowed to print in its own publication what they are willing to say outside.

W. BOSWELL: It seems to me that Mr. Conover in his remarks hit a vital point in connection with our employees' publication. Isn't it a fundamental province of our publications, as he says, to make money for the company? Of course, we are creating a fund of good will among the employees. We want them to believe in the company. We want them to believe it is the best company to work for in our particular community, and it is a good community to live in. That is all well and good about being a good community to live in, but when you get out and begin dealing with things like the community chest, there is a wide difference of opinion among the men as to whether they ought to give or not, and I feel that if we begin exploiting in the columns of our paper the *pros* and *cons* of the community chest or the Red Cross, or whatever the drive is for—theater in Florida, and so on—while they are all good causes your special function is along a given groove of creating that fund of good will among the men between the management and the men. That is my notion about the editorials. We do not write any editorials in our publications. I believe that Miss Buffum ought out in her paper something about preachers. Too frequently your editor is really a preacher and that is not what you are there for. I feel that if we get into this editorial matter too far, we are preaching to the men and our function is not going to accomplish the thing that it should accomplish, which, as I have said before, is good will among the men and between the men and the management, and to make profits for the company.

AIRMAN CLOSE: You have just heard the ideas expressed that perhaps editorials are not the proper function after all. Anybody else agree with that?

F. HALL (G. M. & N. Railroad): When you write on a point like the community chest and try to persuade your men to contribute to the community chest, you jeopardize your influence on other subjects by talking about a controver-

sial subject. In the first place if it is an official utterance, they think you are dictating.

MR. AUGUSTUS: If you have a different opinion on safety or anything else in your organization, you may tramp on somebody else's toes.

E. R. TREVERTON (The Ohio Public Service Company, Cleveland, Ohio): When you gentlemen speak about these controversial matters in your editorials, you should be in the utilities business and you would be almost afraid to print your name.

Backing up the more lazy member, I have found that it pays to pass it on to the boss. We run in our paper just one editorial which is written by the general manager, and he uses it to put out any special information or especially good work done, which helps some.

H. P. McDONALD (Kings County Lighting Company, Brooklyn, New York): It seems to me that there is some confusion here with regard to these opinions. There is a confusion here between opinion and attitude.

Newspapers, of course, write more on public opinion because they represent certain parties, or they represent what is supposed to be certain ideas, but the companies that we represent here simply are trying to develop an attitude or character among the employees, and for that reason, a subject must be an employee's subject. It is only the attitude of the employees that we are trying to correct.

CHAIRMAN CLOSE: Our next order of business is the report of our Judges' Committee which will be presented by Mr. C. T. Fish, of the National Safety Council.

C. T. FISH (National Safety Council): Mr. Chairman and Fellow-Slaves of the Typewriter and Scissors: I am pinch-hitting for Professor Dutton. He was unable to be here today, but he expects to be in New York tomorrow, and if at all possible, he will come around and say a few words.

Before I give the report of the Judges' Committee, I want to express my appreciation of the very kind remarks that Miss Buffum made when she listed me among the experts of employees' publications. She was more than kind to me in her comments on that so-called service for employees' magazines that I grind out every month. If it is hard to write editorials, it is about three times as hard to get out that stuff which goes to editors who are supposed to be critical and is passed on by them to the workers who are supposed to be ready to yell "boloney" at anything that refers to safety. At least I take that attitude when I am writing and try to avoid preaching.

I never feel offended when any editor re-writes it to suit his own uses and I have often wondered who it was in the Hooker Organization that improved it.

Now to return to the Judges' Committee. They picked out three of us. Professor Dutton, who is on the faculty of Northwestern University and associate editor of *Factory*, published by the McGraw-Shaw Co., was made chairman.

The others are Mr. W. L. Ballou, an advertising man of Chicago, who got out that ill-fated *House Organ Review*—It was a good publication while it lasted, but the market seemed to be too thin for it; and the third member of the committee is myself, originally a printer, subsequently a bookkeeper and now an editor by accident.

We had widely different points of view. In fact, we were 40 points different on one publication and I insisted that it was impossible for any publication to be as rotten as the grade given by one of us and still survive. Another time, I accidentally graded the same paper twice. The second time was on a hot day and I had just discovered a bad typographical error in my own magazine, so my rating was 5 points lower than the first time.

We try to keep our personal taste out of the matter, but it is bound to creep in. Perhaps we like the cover or we are particularly interested in some article or perhaps we like the flavor of the Scotch jokes.

As for our basis of award, first of all came safety. The contest is held under the auspices of the National Safety Council. We had to give it a fairly prominent

e, and we tried to take a liberal attitude in our view of safety. A department cannot publish as much safety material as a rolling mill, and we made advances for public and home safety, and health, and even thrift. It was easy to find from some of the magazines that the editor personally and the company and him was strong for safety, and that counted a lot.

The schedule of points that was drawn up is not arbitrary. You cannot draw a hard and fast line. If the safety story is really effective, it can also be listed for general interest, and educational features.

Another difficulty we were up against, was the borderline magazine—like the one gotten out by Mr. Augustus. It was quite a problem to tell whether to place the magazine in class one or class two. We placed it in class two.

Just as an experiment, I took one magazine, *The Bancroft Bulletin*, published by Joseph Bancroft & Sons, Wilmington, Delaware, and graded it according to standards of class one and of class two. There was only about one point difference.

Makeup and art, according to the scale of points, could not make more than two or three points difference between a good magazine and an indifferent one. Appearance, however, cannot help but exert a powerful influence.

Report of the Judges' Committee

By H. P. DUTTON

Chairman

The committee—Mr. Fish, Mr. Ballou, and myself—after rating each publication independently and averaging these individual ratings have come to the following conclusions:

For publications in Class I the *Wisconsin Telephone News*, with an average rating of 90.7, takes first place. *Norfolk & Western Magazine*, with a rating of 87.7, takes second place; and the *Hercules Mixer*, with a rating of 87.7, takes third place. The following publications have been awarded honorable mention:

Louisville & Nashville Employees Magazine.....	87.3
Telephone Topics (New England T. & T.).....	87
The Mouthpiece (Michigan Bell Tel. Co.).....	87
General Electric News (Schenectady).....	86.7
C. C. C. Mutual Magazine.....	86.3
International Paper Monthly.....	86
The Ohio Bell.....	86
Vacuum Oil News.....	84.3
Illinois Central Magazine.....	84
Telephone News (Bell Tel. Co. of Pa.).....	83.3

Class II *Mead Cooperation* takes first place with a rating of 90. The *Bancroft Bulletin*, rating 88.3, takes second place, and the *Armco Bulletin* came third with a rating of 85.6. The following were awarded honorable mention:

Consolidated News.....	85.6
Motor Coach.....	85.3
United News Letter.....	82.6
House Dope.....	82.6
Reo Spirit.....	82.6
Gas News (So. Calif. Gas Co.).....	82.3
Harrison Radiogram.....	82.3
Tick Talk (Western Clock Co.).....	82.3
Twin Topics.....	81.3
The Hardwood Bark.....	80.6

In Class III the *Hawthorne Microphone* led the list with a rating of 87.6. Next came *The Bessemer* with a score of 77, and the *M. S. A. News*, a mimeographed publication, took third place with 75.3. Since the total number of contestants in this class was less than 10, specific awards of honorable mention was deemed inadvisable. *The Exciter* and the *Dunlop News*, however, ranked close to the place takers, and none of the publications lagged far behind.

In going over the papers the judges were impressed with the fact that many publications, while not conforming to the scale of points adopted as a basis for rating, nevertheless showed evidence of very intelligent adaptation to the specific problems of their publication. Since these purposes are so diversified, ranking by points cannot give a really accurate indication of their effectiveness.

The rating, however, may afford the editor some indication of his points of excellence and show his publication compares in a more general way with others in his field.

The committee was impressed with the fact that a large majority of the publications were excellent jobs of printing and make-up. As might be expected there was more variety in the editorial point of view and in the general contents. In the great majority of cases the editorial attitude showed an intelligent appreciation of the point of view of men as well as of the management.

Your Judges' Committee would offer one suggested modification of the present rules. Certain publications, for one reason or another seem to be in a position to be serious contenders in every contest. Would it not be a good idea to borrow from the practice of our golfing friends, handicapping for the ensuing year, the winners of first, second and third places?

While the Judges' Committee, pending the wishes of the section, has not worked out any scale of points, it should not be difficult to devise an equitable scale of handicaps and after a year's experience this could be corrected, if necessary.

MR. FISH: The certificates for the winners will be distributed as soon as possible after the Congress. Our last meeting was just three evenings before I left for New York and it was impossible to arrange all the details.

Class three was a difficult one. We had printed magazines of the newspaper type, and also some mimeographed magazines, and there was one little hectograph sheet produced on one of those gelatin pads, and gotten out with considerable ingenuity; but we hadn't any standard by which to judge it.

CHAIRMAN CLOSE: You have heard the report of the Judges' Committee. We all join in felicitating the winners and condoling the losers.

These contests have had a very important effect in stimulating interest in our section and I hope that we can keep up this very interesting and important feature of our Section.

ADJOURNMENT

October 4, 1928

Granite City, Ill.**

Luncheon Session was called to order at twelve-forty o'clock by the chair-
Gilbert F. Close.

IRMAN CLOSE: Our speaker is Dr. James Melvin Lee, head of the Depart-
f Journalism, New York University. I suppose there are a good many of us
at would like to know how we got to be editors or why, and Dr. Lee is
to tell us. I don't know whether he is going to tell us why we are editors or
man ought to be an editor. Nobody is better qualified to give such a talk
rofessor Lee. We appreciate his giving us this time in the midst of his
us duties.

Why Be an Editor?

By DR. JAMES MELVIN LEE

a, Department of Journalism, New York University, New York City

much easier to answer "why be a speaker?" I can give you one very good

In no other way would I know how many dining rooms this hotel has. I
rom today's experience. That is another story, as Kipling would say.

king of Kipling, although he is a great master of prose, when he has a real
e, he puts it over in the form of verse. You possibly may recall his
quatrain:

keep six honest servants.

They taught me all I know.

They are who, what and when

Where, why and how.

pose when the cubs come to you, you tell them to get the answer to all those
stions. Many textbooks have been written around lessons in that quatrain
ling's. Which one of these questions you answer first will depend upon
ortance. I may have a cold and you will never know because the "Who"
portant; but if Smith or Hoover, either one of them, has a cold, you will
bout it in the morning.

uld much rather talk to you on either one of those questions than the

It would be an easy task. I could talk to you on Who are editors, but
I would be giving you almost a book on Who's Who in Journalism. I
peak to you about the Where are editors and I would be compiling some-
ke Ayer's Annual. I might speak to you about the When, and I have dug
When a good deal and produced a history of American Journalism. I
desire to advertise that book to you, although I can bear a message of

me from what I have heard at the table this noon that your discussion
y took up the question How, and that is much more attractive than the one
discuss this noon. A compilation of the answers of the How will give you a
manual on your special line of work in journalism. That question Why
hard one to answer. I remember when I used to cover the police courts,
the judge talk to the jury repeatedly. He would warn them, "Be careful
interpret a reason. Sometimes the Why on the surface isn't at all the

Why a man did it." When they stop to consider why these men were before the judge, we wonder why they did it.

Really, I don't know why I should be here right now. I dare say a great many of you at the close of these rambling remarks will be qualified to say why I should not be here. An old city editor of mine said "If you can't get the Why, there are Why-nots; bring them into the story. That will enable you to answer the six questions completely." That is not a bad thing to do. I can tell you some why-nots—we ought to be editors merely for the sake of the money. I don't believe many of us are in it for the salary we draw. I think all of us could earn more money in other fields. Certainly, we are not in our present line of work for honor. Our names are not blazing on the boards as the butcher, the baker and the candlestick maker appear in their business. We are not in our business because we have sought soft jobs. We are not in a line of work where we can easily escape from our mistakes.

Speaking as a teacher, it is rather easy. You can make all sorts of mistakes, and until many years after graduation your students don't know you made the error. A doctor's mistakes are soon buried and covered up; your lawyer's mistakes the client never knows, they are taken up to a higher court; the manufacturer takes his mistakes and dumps them in South America or he sells them as seconds without his name attached to the product. The preacher—well you have to wait until you are dead to find out whether he made a mistake.

The editor, therefore, has his mistakes in cold type. He has to face them the minute his periodical comes out. He has a hard time passing those mistakes.

That may really be one of the reasons why we are editors. We like to face difficulties. We like to have new experiences every day. We are not contented with having produced one good cake of soap or one good car and sit back and draw our dividends. We want something new every day. That gives a variety of experiences. You are dealing with men and you are dealing with materials and you are dealing with management. But more than everything else you are dealing with life, and that is one reason maybe we are editors because we like to deal with vital things.

Along that same line of experiences, I think editors, more than any other group, have learned to take the thing that is working against them and make it work for them. I could give you numerous illustrations in the editorial field, but if I did I might betray confidences, so I will go into other fields.

A very distinguished individual says that his success in life is due to the fact that his father on his dying bed gave him this bit of advice: "Son, whenever you have an important decision to make always scratch your head and count nine before you hand down that decision." He has anecdote after anecdote to show that his success has been due to the fact that he counted nine before he made an important answer. One important illustration is his first job, sweeping out a little country store, for which he got \$3 a week. One morning he started to sweep out the store; having finished that he started to sweep off the walk, when he noticed the wind was blowing his way, and as fast as he cleaned the walk the dust blew right back. He went to the other end and began to sweep with the wind. The rival grocery man across the street saw this and said: "Bob, how much are you getting?" "\$3 a week," he said. "I'll give you \$4." Bob was ready to grab at that when he thought of his father's advice, and he began to count. The grocer, noticing his hesitation said, "I'll give you \$5." "I'll give you \$6." By the time he had counted nine, he had been offered \$7.

There was a good illustration. You can see what that means. It was his ability to take the thing that was working against him and make it work for him. I remember speaking to a group at Kansas City. While there I heard the story about the junior in the State University who was working his way through college by conducting a chicken farm. During the summer he grew corn, wheat,

age, carrots and things of that sort, with which to feed his fowls in winter, by saving money. This particular year the State of Kansas (as it sometimes had an epidemic of grasshoppers. They were eating up the things he expected to feed his fowls in the winter. What did he do? He set traps and caught grasshoppers and dried them in the hot Kansas sun. That winter he fed his fowls dry grasshoppers. He got more cash from those grasshoppers than from the cereals which he fed the chickens in the winter. We all know that fowls do better on having a meat diet than on a regular cereal diet.

A good old Southern gentleman found his exchequer was low because of the time his friends came to visit him, it drew heavier on him. What did he do? He took the thing that was working against him and made it work for him. By the help of five letters he put above his front porch, the word "HOTEL." The thing was working against him, now it was working for him. It was as comfortable as before, even more so as guests felt more free to come.

That's one of the things about editors, I think—why we are editors. We know how to take the things that are working against us and make them work for us. I think really the Chairman spoke the thing "Why we are Editors" with apology. I might have spoken otherwise. Shakespeare said some of us are born editors, some of us achieve the editorial chair, and some of us have editorial jobs thrust upon us. That doesn't explain why we continue to be editors. I think the real reason may be found in the philosophy we live. I think, more than any other class of workers, we believe that if we are not finding pleasure in the routine of the day we are missing the best that life has for us, and I submit to you that that is the real reason why we are editors—because we are finding pleasure in our work and in no other line of work do we find the same pleasure that we find in being editors.

He started off with a personal allusion. Elbert Hubbard gave this recipe not for an editor but for being a good after-dinner speaker: "Select a subject," he said, "about which you know a lot and your audience little." He was one of the few who practiced what they preached because he talked about himself.

A Fox had a great blue print for short stories. This might be helpful on the house side of journalism. He said that when he played the piano and was about to leave he hated to leave until he struck the same note at which he opened. He struck this note it was all right for him to leave. I know less about music than about any other topic but those who know say there is a very definite connection between the opening note and the concluding note. He took that as a blue print for many of his short stories that he put in his volume. The concluding note is in relation to the opening note. For example, the first of the story depicts a man sitting by a fire sucking his thumb, and he is the villain of the story. He starts what is coming to him, and in the concluding note he is sitting by a fire sucking his thumb. When you are writing news stories, strike the same note in conclusion that you opened with.

He started with a personal allusion and will conclude with a personal one—why here. Because I have been receiving so many of your plant papers during the past year. I want them to come to me during the next year.

IRMAN CLOSE: We appreciate all the help and inspiration of your talk. You have given us a vision of our jobs. While we may have had it in the background of our minds, we haven't seen it as clearly as you have presented it to us. I wish to thank her for his suggestion that you send him your magazine.

ADJOURNMENT

October 4, 1928

GILBERT F. CLOSE, Chairman

Editor "The Commonwealther," Commonwealth Steel Co.
Granite City, Ill.

The second session was called to order at two-ten o'clock by the chairman, Gilbert F. Close.

CHAIRMAN CLOSE: You will remember that at our session yesterday afternoon, Miss Buffum prepared a paper on a "Volunteer Critic's Conclusions Concerning the Editorial Contents of Employees' Publications." She told us quite a little about what she discovered in looking over a lot of our publications from the point of view of editorial policy and editorial contents, etc. Now we are going to approach the general editorial this afternoon again from a somewhat different point of view. Mr. E. T. Wilkins, one of our old friends who has been an active member of this section for a good many years, is going to talk to us on the opportunity for improving the editorial contents of employees' publications. Mr. Wilkins is the editor of the *Schenectady Works News* and those of you who have read his paper will agree that he knows a good deal about the subject and is well qualified to tell the rest of us some things from his own experience in this work.

Opportunities for Improving the Editorial Content of Employees' Publications

By E. T. WILKINS

Editor, "Schenectady Works News," General Electric Company,
Schenectady, N. Y.

We, the members of the Employees' Publication Section, are assembled at this National Safety Congress to discuss ways and means of improving the editorial content of the most valuable and most direct medium for dealing with human relationship in industry.

An employees' publication, therefore, is the voice of your organization seeking good-will among your employees, urging them to greater efficiency, creating loyalty to the company, stimulating interest in work and pride in quality of product, fostering initiative, promoting safety and creating a spirit of harmony and cooperation between men and management.

The editor, on the other hand, is the spokesman for the organization through the employees' publications. As an editor of an employees' publication, you are the sculptor and the contributors are the clay. While you can't altogether choose your own clay, you can, at least, refine it, and certainly in your hand lies the shaping of that clay. I earnestly entreat that the clay that passes through your hands be moulded into something worthy of the stamp of approval of your organization and the principles for which it stands.

What the editor writes and publishes in the employees' publication spells loss or gain in prestige to the organization. If he uses phrases that are empty of thought, he depicts a hollow organization. If he overstates, he portrays an organization prone to exaggeration, which is distasteful. If he boasts or brags, he pictures an organization overpleased with itself, and resentment naturally follows. If he is flippant, or careless, or smart, or indulges in ill-timed familiarities, all these shortcomings are charged up to the organization that sponsors him.

If, however, he selects or writes sound, helpful articles, he establishes in the

s of his readers a sound and helpful organization.

incerety, therefore, should be the keynote of an employees' publication. The editorial content should be written in language which is clear and simple, but dignified—neither slang nor poor English is necessary to secure reader interest.

The material used should be concerned with the lives of the members of the organization at work, at home, and at play.

A friendly tone should permeate all of the articles. Personal reference should be used with caution.

The employees' publication should neither preach nor assume a paternalistic attitude. A preaching or commanding attitude is bound to create contempt and loss of interest, and will lose for you much of the good that may already have been accomplished.

Talk to the employee in his own simple language about the things in which he is most likely to be interested. Talk to him from the viewpoint of the man in the shop rather than from your own personal viewpoint, or from the viewpoint of the top-ups in the management. Make your viewpoint the viewpoint of the men in the shop, and you are more likely to put across your message in a way which will be understood by the majority. To get this viewpoint, talk to the men and discuss their ideas on important subjects.

To win immediate favor, write something to make the readers laugh and forget. To derive some benefit, write something that will make them think and remember.

The question of editorial content is one deserving most thoughtful consideration, especially as it affects your employee contributors.

Don't destroy your contributor's style and make it a pale imitation of your own. If your contributor chooses to write in short, staccato sentences, and you prefer long and balanced ones, there is no reason why you should destroy the effect of his effort by sprinkling it with conjunctions. With many employees' publications, monotony of style is a curse. Think what the *Saturday Evening Post* would be like if it were all written by George Horace Lorimer.

Obviously, there are some subjects which must be dealt with by the management, and still others for which the editor should be solely responsible. In the majority of subjects, however, the article will be far more interesting if it is dealt with from the viewpoint of the employee.

Use Names to Maintain Interest

The use of names all through the editorial content of your publication is sure to maintain reader interest. "Mr." and "Miss" should be used sparingly. An employees' publication filled with live news of the plant, of employees, their activities and their interests, is a publication in which not only the man of the shop finds interest, but those at home and outside of the plant are likewise interested.

Safety material should occupy an important part of the editorial content of an employees' publication. In fact, the judges of the plant publication contest awarded twenty-five points for safety material in Class 1; twenty-five points for Class 2; and thirty points for Class 3. Since one of the reasons for the existence of the employees' publication is for the welfare of the employees, I feel that the judges made no mistake in giving safety material such a high rating. Safety material is usually divided into two groups; that of local interest, and that of general interest.

At the Buffalo Safety Congress, in 1923, I suggested twenty-one proved methods for presenting safety and health through employees' publications, so you can see that there is a wealth of safety material available for the live-wide-awake editor. It

is, therefore, not a question where to get safety material, but how to use it to improve the editorial content of your publication. Do not centralize your safety material on one page, or devote a certain section of your paper exclusively to safety. The best way is to scatter this material well through the publication. Some editors make one big shout on one big page, but twenty-one whispers will serve a great deal better than one shout, for it is through the constant hammering, the everlasting trying, that we are going to get somewhere in safety educational work.

This leads us into another subject, and that is, devoting full pages to departmental activities throughout the plant with special illustrated headings for each department. This has a tendency to promote class spirit among the employees rather than creating a spirit of harmony and cooperation between departments, and should be discouraged wherever possible. The editorial content will be greatly improved without departmentalizing your publication.

Stories foreign to your organization seldom are effective, unless there is some tie of interest. Therefore, if you want to improve the editorial content, syndicated material should be used only on special and infrequent occasions, and then only when it is exceptionally good and applicable to some particular thing which you are trying to bring to the attention of your readers. Just as soon as the workers in the plant make the discovery that you are trying to fill them up on a lot of material written by some person wholly unknown to them, on conditions prevailing in their plant, they lose interest in it entirely, and the whole purpose of your publication is wasted.

General interest stories must, to be of real value, contain news of your immediate plant, its product, or its employees.

"The man who stands all day at a machine," says A. J. Andrews, editor of the *Scoop*, in the last issue of the *News Letter*, "usually fails to see beyond the walls of the shop wherein he works. It is part of the business of your magazine to tear down those mental walls which close about him—give his imagination the opportunity to see the distant horizons of the institution of which he forms a part. Show him the origins of the raw materials with which he works—let him see the product of his work advancing civilization and benefiting his fellow men. Tell him the history, not only of your company, but of your product. The tools and materials used in its making. Give him vision to see his work making him of service to the world. Put romance into his job. And, by the way, can you see far enough across your desk to find the romance in yours?"

The real news for an employees' publication varies to such an extent with the newspaper that there is little comparison. The news in the plant publication is not necessarily new, but should be presented to its readers in such manner that it is news. This brings us up to the point where we may inquire what is "News?" News, according to a winning definition submitted by Mike Wallach of New York City in a contest conducted by the New School for Social Research, is as follows:

"News is a perishable commodity, distributed by the newspapers, marketed daily for consumption by the literate mind. It constitutes written presentation of the events of the world, the nation, the state, and the city in all fields of intellectual and emotional interest, such events being of sufficient importance socially, economically, politically, scientifically, or individually to engage the attention of vast numbers of people. Like any other commodity, its careful preparation, the quality of its ingredients, the integrity of its purpose, reflects credit or discredit upon the honor of its purveyors. Substitutes for truth, or adulteration of facts, cheapening of method in the manufacture of news, constitute abuse of public trust and threats against the health of the public mind."

In rating news items in employees' publications, the judges of the Plant Publication contest, give a credit of twenty-five points in Class I; twenty-five points in Class II, and thirty points in Class III.

News Articles

1 news articles should be short and to the point, without being blunt and
pt. A sure way to breed lack of interest and staleness is to fill up the pages of
publication with long, rambling articles. The average reader does not like to
long discourses on any subject, and it is, therefore, important that you keep
articles short, preferably not more than one page in publications measuring
3½ and over. If the reader can see at a glance that an article is short, he will
than likely read it, whereas if it is long, he will pass it by for the time
s, intending to come back to it at some later time and read it. Nine chances
of ten he forgets about it entirely, and eventually the magazine is cast aside
out the article having been read at all.

d lest some well-meaning editor may misguidedly assure himself that the
cular message on which his pen is busied cannot be told completely in less
six or eight hundred words, let him delve a bit among admitted master-
s that have moved generations of readers. For instance:

e creation, as related in Genesis, requires less than 800 words. The Beatitudes,
ronicked by Matthew, are complete in approximately 140 words.

e complete document that published the Monroe doctrine to the world con-
s 575 words, but after the proper diplomatic conventions had been satisfied
e elaborate preamble, 102 words sufficed for a warning that has restrained
pean aggression ever since.

coln's Gettysburg address, in spite of the wealth of its message, betrays not
ightest straining for condensation in the perfection of its 271 words. Because
ffecting portrayal of emotion, Lincoln's letter to the mother who had lost
sons in battle will never be forgotten, yet salutation and signature, it does
xhaust 150 words.

Editorials

editorials should carry with them some news value. The timeliness of edi-
s should be readily recognized and understood. The editor should keep his
ind ears open and take advantage of every opportunity which presents itself
riting editorials. Such subjects as safety, thrift, company policies, employee's
and regulations readily lend themselves to editorial comment.

glancing through employees' publications there is plenty of room for improv-
e page used by the editor for editorial comment. This page should be dif-
from a typographical point of view than the rest of the publication. One-
eads are suggested, and these heads should be set in special type, all caps,
lented with copy run around. This page offers good space for the use of
submitted by your contributors. However, if you endeavor to maintain an
's Page, don't use it for news articles.

onsidering how to improve the editorial content, I cannot refrain from men-
g a few suggestions on make-up and art which the judges of the Plant
ation contest give fifteen points in Class I, ten points in Class II, and five
in Class III. You have, of course, only two things with which to work—
nd paper. But, you have numerous ways of combining these two to make
express exactly what you want them to. Four essential features, therefore,
be considered. First, balance of material; second, artistry of appearance;
consistency of type; and fourth, harmony.

'Balance of Material' I mean a certain proportion of light and heavy mate-
ng and short articles, a certain amount of news, and human interest stories
ng them divided as evenly as possible through your publication to appeal to
eaders and their various interests.

Various editors cite the newspapers or the magazines as showing the proper balance or range of material to be used in employees' publications. Whether the newspapers show the proper balance of material for an employees' publication would depend on the purpose behind the employees' publication. If the purpose is to attract a group of readers having varied interests, which seems to be its purpose, then perhaps it might safely parallel the newspaper in balance of material.

In other words, the specific needs of an employees' publication compared to the purpose behind magazines or newspapers would determine the wisdom of copying their style.

The laying down of set rules on this subject would seem to be dangerous. About as much as can be said that while the study of newspaper and magazine make-up will help any editor, the most helpful plan might be to study successful employees' publications and to profit by their experience. A good exchange list helps.

Artistry of Appearance

By "Artistry of Appearance" I mean the setting of your articles and how they are combined. Placing print and pictures in proper relationship to an artistic appearance on the finished page. You have as your tools the various styles of type, art work, pictures and white space. They must be combined in their proper relation to produce an artistic and yet readable page.

No matter how large or how small the publication, whether it be a four-page or a thirty-two page publication, the pages should be planned in pairs. Unity of ideas and compactness of thought govern the artistic layout. Too few editors plan by the double-page idea, with the result that the publication appears as a collection of unrelated pages. Especially in the matter of picture layout, editors who succeed in developing artistic as well as harmonious pages probably are in the minority. The modern desire for illustrations too often is expressed without considering the weight of the illustration in connection with the size of the page on which it appears. The result is generally anything but symmetrical, and may lead the eye off the page, or in other directions.

Plans may be expressed in verticle lines on facing pages, or in triangular form over the two pages; or in circles, so that the focal point is always center. Simplicity should be the governing note of any layout.

Consistency of Type

The subject of consistency of type is one which will mar or improve the appearance of the editorial content of your publication. It is through type, after all, that you speak to your readers, and it is through the type you must touch their feelings.

One of the marring features of otherwise good body type is the heady page with long, complicated headlines and long hangers or second decks on short stories. Headlines should be considered in proportion to the importance and length of the story, as well as the type used in the body of the story. It is a good practice to use two-line heads for all stories. A one-column story should have a one-column head, a two-column story a two-column head, and a three-column story, a three-column head.

Good headlines are snappy and never labels. The story should be told in the head. *The Verb Is the Life of Every Headline.*

Avoid all awkward expressions. Negatives should be avoided, and never use the word "may." The head should, as a rule, tell what happened, or is going to take place, and not what did not happen.

void ending a headline with a preposition, an article, or a conjunction. Do not divide phrases or words in the lines of a head, and try to make each head fit.

Furthermore, one must consider the running head, the line which heads every page of the publication. In the opinion of many successful editors, the running head is desirable. The repetition of the name on each page is a help in familiarizing the reader with the name of his publication, and, also, is most useful where publications are filed by pages or articles. However, the running head, where used, should be as simple as possible.

Harmony

"Harmony" I mean simply to have your publication a complete unit. Have your material and your make-up harmonize with your publication, your standards, your policies. Each publication is usually different. It is for you to discriminate, and produce a harmonious publication.

In my opening remarks, I claimed that the employees' publication is the most able and most direct medium for dealing with human relationship in industry. We, as editors, are the spokesmen for the organizations through these mediums. With circulations running into thousands and tens of thousands, the influence exerted by these publications is enormous. Therefore, the position of editor today is on a higher plan than ever before, and should be classified among the professions recognized by the management of our industries and corporations as such. Under such conditions we, as editors, should endeavor to improve the editorial content of our employees' publications by adopting a code of ethics. This code, if adopted and placed in the editorial offices of our members, will create many opportunities for giving the employees and employers a better conception of the motives influencing all of us and will, therefore, have a most beneficial effect.

Following is the code of ethics proposed for the Plant Publication Section:

The employees' publication's first duty is to print the news honestly and fairly to be unbiased by any other consideration, even including its own editorial opinion. Its second duty is to construe honestly and fairly, in its editorial columns, happenings at home, in the office, and the shop.

Its third duty is to protect its readers, in so far as may be reasonably possible, from dishonest and misguided persons, who may seek to exploit someone's misfortune by allusion, insinuation, or innuendo.

Finally, its duty is to itself, the employees, and the company—and the principles which it stands for.

In furtherance of these duties, we hold these principles to be compatible with high ideals and sound business conduct of a successful, prosperous and useful employees' publication.

SERVICE for our own company and its employees. Our criticism shall be constructive, not destructive. Our columns, whether news or editorial, must be governed by the policy and general welfare of our individual organization, for we are entrusted to us the guardianship of our company's prestige.

FAIRNESS to the readers, the public and the organization's competitors. Recognizing honest differences of opinion, we may vigorously maintain our own position without denouncing others as dishonest and unfair. Under no circumstances must we countenance the use of our columns to vent personal spite nor to innuendo, often more deadly than direct charges. We regard it as unwise to underestimate our employees, unethical to disparage them, and dishonest to misrepresent them.

DECENCY, which should be the guiding star in the printing of news items, editorials and all feature articles or illustrations. "Is it fit to print and to be read

by own mother" should be the crucial test. It is an editor's duty to keep the columns of his publication decent and thus strive to hold steady the employee's mind in the path of righteousness, morality, and the service of God. Let us be enterprising without being sensational.

4. **CONSIDERATION** for the unfortunate and for guiltless victims of the faults of others. We should protect the names of employees, their families, and their associates. No story justifies needless damage to a good reputation, nor wanton pain to an innocent party.

5. **RESPECT AND TOLERANCE** or those of different religious races and circumstances of life. Ridicule may bring only pain to them, but its author cannot escape real injury in loss of the respect in which he is held by his coworkers and by himself.

6. **HONESTY** is an employees' publication's paramount duty,—to print news honestly and fairly to all, unbiased by any other consideration, even including its own editorial opinion. Honesty must always be exercised in our dealings with our company and our fellow workers, our competitors, and with all whom we do business.

7. **TRUTH**, first, last and always, to the limit of our ability; to be accurate as human fallibility on the part of others as well as ourselves will permit; to willingly mislead none, and to be fair to all. There are two sides to every story. Let us weigh the truth of both. If we do anyone an injustice, we should correct it at once, whether the injured person demands it or not.

Though temporary prosperity may be achieved by violation of some of these ideals, we conceive our duty to hold steadfast to these principles and believe permanent success will reward their faithful performance.

CHAIRMAN CLOSE: We have heard this interesting and fine paper by Mr. Wilkins. He presented in the latter part of his paper a sort of program for the Section, a sort of code. I just wonder whether the Section wants to take any action on that, whether they want to just consider his suggestions of helpfulness, or do they want to go any further on that. Any thoughts on the matter?

LESLIE MARSHALL (Firestone Tire & Rubber Co., Akron, O.): I move that as it is a valuable consideration, it be referred to some other committee for further investigation and precise drawing up for submittal at the next meeting.

CHAIRMAN CLOSE: The motion is that if we are in favor of it, we refer it to some committee for further action, with the idea of drawing it up and adopting it as the code of the Section. What committee shall we refer it to?

ERNEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, O.): I would ask what are we going to do with it?

CHAIRMAN CLOSE: To adopt it and send to every member of the meeting to remind them of their privilege and high duty.

MR. AUGUSTUS: Do you have to wait a year for that? I would offer an amendment to that original motion and refer to whatever committee that is given authority, that when they have drawn up the proposed code of ethics, they send to the Section, have it mimeographed, and we will know what it is.

CHAIRMAN CLOSE: Is that the intention? The motion is as it now stands, that be referred to a committee with power to draw up the recommendation and have promulgated as soon as possible to the members.

(The motion was seconded and carried.)

CHAIRMAN CLOSE: I will leave this as one of the first duties of the new chairman to see that that resolution is carried out. Mr. Kane is going to be our new chairman after this meeting adjourns. We were to have the discussion on Mr. Wilkins' talk read by Mr. Sterling Patterson, but we heard a day or two ago that Mr. Patterson had met with misfortune of some kind and he will be unable to be here. We

I be glad to throw this question open at this time for a few minutes for a discussion.

The next subject is a round table discussion of questions previously presented, before we have that discussion, I am going to ask Mr. Conover if he won't read the report of the findings of his committee who sent out a questionnaire to 300 or 400 editors. Mr. Conover has some very interesting information. I'll lead up nicely to our round table discussion.

Report of the Editorial Questionnaire Committee

By R. G. CONOVER

Yale & Towne Manufacturing Company, Stamford, Conn.

During the time elapsed from our Chicago meeting last June up to three or four weeks ago, attempt was made by the use of a questionnaire to find out the end the goal and problems of the members of the Section. The idea was in cases that we had a number of editors of small papers who may have attended these Section meetings, and while they were greatly edified perhaps by papers read, for practical utilization it was far beyond benefit and value. As to the National Safety Council in Chicago and through the courtesy of Mr. Fish, I obtained a list of 334 publications and editors. The editors previously were those active in furthering the aims of this Section. Of those 334 I received replies from 114. That is, 114 questionnaires were filled out. The benefit of those present who were not in Chicago at our last meeting and this resolution was adopted launching this questionnaire, it is as follows:

MEMBERS OF THE EMPLOYEES' PUBLICATION SECTION NATIONAL SAFETY COUNCIL

At the last session of the Employees' Publication Section, in Chicago, a resolution was adopted directing the gathering of data concerning our Editors and publications. The writer was named at the convention as the editor-member and assemble the data desired.

With such data at hand it is hoped that the Section, whenever requested, can helpfully just how our publications might be improved. This advice can be made-up, editorial forcefulness, effective general content—and perhaps how any selected Section publication might be issued at less cost. Such would naturally consider whether or not an editor has to conform to a publication policy set by his management. Advice on cost can also be given though the editor does not care to name his publication budget total.

The resolution recognized that our smaller publications may receive but little from technical addresses or typographical essays delivered at our Section. The budgets of these smaller publications may permit only meagre use of lithography, photo-engraving, or ornate printing. To give learned talks, for example, about the half-tone process, may be helpful to higher grade publications, but a smaller publication editor may not be much benefited thereby. He has problems more vital to him although of a smaller calibre. He is more likely to listen to brother editors who, with data before them, may be able to say to him assuming that you must keep your publication of the size, and volume, and at the cost that it is now, we would suggest that it can be improved by doing it so."

The writer will appreciate the filling out and return of the questionnaire below so that a report may be presented at our next annual session in New York. With this data, editors of publications of every grade may be aided, according to problems and needs.

Publication Title? Published by? Where?

Monthly? Semi-monthly? Number printed?

Number pages? Size pages?

Special cover? Pictures?

Does management lay down detailed publication policy?

Do you publish to benefit others besides employees? Whom?

Do you care to name publication budget total?

With and without salaries?

What section conventions have you attended? What years?

What publication problems would you like advice upon?

Do you publish paid advertisements?

How many employees in your plant?

Are you employed at other tasks besides editing?

Is your publication made up by you or by printer?

Yours very truly,

(Signed) _____

Director of Publicity, The Yale &
Towne Mfg. Co., Stamford, Conn.

Response. Out of 334 employees, publications circularized, 114 sent in replies—a return of 34 per cent.

Attendance. Out of 114 editors responding with questionnaire data, 50 had never attended an Employees' Publication Section gathering. This makes the convention attendance 56 per cent. More in detail, the replies show that 19 editors attended only one of our sectional meetings; 13 editors attended two of our meetings; 8 editors attended four of our meetings; 6 editors attended five of our meetings.

Advertisements. Of 114 editors responding, 93 report they do not run paid advertisements. This makes about 18 per cent who do. Some of the editors are tactically opposed to paid advertisements. One says, "Do not believe in it." Another says, "Absolutely not." Another says, "Nothing doing." One editor says, "Not now but may in a short time." Another editor says, "Our cost of each issue is entirely covered by advertising revenue which yields \$20 to \$30 per month."

Number of Employees. Large and small manufactories and other various kinds of corporations are covered by the replies to the questionnaire. The number of employees ranges from 80 to the very large employment roster of 170,000. This is a widely differing volume and class of employee readers, calling perhaps for special editorial treatment in many cases. Twenty editors report the number of employee readers at less than 1,000; 42 between 1,000 and 5,000 employees; 19 editors report employee readers numbering between 5,000 and 10,000.

Ten editors report their readers numbering between 10,000 and 15,000. Twenty-three editors report their readers numbering from 15,000 to 170,000.

Amount of the Publication Budget. In the questionnaire sent the 334 editors, all were asked if they cared to state the amount of their publication budget. Quite a number responded. From the figures given, and the information also submitted regarding the size and number of pages, of the publication, it might be possible for members within our Section to point out how an improvement could be made without increase in cost. However, that is for the Section to take up. Of the 114 editors who returned questionnaire, 16 left the question line blank. Nineteen stated they had no budget or else that they did not care to state what it was. Those editors who gave figures ranged in totals from a mimeographed publication costing \$150 a year, to a publication costing \$100,000 a year. Four publications cost less than \$1,000 a year. Thirteen cost between \$1,000 and \$5,000. Nine cost between \$5,000 and \$10,000 a year. Seven cost between \$10,000 and \$15,000 yearly. Four cost between \$15,000 and \$20,000 yearly and 7 cost between \$20,000 and \$100,000 a year. One editor wrote, "We have no budget. We let the paper cost what it may, but try to be economical."

These figures admonish us again not to judge and criticize the publication with a \$100 a year budget on the same high plane as the \$15,000 or \$50,000 a year publication.

Another point is "Is the editorship subject to management's detailed policy?" Twenty-two of the 114 editors report flatly "No" to this question. That is, they are not required to follow specific instructions from issue to issue. One editor says, "Management does lay down a publication policy." Another says, "Publication is passed upon and issue passes through a publications committee." Another says, "Management approves copy." Another says, "Publication left to editor, management executive." Another says, "Directed by Editorial Board." It may be gathered from those replies that the editor alone is not always responsible for the contents and typographical appearance of his publication. Let us bear this in mind when criticizing.

Additional Tasks. Only 11 of the 114 editors state that they have no duties additional to their editorships. Of the 103 editors quite a number have tasks added with publicity, insurance, advertising, personnel, safety, industrial relations, athletics and printing. These are some of the interesting comments made by editors in stating they have duties additional to editorship. One says, "I have other tasks—plenty." Others, "Very much so." "Editing not considered as a job but a duty and social recreation." "Athletic, picnic and safety." "Yes, about 14 other tasks." "Editorship a side line." "Yes, numerous." "A few other little jobs." "Have 21 other assignments."

Up of Publication. Of the 114 publications reporting 6 editors only say that they do not make up their publications, that the work is entirely performed by

the printer. In several instances, mention is made that the make-up is the result of joint work between printer and editor. In other cases, editors say they do the work entirely. One editor says, "I make up without assistance from anybody." Another says, "Written, made up and printed by us." Another says, "Printer makes up from our exact dummy." One publication is reported printed on a Rotospeed Duplicator. One publication reports, "Printed at our own plant."

Advice on Publication Problems. To the query concerning the matter of problems confronting editors, there came a number of interesting answers. But at the same time, 49 editors of the 114 who replied left this line blank. This may mean they need no help on the subject, or it may mean that the query had little significance for them. One editor answered, "We have no problems." Another editor, "How to get out a paper without doing any work." Some of the other problems outlined by editors were: "Do editors work full time?" "How to get material received into 32 pages." "What proportions of space to be allotted for company policy and sugar-coated stuff, safety, plant news." "How readers' interest may be measured, best methods inducing correspondents to write." "How to judge accurately whether publication is accomplishing its purpose and is being read by majority." "Interesting copy and other plant news." "The real test of readers' interest." "Are standard departments advisable?" "Methods of securing educational copy to benefit own employees." "Getting cooperation from correspondents and employees." "We want criticism from responsible sources." "How to get news easier." "How to obtain enthusiastic cooperation from correspondents." "Cover suggestions—way of improving art and illustrations." "Economy in single and group cuts." "Typography and make-up." "How to get news and keep on getting it. What type of news is best to publish and how best to tell it."

Round Table Discussion

CHAIRMAN CLOSE: I think we should have our discussion now. I am going to ask Mr. MacReynolds to collect any more questions that may come up. In the meantime, we have a number of questions which were submitted yesterday. There are three questions which cover the same general subject, and one person wants to know what methods have been found effective in getting better responses from correspondents. That also is one of Mr. Conover's problems. That is, "How do you get them to send in the news of their particular group?" Another, "What methods are being used to stimulate interest and encourage employees to contribute?" Another, "How to get articles for the papers and what method to use in getting persons to write?" "How to reject material that isn't wanted?" Who would like to say a word on "How do you get your material?" How do you get the correspondents throughout your plant to send in material? Who has a word for it on that subject?

E. T. WILKINS (General Electric Co., Schenectady, N. Y.): We have 18 reporters at Schenectady. They are elected by popular vote in the Works once a year. They doubtless are the popular employees of each section. We divide the 605 acres off into 18 sections—and we have at least 53,000 employees—or 3,000 employees to handle. They in turn have subreporters whom they appoint in the various sections of their department. We have a dinner once a month or thereabouts and we discuss our problems; they have abundant interest there, and we have no trouble in getting news items for the *News*. In fact, I have too much. I can't use all of it. I had to put out a letter of apology in my last issue because I couldn't use the material on hand but would use it as soon as I could. I think that your problem of success is to get your editors and your reporters and have them elected by popular vote and then have them subdivide their districts into sub-reporters and I am sure you will get results.

IRMAN CLOSE: Mr. Wilkins says he has his reporters elected by popular vote. How are you going to be sure that the popular man is going to be a good one? Perhaps it might be better to have the editor-in-chief appoint his reporters. Does anybody do that?

G. CONOVER (Yale Towne Mfg. Co., Stamford, Conn.): I have been through a good deal of that. I understand the difficulties. In our plant we have organized what we call the Scribes Club. We give a couple of dances in winter, an outing in the summer. Although they are dances and social gatherings, mainly, we manage to get in talks about correspondents. No matter what you approach to 100 per cent results is far from favorable. It is an uphill battle. When Brother Wilkins says he can't publish all the material he has, I think there is a millenium up there. As for electing them, I think you said is a deterrent to trying that way. I have asked our men to name anybody in the room that he thought was especially fitted as a correspondent nine times out of ten they made a mistake. They will pick a man or woman for no reason he thinks would be a fine writer of news. Experience has it isn't so. You have to smell around and find out for yourself.

IRMAN CLOSE: I think one trouble is that our reporters, while their experience is good, put off the matter of turning in news until the last minute. Then you are all ready, you haven't got it. I find that one of the best solutions is to pick up the telephone and jog them up and in that way you can get a casual word with your fellows. You can generally reach him by phone or go down in the shop and look him up. My experience has been that if I let him slide and send out a letter, saying please send your news by a certain date, you don't get very much. But if two or three days before the time I jog them, then I am very frequently in the same position as Mr. Wilkins—I have no idea what to do with it. It seems to me that that personal touch at the last minute is a great help.

EST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, O.): We don't have reporters at all. Like Mr. Wilkins, we have more material than we can do with. I found the best way to get live news that you want is, about a week or ten days before the deadline date, personally go yourself and talk to different boys who may have news, or send an assistant out and let him spend a day and a half around the different departments getting in touch with the different fellows most likely to have news, but won't take the trouble to write it down. Before you get away from him you've got four pages of stuff. I tell you it but won't write it. We've got all kinds of stuff that way. We have as much material of that kind as I have seen.

IRMAN CLOSE: We have done that more or less, too. Frequently, you get fellows who have a certain amount of ability in writing, tickled to death to write you items. But in some departments if you are going to get it you have to go down and talk it out of them.

. STRICKROTT (Mohawk Hudson Power Corp., Albany, N. Y.): I think the question comes down to one point, that is, to get somebody that is interested in the thing in the first place. We have been through all this and when we started out with our paper, the thing was first to find somebody that had some ability. We gave up that idea pretty much. Then we tried to get somebody that had a pretty good education. We came down from that to the other end to somebody that knows the organization pretty well.

When you get through it, if you can find somebody in the organization interested then he or she will find a way to do it. If they can't do it themselves, you'll find somebody in their particular group to help them out. If you work with them you can develop a news sense. They can at least give you news facts and bring their particular section of the company and with that background of

interest you will be able to work in such a way so you will be able to get the thing across.

CHAIRMAN CLOSE: Does anyone give any particular reward for turning in news? Or has anyone tried paying their people? Does anyone pay their reporters?

C. E. KANE (Illinois Central System, Chicago, Ill.): The Illinois Central is not like some of the others. It is a bigger publication and on a larger scale. We carry articles by the correspondents each month and award prizes. We found it works well.

We have three prizes; first prize for three-column head stories; second prize for the best two or one-column head; and the third prize for the second best two or one-column head. I find that wherever we award a prize, for a long time thereafter we have interest at that particular place; and while we strive to reward merit as it arises we also do try to keep the prizes from going to the same place all the time. We attempt to regard the correspondents and the editor together. I find that contact as you mention here is a fine thing to get the people together on more of a basis talking about the publication and it tends to keep their interest between meetings. Of course, we always give credit when a story is written by an editor or a correspondent, chiefly if the name is handled or the thing is handled carefully.

MISS M. LAABS (Seaman Body Corp., Milwaukee, Wis.): We have such a group in Wisconsin. There are 13 editors who belong to it. The reporters come down to our dinners. The editors bring along two or three reporters, and we have a speaker, and in that way we reward our reporters. We don't reward a man if he hands in material, but we penalize him if he doesn't. We have a space for him or his group with a heavy black line. If it is habitual we say, "This space again reserved for the crimp cutting department," or "What is wrong with administrative?" When they see their names, they are going to get after him.

One man took a heavy piece of paper and attached a pencil to it by means of a string and sent it in a Western Union envelope. On the top of the envelope he wrote this, "Expect an answer. Hurry up." Inside, he had a question on the paper, "What news for our next magazine." At the bottom, "This is not to come back blank." He sent out 250. In his plant, he got every one back. Where he didn't have news items, he had cartoons or jokes or ideas for 32 pages. An extra special edition came out of the hurry-up notice. He had 64 pages of extra news. He had said he was going to print every single item. That was one way of doing it. It was tried in another plant. One man got 75 per cent returns.

CHAIRMAN CLOSE: That's interesting. The man who said he would print everything that was turned in had a nerve.

What are you going to do when your plants are two or three hundred miles apart, when you don't come in contact with these correspondents or editors or reporters?

Mr. Kane edits a railroad magazine. He has that problem in a large degree.

C. E. KANE (Illinois Central System, Chicago, Ill.): When the travel is far, it is simply impossible to get the material by personal contact.

CHAIRMAN CLOSE: We are going to pass on to our next question, "How do you get by when you have lots of plants scattered around and can't have the personal contacts?"

ERNEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, O.): We have four or five places to get news from. We have one man, usually the employment manager at that distant plant, who although we don't call him assistant editor, we depend upon to get that material from his plant and forward it to us. He edits it. When I get it, all I have to do is to write a head on it, and maybe cut out a few words here and there, and it is ready for the printer. He serves

the same purpose as either myself or my assistant in the home plant, and the boys all look to him to turn their news in.

CHAIRMAN CLOSE: You've got to have a key man in each of your places to handle it. Now we are going to another question. "Many house organs have a standard make-up for cover, and other changes from month to month. Which way is the better? Is it better to stick to your standard cover or change it right along? I presume those who change it will say it is better to change; those who don't, will say it isn't." Has anyone any thought on that subject? Variety is the spice of life. If you look at anything too constantly, you don't see much after a while.

HARRY A. GROESBECK, JR. (Walker Engraving Co., New York): I should think a part answer is to notice our large magazines. While you may change from month to month, there is always a mark or portion of it that carries along—one name and what goes to make that one name worth while. Take the *American Magazine* or the *Saturday Evening Post*. There might be a drawing there. Peeping through it you will see some of the title, so it is of some benefit to change but always have quite a percentage of your title or magazine or front page cover remain there so it does not lose its identity.

CHAIRMAN CLOSE: I think so. There ought to be enough on the cover to identify it the minute anybody gets it. He knows there is the plant publication again. Certainly that much ought to be done.

MISS RUTH MILLER (W. T. Grant Co., New York City): We have done something like that with our magazine. Our cover is a frame. It might be a picture frame, inside a cut. The cover is arranged in such a way that we can use anything in that frame. I have used photographs of people, cartoons, etc. This time we have used quotations. Fancy type, all sorts of photographs. I have purchased unusually good photographs our own people had painted and mostly the pictures have carried out some special idea. No matter what I have tried to use in that cover, the idea itself fits into the frame, which we have used as our standard.

CHAIRMAN CLOSE: We are going to rush along. "What size type would you recommend for a monthly magazine, 6x9 page size, two columns to the page? Some of our technical fellows what size? Everybody seems to agree on 8 point.

MR. AUGUSTUS: The size of the type should depend upon the width of column. A page 6x9, two columns, not less than 8 point, nor more than 9.

CHAIRMAN CLOSE: "In an effort to make a sheet newsy, how much value do you attach to personal items, anecdotes, jokes, etc., in comparison with such personal items as births, marriages, trips, etc.?" That is an interesting question. How much should you devote, or should you use at all, jokes on the other fellow and these kidding items, etc.? There is no question but that the fellow who gives them to you is tickled. The question is how about the other fellow?

It seems to me you are perfectly within your right to use them if you can keep the sting out of them. You don't want to put anything in your paper that is really going to hurt seriously a man's feelings. You don't want to put something which would embarrass, because the man might want to take the paper home, for example, and his wife is going to see something which she probably never heard about before. To a certain extent, joking items get a good laugh on a fellow, while the boys in the shop are tickled to have it come out in the paper. If it is a friendly sort of thing, he probably gets as much fun as the other fellow.

We use them more or less in our paper in a general way. How many of you use items of that kind?

(About 20.)

How many of you think that items of that kind should be taboo?

(About 7.)

We have a respectable minority who object. Somebody who voted against tell us why.

E. E. CRISWELL (New River Co., Macdonald, W. Va.): I had my hand up in both cases. We use items of that type and we have had, to my knowledge, five fist fights on account of it. That is the chief reason why I am recommending not using them. You say to keep the sting out of those items. It's pretty hard to know when you have the sting out of them. What will ride or sit well with me, won't go well with you. I say you can use those items if you personally know what it is all about, and know the man the joke is on. But if you don't know him and don't know what the joke is and the real point behind it, I think it would be advisable to lay off. When I say we have had several fist fights, I mean it. A couple of correspondents got in bad trouble. So far, I am not in trouble myself.

CHAIRMAN CLOSE: "Which type of employees' publication is the most effective in bringing about friendly relations and better understanding between management and men, the magazine type or the newspaper type?" When we had our regional meeting in St. Louis last spring we had a debate on that subject. We had one man who got out a newspaper type, present a paper on the advantages of that type; then we had a fellow who got out a magazine type, criticize his paper and he presented the advantages of that. We didn't have any formal judges but I would say the bout was more or less of a draw. There is a good deal to be said on both sides. How many of the editors here get out a magazine type?

(About 18.)

How many get out a newspaper type?

(About 8.)

R. G. CONOVER (Yale Towne Mfg. Co., Stamford, Conn.): When you ask about that, what difference will it make? I'm getting out a newspaper type because my management says it must be done. If the editors could go to their management and say that they are convinced from one of our section meetings, offering well-meaning evidence and suggestions, that the magazine is better than the newspaper type, if you convince them it is all right. But suppose you can't?

CHAIRMAN CLOSE: If you can't, you can't.

MR. CONOVER: We might tackle it. If you can show more reasons for the magazine than newspaper, we are going to run a magazine. There may be deeper reasons. It's what the management in my own company says. Some years ago they held several meetings on that subject and it was executively discussed. They concluded they would run the newspaper type. I would have a hard job to have the president and management alter that.

CHAIRMAN CLOSE: In connection with that question, here's another question, "Is it better to get out four pages every two weeks or eight pages once a month?" I think that is more or less involved in the other question. You can get out a newspaper type of magazine twice as often as you can a regular magazine, I suppose, without any greater expense, and I presume that the expense is the big item. What do you think about it?

(Several suggest eight pages once a month.)

LESLIE MARSHALL (Firestone Tire & Rubber Co., Akron, O.): I think the semi-monthly publication is the more valuable for our industry. It brings the facts more quickly to their attention. You can bring them news about births, deaths, etc. They don't get old. Our aim is to get as many names of individuals as possible in our employees' publication. If it goes too long, they lose interest and turn over a picture to you and if they don't see it for two months, they also lose interest. Whereas, with the semi-monthly publication or weekly publication, you have a chance to quicken the interest and to cash in on it.

CHAIRMAN CLOSE: The question of distribution. What is the best way to distribute your paper or magazine? I suppose probably the most common way when

he paper comes out is to have them distributed at the check gate or some place here when you go home. Some are mailed out. Is it better to mail your paper or distribute it at the plant? It is a lot easier to distribute it at the plant.

MR. AUGUSTUS: We have tried both. It is better to mail them out. We have come to that conclusion because of a number of reasons. In the first place, if you put them out at the pay window, as we used to do, we had men coming in on duty and men going off duty at the same time. The fellow who is coming on, took the magazine with him. He went to his locker room, either left it there, laid it down some place and somebody else picked it up, forgot it, or took it out on the job; while the machine was running, and the current on, through the machine the magazine went. Sometimes a two-ton roll has been destroyed that way and damage done to the machine. Is it better to spend \$50 on postage or \$1,000 for damage to paper and machinery?

On the way home, they might stop at a pool room, or see a friend, and leave it here. By mailing them, we get it into the home. We have found out that the wife and family do read the magazine, and if they don't get it they are the first ones to call up and find out what's the matter. By spending \$40 or \$50 a month, we are getting it into the home, and the man can sit in the chair, smoke his pipe, put up his feet and read to his heart's content, and the wife can read it when he gets through with it.

CHAIRMAN CLOSE: Do you have any trouble in getting your list corrected?

MR. AUGUSTUS: Yes, we are starting a new system. Once a month we are going to put a card at the pay window or the day before pay day send it to the foremen, requiring the man to fill in his name and change of address, if any. He must present that at the pay window before he gets his pay check.

CHAIRMAN CLOSE: We had much difficulty keeping addresses up to date, particularly where we have had colored men and foreigners. People of that type move around rapidly. It is impossible to keep track of them. I think that is perhaps the only real serious problem involved in mailing the magazine. I am interested in knowing how many folks mail out their paper.

(About 10.)

E. E. CRISWELL (New River Co., Macdonald, W. Va.): My company operates a number of coal mines. In the gaseous mines our magazines are put out—understand we have a definite date that the magazine comes out—to those people who ask for it, when they check out at the end of the shift. In the non-gaseous, it is put out at the payroll office. They go in and ask for it. Those who ask, get it; if they don't ask, they don't get it. I figure that if they are interested in the magazine, they will ask for it. If we thought nobody reads it, we might as well suspend publication. Therefore, we put it in the hands of those who want it. Those who don't want it, don't get it. We have found a good deal of success in that plan. Practically all of them want it. Most of them ask for it.

A. V. CRAIG (New York City): I have been listening to these very valuable talks. I want to make a motion. Before I do that, I want to commend the excellent talk of Mr. Wilkins. It shows he understands the newspaper field and understands the whole thing clearly. I move, Mr. Chairman, that this body appoint a committee to work out a style book for house organs. Every big newspaper has such a thing, even the Government Printing Office.

When you realize the importance of the work, you will see the need of such a thing. I don't know how many of you people who are editors know what it is to use such a manual, such as newspapers have to do. I think it would be a great help to do such a thing. For instance, the gentleman gave statistics of research which are valuable. Of course, I wouldn't suggest that everything be introduced but you ought to have a book like that which would be a guide to the other people and put your work over more helpfully. That's the motion I make.

CHAIRMAN CLOSE: The motion is that this body appoint a committee to work up a style book, for the publications, and this book would be given to different people in getting out their publications. It is a good thing to put out. Many people, no doubt, need the experiences of others in this field, especially when the responsibility of getting out a publication for which there is a printing bill, a paper bill, etc.

NILS JUELL (Michigan Steel Corp., Detroit, Mich.): I wonder if it wouldn't be better to amend that motion providing you have orders. It would entail quite a cost. As I understand it, it would direct and would permit the committee to go ahead.

CHAIRMAN CLOSE: I might say that this section of the council has no funds of any kind. We don't even have a treasurer. As a matter of fact, the council told us we better not have any money, and we haven't any money. I think this question might very properly be referred to the Executive Committee of the council to see if there isn't a way it can be worked out. If you are in favor of having us do that, will you so signify?

(The motion was seconded and carried.)

I want to read these one or two questions. "How many pages should a publication have before using a cover page?"

(Unanimous reply of audience "Not less than 16.")

CHAIRMAN CLOSE: I think that is the answer. It will take 16 pages to carry a cover. If you get much beyond that, you are a lot better off if you can have a nice cover on it.

Here's another question. "I would like to know of any practical method of keeping or filing photos in such a manner that they may be exposed to view and not damaged, some method that makes them accessible and does not require too much time. Any one any suggestion on a good method or system of filing photos?"

O. D. FREDERICK (Dierks Lumber & Coal Co., De Queen, Arkansas): I had the opportunity to see an example in the Texas Power & Light Company, Dallas. They had a very nice system of filing their photos. They had a card index. The photos were pasted or pinned on this card and if for any reason they want to refer to them they had a key in the index file and no matter what size of the photo, it was put on this card and filed away in this card index system. I thought it was complete.

CHAIRMAN CLOSE: That's interesting. "If your magazine circulates among other than employees (stockholders for instance) and the management insists that you consider them outside readers, in your selection of material, what are you going to do? Are you going to do it or lose your job." Whether you think it is a good thing or not, you will do it.

We will go on to our next subject. We are very glad to have with us here Mr. Harry A. Groesbeck of the Walker Engraving Co., New York.

Getting the Most Out of the Illustration Budget

By HARRY A. GROESBECK, JR.

President and General Manager, Walker Engraving Company, New York City

One must take a rather broad view of a topic like this, for it embraces not only illustrations and pictures, but translates them into printing plates, and finally, deals with the actual printing of them. It may be difficult to believe that different types of illustrations affect the printing process itself, but they do. They affect its appearance, cost, and the returns from the readers, which, after all, represent the objective.

In looking over a number of plant publications, one feels a lack of professionalism and a spirit of uncertainty as to their purpose. Not in all of them, to be

re, but in enough of them to give that reaction. In one magazine evidently tended for internal distribution exclusively, the effort to appeal to the vanity of some employee, whose youngster was pictured, was like the well known arrow which was shot into the air. In another was illustrated a piece of pipe with some fuses wound around it. The heading of the article was on being considerate of one's fellow workers. The two did not hook up together, apparently, until well into the text, where the danger of fuses in that environment was explained. There was no title to the picture, which helped the mystery. One could go on at length with such examples, but these will suffice to bring home the fact that there should be a good and sufficient reason for all illustrations, and that reason should be flashing like an electric sign at night, to catch the eye of the casual reader instantly. If Mr. Jones' little boy needs illustrating, let there be a typical newspaper heading and title to the picture. If fuses are in the wrong place, when posing around a piece of pipe, let there be a "scare head" to the picture. "Dynamite in the wrong place" would at least excite some curiosity.

Just because a plant publication is to be distributed only in the "family" is no reason why it should not have the same reader appeal as a great daily or a broadsheet. Even though this particular reading public be simply employees, they act just the same as those who pay their money and get their publications at the newsstands. It would seem, therefore, that newsstand publications would offer an excellent example to be followed; in fact they should be excelled, because it is human nature to pay more attention to something which has been bought, than that which is given away. "Easy come, easy go" applies to plant publications very decidedly.

One very good reason for taking a "professional" publication as a guide is, that their publishers have all studied the psychology of John T. Public through many generations and his likes and dislikes are catered to with the most discriminating care. Such publications need not wait long in order to learn of their stakes; their paid circulation and their sale of advertising space are indicators of the highest order. True, such publications are supported largely by their sold advertising space; but the advertisers, in turn, are supported by the readers, and complete the circuit, each must get his money's worth. So the editors obtain the best possible reading matter for their particular field; the art department operates with the editors to illustrate the text with an eye appeal equally highbrow or lowbrow, as the case may call for, and the advertising department juggles up to them with "next to reading matter" stuff so that the reader simply cannot escape if he has the slightest potentiality as a purchaser. Even if the so-called "reader" just wants to look at the pictures, he can be snared by a judicious placing of them throughout the text. But the plant publications carry no advertising (and there is no denying the fact that modern advertising is good to look at) so the appeal of both illustrations and text should be even more skilfully handled, if it is to get its message across to its "free list" subscribers.

It is a matter of historical record, that pictures came before alphabets. We are told that pictures speak a universal language, and by a stretch of the imagination, we may believe the old Chinese proverb that "A picture is worth ten thousand words," but it is no mean accomplishment to make pictures carry their message effectively and efficiently. Effectiveness and cost, therefore, may be isolated as the two factors upon which depend the success of the "Illustration Budget."

According to the Dictionary, "Pictures" are "images; works of art; likenesses." As such they stand alone and their value depends upon the skill with which they have been made; humor; historical interest; news value and so forth. It takes a pretty good picture to hold its head up all alone and be worth the space it occupies. Illustrations, on the other hand, are just what their name implies. They illuminate; they explain; they must necessarily be related to the context or

they will become just pictures again and if they were not built to stand that strain they are surely a waste of space.

It would seem, with the foregoing in mind, that pictures and illustrations should have different treatments, in so far as placing and decorations are concerned. The *National Geographic Magazine* and *Collier's Weekly*, represent two extremes in good taste and effectiveness. While the former is severely plain, it is dignified, beautifully executed and replete with "pictures." These really tell their own story and in many instances the legends under them are hardly necessary, save to complete the picture and to attract one to the general text. *Collier's*, on the other hand has few pictures, but many illustrations. They are all by artists of National repute, they have the eye-catching feature which halts the busy individual who "runs and reads," and they too lead one to the text unless one's curiosity is sound asleep. But note the care with which the pages of these two publications are laid out. The effect is not a studied one, yet they each, in their class, represent high spots in editorial and artistic ability and every nickel's worth of value possible, is obtained. There is no evidence of misapplied effort and the outstanding feature is simplicity. There are no disturbing borders, no tricky typographical arrangements, but just enough novelty, either in the pictures and illustrations themselves or in their environment, to give satisfaction to the eye and excite interest in the text which they "illustrate."

When this can be done with plant publications, even though it be in a lesser degree, the money spent will pay larger dividends. Even such trifling details as selecting the high spot in a picture, where the interest is centered, and cutting off all the remainder will prove to be a step in the right direction. This is particularly true of snap shots and other photographs, made under conditions which do not permit of a study in composition. A square inch of interesting detail can be enlarged three or four times in a halftone plate and give ten times the return that would result from the same section, surrounded by packing cases or something equally uninteresting. Emphasis can also be concentrated on a square inch hidden in some picture, by drawing a white line around it. If an air brush artist is available, all the comparatively uninteresting parts of picture can be grayed down to a phantom, leaving the essential feature in full color, yet surrounded with its original environment which may be needed for complete understanding of the subject. Details in planning these apparent trifles work wonders in effectiveness and add little or nothing to the cost.

Borders and decoration always add to the cost and should only be used when there is a definite reason for them. In an obituary a dignified frame acts as a silent tribute; in a page group borders may be used to hold pictures together, but it is well to remember that white paper makes one of the best and least costly borders available.

The size of a picture or illustration is an extremely important factor. It is not good design to crowd a space, but it is equally bad practice to make plates too small. If a picture is of so little importance that it merits a space so small as to destroy its clarity, it is better to leave it out. Small pictures are like small type, they should not be used except in cases of evident necessity.

In publications distributed to employees only, great value can be obtained from pictures and illustrations depicting the work of other departments. In these days of quantity production and highly specialized work, men in one department know only too little about what happens to their product as it passes along in the manufacturing train. In publications sent to consumers, "family stuff" makes a great hit. Intimate views which show how the consumer's interests are safeguarded offer a great selling feature on which the ever ready sales department can capitalize.

In the making of printing plates the way to get the most for the money is to

inate waste of time and material. First, employ the services of a photo-engraver who knows not only his own business but something of yours. Take him your confidence and let him decide your technical problems for you. Introduce him to your printer too, for the engraver's work is not finished until the etched sheets are off the press and if printer and engraver work together, the results cannot help but be improved.

Too many people are studying the photo-engraving business from the wrong point of view. They are burdening themselves and their staff with details of chemistry, optics and physics, which they will seldom be called upon to use in actual practice and at the same time they are overlooking some very essential things which they should master. The user of the photo-engraving process should be fairly conversant with the general principles of photography, especially that part of it which makes halftones and line plates possible. The proportions of copy and how it can be made to fit a given space are among the first things to study and many a plate has been wasted because it was marked to be made a certain size, only to find that it came too high or not high enough.

This is particularly true in grouping, where subjects must fit into borders, and a single step costs real money. A slide rule is not difficult to master and will solve such a problem. If this instrument seems too complicated, there are other methods for accomplishing the same result, which any engraver will gladly demonstrate. The color of a copy is another vital factor to be studied because most commercial photographic emulsions are blind to certain colors and will spring great surprises on the uninitiated.

Next comes the method of stripping negatives together. This is a practice well known to some and intelligently employed, but to others, it is an "Alladin and lamp" method and they just shut their eyes and say "strip this in." Stripping negatives together is merely an assembling operation, exactly like cutting photographs and mounting them together. The substance of the negative film is thinner than a photograph and permits of a neater job than combining the actual copies. It is therefore to be recommended in some instances, but the method does not perform miracles.

When to use the line process and when to use halftones are questions which can be answered readily after a little practice. Photo-engravings are relief plates, produced by protecting certain areas of the metal and etching others until they are deep enough to skip the printing rollers as well as the paper on which the rest of the plate prints. The whole essence of the process is to get the etched parts deep enough for the grade of printing paper to be used. Rough, soft-stock requires more plates than hard, smooth stock, because the plate sinks more deeply into the soft paper. In line work, deep plates cannot be obtained if the lines are too close together as there is insufficient space in which to do the deep etching. In halftones, a screen of suitable coarseness must be selected for the same reason; this is why there are so many different screen meshes from which to choose. With a knowledge of these factors, the choice of the line or the halftone process becomes simple. Line work will reproduce tones, if the tones in the original are composed of isolated areas with spaces between them wide enough to permit suitable depth of etching. If this condition does not exist, then the halftone, with its symmetrical arrangement of dots, must be employed to break up the tone into spots which can be etched to proper depth.

This article does not touch on the technique of photo-engraving more deeply, for to do so it would take upward of fifty thousand words to describe, even briefly, the intricacies of the process. Even were it possible to devote the space to it, the subject would be too complicated for the casual reader. If one wishes to make a study of the process, there are excellent books on the subject, but none will be as much help as a heart to heart talk with an intelligent photo-engraver. To a man, one should turn in his troubles as one would consult a physician.

With a knowledge of how to prepare copy and how to order plates, the requirements for the customer's technical knowledge ends and the remainder of the process should be left to the engraver. Tell him what is wanted, not how to do it, and you will get the most out of your Illustration Budget, so far as photo-engraving is concerned.

MR. GROESBECK: Somebody asked here what is the best way of keeping used engravings or used plates, which you want to use over again, how to keep them from being scratched up, so they won't get lost? If they are blocked or stored on edge rather than flat, they should be kept away from moisture and dampness. Celophane, very thin paper, wrapped around candy boxes, is excellent to protect engravings. They can be wrapped with that whether blocked or unblocked, sealed with sticker tape used in packages and stored away. That celophane also has the advantage of being transparent so you can see what the plate is. The plate should be clean when put away. If there is any ink on it, it will gradually solidify. It will be like enamel to get off. It doesn't harm the plate to be greased. In fact, if there is a little oil on it, it will keep the mixture on it. Air is the worst enemy. It oxidizes the copper and zinc that the plates are made of.

But wrapped up in that way it is not convenient to use celophane. Simply use newspaper, but wrap them to keep them as free from air as possible. If they are blocked, stand them on edge. The celophane is thin and as transparent as glass.

DONALD R. PRATT (Union Carbide Co., New York): My questions are in regard to making an engraving and enlargement from an actual photograph. A great many of the illustrations used in our paper are photos about $2\frac{1}{4} \times 27$ picas wide. We have occasion to use them to widths of 37 picas. We have made a practice of getting an enlarged print of that 5×7 . Just how far can you enlarge from the smaller print?

MR. GROESBECK: It is the same as any other photographic process. We have made plates three and four times the size of the original copy by direct enlargement. That is a matter of mathematics pure and simple. It depends on the focus and the camera, in making enlargements. To enlarge direct from the photograph itself, it is rather hard to get an enlarged print and reduce from that. If the original negative is available when you get an enlarged print your results are pretty good. If you work from a print you have to make a negative, project from that, from that make your half tone. The most direct method is to enlarge from the smaller print, unless it has been retouched, then enlarge it. You magnify the brush marks and that is objectionable. A little bit of Chinese white on the print, when enlarged it comes out larger.

R. G. CONOVER (Yale Towne Mfg. Co., Stamford, Conn.): Before we adjourn, I would like to inquire if we are to have another judges decision on publications this coming year. If a new committee has been appointed to judge the publications for next year and if that committee is willing to do the work, I have no doubt we will have a contest.

I would like to make a motion, in the light of data furnished in those 114 replies to questionnaire that it just take into consideration plant editors and publications of the two lowest classes and judge them additional to their other forms of judging, by the amount of money they have to spend. The lowest class was up to \$1,000. The next class was up to \$5,000, and I would make a motion that the judges be asked to make a decision on those kinds of publications with no larger budget than that, rather than that treating them alike from points of excellence regardless of money to be spent.

CHAIRMAN CLOSE: Is that motion seconded? Of course, at the present time we have three different classes. The third class being the magazines of the type which you speak of. Possibly Mr. Fish who was on the committee last year can tell us whether that was considered this year or not.

T. FISH (*National Safety News*, Chicago, Ill.): We tried to take that into consideration. Of course, we did not know how much money the editor had to do or how much time he had. We couldn't tell whether he was full-time editor or part-time. If you are involved in too many side issues, the job will be so busy that nobody will be willing to undertake it. And after all, according to the scale of points, the appearance is comparatively a small matter. It did influence us unconsciously, although we tried to judge the publications chiefly on their merit and their effectiveness in putting over the message.

CHAIRMAN CLOSE: Does anybody want to second the motion?

R. CONOVER: It seems to me the classification could be made by money expended. Marvelously inexpensive papers don't have a chance against some of the publications where the cost runs \$15,000 or \$20,000 or \$25,000. Some of the publications you don't know about.

W. ASHE (General Electric Co., Pittsfield, Mass.): I was on the judges committee for three years, and I can give my experience. I think the average judge in doing the judging to visualize the conditions under which the editor operated. What I mean by that is, he could take a paper, if he were in earnest about it, whether it was four pages, printed on very simple paper stock or whether it was a very ornate publication such as the Telephone Company's, and he analyzed it and really tried to see whether under the conditions under which the editor operated whether he is putting it over. That is the test of the value of the paper, whether he feels that that paper is doing a real constructive piece of work in the industry and it is going over. In that way, I think, if you try to grade these things on how much the paper costs, you will get into a multiplicity of complications; and if editors don't put any time in; and when you get into many complications, I think the present system of judging is best. If you are going to change it year after year, you are going to lose stability. Anyone who has done much research work in a big organization really knows after you establish something fairly good, you don't change it slowly.

I think that this year the judges went ahead and added a third classification. They made certain modifications in the rating. Looking at that from the standpoint of the judging for three years, I think they have made definite progress. That is the way to go ahead. If after going ahead for four years, you change your basis of method, I think you lose a lot without gaining anything. The point I am trying to make is that the man who is putting out the simplest type of publication is the one who receives careful consideration with the judges. It is a task to judge. I think in my case it took two hours a day for a period of six weeks to judge 250 magazines. It is quite a task because you have to go through every magazine five times. When you do, you have a good idea of what to do.

R. CONOVER: I would like to say one more word. It took quite a long time to do this. After you get it, how are we going to help it if we don't make use of it? The idea is if you take a man who has \$1,000, if he is getting the most out of the \$1,000 in his paper, he might get more if he had a larger amount and good experience and advice. I wouldn't suggest that we curtail or change the method of judging. I was a judge myself for three years, and I know the labor attached to it. This idea is merely supplementary to their other efforts.

NEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, O.): Along the line of Mr. Ashe's suggestion or objection, I don't think if you pass this it should be entirely on the gross cost because you may have a fellow who may have only \$100 to get out 10,000 four page magazines a month. Some of these railroad magazines go to a great number. Take, for instance, the Pennsylvania Railroad Magazine. They get out a newspaper which can't compete with Bell Telephone Magazine. Their budget, so far as unit cost compared with my magazine is concerned, is far less. I have only \$1,600 a month. Now, the total amount of money expended may be as much as they are spending per month, but they are reaching a whole

lot more readers. If you base it on cost, it should be per unit cost per month.

CHAIRMAN CLOSE: Well, I think there are a good many things involved in it. If you are getting out a magazine distributing to 10,000 people and somebody else gets out the same kind distributing to 1,000, the unit cost on the 1,000 fellows will be out of proportion. There are a lot of things involved. I think we might very properly present this angle of the situation to the judges with the recommendation, if you like, that they consider it in their work. I was appointed one of the judges and so I am a little bit hesitant in making any recommendations; but I think perhaps it would be better if they receive the recommendation or a suggestion to consider, rather than to have this body command that they give the matter of expense certain weight because of the fact there are so many items involved in it. I do think it ought to be considered but just such difficulties prevent us from formulating a rule to cover it. I frankly don't see how it can be done.

MR. CONOVER: Suppose we recommend that they consider it.

CHAIRMAN CLOSE: In my capacity, not as chairman but as prospective judge, I would prefer that.

MR. CONOVER: I make the motion that way, that the unit cost be taken into consideration.

(Motion seconded and carried.)

CHAIRMAN CLOSE: I will give the new chairman an opportunity to say a word before we adjourn for the season. Mr. Kane, won't you present yourself.

C. E. KANE (Illinois Central System, Chicago, Ill.): I don't want to delay anybody any more than I have to. I think the session proceeded very nicely under Mr. Close's direction. There is very little that can be changed in the way of improvement. I only hope that everyone who is here today will endeavor to stir up a little more interest among the persons with whom he is acquainted so that next year we will have a turnout bigger than this year. The growth of the section has been very encouraging. I think it is largely due to the excellent *News Letter* that has been put out, and one of the main efforts of the incoming administration will be to foster the *News Letter*, to increase its value to the membership, and if possible to encourage regional meetings, say six months from now so that in every possible way the contacts between the various members of the organization will be maintained, so that we may have discussion such as we have had here today, and which I think is a fine evidence of the possibilities of the organization. I believe that is all I have to announce.

MR. AUGUSTUS: I move that a standing vote of thanks be given to the outgoing officers and members of the committees for the splendid work they have done in the past year.

(Motion seconded and carried.)

ADJOURNMENT

INDEX.

Volume I.

C Session, Minutes, 59-90.
 Mining Committee report, 77.
 Cement Statistics: Cement industry, 792-793.
 Cement industry in "what organized safety work has done for the cement industry" (Posselt), 795-799.
 Instruction section Statistics Committee report (Robinson), 927-928.
 Discussion on man-failure, 1010-1011.
 Kodak Co. in "Solving our most serious problem" (Armstrong), 167.
 Statistics, 175-176.
 "One-man car operation from a safety viewpoint" (Scanlon), 983-985.
 Voltage electrical accidents, 274.
 Massachusetts in "Part mechanical safeguarding plays" (Beyer), 63-64; 66.
 New York State accident statistics, in "Economic value of safety to the contractor" (Hamilton), 923-924.
 "Our most serious problem and how it was solved" (Black), 162-164.
 Status of the chemical industry as revealed by accident experience" (Armstrong), 888.
 Itall, M. J., Associates. In "Our most serious problems and how they were solved" (Lord), 161.
 Costs: "Cost of an accident" (Darling), 158.
 Rome. (See Airports.)
 Dynamics Sessions: Minutes, 423-463.
 Autics. (See Aircraft.)
 "Accidents analysis" (Brown), 756-759.
 Aeronautical lighting as an aid to safety" (Hingsburg), 545-562.
 Aircraft accidents—method of analysis" (Ames), 760-772.
 Airports and airways sessions, 497-542.
 Commercial airplane—structural reliability from the operator's point of view" (Smith), 412-417.
 Communication as an aid to safe flying" (Hunsaker), 579-584.
 Control of aircraft in air transport service" (Fenderson), 659-662.
 Desirable aerodynamic characteristics" (Glemin), 423-435.
 Directional radio as an aid to safe flying" (Bellinger), 564-572.
 Discussion on balloon equipment and personnel in electric storms, 69-705.
 Discussion on Captain Behr's paper (Shoemaker), 478-489.
 Discussion on chrome-molybdenum steel tubing, 418-419.
 Discussion on crystallization of aircraft engines, 662.
 Discussion on engine rating, 460-461.
 Discussion on heating hangars, 663.
 Discussion on ice formation, 419-420.
 Discussion on insulating vibrations from relays, 418.
 Discussion on location of pilot's seat, 417.
 Discussion on paper of Professor Rossly, 686.
 Discussion on parachutes, 741.
 Discussion on Professor Rossly's paper (Woodman), 696-697.
 Discussion on qualifications and licensing of pilots, 645-646.
 General legislation relative to safety" (Macacken, Jr.), 772-777.

"Field service and maintenance of aircraft engines" (Woolson), 456-458.
 "Fire prevention in modern airplanes and recent experimentation" (Echols), 475-477.
 Fire prevention session, 474-495.
