Our studies of accidents from poles falling develop that they most always occur from poles falling while linemen are on them engaged in removing wires or crossarms. The serious aspect of such accidents has long been recognized and the Telegraph Company has for many years issued specific instructions to each

employee on the importance of determining whether or not poles are in a reasonably safe condition before undertaking to climb them.

While it is true that the taking down of poles whether defective or otherwise, is an operation more or less hazardous, local conditions vary so greatly that the method to be followed must generally be left to the foreman in charge of the work. We attempt to meet this situation by having only experienced men in charge of such operations.

It might be expected that experienced linemen would use due caution while engaged in the operation of removing wires or crossarms from poles known to be more or less defective. As a rule poles removed have served a purpose and are not fit to properly carry the load which may be placed on them, but as a matter of fact, we have found that many of our men must be continually warned against following unsafe practices while engaged in dismantling wires or crossarms and we considered it necessary to issue special instructions covering this particular phase of pole work. The slides which will be shown have been taken from our handbook which is placed in the hands of all employees and was issued for the purpose of suggesting safe methods and impressing our linemen with the importance of the general subject.

While the methods followed by the Telegraph Company may not always be applicable to power lines or other classes of pole lines, the general policy of proper inspection of the structures to be climbed; providing the necessary reinforcement when such structures may be found to have insufficient strength; and employees following methods while engaged in work on these structures, which will minimize the liability of personal injury in case of structural failure, we think may be advantageously applied to any type of pole line or aerial wire structure.

There has been an encouraging reduction in the number of accidents from falling poles during the last few years and there has also been a reduction in the seriousness of the accidents which have occurred. We believe the reduction in the number of accidents has been principally due to steps taken to prevent the structure from falling and the seriousness of accidents from educating our men to exercise greater care while engaged in the work of dismantling poles to be removed. We have impressed upon them the importance of giving careful attention to:

1. Properly inspect and test all questionable poles before climbing them.
2. Avoid unnecessary risks of strapping themselves to poles or crossarms with safety straps.

Slide No. 1.—There are two methods of inspecting poles to determine whether they are safe for climbing, one by applying stress against the structure with a pike pole generally known as the pike pole test and the other by examination of the wood with suitable tools.

The picture before you illustrates the application of the pike pole method of testing. This method may be used in testing poles that have no wires on them, and for testing poles that carry wires but are not guyed or braced. (This test is made by pushing the pole across the line and is not dependable if the stress is applied in line with the wires even if they are untied.)

Slide No. 2.—Here we see a dangerous method to follow in removing crossarms from a defective pole. The pole has been tested, found weak and the pikes have been used to strengthen it. The pike poles make the pole reasonably safe for climbing, provided care is used. The use of the safety strap is unnecessary and adds greatly to the danger.

Slide No. 3.—This correct method is comparatively safe and it is not difficult. It should be followed when necessary to remove the bottom crossarms first.

In the next three slides we show correct methods of removing crossarms from a defective pole which has been strengthened starting with the top arm. The

use of rope in lowering arms avoids the danger of the arms falling against one of the pike poles and dislodging it. The work can be performed without undue exertion.

When working on a standing pole without a safety strap a lineman generally works on the "upper side" if the pole leans. If the pole does fall it will generally fall "away" from the lineman and he has a fair chance of escaping serious injury.

Here we see the method in which the lineman shown in the previous picture may follow to protect himself if the pole should fall, being in position to jump just before the pole strikes the ground and probably escape serious injury.

When necessary to remove crossarms from a standing pole the safest and easiest method is to always begin with the top arm if practicable. It may be necessary,

Slide No. 2. A dangerous way to remove cross-arms.

however, because of the position of the wires, etc., to sometimes remove the bottom arm first.

Should the pole break while the lineman is working on it he has a good chance to ride down with the pole and jump before it strikes the ground and probably escape serious injury.

A test inspection does not always disclose a weak condition. Thus we consider it a dangerous method to remove crossarms while strapped to the pole with a safety strap. The use of a strap under such conditions is not only unnecessary but is dangerous, because if the pole should fall the man has little chance of escaping without serious injury.

Slide No. 15.—Here we see a condition which is liable to occur and illustrates the position of a man when a pole to which he is strapped begins to fall "toward" him. When the pole falls "away from" a man strapped to it his position is not

so hazardous as when it falls "toward" him, but his chances of escaping serious injury are very small.

When a pole falls with a lineman strapped to it he has no chance of getting away from it. When a lineman uses a safety strap he generally works on the "under side" if the pole leans. If the pole is defective the lineman's weight may break it when he leans back in his safety belt and thus cause it to fall on him.

CHAIRMAN RUTLAND: Now, gentlemen, I wonder if we might take about ten minutes for any discussion or question you might like to ask or discuss at this time. If you want to anticipate, when you rise please give your name.

H. B. HARMER (Safety Engineer, Philadelphia Electric Company, Philadelphia,

Slide No. 3. Correct method of removing cross-arms from defective pole.

Pa.): I would like to know why it is necessary for poles to fall? Why are there no picks or guards or something of that kind? I would like to know the general practice as a question. It seems to me unnecessary nowadays as to why we should have accidents of poles breaking off.

PHILIP SHATBOLT (Counties Gas and Electric Company, Norristown, Pa.): I want to ask a question along these lines. Is it considered all right by member companies to work on a pole while using a safety? The companies with which I have been associated have spoken strongly against it. We have never had a pole fall. By using the picks we hold it enough so a man can get his guy line fast. After the line is fast it can't come down until loosened and then he can lower the pole in any direction by the use of those lines. I want to ask if member companies as a rule figure it a good practice to work a man without a safety pole?

MR. HARMER: I say it is bad practice. What do you have the safety for? That is why safety is provided to the men and why we ask them to use them.

W. F. NORRIS (American Telephone and Telegraph Company): It is our practice to use the safety strap. We further make a practice after we have secured our pole with picks to guy it with ropes, the idea being that when you take off a cross arm as in the illustration, you are liable to twist your pole and your picks will cut out and we find it very necessary to use the ropes.

MR. MOTT: Mr. Chairman, while the pictures illustrate just what they try to put over, you must be governed by conditions. Take the pole in a field. We assume the wires have all been removed. Why send a man up at all if the pole

Slide No. 15. In this position a man has little chance.

is deteriorated? It is only junk. This idea of testing with a pick pole is an illusion, in my judgment.

Proficient climbers climb a pole where fibres are pretty well down but after they have rattled it and shaken it with a pick pole and climbed half way up it clicks. It might have stood before but it will not stand after. That picture if on the street somewhere, we could understand why you had to dismantle the cross arms but out in the field it is not necessary at all. The rope is the only way to really secure a pole you have to take down. The gentlemen mentioned about the lowering of the pole. A number of years ago we took a line of poles which went over the top of the elevated stations. We removed the cross arms and in those days we had accidents to line men. We don't have the same type today. We dropped the poles right there on Third Avenue between the curb and the elevated railroad. Cut them right down. No picks, no nothing. We blocked off the street while they were dropped. You cannot cover every condition in pictures. The story must go with it more or less.

J. BATES (Pacific Gas and Electric Company, California): Our practice is 18 inches below the ground line and test with the swinging bar. The pole is then picked until such time as they can guy it with ropes. As far as working without a safety belt, that is the only rule which we have which carries a specific discipline. A man who works in an elevated position in the company without the use of a safety belt is immediately discharged and the dropping of poles is a very bad practice.

S. M. HOUTER (National Electric Power Company, Asbury Park, N. J.): It is customary when we set poles to concrete the pole. We leave no space for a man to test the pole. I would like to know if you know of any filler we could put in between the sidewalks and the pole, a distance of, say, four inches that could be taken out or the kind of material you could put a bar through to test the pole. Could you tell me how to handle this situation?

MR. WARE (Public Service Electric Light and Gas Company, Newark, N. J.): We have practically the same problem and we are now endeavoring to develop a creosote wooden block shaped so they will keep it in position and a man can remove wood blocks with a bar with a lock on it. We are trying to develop it with a key so that an authorized person only can get at it. We expect to get something on that in the next few months.

I would like to say in regard to pole accidents, one of the most important parts is to maintain the pole in safe condition. That calls for a system of inspection of poles which we have been carrying out for the past ten years. We don't have such conditions arise as illustrated by the pictures. Where poles and cross arms are removed, where we find a pole defective, we never send a man up on the pole. It must be replaced. Of course, when the new pole is erected, the first thing that is done is to see that the old pole is lashed to it at the top. That is the first step and after that it is safe for a man to climb it and work on it. To our mind that is one of the most important questions facing the utility company.

I would like to put another question regarding men getting electric shock while working on poles. We have been using a standard 14 inch rubber glove and still have accidents. The men received shock because of the gauntlet. We are endeavoring to get a longer rubber glove or a short sleeve that will overlap the gauntlet and extend to a point just above the elbow. We have succeeded in getting such a sleeve and are using it. A manufacturing concern is furnishing us with a small supply of 19 inch rubber gloves. I wonder whether other companies are finding a need for rubber gloves?

E. S. HOFFMAN (Jersey Power Company): We have found out that the longer cuff is uncomfortable. We do have a rubber sleeve that fits over the glove up to the shoulder and where it is necessary to use a rubber protection we find the men are more apt to use these.

CHAIRMAN RUTLAND: I don't think we will have much time left to continue the discussion of this particular subject. There may be some other subjects. I think they have covered the pole situation pretty well and I think the gentleman who asked the question in regard to the gloves has received his answers.

MR. HOFFMAN: Sometimes we have several jobs where it is necessary to install boxes of sand. Sometimes we go around and find tools, waste and materials in the sand. Sometimes the sand becomes moist. I have heard that some people put a piece of paper in the sand bucket and the sand is kept dry and if anybody places anything in the bucket the paper is broken.

CHAIRMAN RUTLAND: Can anyone answer that question specifically? I mean without much discussion? I suggest that you write the Council and let them look it up for you.

E. J. KREH (Duquesne Light Company, Pittsburgh, Pa.): I find there are a

great number of companies whose men contract poison ivy. They find they can prevent poisoning by ivy if the men cover their hands, but after the blisters have been raised they want to know how to reduce and cut out the painful itching and other irritations. Is there anything that can be used.

DR. WIENER (Eastern New York Power Company): We are not troubled in this country so much as in the tropics. They have found a remedy, powdered quinine. The quinine tablet contains two or three grains of quinine and the rest is saccharine, but the powdered quinine is rubbed right over.

CHAIRMAN RUTLAND: I am sure he has the authority to give the correct answer.

MR. HARMER: Another remedy is that available to all of us. We recognize poison ivy. We know it. As soon as you see that you have it, wash your hands in the commonest kind of soap you can get and you will not get poison ivy. If you clean your hands you don't have any poison ivy. Common ordinary soap is sufficient to kill all of that oil that comes off the poison leaf.

MR. OLSCHESKY, JR.: We have recommended a common, ordinary laundry soap. Work up in the hands a good lather. Five or six times this should be done. If it is not gone then, the doctor is the next best fellow.

DR. WIENER (Eastern New York Power Company): If a man has exposed himself to poisonous plants, if he feels it and there is not already the stage of itching and inflammation because of the blister, it is all right to wash your hands in tough soap, the tougher the better; but the question is, suppose the man is already poisoned? As a preventative, the idea of using a tough soap is excellent but after it is there, that is different.

H. F. WEBB (General Safety Division, West Penn Power Company, Pittsburgh, Pa.): I have three questions. Probably the members might be interested. Number one: What protection do you give your men handling creosoted poles, and when they become poisoned what do you use at that time? Number two: What protection do you put around the steel legs of your towers, preventing children from climbing and at the same time facilitate or allow your workmen to climb when necessary to do some work on them? Number three: What hand protection do you give your workmen when they are called to clean highway lighting globes to prevent severe lacerations, knowing that leather gloves get wet or slimy, or canvas gloves too bulky? If you use a thin rubber glove the glass will cut through. If you use a canvas glove the glass will cut through.

L. E. DICKINSON (Pacific Gas Company, California): One ounce of epsom salt and one pint of water, to treat creosote poisoning, applied externally, of course.

DR. WIENER (Eastern New York Power Company): We have had in the last few weeks a number of creosote burns. They are quite a problem. So much so that we have written to the American Medical Association asking their opinion; and the reply was received that the best preventative is to cover the exposed parts with an anti-fibrous grease. We have now in the market an excellent ointment. I am not advertising this at all. It is a remarkable thing. As soon as you apply it, it seems to have an anesthetic property and a definite pain is quickly relieved and it is healing. It is merely an application of this once or twice a day.

MR. KREH: About two years ago a row of linemen were all burnt with creosote. The foreman used Unguentine and had good results and we are using it and we have not had a creosote burn for two or three years.

MR. WEBB: I learned only yesterday that one of the exhibitors is preparing something. I think it was called Iscopilen made by the U. S. Alcohol Company. I am sorry I have not got the name straight. It was claimed to be a positive cure.

CHAIRMAN RUTLAND: That covers the question of creosote. The other question was a means of preventing children from climbing steel tower structures. Who will answer that?

PHILIP SHATBOLT (Counties Gas and Electric Company, Norristown, Pa.): We are using an angle arm and extending it three feet beyond the tower legs. That is covered with a wire netting and strips of barbed wire and at the leg there is a trap door cut in to hold it and hold the leg so when the man has occasion to go away he can lock it and the trap door will fall down through the side and after they are through it can be closed and locked. We had very little trouble.

MR. HARMER: Is that a general practice or an isolated one?

MR. SHATBOLT: We are using that on all the towers on which we are fitting guards.

CHAIRMAN RUTLAND: The next question was the manner of handling street lighting globes. What method of protection to the hands?

MR. KREH: We insist that all of our employees, when descending a pole, must have rubber and leather gloves on. That includes our trimmers and cleaners in street lighting work. For some time they objected and thought it could not be done. For the past three years all our trimmers and cleaners have been using both leather and rubber gloves in their daily work.

L. E. DICKINSON (Pacific Gas Company, California): I would like to see statistics published in such a fashion that various utilities can compare them by department, not by company or not after a fashion as printed last year.

CHAIRMAN RUTLAND: Is your particular company keeping statistics by department?

MR. DICKINSON: Yes.

CHAIRMAN RUTLAND: Well, if they are all doing it, it will be all right, but if not, it will be a double job. There are not a great many companies who keep them by departments. I know that Mr. Burns had that question before.

MR. DICKINSON: It seems to me they could differentiate between the electric department, gas, office, construction, and water department, instead of publishing it as statistics for the whole company.

MR. HARMER: It would be a good idea to have the records that way. Generally, statistics have never been compiled that way but I think as a departmental activity, the comparison of records between departments have a great deal to do in helping your problem.

CHAIRMAN RUTLAND: Let me suggest that those companies who are not keeping their records by department, give this question some thought. It might be very helpful and it might be an additional step in securing statistics from companies by department for the general committees. You will find that helpful.

CHAIRMAN RUTLAND: As your retiring chairman I have appreciated very deeply the responsibility resting on myself in the preparation of the programs, in the correspondence and publications of *News Letters*, posters, amusements and various other work. I appreciate it more because I realize that you gentlemen come here for something to eat, for material to take home to work with, looking for new tools. It has been our intense effort to get the best we could for you. I hope you enjoyed the session, the discussions we had, the talks made. As I have served this year as your chairman and coming in contact with the Executive Committee as I have, it has given me a little broader outlook on life and it makes me love these men more who have worked with us and who have had experience in accident prevention work. I hope I won't now lose the contact I have had in the last four or five years. I have enjoyed it. It made our safety department for the company I represent. It will yours. I am very happy to have served as your chairman.

I am glad we have a man coming in who is fully capable and who will take

the reins and carry them still further and expand the activities of this Section even beyond a dream that might have been made several years ago. Now I want to take this time to have a word or two from the incoming chairman.

H. F. Webb (General Safety Division, West Penn Power Company, Pittsburgh, Pa.): Last year during my attendance at the Congress I heard the story of a town in Texas which was going through a young riot and in order to get assistance to squash the riot, they called upon the Texas rangers, and a body of men went to the train to meet this troop of rangers. When the train pulled in one man stepped off and the town spokesman said, "Where is the rest of your gang?" and the ranger looked at the body of men and said, "Is there more than one riot?"

It is clear in my opinion that all Texans are born leaders and judging from the past leadership of Carl Rutland, we know we have had a successful year in

so far as public utilities is concerned. Carl is a leader and he can get more work out of a body of men with less effort than any man I know. In addition to that, because he comes from Texas, Carl is a square shooter. He is an enthusiast, particularly a safety enthusiast and worker, and in addition to that Carl Rutland is my friend. I think we ought to all stand and offer a vote of thanks for the past.

Now for the untiring work that Carl Rutland has given during the past year.

I have also heard it said that the way to make a speech is to stand up, talk up and shut up. That is my motto. Nevertheless I want to tell you a story that Charlie Schwab told about a New York girl that he brought to his mansion in Pennsylvania to act as a personal maid to Mrs. Schwab. She was beautiful and one of the farmer boys who worked about his estate became very much in love and they decided to get married. They talked it over with the Schwabs and they decided to hold a real wedding in the mansion and give them a real start. Of course prior to the wedding they were prompted and told just what to do and how to behave and the wedding took place and a great many notables were

there. Everything went smooth and fine. Later all the male guests gathered around the beautiful bride to kiss her. Mr. Schwab noticed that the new groom was ill at ease. He was putting his hands in his pockets and standing around and Schwab walked up and said, "John, everyone has greeted the bride but you. What is the trouble?" He immediately saw his mistake and rushed up to the bride and shook hands with her and said, "I'm pleased to meet you."

Gentlemen, that is the way I feel. Many of you know me and I am glad to say I know you. I hope we will have a successful year. This is a great year for politics. I was reading *Safety Engineering* the other day. It said: "Some of us may be Republican and some of us may be Democratic and we may argue about the different points of the different parties, but where it pertains to accident prevention, there can be no argument." So I am mighty glad I have been elected to this great national party "Safety" and I assure you I will do everything I can to promote the activities of this wonderful section. It is amazing the way the Public Utilities Section has grown in the past years and I realize the responsibility thrust upon me.

I don't think I could hardly get away with it if it were not for this wonderful group of accident prevention specialists who are going to support and back me through this entire year.

It is always customary for the incoming chairman to ask for cooperation. I am not going to ask for it that way. I will say that actions speak louder than words. I am reminded by the poster that if we put our shoulders to the wheel, we will all be assured another successful year in fighting public utilities interests.

CHAIRMAN RUTLAND: There will be a general round table discussion at two o'clock this afternoon in this room. Fortunately the chairman of that Section is our own good George Opp, who achieved high fame last night when you heard his name read as Vice-Chairman in charge of Local Councils. He is a night and day man. George last year was chairman of our Section and has been a member of the Executive Committee now for three years. As I said, last night he was elected Vice-Chairman in charge of Local Council because they need such a leader as George is, and now next year there will be a marked increase in their activity.

Our meeting is just about to close and we are reaching a climax but we are going to be sent away with a good message. George Opp will speak. I take great pleasure in introducing Mr. Opp.

And Now What Are We Going to Do About It?

By GEORGE OPP

Safety Engineer, The Detroit Edison Company, Detroit, Mich.

A Congress of this kind is generally words, words, words. We hear what has been done. We hear of plans that are being made. We start home feeling inspired for at least a short time but getting home we are tired and the spell of inspiration dies down and sometimes nothing results.

Today is a day of questions. Questions on every hand, whether social, political or otherwise. Time was a few years ago when everything was an exclamation—Oh! How wonderful! Well! But today it is a question. What is it? How does it work? Why? Who? What? The question today is a matter of our own personal interest in taking back from this Congress some of the good derived from the splendid program set up for our benefit. I want to commend those responsible for the Section's fine program they set up, beginning with "First Principles" presented in that wonderful talk by Dr. Grafflin, getting back to the fundamentals of

all things, safety included, then carrying on with definite and concrete illustrations of various aspects of splendid safety work and winding up this morning with an opportunity to take the burden off your own chest by asking what you might do about some of your problems. Questions! Questions of all kinds!

What Are We Going to Do?

Now for the answer to what are we going to do about it all? We feel we have accomplished something and have just pride in feeling so. The presentation of trophies at yesterday's luncheon is illustrative of the work that can be done by real, intensive, safety effort. Two of the three prizes awarded went to companies belonging to an organization that has been real intensive in safety work and in that respect the wards indicate what can be done by making our efforts all the

more intensive for the future. But let us not stop there. Let us not merely set up records of our own. Let us not be selfish and keep our safety efforts within the walls of our own plants or restricted to work along our own lines. Spread it out to include the community, to include the State and national organizations wherever we may come in contact with them in order to make our own Public Utilities Section more effective.

How can the Public Utilities Section do a bigger, broader job in organized safety? Can we not stimulate an interest in safety among the companies we serve, the many small plants where organized accident prevention has a big field for improving our national accident record—not too good by and large the country over. Can we not stimulate interest in public safety in the schools and on the part of public officials in the communities we serve. No danger of a power probe into that activity either.

I would ask you to give serious thought to the question of having a full time consultant attached to the Public Utilities Section. One who can visit all of us

occasionally, help us in our problems; give concrete, expert advice when needed for intensifying systematic safety service.

Then take the matter of getting the contact with your own local community councils. Show them that you can stimulate their interest, that you will back them. Tie in with them, because they can help you.

It is all of these things that are needed to hang up an even better record than in the past. Let's not forget there are even better marks to shoot at. We must realize that we have a whole lot more to do than what has already been done.

Two railroads of this nation (two leading railroads) by reason of the interest stimulated by the National Safety Council contest, stand to save no less than one hundred ten lives of employees alone on the basis of the records they have set up to the first of October of this year. The Cement Association has member plants who have achieved marvelous results. Think of it! One of their plants, employing over a thousand men, went one year without a lost time accident. Then, not satisfied with that record, they came back a second and a third year with clean records. That's a real record! There are any number of records we might refer to. All ought to stimulate and urge us to renewed effort. Let us not feel content. As Kettering of the General Motors says: "When you are satisfied with yourself, the concrete in your brain has set."

The job of safety is not done—will NEVER be done. It is deserving and clamorous of our best efforts to keep going and even when the Angel Gabriel sounds his trumpet on Judgment Day we will have to rush up and yell: "Hey, Gabe, our safety work is not yet done."

How are we going to tackle it best and hardest? That is for *each* of us to solve.

As the sun came up this morning, I saw the various architectural beauties in New York City's landscape. Some wonderful, some big and massive; others, sharp spires, piercing the blue atmosphere of the sky. Each of them built according to the design of their own builder. That is the way Safety needs to be done. Build on your own plans, wherever you are, down to your own local conditions, but upward all of the time.

Now it is a fact that the viewpoint of safety workers has had to be changed. We did not have as wide a vision ten or fifteen years ago. That vision has gradually broadened and then suddenly opened to a wonderful vista of possibilities undreamed of in the earlier days. At that early time it was considered merely as a garden plot and practicing Safety in those days meant going out and plucking a weed of indifference or a sprout of carelessness out of the garden, so as to permit the full fruition of the garden. Since then this plot, due to the wonderful metropolitan development attendant upon industrial progress, has become the center of a great big city. It becomes a building site. And its full utilization is now required. We set steam shovels digging deep, deep; taking out the muck of carelessness and quicksand of indifference. We put down our caissons to the solid bedrock of common sense and build upon it the foundations to support a big building. Along comes the steel industry and supplies the frame-work of the superstructure with their wonderful accident record; the cement industry furnishes more "building material" in the substance of the splendid record set up in that industry. Many industries are contributing to building "Safety" but there is still much to be done before that structure of ideals is completed. We, the Utilities, are asked to take our part in the final building. What are *we* going to do about it? This building of our conception of Safety shows progress commensurate with our application of hard and persistent work. We go forward—we cannot stop or step back.

This has been a wonderful Congress; a marvel of inspiration, sincere attention on the part of the audience and conscientious effort on the part of the speakers. It stands as a peer of accomplishment and without a peer in the history of the

National Safety Council. It is outstanding as the greatest "gathering of the clan" of safety the world has ever witnessed—and comes as the finale of a year of the most dynamic effort in behalf of a full and complete program of accident prevention everywhere—in the shops of industries, on the lines of railroads and utilities, in the schools, on the streets and highways and developing at last in the homes, quite generally. Let us go back seriously to our jobs, feeling the inspiration of the "spark" that comes from this yearly contact and be ready to do our share. Let ours be a more systematic safety job. Intensify effort and magnify responsibility. When local and regional Congresses are called, let us put our shoulders to the wheel and see that they are made successful. Participate in all forward-marching activities of our section, help to generate that invincible interest in our work to tide us over until we get together again next year, each of us bringing, I trust, a record of even better accomplishments than we were able to tell, some with justifiable pride, this year.

Now, what are *we* going to do about it? That depends on your answer to the corollary question: What are *You* going to do about it? You answer, each of you, for yourselves.

ADJOURNMENT

Joint Luncheon Public Utilities and Electric Railway Sections

October 3, 1928

T. G. BRABSTON, Chairman
Superintendent of Transportation, Birmingham Electric Company
Birmingham, Ala.

The joint luncheon session of the Public Utilities and Electric Railway Sections at the Seventeenth Annual Safety Congress, was called to order at one-thirty o'clock by the chairman, T. G. Brabston, Superintendent of Transportation, Birmingham Electric Company, Birmingham, Alabama.

CHAIRMAN BRABSTON: Gentlemen, we are going to be very happy at this time. We are going to be entertained by some gentlemen representing the world's greatest railroad.

(A quartet representing the Pennsylvania Railroad rendered four compositions.)

CHAIRMAN BRABSTON: I am sure we all realize now after hearing these songs, why the Pennsylvania Railroad is so distinguished for its courteous and efficient service, and I am sure I reflect your sentiment when I say to this quartet that we are greatly appreciative for their contribution.

We have at this time a rather interesting event on the program. There is constantly a rivalry between departments and companies in establishing successful records. And that reminds me of the man that came up to my town from somewhere, and said to the waiter who was a darky, "If you will wait on us now satisfactorily I will reward you with the proper sort of tip. By the way, I have never been down here before, what is the average tip?" "Well, boss, ah'll tell yo', the average tip hits a dollar." "That is perfectly all right. You wait on us properly and I will give you an average tip." When he got through, the darky asked if the service was all right and the man said "Yes," and handed him a dollar. The darky said "I thank you. I have been working here close on to three yeahs and you am the first man what come up to the average."

We have 23 companies here who have a distinction that have certainly come up to the average. There are three trophies which are to be awarded to those companies who have established themselves in having records worthy of recognition and outstanding in the industry, and the first of these is presented by Mr. Floyd W. Parsons, Editorial Director, Gas-Age Record, New York City. I think it is a wonderful incentive and spirit that has prompted the offer of this trophy. At this time it is my pleasure to present Mr. Parsons who will make this presentation on behalf of that publication.

Presentation of Trophy

By FLOYD W. PARSONS
Editorial Director, "Gas-Age Record," New York City

In the words of the horsethief who was about to be hung and asked to speak on that occasion, I am the one most interested in this part of the performance and the least enthusiastic about it. If any of you play golf and play a blind hole and the caddy says, "It is just over the hill," and you shoot over and you find the ball is way off—that is just about the position that I am in today. First I did not believe

I could use my vocal chords. We editors dictate from seven to ten hours a day. We really work, and so I only expected to say a word.

I understand it is intended that I speak for just a few moments and then present this trophy. I visited a throat man this morning, so after leaving the throat man I went down to see my dentist and he put something in my mouth. He said, "What can you do for fifteen minutes?" I said, "If you will give me that package I will write a speech that I am going to make in about thirty minutes." So I did that. I have never been to one of your meetings. I have written stories and syndicated them and put some in the Saturday Evening Post and helped the movement along as best I could.

My experience with accidents started when I was six. They were building a new jail in our town. They left one of the cells outside. I was the prisoner. I had to escape. I fell off and cut my head and still have the scar. Later I jumped on a freight train and was thrown between the platforms of two cars; and the wheels went around and knocked me around until twenty cars had passed. I was still alive. That gave me a positive indication that there must be a good God that saves us. Later, I was a mining engineer and I went in with twenty-seven men to try to rescue a lot of men caught in the drainage. We organized our party and three came out. The other twenty-four came out some days later pretty stiff and dead—so that I have some acquaintance with what accident prevention means. When I first went into the mines in 1902 we shoved off and lit gas feeders and then took our coats and beat them out. That was when we talked about safety lamps, so that I have seen the development of industry, of accident prevention, for twenty-five years or more and have carried my little part in this movement in an editorial way in the big magazines.

There was a timid old lady who went to cross a ferry, and after starting she became a bit nervous and said to the darky boatman, "Has anybody ever been lost in crossing here?" The darky replied, "No ma'am, no ma'am; my brother was drowned last week but we found him the next day." So it is almost entirely a question of the point of view.

Today we are bothered with a lot of bunk and half truths. "Did you know that Harry made \$5,000 a week," said Abe to Solomon. "I don't believe it" said Solomon. Abe said "I will prove it. Did not Harry make \$5,000 in Washington?" "Yes, that is right" said Solomon "but wrong in four places. First, it was not Washington, it was Cincinnati. Second, he did not make it in a week but in a year. Third, it was not \$5,000 it was \$500; and fourth, he did not win it, he lost it."

Today we are perjuring in industry and life generally and we get a number of falsities. We believe guinea-pigs come from Guinea; lead pencils have lead in them; the staff of life is bread, the worst thing that nine out of ten can get; and that fish is brain food, but it is nothing of the kind. That the ocean is flat—nothing of the sort; it is a gently sloping hill. We take histories and fill them with exaggerated tales about the early hero. If you will examine our forefathers and what they did you will find they were a pretty tough bunch. Tremendous changes come along and cause great hazards to arise. We are always fooling with things we know little about. Radium has killed a lot of people. Radium, which you read about, is doing a lot of damage. The aeroplane—all these and other new things—are taking toll in life, but that is the only way we can improve life and relieve the over-carrying of the burdens that we shouldered under the old methods. The automobile is a great thing but the carbon monoxide from them as they roll along the streets goes into the lower parts of buildings, up the stairs and in the remote office and helps to give us a new problem in polluted atmosphere. Accidents,—the kind of taxi drivers we have—and that reminds me of a story.

A lady got into a taxi and told the man where she wanted to go. The taxi started off with a terrible jerk and the driver dodged everything on the road. When she arrived at her destination and wanted to get out she said, "This is the first time I ever rode in a taxicab and it is terrible." "That's nothing" said the driver; "this is the first time I ever drove one."

People who invest their monies in companies do not see the reports of minor accidents that cause delay and loss of time and reduction in production. The general plan we have in facing life is filled with so many inconsistencies. We go to an extreme in saving along one line and wasting along the other. That reminds me of the ducky who was going fishing, and he met an older boy along the road and he said, "What's the matter with your cheek, it's all swelled up? What have you got in your mouth?" "Well," replied the little ducky, "I'm going fishing." "Well, what have you got in your mouth?" "Worms!" The old boy said "Worms? Why don't you put them in your pocket?" "Put them in my pocket? Do you think I'm going to put them in my pocket with my lunch?"

Gases have quite a black eye. In fact the gas industry which has just awakened is about to play a dirty trick upon a lot of people who want an easy way to get out of the world. We are well along in our research to make it impossible to commit suicide with gas in comfort. The research men tell us they are well on with the experiment and when you try to take a little gas to end it all you get so damn sick before you die that your purpose is entirely defeated. Also we find that our ordinary radium gas fire is the nearest thing to sunlight. There is quite a craze around about ultra violet light. If you don't get it you can't absorb phosphorus in your system. We also have discovered that in our ordinary radium fire we have ultra violet rays. The use of gas will become more prevalent because fellows will strip off nowadays and the rest of the family get the ultra violet ray for nothing. It shows how things are changing nowadays but there are new days coming on.

The utilities, I will say, have gone a long way. One hundred thirteen units were in the contest just held this year and these employed 72,000 men. Out of the 113, 93 made complete returns. Fourteen of these units came through this contest without a single lost time accident, and when you consider that the accidents in the gas industry extend from traffic conditions to fitting and on through all of the other operations of building, chemical departments and all, that is really quite some record. In this contest the unit of the Southwestern Gas and Electric Company, the unit situated in Dallas, Texas, has won first honors. They employ 105 men and they worked 181,710 man-hours, and I want to present this cup to Mr. J. Allen Read, Safety Director of this particular company. Is Mr. Read here?

Accepting First Honors

J. ALLEN READ (Safety Director, Southwestern Gas and Electric Company, Dallas, Texas): The Chairman tells me to make my remarks snappy so I am going to. This is, indeed, a surprise to me. I have not even seen our last month's report. I thought it was hopeless. I felt that the small gas portion of our company had no chance at all. I want to thank the *Gas-Age Record* for this cup and thank the section; and I am sure we will duplicate this record not only when we have a contest but also when we have not.

I want to pay a little tribute to the company that won this cup. This was not won by any individual. It was won by every employee of the Southwestern Gas and Electric Company. They operate in some 80 or 90 towns from Mississippi to Arkansas and from Mississippi to Texas. Three hundred fifty to 400 employees have just completed a year with but one lost time accident, and that happened when a negro boy threw a stone in one of the fellow's eyes. This is only the gas section but all our sections are endeavoring to prevent accidents. I thank all of you. I am just so surprised and thrilled that I can't say anything.

CHAIRMAN BRABSTON: That is fine. At this time we are going to have the presentation to this other group who have so singularly distinguished themselves. Mr. Ernest W. Beck, Vice-President of the National Safety Council, will now make his presentation.

Presentation of Trophies

By ERNEST W. BECK

Vice-President, National Safety Council; U. S. Rubber Company,
New York City

Mr. Chairman, I feel very much out of place here, not being affiliated with a public utility. I am pleased however to come here and encourage the proposition of a no-accident contest. The previous speaker who presented the trophy spoke of the number of contestants. I noticed one or two gentlemen making a few notes regarding the number of units without a lost time accident. I want you to know that improvement as a result of this no-accident contest is equal to 280 per cent. In other words, the persons employed to no lost time accidents were 37 to 1, compared with the record of two years ago of 12 to 1. That is wonderful.

I have been quite tied up with these contests because I am convinced that this element has accomplished a great deal. I say that from experience. My company has shown an improvement each year for the last five years over the average of the last three years. These things don't just happen. The gentleman when he accepted that trophy gave credit to where it belonged—each and every one of the organization. He knows and I know that there must be somebody at the top who is giving the contest his approval, who is approving the expense account, making out the budget, believing it is good from a financial point of view and an humanitarian point of view. The expense is infinitesimal with the enormous savings it represents.

Your contest was started in March 1928 and was operated six months and showed the good results. You have six groups, gas, electricity, combination of gas and electricity, telephone, telegraph and water. I am surprised you did not get enough in your water group to contest for a cup, especially under the Eighteenth Amendment. You, have, however, been successful in getting 113. I believe you can get more and in another year the National Safety Council will be able to report many more in the contest, and the reason is because of the success this contest has had.

Any man who turns down a sound no-accident proposition I cannot understand. He cannot be sold on safety. It is a very, very essential part of a properly organized safety program. I have been asked to present this trophy to the group known as the electric group. In this group there were seven companies who operated without lost time accidents. Competition must have been very keen. That is a wonderful record. Is Mr. Watts in the room? Mr. Watts, in behalf of the National Safety Council, it gives me great pleasure to present this trophy and I hope you and your organization will be successful in winning another next year.

Acceptance by the Electric Group

MR. WATTS (Southern, O. Pub. Service Co., Zanesville, Ohio): When an occasion like this arises, a fellow is more or less swept off his feet. We did not, until a few minutes ago, know we won it. I suppose you men want to know where Zanesville, Ohio, is located. It is midway between Columbus and Wheeling, West Virginia. Our company employs something like 135 employees actually engaged in the manufacture and distribution of electric energy. We have found by experience that the safety director cannot sit behind his desk and preach safety. He must

get out on the firing line. As late as last Saturday we had occasion to put in a two and three quarter mile emergency line and had to employ something like 35 men. I took it upon myself to go with them to see that they got by with it. I want to take this occasion on behalf of my company and myself to thank the National Safety Council for this trophy.

MR. BECK: The losers win. I know of no factory, even if they showed red figures but what have felt that they really were better off than if they had not joined so I am going to mention as honorable the others who have operated without lost time accidents: San Antonio Public Service Company, Citizens Gas and Electric Company, Wisconsin Electric Company, Superior Water Works, and Wisconsin Power Company.

Our next group is combination gas and electric. It is a large group and the plant winning a prize is a plant working a large number of man-hours. The winner of the combination gas and electric group is the Lake Superior District Power Company, at Ashland, Wisconsin. They serve 36 companies in Michigan and Wisconsin, having a total population of 65,000 members. All companies are rendering electric service and one town served with gas and one town operates street railways. We are extremely fortunate today in having the vice-president and general manager of that organization with us. I have checked up on him and I have a wonderful record of the work he has been doing for safety. I know he must have it. You must meet the man and talk with him and you will know that he is a safety enthusiast. He is here today and it is a pleasure to have him with us. I will now present the trophy to Mr. G. W. Hodgkins.

Speaking for the Gas and Electric Group

G. W. HODGKINS (Vice-President and General Manager, Lake Superior District Power Company, Ashland, Wisconsin): Mr. Chairman, gentlemen: I am a long way from home and I want to tell you where I come from so you will live with me for a few moments in my home.

A year ago I was at a meeting and the gentleman that introduced me said that we build only nine hole golf courses in our section of the country because the summers are so short we cannot get all the way round the course. We live on Lake Superior at the western end. I have heard your safety directors talk. I have heard the men most interested expound their different ideas on safety practice but I am convinced of one thing and that is that first there must be some background to tie to. I know it is easy to issue bulletins for boards and put up your safety signs on your boards around your plants but I also know this: You men all know Abe Lincoln. You probably have all heard the story of the time Staunton wanted to do something and Lincoln said not to do it and the men went back to Lincoln and reported Staunton as having said "Lincoln's a damn fool" and Lincoln said "Staunton's usually right." You understand that Lincoln was President of the United States. A man whose every wish, every order, could have been fulfilled. Yet, he said, "Staunton is usually right."

From that attitude of mind, Lincoln developed a personal following from his bitterest enemies until today he comes to us through history almost a Christ.

In any industry you have got to develop the thing that Lincoln developed to achieve the highest degree of work, whether it be safety work or some other kind of work in your organization and when I say that, I don't mean loyalty to me—I mean loyalty to every man who has men responsible to him and men that look to him for their welfare.

If I were to wish for success, the greatest success that could come to me, it would be to have the feeling that the men who work under me believe in me and I want the men who are responsible to me to have the whole work under them of

the men responsible to them believe in them because nothing in the world runs as counterfeit as insincerity.

You can follow out a set of rules and orders because they are given you. The men that work for you know as well as you when the men to whom you are responsible are insincere. Men get wrought up and some one will criticise some man in his organization, but this is also true. You can criticise the men in your own organization but when it comes from somebody outside or somebody above in your organization you know that you will fight for every man in it who is depending on you for his welfare.

I spoke of Lincoln. It was my good fortune to be in Washington when Colonel Lindbergh came home, and I would not have missed that trip. I would not have missed seeing the things I did see for anything. I sometimes wish that some of the people back home who are sending some of the representatives down to Washington could go down and see some of the things that I saw.

You know that this country was not built in a minute or a day. It meant the sacrifice of years and sacrifice on the part of the greatest men of the nation, and that is what we mean when we talk about patriotism. You can't expect a man to come to this country off a boat and understand all the pictures that have gone before, pictures that our native born American can absorb. Yes, I went down to see the Statue of Liberty. It stands, a metal piece, and perhaps to some people it means just that. To me it meant more than that. It meant that the time of discord with France was over and we have an anchor out in the harbor, a present made to us by France; and those of us here and those of us there know what the Statue of Liberty stands for.

Gentlemen, I only cite these historical things to have you believe that the thing which will make industry prosper, which will make safety work more effective, is the loyalty which is born of association, respect and regard for the men you work for and with, and success can only come in that way.

I don't take any personal credit for this wonderful trophy I am taking home with me, and a few moments ago as they were singing their song, I wished it were possible for those back home, all of them who are associated with me, to be here today to get some of the inspiration that I will fail to take back.

You know the public utilities today are occupying so much of newspaper space. I wonder sometimes if the men who are writing these articles know men in utility business. Sometimes I doubt that they do because as I go around the country and look into the faces of such as are gathered here today, I don't believe it is possible for us to be such a damnable lot as some of the newspapers represent us to be. We all have to work. I don't believe any other industry furnishes men who are more sincerely and conscientiously trying to do the thing they should do, more than the men in the utility industry.

I want to add this, Gentlemen: I believe it was just our good fortune to have first prize. I don't believe we did any more than other organizations represented here today. We have all sincerely tried to do our best. Next year it will be some other company and I will be just as glad for you as I am for our own company.

As I go about the country I have pride in knowing the men engaged in the industry. I think this is true: generally speaking, we go back to the question of loyalty and I think the companies that have the least turnover have the greatest loyalty, and the companies that have the greatest loyalty have the fewest accidents; and I believe, the companies that have the fewest accidents have the best records in earnings.

Our Safety Director, Mr. Jule, gave me some records of accidents but I won't take up your time with those.

We should develop a sense of responsibility and gather about us younger men. It has been my good fortune to be associated with a company small enough so that I know the men.

Many of the boys are sons of fathers who are either on pension or are getting old. If there is any one accomplishment that I feel more proud of than any other, it is the fact that I have been able to gather about me young men whom I have known all my life and who have known me all their lives. We work together and it is just as easy to get into my office as it is to get into any other office on my property.

I am going home to my property with a thrill that comes to an organization in a thing of this kind. I want Mr. Jule to stand on his feet to show you the man on the property. He has not taken the prize himself but has been with the men throughout the territory. Mr. Jule!

(Mr. Jule stood up for a second.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Quarry Section

New Section Officers

General Chairman—R. E. COLVILLE, United States Gypsum Company, Chicago, Ill.
Vice-Chairman and Chairman Engineering Committee—F. F. McLAUGHLIN, Rock Cut Stone Company, Syracuse, N. Y.
Secretary and News Letter Editor—J. R. BOYD, National Crushed Stone Association, Washington, D. C.
Poster Committee Chairman—H. F. YOTTER, The General Crushed Stone Company, Easton, Pa.
Membership Committee Chairman—D. C. SOUDER, The France Stone Company, Toledo, Ohio.
Statistics Committee Chairman—W. W. ADAMS, United States Bureau of Mines, Washington, D. C.
Executive Committee: THE OFFICERS AND
A. J. R. CURTIS, Portland Cement Association, Chicago, Ill.
N. S. GREENSFELDER, Hercules Powder Company, Wilmington, Del.
OTHO M. GRAVES, The General Crushed Stone Company, Easton, Pa.
WARREN HAYES, National Slate Association, Philadelphia, Pa.
V. P. AHEARN, National Sand and Gravel Association, Washington, D. C.

Retiring Officers

Chairman, D. C. SOUDER, The France Stone Company, Toledo, Ohio; *Vice-Chairman*, R. E. COLVILLE, United States Gypsum Company, Chicago, Ill.; *Secretary*, J. R. BOYD, National Crushed Stone Association, Washington, D. C.; *Poster and Slide Committee Chairman*, FRED E. HATFIELD, Indiana Limestone Company, Bedford, Ind.; *Membership Committee Chairman*, C. ZIOLKOWSKI, United States Gypsum Company, Chicago, Ill.; *Publicity Committee Chairman*, NATHAN C. ROCKWOOD, Rock Products, Chicago, Ill.; *Engineering Committee Chairman*, R. E. COLVILLE, United States Gypsum Company, Chicago, Ill.; *Statistics Committee Chairman*, W. W. ADAMS, United States Bureau of Mines, Washington, D. C.; *News Letter Editor*, D. B. BUETTNER, JR., The France Stone Company, Toledo, Ohio. *Executive Committee: THE OFFICERS AND* A. J. R. CURTIS, Portland Cement Association, Chicago, Ill.; N. S. GREENSFELDER, Hercules Powder Company, Wilmington, Del.; H. F. YOTTER, The General Crushed Stone Company, Easton, Pa.; E. D. SHERIDAN, Chico Stone Products Company, Dallas, Texas.

October 2, 1928

D. C. SOUDER, Chairman

Director, Insurance and Safety, France Stone Co., Toledo, O.

The first session of the Quarry Section at the Seventeenth Annual Safety Congress was called to order at ten o'clock by the chairman, D. C. Souder, France Stone Company, Toledo, Ohio.

CHAIRMAN SOUDER: As Chairman of the Quarry Section, I am reporting on the activities of the past year.

One of the important moves that have been made is the completion of a Safe Practice Pamphlet for the quarry industry. That pamphlet has been put up in pretty fair shape by our vice-chairman, Mr. Colville, and we anticipate completion by the first of the year. He has to secure some more information from some of these quarries of the General Crushed Stone Company which have gone for 18 months without an accident. He has been getting most of his dope from the quarries that have had too many accidents.

As for the activities of the Quarry Section, that is about the extent of our year's work.

I am now asked to present to the members Mr. John Rice, president of the General Crushed Stone Company, who has devoted the better part of his life to the crushed stone industry; and previous to that time was affiliated with the stone industry. It was one of Mr. Rice's plants that secured the trophy presented by the National Crushed Stone Association for the best record during the year 1927. This plant, I am told, has an average employment of about 75, and is a producer of crushed stone products. In addition to proceeding for 12 months they, I understand, had a straight run of 18 months, approximately, without a lost time accident, then had one lost time accident, and have now gone about 6 months without a lost time accident.

I take great pleasure in introducing Mr. Rice.

What Safety Means to a Quarry Executive

By JOHN RICE

President, General Crushed Stone Company, Easton, Pa.

I am going to talk to you very informally without burdening you with a lot of statistics, first because they are uninteresting, and second because the General Crushed Stone Company with which I am connected has not been practicing scientific safety methods long enough to make comparison with past performance illuminating.

Perhaps my personal experience outlining the gradual evolution of thought about safety is quite typical of the growth of the movement among executives and students of human engineering generally, and this is my excuse for using it as the basis of this address.

There was a marked contrast in the relationship of the employer and employee during the past (let us say) seventy years with the antecedent time. In the early days before the time of large corporations employers were individuals or partners directing a comparatively few men. Prior to the Civil War much of the work was done by slaves and bond servants. The more intimate contacts and simpler character of the service performed together with the fewer number of individuals involved in the first instance and the self-interest inherent in slaves and bond servants in the second instance did result in some personal interest in the welfare of labor.

However, with the growth of corporations, with no personal contacts between executives and large aggregations of labor, with the introduction of machinery, with the opportunity to replace the waste due to accidents, sickness and death from emigration and from a prolific native stock, with the fierce struggle of pioneering business enterprises for financial success regardless of ways and means, little heed was given to the welfare of employees from a humanitarian standpoint and no conception of the waste from an economic one.

My personal executive experience covers a period somewhat over forty years.

The first ten years was for the most part devoted to general contracting and I was in quite close contact with my men. I was not by nature very hard hearted and had an emotional sensitiveness to human suffering, but I can not recall that I had any great concern about my men's welfare or safety and certainly no well defined policy or principle concerning it. Employers liability insurance covered the risk and that was all there was to it.

During this period, however, I became aware of the instinctive willingness of men to risk life and limb, when by reason of some accident or other untoward circumstances, structures, machinery or property of any kind were in jeopardy, by rushing to its rescue regardless of the danger. It was also quite obvious that men often took unnecessary, perhaps reckless risks, in the regular course of their work to expedite its accomplishment which otherwise would frequently have added to the cost of same. What I am emphasizing here is not my approval or admiration of such conduct but the evidence of men's willing cooperation notwithstanding the danger and resulting physical penalties.

Under the then existing law, drawn largely in the interest of the employer, the defense of contributory negligence and the act of a fellow workman were usually adequate to deprive a workman of any redress for accidents sustained by him.

In view of my observations just presented this seemed a rank injustice and led me and my associates to abandon the carrying of liability insurance when in connection with a contract for ballasting the Lehigh Valley Railroad, we entered into the crushed stone business about thirty years ago. We set up a reserve approximately equal to the insurance premiums and paid the men from this reserve for their expenses and lost time resulting from accidents on the theory that a business ought to be charged with this expense and not the men themselves. Parenthetically, this was of course the grounds for the passage of the later Workmen's Compensation Acts.

Whether as the result of this policy of intended justice and fairness or not, it is interesting to note that we have never had but one lawsuit with any of our employees as the result of an accident and that one we won.

As a further evidence of added and growing interest in our men some ten years ago, we inaugurated a profit sharing system through which our men ratably benefit in our success.

Moved by a continued regard for the well being of our men, a few years ago we effected a plan of group insurance carrying from \$500 to \$1500 per capita according to a wage classification and paid for by the Company, further increased by a plan which is partly paid for by the men themselves. This group insurance now amounts to nearly \$1,000,000.

The purpose of reciting these acts of modest generosity or enlightened selfishness as they may appear is not to exploit our virtues but to point out that notwithstanding a fairly well advanced theory of the relationship of employer to employee during all these thirty years, not until within the last three or four, did we even give any study or analysis to a definite policy of systematic safety from a humane or economic standpoint. We really gave little thought as to how and why accidents might and should be avoided. It was to the persistent efforts of those interested in the National Safety Council which awakened our vision to the fact that we were overlooking a matter of great importance which was doubtless quickened by our recent adoption of the plan of self-insurance instead of through the various insurance companies otherwise required by law.

We began a thorough study and research in this movement with the result that we formed a definite organization charged with the responsibility of carrying these theories into practice.

This plan consists of a general committee made up of the executives and assistants in the main office together with a new officer entitled Supervisor of Insurance and Safety. At each plant is established a committee with the superin-

tendent as chairman. These plant committees meet frequently to confer with the main office committee and also locally to discuss practices and plans. At some plants they meet in the evening to avoid distraction by their current duties, being allowed their regular hourly rate of pay as though at their regular jobs. This has the effect of making the men take the purpose more seriously and thoughtfully.

Of course, one of the greatest difficulties is impressing the men with the seriousness and importance of the work. Their first reaction is that they can take care of themselves and resent the suggestion of a nurse's solicitude for their welfare. Upstanding two-fisted men like to take a chance, they like the dramatic, the sensational and as I have already observed there is an instinctive impulse to do the helpful thing regardless of danger to themselves.

However, the appeal to them that the idea is not born of a maudlin sentimentalism, but on the one hand to avoid suffering and loss to them and their families and on the other hand the loss to the company through the displacement of a skilled or trained employee, the direct expense of the accident through compensation and the indirect loss due to stoppage of work and demoralization of other employees.

One method of arousing and holding the interest of the men is posting on a conspicuous bulletin board the striking posters of the National Safety Council. In order to further attract the men to these posters we have subscribed to a news service which gives the latest information as to events most likely to interest men of our class, similarly posted on the bulletin board. By their inspection of the lessons borne home to them by these posters, they are influenced by the injunction of the Pennsylvania Supreme Court to "Stop-Look-Listen."

It is but a step to further impress upon the employees the necessity and desirability of prevention of accidents to machinery and property as well as to the life and limb.

The constant dwelling by the committees on all phases of these questions develops in them secondary ideas such as neatness, order and forethought. It results in a place for every thing and every thing in its place. As leaders learn, others follow. The best way to learn is to teach.

Neatness reduces fire hazards by the practice of gathering up inflammable material and having a safe place to dispose of it. Cleanliness of machinery often discloses latent weaknesses which otherwise is only ascertained by a breakdown.

A questionnaire to our superintendents as to the effect of the movement, discloses in their judgment a distinct improvement in the morale of their men, a greater interest in their work and many resulting economies.

As one of them expressed it, they have all come to realize that a trained man on the pay roll was a lot more valuable than on a compensation list.

There is a growing and increasing belief by the men that the company is really interested in their welfare, not sentimentally or piously but sensibly and wisely.

It is interesting to note that in the Safety competition inaugurated by *The Explosives Engineer* under the auspices of the United States Bureau of Mines for such quarries in the membership of the National Crushed Stone Association as entered the contest, our White Haven plant won that trophy for 1927, not having had a lost time accident for eighteen months. Our Winchester plant during July had only forty-five minutes lost time as the result of accidents of any nature whatever, men or machinery which is an admirable record in our experience.

I can not reduce to dollars the resultant benefits of this intensive safety movement on our part but I believe it is no exaggeration to say it has effected a saving of ten per cent in our operating expenses and thirty per cent in our accident expense.

The movement is humane, economical and profoundly wise from any point of view and speaks well for the vision, labor and persistence of those pioneers of the National Safety Council in so earnestly keeping at it until it has become impressed upon most executives as a necessity to industrial progress.

fact, I don't know of any case where it has been done that way. I don't think that that is always the way to approach safety in any aspect, whether it be goggles or any other line of work.

The work which I have done on the Technical Committee of the Bureau of Standards in Washington has put me in contact with many different types of goggles. And about the first thing I would say is—fit the man with goggles. It is very important that the goggles be comfortable; and that comfort may be influenced by the length of his eyelashes, the width of his temples, the distance between his ears and eyes, if he uses the temple type, or simply the fact that you have given him goggles with the head band tightened up. The goggles should be fitted to the man. If you use the eye cup type of goggle, which I believe is the type best fitted to quarry conditions, give it to the man with the head band relaxed, and he will tighten it himself to the right tension so that it will not hurt him; and the result is that it is comfortable.

A great deal of trouble is experienced with men who think they can't see through goggles, that they must be able to see through the side of their screen in some way. Those of us who wear glasses know that if you want to see something you turn your head and look at it. And after a man has worn goggles for a period of, say, a week, he becomes used to them and will forget about those side screens.

And another thing which I am glad to have a chance to present to you is that you men in a leadership capacity should wear goggles when you go on the job in places where you expect your men to wear goggles. Your eyes are just as valuable to your company. Therefore, as protection to your eyes you should wear goggles; and also as an example to your men you should wear goggles; as a representative of your company's policy, you should wear goggles.

Now if you are going to go out and wear goggles you want to put on those goggles a preparation which is variously known as "Anti-Sweat Pencil," "No-Mist," or "No-Sweat"; it is all the same, a glycerine soap. Rub it on the goggles, on the inside and on the outside. Rub it off dry with a clean rag and the goggles will not mist up for a period of four to five hours under ordinary circumstances. If you are a man who perspires very freely, you may need a sweatband to keep the perspiration from running down inside the goggles. But that is the exception and can be determined by examination of the men.

Another important thing is to see how good your men's eyesight is. Men have accidents due to defects in vision, which they do not suspect. In my own case I qualified as a sharpshooter and thought I could see pretty well; I took the examination as locomotive fireman and the examiner told me that I would have to have glasses. And the same way with some of your men, perhaps they need glasses and don't know it. If they do, they should have prescription goggles. That may sound like a lot of expense. I don't say that all of your men need prescription goggles. The definite work they do will determine whether it is logical for them to have prescription goggles or not. I have a pair which I have used for years, and they have saved my eyes.

The chairman spoke of a pair of goggles being brought in with just so much left of them. If that goggle was broken in the prevention of an accident, certainly you can afford to buy that man another pair of goggles. It has probably paid for all the goggles you have in your plant; and I know of many cases where that has happened.

I had a personal experience, occurring in my railroad connection, where I went into a shop and found a man working under a car with his goggles over his forehead; they were not protecting his eyes, and I told the foreman I thought he ought to have them on. The foreman told him to put them on and he did so. As a result of that visit he was wearing them two weeks later when his goggles were struck by a flying rivet and the lens broken. And I got a very nice letter

telling me that while my name didn't appear in the report which was the basis of a safety bulletin throughout the shops and later throughout the entire Pennsylvania System, that I had saved that man's eye. That satisfaction will never be taken away from me, and I am going to tell everybody I know about it, because if you ever have the same experience, it will pay you in things you can't measure in dollars and cents.

J. R. DAVIS (U. S. Gypsum Co., Chicago, Ill.): I want to say that I agree with everything Mr. Chapin has said, but I also agree with what Mr. Souder has said. I have fitted men with prescription goggles and I have worn goggles out about the plant as an example, and I find that sort of work and that sort of approach to the problem will probably touch 90 per cent of your men. But the other ten per cent are not touched that way, and it takes a little of the old strong arm discipline, the method Mr. Souder mentioned, to make those fellows understand that they must wear goggles.

R. P. BLAKE (Independence Bureau, Philadelphia, Pa.): I view accident prevention work as you would view any major activity in your business. Now the plant executive, giving any orders to any of his men, covering any of their ordinary work, if he found any man persistently refused to obey those orders he wouldn't think of anything but firing him. You can persuade 90 or 95 per cent of your men to obey reasonable safety requirements, but the other five per cent require strong arm methods. I think many people fail in thinking that they should never use discipline in safety.

R. E. COLVILLE (U. S. Gypsum Company, Chicago, Ill.): There is only one point that I want to add to this, and that is about that brought out by Mr. Blake. He mentions any reasonable suggestion or requirement, and that is very important. We have had men come into our plants, so-called safety engineers, who want every man in the quarry to wear goggles, and that may not sound extreme, but in some cases it is. So don't ask a man to do something that is unreasonable and not necessary. We want to prevent every accident which we can conceive of, but we don't want to waste their time or ruin our chances of their cooperation. So be reasonable. Tell them only what they need to do, and then force it through with a little strong arm stuff, if it is necessary.

Safety Success Comes from Organized Effort

N. S. GREENSFELDER (Hercules Powder Co., Wilmington, Delaware): One thing that has impressed me in my observations, particularly in connection with the national safety competition which started about four or five years ago and is conducted now by the U. S. Bureau of Mines, is that success in safety is largely the result of organized effort. Mr. Rice said that the organized effort in his company is something of comparatively recent date, and I think in the crushed stone industry in general the organized effort is a number of years behind that in other industries. But if you will examine the records in the Bureau of Mines, reports on the national safety competition, you will see that without exception the companies that are making the best records are those who have been well organized on safety for a number of years, and in practically all industries these belong to industries with associations that have been thoroughly organized on safety.

Take the Portland Cement Association, which perhaps comes nearest to this industry in the type of its operations. I think you are all familiar with what they have done in their organization. It seems to me that the safety work is the thing they devote most of their attention to. It is the thing that the man on the outside hears most about. During this last year they have been holding safety meetings in all parts of the country where there are cement quarries, and I have attended some of them. I am sure they are productive of a lot of good. That is one evidence of what they are doing in an organized way.

Recently I received a letter from your chairman, stating his opinion that the crushed stone industry should have some one who was devoting at least a part of his time to safety matters, and to my mind that would be one way of increasing the results that have already been started. Because it takes some one to direct the organized effort in the crushed stone industry. We have a few companies that are outstanding examples of it—Mr. Rice's company and Mr. Souder's company, and some others, that are really well organized. But I think the majority of the quarries need a little string and stimulation, somebody telling them and showing them how to do these things to get results throughout the entire industry. I believe such a step would be well worth while.

MR. COLVILLE: Just in that connection, Mr. Greenfielder, it is planned next year that the Quarry Section will have a very close tie-up with these various associations, the State Association, the Tile Association, the Sand and Gravel and Crushed Stone. Mr. Boyd is secretary of the Quarry Section and secretary of the National Crushed Stone Association, and that is a mighty fine thought. I think that in the past the Quarry Section has not given individual attention to the divisions of the quarry industry, and that is one thing we want to try and work out.

CHAIRMAN SOUDER: What is the John T. Dyer Quarry Co. doing in this accident prevention?

Reducing the Total of Lost Time

H. H. ESCHELMAN (John T. Dyer Quarry Co., Norristown, Pa.): I believe we have reduced our accidents somewhat in the past two years. In 1927 we had 41 accidents and two compensation cases—that is, those were lost time accidents. In 1928 so far we have had 22 accidents, and two lost time accidents; out of that, 22 were minor accidents, eye cases. But since we started goggles, in 1927 we had 142 minor eye cases and in 1928, we had 22; we lay that to goggles. Other than that I think our safety organization is getting along well there and doing good work.

CHAIRMAN SOUDER: How do you do it?

MR. ESCHELMAN: We give each and every man a pair of glasses or goggles whether he wants them or not. When he is hired he gets a pair of goggles. Some of them carry them in their pockets, some of them wear them, but they carry them at all times. If they are moving around from place to place, on windy days—that is our worst condition, blowing dust and chips and so forth—they wear the goggles. Other days it isn't necessary to wear them. We don't have to force them when they need to wear them; they seem to take right to it.

DR. E. M. PARLETT (Pittsburgh Limestone Co., Newcastle, Pa.): One manner of educating the men to wear goggles is to make up a photographic bulletin of every pair of goggles that has been fractured on the job. We do that, and at the end of the year we make a composite photograph of all those men, giving their names and the plant in which they work. This, of course, is posted on the bulletin boards around the respective plants. Now, for instance, last year there were 26 eyes saved, and here are the names. These bulletins stay up for a period of three weeks, and then are put up again at the expiration of three months. I don't think anything in the world has such a personal appeal as a bulletin of photographs of that sort. Everybody at the plant knows this particular man, and they talk it over with him, and I think it makes a wonderful exhibit. We don't have the slightest trouble in getting our men to wear goggles.

QUESTION: Do you do that only as regards eye accidents?

DR. PARLETT: No, we show the right and the wrong way as regards other accidents, as well, but the eye problem is handled in this manner. All of our men wear goggles around their necks all the time.

W. C. BRYANT (Hartford Accident & Indemnity Company, Hartford, Conn.): It might be interesting to know that I had a test made of goggles in three quarries, covered by our company, just recently, and in two of the quarries they selected a cup type of goggle, and in the third quarry, where they employ about 75 men in the quarry alone, they tested it out with five or six men, and the test is now going on, and those five or six men selected a sandre goggle. Now in the other two quarries they have selected the cup goggle, and they have been ordered, and in one of these quarries they are asking for the goggles, wanting to know when they are going to get them.

The Group Accident and Sickness Plan

MR. COLVILLE: Did you fellows ever see the operation of a group of accident and sickness insurance plan? The way it works out is something like this—when you try to show the advantages to your men there are always a lot who don't believe in insurance; their fathers never had any so they don't want it. But you get a lot of them to enter into it and there are a few left. If you wait a month or so until the cold weather sets in and a few fellows get colds or appendicitis, or are off from work, where there is a group accident or sickness plan in force, then you ought to see the fellows climb on the band wagon. When they see the benefits of the plan they want to be in on it.

Now the same thing is true with Dr. Parlett's thought on goggles, I think. A lot of this is in selling your stuff. You are talking to a bunch of men who have to be sold on this idea. You may sell them in various ways, through appealing to their emotions or possibly through fear of discharge, but anyhow you have got a message and a sale to make.

Now the easiest way that we get our thoughts is through our eyes. I don't know the percentage, but a large percentage of what we learn is through our eyes; a small percentage is through our ears and the rest through other senses. So I think this is a splendid thought you have got there, Doctor, and why not give it a little publicity? I think Dr. Parlett's idea can well be adopted by all of us. It is not expensive to do that; you can do it by drawings or get a snapshot of the man and place it on your bulletin board; but make use of it. There is no use of having accident statistics unless you use them, and I commend that to every man here.

Absence of Goggles Cost an Accident

C. L. HAAS (Coplay Cement Co., Coplay, Pa.): I have been safety manager of our plant for the past two years. Last year we had a little argument on glasses. It was on a riveting job. The rivet heater thought he would do a favor for the bucker-up and try to see if this rivet was up. He looked up and received a scale in his eye, coming from the rivet. And as a result we had quite an argument over the men in the air not wearing goggles. I would like to know if any member here can give me some information about that, when the men are working in the air and are rather nervous about wearing goggles.

CHAIRMAN SOUDER: On the answer to that question, we will give you boys a chance to think it over, and will go on to the next speaker. Now our next speaker has been very faithful to the Quarry Section. He at one time was working in the largest lime plant in the world, at Genoa, Ohio. He took an active part in the welfare of his men and was picked at that plant to lead the men in safety. From that step, he is now Assistant to the Vice President, in Charge of Operations, of the U. S. Gypsum Company. I now take pleasure in introducing Mr. J. R. Davis, of the U. S. Gypsum Company.

Practical Accident Prevention

By J. R. DAVIS

Assistant to Vice President in Charge of Operations,
United States Gypsum Company, Chicago

Last year at the A. B. C. session of the National Safety Congress, which many of you doubtless attended, Mr. Colville, manager of the insurance department of our company, read a letter written by Mr. Knode, our vice-president, announcing a new plan of accident prevention. The plan was, in substance, that the United States Gypsum Company would cut the red tape of accident prevention; that we would stop *asking* our men to work safely, and *demand* that they work safely; or in other words, that we would become "hard boiled" in the matter of safety.

The reaction to this letter, by those attending the A. B. C. session, was varied. One or two of those present reacted favorably, but the majority felt that the plan was too drastic to achieve the results desired. The plan, however, was put into effect; and today I want to discuss the reasoning that led to its adoption, in the hope that our experience may be of benefit to others who find themselves in a similar situation.

A year and a half ago the United States Gypsum Company was practicing all the conventional ideas of accident prevention. We had safety-committees, gave safety prizes, gave safety dinners, conducted no-accident campaigns, held safety rallies, etc. Despite these efforts we were confronted with steadily mounting accident costs, and an alarming list of fatalities. Mr. Knode, our vice-president, was the only one among us who saw clearly the cause and the remedy, and it was his clarity of vision that developed the plan announced at the A. B. C. meeting last Autumn.

This plan has produced results; and I expect as I have said, to show you that sound reasoning led to its adoption, and that, in our case at least, the decision to adopt it was the right one.

Accident Prevention Like Life

Accident prevention, looked at in one way, is like life. Some succeed in life; others do not. Some succeed in preventing accidents; others do not. The sound preparation for success in life is education, acquired either in institutions of higher learning or in the school of experience. Education by itself does not bring success. But education, plus application, plus the desire for success, inevitably brings success. The same chain, education, effort and desire, prevents accidents. In other words, education as to the causes of accidents and the manner in which accidents can be avoided, plus the application of that education, plus the desire to avoid accidents, brings success in accident prevention.

It appears to us of the United States Gypsum Company that the greater part of the safety work we have done in the past has been educational. Now we are applying the education. And we make the utilization of the education compulsory. No longer do we tell employees that they *should* wear goggles, or that they *should* shut down machinery that is to be oiled, because education and experience have taught them that these things *should* be done. We tell employees that they *must* wear goggles, and that they *must* shut down machinery that is to be oiled; that if they fail to do these things their jobs will be in jeopardy.

And to some of you here today that attitude may seem an about-face from me, for a year ago I told you that safety primarily is a sales problem, that the idea of safety must be *sold* to employees. I still believe that the idea of

safety must be sold or, in other words, I believe that employees must be educated to the importance of safety. Our experience, however, indicated that education reached 90 to 95 per cent of the men and was voluntarily accepted by them, but it was the other 5 or 10 per cent who simply would not accept it that was ruining our accident record and raising our costs. For this reason we changed our policy to one of compulsion and demand that they apply their knowledge of safety or suffer the consequences.

Application of a Common Principle

The statements I have made may sound radical. Actually they are not. All of you gentlemen apply the principle described in your everyday affairs. Experience has taught you, for example, that a crusher must be started before rock is fed into it. Suppose one of your workmen dumped rock into a crusher and then tried to start it. The result would be one or two hours of operating time lost, due to the necessity of cleaning out the plug-up. What would you do to such a man? You would reprimand him or fire him on the spot.

Suppose again that you had planned a shot in your quarry, and had left instructions as to how the shot should be loaded. Suppose the shot to be a failure that delayed operations and piled up expense. In investigating the cause of the poor shot you find that it had been loaded contrary to your instructions, because some person thought it didn't make much difference how the charge was placed. What would happen to that person? He'd be severely reprimanded or fired; and neither reprimand or discharge would strike you as particularly radical.

But if some workman violates a safety rule, and is laid off, or fired, in consequence, the action is considered radical, or "hard boiled." Why should it be? It is no more than the application of the same discipline to the matter of safety as is applied to costs, quality and numbers of other things connected with manufacturing. You discharge a workman who wastes your money or time. Certainly a careless workman wastes both. And certainly a workman discharged for violating a safety rule is an example to other workmen.

Now let's see if comparable discipline is applied in your own home—and applied to a problem of domestic safety. The example I am to cite will not be within the personal experience of all of you gentlemen, but it will be near enough to personal experience to bring home my point.

Let's say each of you lives near a river; and let's say that each of you has a small son. The river you regard as dangerous. The son you regard as precious. On a certain night the young man comes home with wet hair. You ask him how he got his hair wet. He tries to evade a direct answer, but you finally drag out of him the confession that he has been swimming in the river. Immediately you are alarmed for his safety. By reason and persuasion you attempt to convince him that the river is dangerous, and that he should not go swimming in it again. A week passes, and again you discover your son with wet hair, and again he confesses, reluctantly, that he has been swimming in the river. You repeat your arguments; he promises to respect your wishes. Another week passes, and once more you find the boy with wet hair, and once more you extract the confession that he has been swimming in the river. What do you do? Do you again reason with the boy. Hardly. Convinced that reason and persuasion are of no service, you take the boy to the wood shed; and there you discipline him—with a strap.

Are you acting differently then, than we act when we discharge a man who violates a rule of safety? Are you dispensing a different brand of justice?

After all, accident prevention simply is good business, as discipline is good business. And the plant wherein discipline is maintained not only will be a safe plant, so far as accidents are concerned, but in virtually every instance will be a plant

wherein manufacturing costs are low, quality is high, and "housekeeping" is efficient.

What Are Accident Costs?

Webster defines mining as "the art of extracting ore from the ground at a profit." Quarrying is open pit mining. If we are good miners, market conditions being favorable, we make a profit, largely by keeping our costs down. Accidents are an item of cost; and if we attempt to operate without an accurate knowledge of cost of accidents, we fail, in part, at our jobs.

But what are accident costs? Are they solely the money paid in premiums for compensation insurance? We don't think so. In our case we compute costs of accidents, not only by the premiums we pay, but by money spent on hospital bills, doctor bills and compensation actually paid to the injured man or his family. These figures we compare with our past costs in the same manner that we compare operating expenses and profits with the past. And it was this comparison of accident costs, on the basis just described, that led us to abandon the more sentimental policy of accident prevention by wheedling and persuasion, and to substitute for it the clean-cut policy of individual responsibility of each workman to observe the safety rules that we make.

And I might point out, that if you find compensation rates high, the best way to force them lower is to reduce the number of accidents in your plants.

Results of the New Plan

As I have already said, the plan of making the individual workman responsible for his own safety has been in operation for approximately a year. You want to know the results, of course. Before I give them to you, however, I am going to read to you a letter, written by one of our works managers who was quick to grasp the significance of the plan. This man has had much experience in mill operation and his point of view is more practical than literary. So disregard an occasional violation of the rules of syntax and grammar; and heed the meat of his remarks. Here is what he said:

"I have your letter setting forth our safety record for the year to date. This report is disheartening, and after all you have done to promote safety, the facts must be a keen disappointment to you....

"I have read the letter many times, and in the following letter I have tried to analyze it from two view points. Though I may not have succeeded in my analysis, I have, at least, set forth my true thoughts, and expressed my attitude.

"Under the present plan we try to promote safety by appealing to our workmen, the strongest note in this appeal being that we are seeking safety for them. We invite them to serve on our safety committees, ask their advice as to how we can better conditions, try by means of bulletins, movies, literature, and 'silver-tongued' orators to show them the errors of their ways, and the heart breaks, wants, and suffering that is caused by accidents.

"We make personal appeals to our workmen, begging them for the sake of their loved ones to work carefully and not get hurt, and as a net result of the time and money spent we have a mounting accident cost, and workmen whom we have not only failed to convince that safety paid dividends, but that we were even sincere in our purpose.

"Now, it is very evident that we have failed. Why? I can only give my opinion, and that is, that there has been too much division of authority, or rather, no authority, and too many uninterested men on our safety committees.

"The plant managers put safety work up to safety supervisors, who pass it on to the different committees and foremen. The safety supervisors have their routine inspections and meetings, and consider the work done when they have

turned in the regular number of suggestions concerning guards and defective equipment, should they be able to know what defective equipment was.

"These reports are all nicely typewritten, and presented to the works managers. And as there are a lot of them, and as he has a number of trusted employees on the committees, he assumes that his plant is as safe as a nursery, and that all his employees are true disciples of safety. Then there is an accident, but no one is to blame. The required number of men have been on the committees. The inspections have all been made on the day and date set. Meetings have all been called to order at the specified time. The minutes and records are all complete. The safety supervisors have done their duty in a routine manner, and have complied with all rules as set forth in the safety bulletin governing the plant safety organization. This done, why should they be to blame for an accident. They all are sorry of course, and express their sympathy in different ways. By sending flowers, or, if necessary, by taking up a collection. This done, their interest, which was first aroused at the time of the accident, stops, and the accident is something that just happened, and happened because we had a safety man in the office reading up on improved safety methods written by a man also sitting in an office; because we had a committee of foremen who served on the committee only because they had to and whose minds were more concerned regarding the quality of a certain product, or the production of a certain machine than they were concerning the inspection they were making, and whose idea of safety was to run in as many suggestions as possible regardless of their value; because we had a committee of workmen, who, believing that we were not sincere in our efforts, were not sincere themselves, but as they had to do something, turned in a lot of recommendations, the chief value of which was to take up the stenographer's time in writing them. This being the cause, the remedy would be:

Character of the Safety Supervisor

"First, a safety supervisor who knew what he was required to do, and had the authority to do it. In a small plant this would be the superintendent, and in a large plant the assistant works manager, for it is just as essential to have someone with authority in charge of safety as it is to have someone with authority in charge of quality or production. In fact the three are so closely related that they should come under one head.

"This supervisor, whoever he would be, would have as his only assistant a man who would keep records necessary to carry on the work. These records should be a true statement of conditions, and not records that lead to the belief that we were making progress when we were not; and should include records of the men, who as far as the workmen are concerned, are the company: the department heads, foremen and the key men on whom the success of the safety movement depends. These men were chosen as foremen, etc., because they were above the average and able to lead, and do lead in everything but safety. In safety, however, we have a division of authority, and, as stated before, a safety supervisor with ideals that do not fit conditions, a foremen's committee, which knowing that they are not held responsible, have no interest other than to get their inspections done and to get back to the job for which they are held responsible, and a workmen's committee, the main function of which is to clutter up the joint meeting with numerous and worthless suggestions, but which must be taken up and disposed of in a manner will not offend them. It is true that it is a part of this committee's duties to interest their fellow workmen in the safety-first idea, and to caution them whenever they resort to unsafe or unsanitary practices. But it is not done. And as I see it, it can not be done. When men are not sincere they can not be convincing.

"Second, as they have no authority they can only suggest.

"Third, as the workman lifting on one end of a board considers himself just as good as the man on the other end, and will resent anything he may say regarding his habits or practices, many workmen resent safety warnings.

"Fourth, the average workman, whether he be a high priced mechanic or a common laborer, has no use for tale bearers, and though he may know of unsafe practices will not report them. The only way such practices can be found out is through the foreman, and as he would be responsible for the safe operation of his department, he would have authority to see that unsafe practices or habits be stopped, or he could dismiss the workmen, and when he did, it would be his duty to talk to the man and impress on him that he was being dismissed because he had persisted in doing what the company considered as detrimental to its interests.

"I would, in this way, show our workmen that safety paid, not only by eliminating pain, want, and suffering caused by accidents, but also pain, want, and suffering caused by the careless workmen having no place in industry.

"Safety is an ideal worthy of our best efforts, and it would be sublime if it could be obtained by ideal methods. But if this is not possible, let us strip it of its glamour and make it just what it should be, a cold business proposition, in which all sentiment is left out.

"This will require work by plant managers, work by the department heads and foremen. And the measure of success obtained will be in proportion to their efforts. To me this does not appear as added work, but an opportunity to show you that we can and will, if it is within our power to do it, attain your safety ideal."

(Signed) F. O. GOTCH, Works Manager.

This was the response of a practical operator to Mr. Knode's plan. And the results of his attitude immediately were apparent in his plant. Others, however, did not grasp the vitality of the plan as quickly as he did; and were slow to put it into operation. But August, 1928, the busiest month we have ever had, and one in which we employed many new men, was one of the best months, from the view point of safety, that the United States Gypsum Company has had. And with your permission, I will read details of our August safety record.

YEAR TO DATE

	AUGUST, 1928	1928	1927
Fatal	None	5	6
Permanent total	None	1	2
Disability one or more days.....	16	111	127
Total reportable	65	420	473

In order to better apply the principle of individual responsibility for accidents, we now analyze all accidents by causes, dividing them into personal and impersonal classifications. We further break them down so that the real cause of each accident may be known, and the proper remedies to prevent repetition may be applied. I have a few copies of our method of analysis if anyone wishes one.

In addition to this we require our foremen to send in a complete report of each accident. This report sets forth the circumstances under which the accident occurred, leads up to a conclusion as to the real cause of the accident, and requires a statement as to what action is being taken to prevent a repetition of the accident. The application of our method of analysis to our August accidents gives us the following classifications of causes.

Personal

1. Supervisor	1
Incomplete Instructions	
2. Worker	
A—Mental Deficiency—	
Ignorance	1
Poor Judgment	6
B—Mental Laxity—	
Inattention	40
Non-cooperation—(disobedience of rules)	2
B—Physical Defect—	
Weakness	1
D—Unsafe Practice—	
Clothing (gloves)	1
Haste	2
Short Cuts	3

The point most to be observed in the analysis just presented is that 40 out of 57 accidents were due to inattention or carelessness. Accidents resulting from these causes are the ones we are constantly striving to overcome, for it is these types of accidents that are most frequent and least necessary. It may occur to you that our August record does not show, in preventing these types of accidents success comparable to the enthusiasm with which I have presented our new plan of accident prevention to you. In our plants, however, the percentage of accidents resulting from inattention and carelessness is declining sufficiently to convince us that we are on the right track; to convince us that so soon as all factors concerned in the operation of the plan are thoroughly understood the results will far outstrip anything that we have accomplished in accident prevention in the past.

ACCIDENTS**PERSONAL**

1. Supervisor (Foreman)
 - A. Faulty Instruction
 1. None
 2. Incomplete
 3. Erroneous
 - B. Operations—Improper
 1. Layout of Machinery
 2. Layout of Operations
 3. Layout of Processes
 - C. Poor Discipline
 1. Rules Not Enforced
 2. Horseplay
2. Workman
 - A. Mental Deficiency
 1. Ignorance
 2. Inexperience
 3. Poor Judgment
 - B. Mental Laxities
 1. Excitability
 2. Violent Temper

IMPERSONAL

1. Building Conditions Unsafe
 - A. Fire Protection
 - B. Exits & Openings
 - C. Floors
 - D. Miscellaneous
2. Working Conditions—Improper
 - A. Light
 - B. Sanitation
 - C. Ventilation (Dust)
3. Housekeeping—Poor
 - A. Improper Piling & Storage
 - B. Insufficient Room
4. Equipment—Defective
 - A. Machines
 - B. Tools
 - C. Miscellaneous
5. Hazards—Mechanical, Electrical, Chemical and Steam
 - A. Unguarded
 - B. Ineffectively guarded

- 3. Sluggishness or Fatigue
- 4. Inattention
- 5. Non-Cooperation (disobedience of rules)
- 6. Worry
- C. Physical Deficiency
 - 1. Defects
 - 2. Weakness
 - 3. Fatigue
- D. Unsafe Practice
 - 1. Clothing—Improper, loose, long sleeves, ties, high heels
 - 2. Protection—Improper, no goggles, gloves, masks, shoes, hats, etc.
 - 3. Short Cuts
 - 4. Haste

CHAIRMAN SOUDER: Now, gentlemen, Mr. Davis is willing to give you what information he can on this subject. It is your turn now; he has had his.

R. P. BLAKE (Independence Bureau, Philadelphia, Pa.): Mr. Davis' report is the most encouraging thing I have heard at any meeting, for this reason: As I have already said, I think if you study the record of the work done by any organization that has achieved an excellent accident prevention record, they have done so by making it a major activity. They use the same fundamental methods of plant operation and of organization to achieve that end, as to achieve any other. And from the realization of Mr. Davis' company that that is the way to do it, and the fact that he is getting that way, even though the progress is slow—because you can't change the viewpoint of an organization in a day or a year, particularly a big organization—I think it is most encouraging. It is the most encouraging fact I have heard on the way to get and maintain a high degree of safe operation in a plant.

E. S. CHAPIN (Independence Bureau, Philadelphia, Pa.): The paper described one thing which I also met in my railroad experience, and that was the authority granted to the safety man. I was with a railroad company, and the top, Class One railroad in accident prevention—that is, those reportable to the I. C. C.—was the Union Pacific. We were not the top; and the Union Pacific proceeded to tell us how they got there. They gave more authority to their safety superintendent, whereas we had the title only of supervisor, which means a great deal of difference in the railroad. And he was authorized to stop a man whom he saw doing something which was contrary to the safety rules. He was a man who knew the operating rules intensively; he had come up from the caboose, and he knew the men on the road and he didn't try any frills with them. He knew just exactly what they should do, and he stopped them if he saw them doing the wrong thing. That, perhaps, is a pretty large bundle of authority to give any one man in an organization, but it worked with them.

They had their safety work divided by geographical divisions, and shops. Mr. Carl Gray, their vice-president, noticed that one of the shops was slipping. Whereas the other divisions were lowering their accident rates, this particular shop was rising. Under this organization method he called in the master mechanic and said to him, "Now we have an accident record since the first of January going up in your shop; if that doesn't come down between now and the first of December, I will put a man in there who will bring it down." Well, when the master mechanic got back to the shop he called his foremen together and said, "Now here is what Gray said to me. Now when December comes I am not going to be on the outside looking in; any fellow in this shop who doesn't do the same thing in his department to bring down the accidents is going out first." And they came down in that shop.

Now that is the attitude from the top down to the bottom. It may represent discipline; it may represent influence; it may represent education—all of them in their proper proportions, but it made every important man in that job get his toes in the ground to make his department safer, and the aggregate result was natural.

From some of my earlier remarks you might think that I wouldn't countenance discipline in the case of an infraction of safety rules. I was thinking of what I was planning to say with respect to making goggle wearing easy or attractive for the men, rather than the requirement that they shall wear them or get off the job. There are some men that you cannot deal with in any other way. Fortunately they are in the very great minority.

I know of an organization producing a commodity which is very dusty, just as dusty as any of your crusher plants, and there is a man with a broom sweeping it up all the time. It happens that that dust is poisonous in some respects. It isn't all poisonous, but he keeps the poisonous places clean and the rest at the same time. The superintendent of this plant had occasion to tell his men that he wanted this work of erecting a new shop done without accident, and that they were to be particularly careful not to drop any loads. And two carpenters (I think it was), hoisting a load, did not have it properly secured and it was established that one had made the hoist and the other had given the signal to raise it, knowing the condition of the load. It was dropped, knocked the scaffold from under two steel workers, and only by their agility in clinging to the girders, did they escape a fall of 30 feet onto the debris below. The carpenters were fired.

Now that plant was not over supplied with labor and they were in the midst of a busy construction program. The carpenters were old employees, but they were fired, and it has had the most wonderful effect upon the workers in that plant. The superintendent did not fire them without, you might say, a court, which was participated in by the heads of departments. All of the sides of the case were thoroughly considered and it was no hasty action. The men in the plant knew just why those men were fired.

MR. DAVIS: I would like to add one thing to what I said. If any of you are new in the safety business, haven't tried safety work before, and are just branching out into it, I would advise you, although we have discontinued committees, I would advise the use of committees up to a certain point. All of those things are very, very valuable from an educational standpoint, but their value exists only for a certain length of time. I would hate to have any of you carry away the impression that you can go right back to your plant and start in, without any education, on a hard-boiled program. The education side is absolutely necessary and by means of committees and rallies and safety talks you can build up that education to the point where, when your men have the knowledge of that which they should do, you can demand that they do it.

G. S. GELSTON (Travelers Insurance Co., New York City): In investigating an accident, do you include the question—What, in your opinion, could be done to prevent a recurrence of this accident?

MR. COLVILLE: We ask for the circumstances attending the accident, the way the accident happened, about the injury itself, and then at the bottom there is a place which is supposed to be an analysis. It shows what is the actual cause of the accident. We give as the cause of the accident—a man may have been asleep, or tired, or he didn't think, careless—what we call the actual cause of the accident. And the foreman must add that to his report. Then right below that is a space for the remedy or corrective measure which was taken, and that must be filled in. The bulletin which was sent out to announce this plan, also announced that no reports would be accepted incomplete; if they are incomplete we send them back to the plant. In other words, it forces the foreman to investigate the cause and think out what should have been done. Of course there are

some cases where it is hard to apply a remedy, where a man has had limited experience.

WALTER J. WOOD (U. S. Gypsum Co., Chicago, Ill.): I don't know whether Mr. Colville or Mr. Davis ever had a chance to analyze our August report of discipline that we sent in from the New Brighton plant, but I would like to say to you gentlemen that we had a two per cent turnover during the month of August, due to discipline, a very appalling figure. Out of a force of possibly 500 men we were forced to discipline 12 men in the month of August.

MR. COLVILLE: That may have been a lay-off for two or three days, although some are discharges. Our thought is this, that a man should first be told what is the right thing, and then he should have some further explanation. Maybe the foreman sets the example and gives him more details, but if those measures fail, then some discipline should be applied. It may be, in the first case, only a warning, where the man is insufficiently informed or where he has just not thought.

JOHN W. DORSEY (Solvay Process Co., Syracuse, N. Y.): Under this new system of accident prevention what are the provisions for educating the new men?

MR. DAVIS: We follow education chiefly by means of bulletins and instruction. The means of education vary in different plants. Some plants have a card with various safety rules which a man is required to learn and return to his foreman, or to inform his foreman that he is familiar with all of those provisions. Also, by means of personal instruction by the foreman, by bulletins and by lists of safety rules.

DR. PARLETT: I think a good plan in these cases of accident, and which would include men who are disciplined, would be to have them appear before the next safety committee meeting and explain the case. We do that and find that it has had a very successful outcome. Naturally, the men don't like to be there, but it makes quite an impression on the safety committee and the general rank and file.

MR. CHAPIN: Along the same line, I know of a division on the railroad with which I was connected which did that same thing. They had the man there, if possible, who was hurt. But they had his foreman there too, and the safety committee asked the foreman questions. One of the foremen told me that he would a good deal rather go on the carpet in the superintendent's office than before the safety committee, because, as he expressed it, "Those fellows can certainly ask you questions that are embarrassing if you don't know how and why that accident happened." Certainly that is a feature of safety work which can be used to advantage, and I think we are here today to get all the features we can.

MR. COLVILLE: Another word of explanation may be in order, regarding our discipline. We don't wait until a man gets his arm cut off and then fire him; that isn't our thought. The idea is to prevent the accident. Mr. Davis read of one case where the responsibility lay on the foreman, insufficient instruction, I believe, was the way it was given to you. Well, a man wouldn't be disciplined for that.

The thought is that there are three places where discipline can be given. One, is improper working conditions, or something wrong with your building construction for which a man cannot be held responsible. That means a remedy in the condition in whatever way you can do it. That is the management's discipline, you might say. The second point is the supervisor or the foreman—that means insufficient instruction. He may have given incomplete instructions. Maybe he doesn't enforce rules. Now the enforcement of rules is just as much a part of the foreman's job as it is getting quality or getting good costs. So I wanted to make that clear, because you may think that the Gypsum Company waits until a

man gets killed and then fires him. The thought is that we are trying to put it where it will do the most good.

CHAIRMAN SOUDER: Our next subject that we take up here is the election of officers. The nominating committee has a slate for your approval or disapproval. Mr. Boyd will take care of that.

Report of Nominating Committee

SECRETARY BOYD: Gentlemen: Mr. Evans and Mr. Cartwright, the two members of the Nominating Committee, were both unable to be present at this meeting, and consequently I will have to read their choice for the officers for the coming year:

CHAIRMAN—R. E. Colville, Manager of the Insurance Department of the United States Gypsum Company, Chicago, Illinois.

Vice-Chairman, and Chairman of the Engineering Committee—F. F. McLaughlin, Rock-Cut Stone Company, Syracuse, New York.

Secretary and News Letter Editor—J. R. Boyd, Secretary, National Crushed Stone Association, Washington, D. C.

Chairman of the Poster and Slide Committee—H. F. Yotter, Supervisor of Insurance and Safety, The General Crushed Stone Company, Easton, Pa.

Chairman of the Membership Committee—D. C. Souder, Director Insurance and Safety, The France Stone Co., Toledo, Ohio.

Chairman of the Statistics Committee—W. W. Adams, Supervising Statistician, Bureau of Mines, Washington, D. C.

Now in addition to the officers just read, the Executive Committee will be composed of those officers and the following: N. S. Greensfelder, Editor, "Explosives Engineer," Hercules Powder Company, Wilmington, Delaware; A. J. R. Curtis, Secretary, Portland Cement Association, Chicago, Ill.; Otho M. Graves, President, National Crushed Stone Association, Vice-President and General Manager of General Crushed Stone Co., Easton, Pa.; Warren Hayes, Secretary, National Slate Association, Washington, D. C.; and V. P. Ahearn, Secretary, National Sand and Gravel Association, Washington, D. C.

CHAIRMAN SOUDER: You have heard the report of the Nominating Committee. Are there any objections before we proceed? All in favor of the report of the Nominating Committee, as read, please raise your right hands.

(The slate was unanimously adopted.)

CHAIRMAN SOUDER: We now have a disappointment for you. Our dear friend, F. F. McLaughlin, is not with us, and as I have had occasion to work with Mac for a number of years, I wanted him to be here, because you can say a lot of things to him and he likes it. But he was good enough to telegraph his speech and Mr. Boyd will read that. He could have come down here from Syracuse cheaper than sending that, I believe.

(Secretary Boyd read the following telegram from F. F. McLaughlin, Syracuse, New York, on the subject, "Getting Tonnage With Safety," as follows:)

Telegram from F. F. McLaughlin

Best and envious regards to those in Quarry Section meeting. Unavoidably detained from attendance. Here is my paper on "Tonnage with Safety."

Success in human enterprise depends on intelligent human leadership. I believe in the necessary mechanics of safety work such as plans, committees, safeguards,

first aid, and all the various ways and means that are guides of action to produce accident prevention.

But quarry safety rules and machine guards are effective only when it is the spirit of our men to observe their use. Safety rules will not enforce themselves nor a removed machine guard replace itself. The spirit of observance can be had from most of our men by driving or by the better way of leading. Only he is fit to lead who has fitted himself for following.

Accident prevention is humanitarian progress and requires applied dynamic sincerity in its leadership. Observation of a number of safety efforts has convinced me that the most perfectly laid plan for safety is but as a house on shifting sands until laid on the foundation of a sincere man's leadership. When the choice lies with themselves our employees will follow a man who is sincere enough to practice what he teaches.

I well remember when we listened to J. R. Davis tell of plans he used to create extremely satisfactory safety records in a quarry in Ohio, of which he was the superintendent. His talk was full of the details of his plans, but the main thing I saw was the manner in which the man himself was absorbed in his effort on behalf of his men. In itself this sincerity invited the hearty cooperation of his men, no matter if the details of his plans were sane or otherwise.

Men put their faith and following in a man, not in a plan.

We all join in congratulations to the men of the White Haven plant of the General Crushed Stone Company upon their attainment of first place for the 1927 "Explosives Engineer" award for safety. Mr. John Rice, the president of this company, who is in this meeting with you, will probably testify that positive active sincerity was the foundation under the effort that secured this fine result.

Do you men honestly want safety with your tonnage? Are you willing to pay the personal price to get it? Then think straight, like your men; be the kind of a man you want your men to be. Be a leader for your men fit to be followed, and it will follow slowly but surely that most of your men will willingly engage with you in the attempt to attain the highest standard you can set for safety or tonnage or both.

ROCK CUT STONE CO.,

F. F. McLAUGHLIN, General Superintendent.

CHAIRMAN SOUDER: Now, gentlemen, we are still ready for some discussion. I will say for Mac that he had a very good record, when he was with our company, in the handling and use of explosives. He never had an accident over a period of 11 years, 1916 to 1927. We feel that that is a remarkable record. He is not with us now and our company hopes that he continues his good record with his new connection.

MR. CHAPIN: I was on my feet before in connection with Mr. Davis' paper, but remarks made after I spoke made me think of another case.

In Pennsylvania one of the steel companies makes investigations of near accidents and they impose discipline for near accidents where they might not impose discipline for an actual accident, because they feel, in an actual accident, that the man who may be at fault has been injured and to that extent has been disciplined. But in the near accident, which might just as well have caused the same kind of an injury, the blame can be more equitably placed, and it may prevent a real accident later on. It is just going one step beyond the recurrence of this accident. It is getting the recurrence before the accident happens, and in that way it is good accident prevention.

The question of diagramming or picturing accidents that have happened has been touched upon, the goggle illustrations were shown, and there again there is room for making the men think—did I ever do that thing myself? Have I ever taken that same chance? And that brings it home to them. I think this Section is to

be congratulated on the papers presented this morning. I know. I have enjoyed them and I certainly wish to all of you, success in your efforts.

CHAIRMAN SOUDER: Mr. Graves, can't you say a word at this time to the Quarry Section of the National Safety Council?

O. M. GRAVES (General Crushed Stone Co., Easton, Pa.): I was extremely interested in what Mr. Davis had to say. To my mind, the letter from that works manager was the most severe arraignment of our present procedure that I can conceive of, and I was in sympathy with it. But it is a most scathing condemnation of much we are doing; and the only consolation I think that many of us can draw out of it is the rather softening addition that you made to it in saying that much of the work that many of us are doing now is simply a necessary preliminary.

It is perfectly useless, I think, and certainly psychologically unwise, to order a man to do anything, to follow the consistent attitude of issuing orders which are not understood, and the reason for which is not understood. Man is certainly a reasoning animal, and the type of man we like to have working with us and for us is that type which sympathetically understands what you tell him to do. The ideal state is that where orders are never given, but we can't arrive at that within our generation; but we should strive for it.

Being more or less a new member in the General Crushed Stone Company, I have the unusual opportunity of observing the attitude of mind of the employees of that company; and as I view it now in perspective, without in the least connecting myself with it, it seems to me that the thing I admire most there is that the men do the things they ought to do because they want to do them. They want to do them primarily because they like the head of the company; they want to do what Mr. Rice wants to be done. That pervades the entire organization.

Also I think they try to do the things they ought to do, not only because of their affection for the company, but because the things they are asked to do are reasonable things. They recognize the propriety of the system under which they are working. And that being so, certainly we have felt, in our safety efforts, which are relatively new, that if we could make the men understand that we were in earnest and sincere, they would cooperate to the fullest. I am proud of that fact, that the men understood that we were sincere and wanted to do it for their benefit as well as our own. No mutual interests are really existent unless both sides are happy. There is nothing to be ashamed of as to the material benefit of the company to reduce accidents. It ought to be and certainly is; we don't try to conceal that from our men or take it away from them. That is one of the arguments we present, because with their attitude it makes them all the more anxious to do it.

Also, we are equally sincere in saying that we don't want this and that man—most of whom we know by their first names—hurt. And we would rather work along that line of thought. We make them understand that there are safe and unsafe ways of doing things, and that we are vitally interested in their methods of working safe, but also interested in trying to so arrange the plant and its equipment that it will be a safe place in which to work and live, and to a reasonable extent they have met us along that line.

CHAIRMAN SOUDER: I would like to hear from Mr. Colville on some problems that he has got up his sleeve, at this time.

E. R. COLVILLE (U. S. Gypsum Co., Chicago, Ill.): Mr. Chairman and Gentlemen: I didn't intend to give a speech; I wasn't on the program and am not going to do it, but I am going to exercise the prerogative of the newly-elected chairman and very briefly touch on one or two points which I believe are worthy of attention.

One thing, as regards the duties of the various officers of the Section. We have tried to outline to each man what is expected of him, in the thought that if a man knows what he is doing and where he is going he can get there quicker than if he has to grope blindly.

The work of the chairman of the Poster Committee will consist primarily in first reviewing the posters which have been made and distributed. Second, he will review the accident statistics. Rather, he won't review the statistics but will take the meat out of them, what they show as needing extension, and apply that in posters.

I am telling you men this because I feel that each one of you has something to give, not to me, but to the quarry industry, the Quarry Section, and each one of you has a peculiar condition which I may not have or the next fellow may not have. So that is the work of the Poster Committee, and we will see that the posters are put up. There have been criticisms or suggestions that there have been too few quarry posters in the past, and we are going to try to overcome that this year.

The Statistics Committee chairman is going to try to divide quarry accident statistics into the natural divisions of crushed stone, sand and gravel, slate, lime, gypsum, and those individual classifications, so that you will be able to tell how you stack up. We may not get this in one year, but we hope to do it. Mr. Adams is the supervising statistician of the Bureau of Mines, and he gets all the reports in and can handle that work very well. In that connection I must appeal to you to send in your statistics. He will ask you for them and you should send them to him.

As to the Membership Committee, my conception of this committee may be a little different than is generally held. I don't believe its prime mission is to sell memberships in the National Safety Council. I say that for this reason—there are too many quarry men. We have a membership of 68, I believe, in the Quarry Section, and how many are there here? I don't believe there are that many different organizations represented, and we want to strengthen ourselves internally before we begin expanding. Does that sound reasonable? Now I am giving out these ideas. They are the children of the brains of the Executive Committee, but we have only one line of procedure. We can outline the plan and present it to you. If anybody has any suggestions or changes to give us, we are very happy to receive them. We don't want to make it a one-man outfit at all. So I am telling you this and if it doesn't line up right, let's hear it.

Now the vice-chairman will be in charge of the Committee on Engineering Standards. Last year the Engineering Standards Committee was able to start a Safe Practices Pamphlet for quarries, dealing with these various divisions of quarry operation, and we hope to complete that shortly and present it to you men.

I have left the secretary's duties to the last, because his job will be to first get out a *News Letter*—not simply a routine *News Letter*, but he will try to coordinate the information which we get from the various chairmen, and send it to you. He will ask you for posters and he will ask you for ideas. So let's view the thing a little seriously and see if we can't help the secretary in his work in that connection.

There is one more thought that I want to commend to your consideration. We talk about safety. I believe the word carries with it some ideas which are not exactly what we mean. I have no criticism of the work, but we do feel—the Executive Committee of the Quarry Section—that we are trying to say accident prevention and compensation. Now that may be a little aside from the point, but that is the thought we are going to carry in our Quarry Section with you men in the *News Letter* this year, the thought we are trying to prevent accidents first. After that, we are trying to handle the material of compensation for injuries.

That concludes what I have to say. I would like to hear from the men present if they have any suggestions, or, for that matter you don't need to do it now, you can write. Now we are looking for help from you members. We will try to lead the work but you have got to follow and push us.

O. M. GRAVES (The General Crushed Stone Co., Easton, Pa.): Mr. Chairman, as I recall it, and if I may interrupt the train of thought that you suggest, when

the report of the Nominating Committee was made we rather apathetically raised our right hands in signifying our approval of the officers which the committee had nominated; and that was about all there was to it. The work devolving upon the chairman of this Section is very arduous, and on him largely depends whether or not it is successfully and earnestly conducted. Many of us know that Mr. Colville has entered on his new duties with the realization of the work involved; we also know that the tasks reposing upon the shoulders of the secretary are numerous, and again it largely depends on the character of that man as to whether this work is adequately or carefully done. We who happen to be members of the National Crushed Stone Association realize that the Quarry Section, in having Mr. Boyd as its secretary, is mighty fortunate. I think we are also appreciative of the fact that we have had an excellent chairman through the past year, and I am taking the responsibility, as one of the members of this Section, to ask for some real applause, in thanking Mr. Souder and wishing God-speed to the new officers.

(The members arose and applauded.)

CHAIRMAN SOUDER: I thank you. Now, gentlemen, there is nothing more to do from a program standpoint. In our lineup for the coming year, Mr. Colville, with your able assistance, will put this thing in a better shape than it has been in the last twelve months. Mr. Colville is located in Chicago; he is in close touch with the National Safety Council. Mr. Boyd is in Washington, in close touch with the Bureau of Mines. We have got a good set-up. We are lined up just right to do something with our own membership, of 68 I think, and if we can get 68 members to keep in the harness and help along here and give some valuable information to either Mr. Boyd or Mr. Colville, I am sure that you will find results.

Practically everyone in this room today is vitally interested in safety, and there is no reason why, in a year from now, each one of you men should not bring with you another member of your industry. Why don't you bring along a plant superintendent, or you may call him a foreman, so that he can find out what it is all about and get this inspiration?

I ask that you please give Mr. Colville your support in the coming year. Also, as to our secretary, write him a letter once in a while. Any of you men, regardless of whether he is a plant superintendent or safety man or who it may be, write a letter to Mr. Boyd along the lines of some of the safety problems you have, some of the good features you have put across so that Boyd can broadcast that to the members of the Quarry Section and to the members in the quarry industry. I don't believe that we have to stop with only the members of the Quarry Section of the National Safety Council. After the other fellows find out what we are doing they will all want to be in here. This same battle has been fought in all other organizations that have started. They have had a hard fight and after they get under way everybody wants to join. As the years go on all industries are coming to the point where they must realize that something will have to be done to prevent accidents.

I would like to have at this time a word from Mr. Boyd, on anything he wishes to say regarding the program for the coming year.

SECRETARY BOYD: Mr. Chairman and Gentlemen: I can assure you that Mr. Boyd, the newly-elected secretary, will do much more for the Quarry Section than Mr. Boyd, the retiring secretary. There is a lot of room for improvement which I well appreciate.

For the benefit of those of you who do not know me at all, personally, I would like to say that of the two classes of mail which might come to my office, that is, mail that would be perhaps flattering and that which would be criticising, I really much prefer to have the letters come in that are criticising. I am not sensitive about having anybody tell me that the job is going rotten. Really, that is the way we can improve the Quarry Section and the program.

Shortly after this meeting, and as soon as possible, I would like to send to everybody present a brief letter which you can consider a kick letter. We all think we had a good session, and probably there isn't one of us who thinks it could have been a great deal better, but let us hear from you. We want you to send in that dope. When I write to you and ask you to send back information regarding what you want on the program next year—which I propose to do—send that information in so that we can build a program for this Section that will attract people. We can't expect to have them come here and sit through a morning with us unless we are going to give them something.

MR. CHAPIN: Some of the remarks of the retiring chairman stuck in my mind. When you go back to your companies you probably will make some report of what you have heard and what the program is for the coming year. I think that about that time is the one to propose that you send your representatives, as the retiring Chairman suggested, next year. If you wait until next year, before the Congress, it will be too much of a shock to the management to realize that they must send these men. So take it up with them immediately and get their approval. I might say that the National Carbon Company has 71 men at this convention here at New York, taken from all over the United States. That is a large wad from one company alone. I know that the Union Pacific is sending 14 men, all of them from West of Omaha, and in a proportionate scale to your industry, I think you will benefit by having the men who, we will say, have made good safety records, given that trip as a reward for their effort. Hold it forth, if you wish, for those who are competing for your prizes, who are working in your plant for safety, that the men with the best records are going to come to the next Safety Council. You will get back all the money you pay for their expenses.

CHAIRMAN SOUDER: Mr. Colville would like to say a word at this time.

MR. COLVILLE: There is one thing that I think can well be put before you men. The Quarry Section is represented by men who do work in lime, in sand and gravel, slate, crushed stone, in gypsum. Now the National Crushed Stone Association has been quite a help to us. They are a red hot organization and each year they have a convention which deals with their own Association, yes, but it deals primarily with quarry operation. Last year they had one at West Baden, and as I understand it, it was quite a session. Now this year, January 21 to 24, at Cleveland, will be their next annual meeting. I don't know just where it will be—that will be announced later—but this is the appeal I want to make. Each one of you men here represents some organization which does quarry work. Now we are asking them for help. We are going to ask every association for help, the sand and gravel, the slate, the crushed stone, and so forth. Now they devote one afternoon of their meeting to quarry safety. It doesn't consist of quarry only, but crushing and transportation and all the operations contingent to that process. Now give that a little consideration and thought. We would like to have a group out there. There was a splendid group there last year but there was not the group we would like to have, that is, outside of the National Crushed Stone Association. There are no restrictions on this at all. They extend a very hearty welcome to everyone and you are cordially invited to attend. We will have good talkers, men who know their stuff, and we expect to waste no time.

CHAIRMAN SOUDER: I want at this time to thank Mr. Rice and Mr. Davis for their wonderful papers that they have delivered and the inspiration that they have given us. I appreciate that their time is valuable and that it has been an effort to make this appointment. We are sorry that McLaughlin is not with us. And I want to thank all of you men for being present and only hope that you continue on with the good work.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Quarry and Cement Sections Joint Sessions

October 2, 1928

D. C. SOUDER, Chairman

**Director, Insurance and Safety, France Stone Company
Toledo, O.**

F. E. TOWN, Chairman

**Superintendent, Manitowoc Portland Cement Company
Manitowoc, Wis.**

The luncheon session was called to order at one forty-five o'clock by the chairman, F. E. Town.

CHAIRMAN TOWN: We have been having a great time over at this table. It has been a question of whether Mr. Souder was going to preside or I myself. However, Mr. Souder has persuaded me to take charge, and as our time is very limited, I will not take time with preliminaries.

I take great pleasure in introducing Mr. R. P. Blake, Sales Engineer, Independence Bureau, Philadelphia. He is here to tell you something new, if there is anything new under the sun, at any rate to inject a little enthusiasm into us concerning safety.

Address

By R. P. BLAKE

Sales Engineer, Independence Bureau, Philadelphia, Pa.

It is a shame to drill down the Chairman but I am going to start in by asserting that I am not going to say a thing that is new to anybody here. My view of how I can be of best service to this group is not to attempt to say anything new but to emphasize:

It seems to me that the present staff of the Safety Movement needs a little more attention drawn to them. A man who was talking with me yesterday injected that idea into the conversation, and it seemed so important to me that I changed my talk clear around to fit it.

He said the thing that is most wrong with the organized safety movement today is that in spite of all the splendid work that has been done, enough American industries haven't seen the light. President Niesz brought that out when he pointed out that about 25,000 deaths occurred in industry in America last year. Had the rate which had been preserved in those plants which are a part of the

National Safety Council been applied to the entire industry, approximately one-third, or 8,000, could have been saved.

Carrying that a bit farther, had all of the American industries done as good work as the leading members of the National Safety Council, such as Union Carbide & Carbon, Inc., and others too numerous to mention, but all doing absolutely first-class work, instead of saving 33½ per cent of the deaths, we would have saved about 95 to 98 per cent of the deaths, and presumably the lost-time accidents in similar proportion.

In trying to get the view of the thing, I attempted to sort of withdraw a bit from close contact with the Safety Movement and tried to get an outline of it as one would get an outline of a big building.

It seems to me that three things stand out as absolutely fundamental. First, enough organizations in every branch of industry in every part of the country, big and small organizations of every type have done excellent work, have achieved excellent accident safety records to prove that anybody can do it. In other words, they have proved that, practically speaking, freedom from lost time through accidents can be achieved as part of ordinary successful operation of any industrial organization or any industrial business.

The next thing is that it pays. It does justify your trying to prevent accidents. In many cases it means from one million to four million man hours of consecutive operation and in small plants without a single lost-time accident. There isn't a single executive who doesn't say that in dollars and cents (keeping off of the humanitarian note) accident prevention work of that kind has paid dividends in returns on the money invested.

You all know, of course, of the very excellent surveys made of accidents, both direct and indirect, by the insurance companies. I take real issue with them in their statement that the indirect cost was a matter of five to one against the direct cost. I believe it is ten to one or more. I am going to attempt to show that here from a brief outline.

First of all I am going to state what I think is the best definition of an accident. An accident is anything that interferes with the ordinary procedure of the work. Only a portion of such accidents cause injury to human beings, but they all cause injury to the operating cost of the plants.

Now those organizations, without exception as far as my knowledge extends, who have done the best work, whether they realize it or not, have attacked their accident prevention work by eliminating unexpected happenings in the operation. It is obvious if we can plan our work accurately and carry it out as we plan it, we are not only going to prevent all accidents from happening, but we are going to attain the lowest possible cost of operation.

The next big cost—and instead of calling it cost I like to call it an indirect saving! Whenever you analyze any operation in any plant, you try to the best of your ability to develop the routine that makes it possible to carry it on practically free from interruption. You have studied your work so that you have not only been able to effect large economies but large opportunities for improvement; and right in there is probably the biggest possibility of saving through accident prevention work. You might call it indirect cost, indirect dividend on safety organization work.

Finally, whenever you organize a plant to an extent where the men work together so well, the entire organization works together so well that you can, practically speaking, eliminate the accidents, you have thereby forged a tool of organization, a tool of personnel, that is going to be extremely effective in carrying out any measure that the management finds practical and profitable. You have formed an organization that is going to carry that particular plant and that particular organization a long way along any path it finds it well to go.

Now, I have mentioned that accidents can be prevented. I have attempted to establish that it pays. I want to draw on the point that anyone can do it. I say this in spite of the fact that only a small proportion of the American industrial organization have up to the present time gone very far in accident prevention work. If they had, what Mr. Niesz said would not apply.

I don't know just how it is best to explain what I mean when I say anyone can do it, except to again recite the fact that in all branches of industry, in all sizes of plants, in plants with all sorts of leadership—by all sorts of leadership I mean leadership with all kinds of industrial theories but reasonably successful—there appear instances where they have succeeded in practically preventing accidents. This leads me to believe that any organization whatsoever that has sufficient capacity, sufficient direction to enable it to continue to exist and make profits under the competitive conditions of industry today, can, if it chooses, prevent accidents almost wholly.

Why don't they do it? I think the first reason is that they don't see the facts. They don't have the figures. They don't get the viewpoint somehow or other, in spite of the excellent work that the National Safety Council has done. In spite of the fact that all over the country are earnest men seeking to reduce accidents, men in every district, in every place in the country, there are a large number of organizations, of moderate size and small, who still don't see the point, who are still running along having unnecessary injury to men and failing to realize the profits that they might have and should have if they are going to deserve the term of reasonably progressive and able people. I think the first reason why more don't is because they don't see it.

Second, there seems to be a widespread idea among the executives of small organizations that because they are small they cannot do it as well as if they were big. I really think that the shoe is on the other foot, because of the fact that the executive of a small plant, with from 25 to 50, maybe 200 employees, has by virtue of his very nearness to those men, the opportunity to inject his own personality, his own energies, his own mental capacity and ability to each individual employee to a much greater extent than the executive of a big plant can, operating as he needs must through his department heads, foremen, straw bosses, and so on.

There are other things that come into the picture; but I have in mind the plant of the American Tar Products Co., with some 18 or 19 men who have operated now something over four and one-half years without a single lost-time accident. There are plenty of other instances but that happened to come to my mind, and the management of that plant, as I size it up, has just the ordinary ability that you would expect to find in any small plant. It probably needs to be less able than would be the case if that plant were an independent organization, because the head of such a plant, one of a chain, doesn't have the financial and other problems that the executive in charge of an independent organization would have. So probably the actual executive ability of the small, independent plant is greater than the plant of similar size that is one of a large corporation, a large string of plants. They just don't see it.

If we should study large numbers of accidents covering all industries, it would be found that as a rule that the special hazard that many plants make so much of is one of the less important hazards, measured in number of accidents, total lost time or any such gauge you care to use. For instance, in the quarry industry, if I recollect correctly, the figures given by the Bureau of Standards, showed tripping and falling as head of the list, and the special quarry hazards such as dynamite were down in fifth or sixth place in the list; and if all of those had been saved the accident record would still have been bad where it was bad in the first place. So that the myth of special hazards as particularly significant

when measured against the total of accidents, is nothing but a myth. If we prevented all the accidents, all the deaths, all the lost time from the special hazards existing in any and every industry, we would still have prevented but a small fraction of the total.

Another point is the human element. It is human nature for us to neglect relatively mild hazards. If in the center of this room were a pair of wide open gears screaming away at us, even though they screamed only for a little while and then became noiseless and we were told that they were still there and still dangerous, we would avoid that spot very carefully, and probably, being creatures of habit, we would continue walking around that spot for a long time after those gears had been removed.

But suppose there were a small depression in the floor, and I called your attention to it and you actually looked at it. In walking around this room later the chances are not one but several that you would stumble and ~~some might get hurt~~.

Why is it so difficult in many cases to get an organization, particularly an organization of size, to undertake any active accident prevention work? Simply that we have a tendency to neglect the hazards that do not appeal to us as outstanding, and continue to do mildly hazardous things, in spite of the fact that we know that if you do a dangerous thing often enough you will get hurt. The law of averages will get you in the end. There is no dodging it.

Now I have talked about why they don't. How are we to get the organizations that haven't yet seen the light to undertake an effective accident prevention work? I know of no way except to collar the executive or the executives responsible and rub his nose in it until he sees it. Gradually people are seeing it. I have paid so much attention to the saving because I believe that is the way.

In the early days of the safety movement we talked about the fine humanitarian principles. We lost sight, we failed to see practical safety from every consideration of good sense and good operation. It is not a special thing apart. It is not a special humanitarian appeal, but in the last analysis it is a chance to save money and a chance to make money. I believe in emphasizing that, because in the last analysis the most tender part of any man's anatomy is his pocket book. If you can hit that, you have got him.

Now suppose we convince our manager that he really is overlooking an opportunity for making money, and he says, "How shall I go about it?" The first thing I would say to this man is this: The first thing necessary for you to improve your accident record is that you yourself, as head of this organization, must want freedom from accidents; and you must not only want it but you must actively decide to go out and get it, because the path or the way to get freedom from accidents, the details and the endless work are so intimately tied with every operation of every organization that the drive must come from the top, the insistence must come from the top, the check-up must come from the top and the motive power must be furnished from the top.

The chief executive should plan the work. If the organization is big enough to justify a man in charge of safety, that man should report to the chief executive. He should work out his plans with the chief executive. Where it is a matter of authority, so far as is possible within the principles of sound direction of that authority, he should have final authority, and when it exceeds what it is proper to give that man the matter should be decided directly by the heads of that organization and nobody else, unless for some reason of plant policy he wishes to permit a committee to decide; and he doesn't want to do that unless he is willing to accept their decision and see that it is carried out.

Now so much for the start in the organization. He must carry on his work, plan his work with the idea that eventually the thing that he must do is to reach the mind of each and every employee in his organization. In other words, he

must weld his organization into a unit to carry out this policy of freedom from accidents. If he finds individuals in the organization—whether foreman or no matter what they are—who will not take such an attitude, he should no more hesitate, if he is unable to convert them, to separate them from his organization than he would if it was any factory management. In other words if you have an employee who refuses to cooperate in some profit making scheme the management has seen fit to follow, you don't hesitate to convert that fellow or fire him. The same rules apply for safety because I am going to show that safety work is as important as any other branch of operation that you may undertake.

I have no patience with the viewpoint that safety is a sort of special function of a committee or a safety engineer attached to a plant without much authority. It has to be a major function of the management of that plant, or it will not be effective. You will not get much in the way of results.

Each bit of work in the plant must be and should be analyzed. You should find out just what each man does, just what he has to do. As I mentioned at the start of my talk, find out what the hazards are, and find out the best way to prevent them. Right there we run afoul of a characteristic of human nature that is frequently operating to interfere with our accident prevention work; and that is, men dislike routine and monotonous work, like frequently to take chances, and we cannot, therefore, get quite as far as we would like to get. But it is entirely possible to show any man that he can afford to do monotonous work during his working hours in order to be able to do things that are not monotonous outside of his working hours.

Summing up again what I would tell this executive when he asked me what he should do and how he should go about it, I think I should tell him that he would need to use the following qualities in real liberal measure: Imagination, first because he cannot prevent an accident if he cannot imagine it happening. Second, attention to details. A tremendous amount of detail work has to be done by somebody, and probably in the ordinary organization will be done by many men under the direction of the big chief. Third, open mindedness. A man must be open minded to any and every suggestion and try to see all sides of every question. There have been some terrible accidents caused by lack of just that one fact, and I think perhaps more catastrophic accidents are caused by that than any other one thing you might mention. Such a thing as the Pittsburgh explosion which was probably caused by that thing. Such a thing as a tank car in which a number of people were injured and killed and which was probably caused by that.

A plant using a material that under certain conditions might give out inflammable fumes, had this called to its attention by the safety engineer, as a possible source of hazard. It was looked into rather perfunctorily and dismissed as a possibility. Some time later the thing that the safety engineer feared actually occurred. A tank car was put in the plant for emptying and because of improper distillation of the material it left flammable noxious vapors in that tank. One of the two men working in that tank car house crawled up on top and into it to look after something and failed to come out. His partner after a short time missed him and got up and looked in and saw the fellow down in the bottom of the tank and he crawled in and did not come out.

A little later a foreman in the next building wanting one of these men, sent a messenger after them. He came into the tank car house, looked around, didn't see them, crawled in and didn't come out. Finally the foreman came around and looked in and discovered them and called help and rescued them, using a mask and a rope. But two of those three men died.

There was a combination of lack of open mindedness on the part of the management. Failure to go thoroughly into the conditions because they didn't see. If they had probed thoroughly they would have seen the danger. Second; failure

on the part of the men on the job. Perhaps they had not been instructed and hadn't been taught to use common sense and reasonable precaution. The only man who did was the foreman who used it after it was too late to save two men and pretty nearly losing the third.

Next is the outside viewpoint. We all get blind spots. No matter what we are doing, working day after day along the same field we develop blind spots and fail ourselves to be able to see around them. Therefore, the value in having others criticize, comment on, and examine our work from time to time. The ordinary plant expects to have somebody from outside come in and audit their books from time to time, not because they expect to find anything wrong but because the subject is so important that they want the outside checkup and outside okay that everything is going as well as could be expected.

I believe the accident prevention game is so important that the organization, no matter how good work it is doing, that doesn't have such outside, unbiased checkups from time to time is overlooking a serious possibility of trouble.

The last qualification I would mention, and I mention it last because I think in the last analysis perhaps it is most important, is persistent patience. Some of the best accident prevention work that is being done today is being done in spite of the many and repeated previous disappointments and failures. I would point to the accident prevention work history of the Kimberly-Clark Co. As I got their story, they ran for a number of years trying hard to cut down accidents without much success. They finally showed one year in which they made a real reduction. The next year they were worse again. They rolled up their sleeves and kept on and finally they achieved one of the most remarkable no-lost-time accident records that we have today.

That is what I mean by persistent patience. You have got to keep at it and doing the little things and big things persistently regardless of the standpoint. We must keep our courage up regardless of whether we seem to get results, knowing all the time that we will get results if we keep at it. If you use intelligent effort, hard work and patience you get results.

In conclusion I want to say this: One of the most hopeful things in the safety game is that we are now beginning to realize and organizations are now beginning to realize the points I have made. Safety has got to be, by right and virtue of the profits to be made in accident prevention work, regarded as a fundamental feature of the executive direction of any plant, a fundamental feature of industrial work regardless of what you are doing. And I cap that off with this statement—that it is becoming and will increasingly become a measure by which the ability and standing of any organization will be judged.

In other words it won't be long until an organization that is not doing excellent accident prevention work will lose prestige and will be looked at as being not up to the reasonable standard in ability.

CHAIRMAN TOWN: As I have been listening to Mr. Blake I have been wondering whether he is a cement operator or a quarry operator. I think his talk remarkably fits all of our conditions and it is very interesting to get the viewpoint of a man who is not actually engaged in either one operation or the other.

ADJOURNMENT

October 2, 1928

D. C. SOUDER, Chairman

**Director, Insurance and Safety, France Stone Company
Toledo, O.**

F. E. TOWN, Chairman

**Superintendent, Manitowoc Portland Cement Company
Manitowoc, Wis.**

The afternoon session was called to order at two-thirty o'clock, Chairman F. E. Town presiding.

CHAIRMAN TOWN: One of the first things we will do is to reverse the order of business a little bit in order that we may take care of any unfinished business that might be necessary while everybody is here. I will ask Mr. Souder if there is any unfinished business that the Quarry Section would like to handle.

D. C. SOUDER (Chairman Quarry Section): There is one thing that the Quarry Section would like to ask. You are well aware of the fact that we are a baby industry in the National Safety Council, and the past three years we have affiliated ourselves with the cement industry in a point session, and we go on record as asking that we still be given consideration in that respect for next year. We want to be affiliated in this joint session with the cement industry as our men feel that they secure some information in this joint meeting that is very valuable.

The only unfinished business we have is asking for that affiliation.

Joint Meetings Important to Both Sections

CHAIRMAN TOWN: I am going to assume the responsibility of replying to Mr. Souder and state what I feel positive is the viewpoint of the Cement Section in respect to Mr. Souder's suggestion.

We know that in a large percentage of cement plants the quarry constitutes a vital department. There are a few plants, of course, that do not use limestone, but in most cases the quarry is the beginning of the industry, and sad to say our records show that the largest percentage of accidents in the cement industry is traceable to quarry accidents; the largest percentage of increase in accidents during the last eight months was traceable to quarry accidents.

This shows us that something is vitally wrong in the quarry. Because it is so vitally a part of the cement industry, I think there will be no one in the Cement Section that will not feel that it is of just as much importance to the Cement Section that we continue our affiliations in at least one session with the Quarry Section at these annual meetings as it is to the Quarry Section itself. I shall at least check up with the officers of the Section and hope that the Program Committee will see that it is made possible to continue these meetings in this way.

I think perhaps one of the benefits that can come out of these meetings is a mutual discussion of the problems that are existent in the quarry end of the game as well as those that are pertinent to other departments of the cement plant, because in a great many cases they are all traceable to fundamental conditions. Sometimes things that can be worked out to eliminate accidents in other parts of the plant, can also be used in a valuable way in the quarry.

Now we are privileged to have a paper by Mr. J. R. Cline, Assistant Superintendent Universal Portland Cement Co., Pittsburgh, Pa. I am sure that Mr. Cline can handle his subject in a way that will be of interest to all of us.

Putting Safety Across in the Cement Plant

By J. R. CLINE

Assistant Superintendent, Universal Portland Cement Company,
Pittsburgh, Pa.

"Putting Safety Across in the Cement Plant" could be better discussed by someone from any of the 34 plants that have gone without a lost time accident for the first eight months of this year; for at the plant where I work there have been only two lost time accidents this year, the same number that occurred last year. Our best record is a period of 369 days without a lost time accident from October 10, 1926, to October 15, 1927.

Never having had a perfect year in safety, it would be better to change the subject of this paper to "How We Try to Put Across Safety in the Cement Plant." The first requisite needed is to have superiors who are vitally interested in safety, higher-ups whose first question is not, "How much clinker have we produced?" or "How much cement have we shipped?"—but "How is our accident record? Are we still free of lost time accidents?"

The first thing done in our plant was the guarding of every known hazardous place. Substantial guards were put on gears, shafts, pits, stairways, ladders and railings, and additional ones are being installed on new places constantly brought to our attention. Guards once placed must be maintained in perfect condition, as they may shake loose, wear out or be broken. If not maintained they become a hazard instead of a safeguard.

After guarding the dangerous places the next thing done was the maintaining of a number of bulletin boards in conspicuous places, with the changing of bulletins at least once a week, to teach by word or picture the sources of danger that constantly surround all employees, and to maintain interest in this source of display.

One feature display on our bulletin boards is a calendar for each department and one for the entire plant, showing for each day of the corresponding month of the previous year the number of accidents, trivial, lost time, eye, or a clean slate, as the case might be, that occurred during that month and the record right up to date of the current month. The figures for the previous day are placed the first thing in the morning and create a lot of interest.

Cleanliness of the plant property is essential. All dirt cleaned up, scrap properly disposed of, passageways properly marked and kept free of obstructions, building maintained in proper repair and grounds kept clean and provided with grass plots and trees to make the general surroundings more pleasant to work in.

Proper lighting is essential for both day and night. Windows and openings should be kept clean to allow all the daylight possible to enter as no light is superior to daylight for general working conditions. For night lighting plenty of electric lights should be at all points in and about the mill so the hazards of darkness cannot exist. Numerous places for plugging in extension lines should be accessible over the plant so there will be no excuse for a man not having proper light to do any work required.

All the things mentioned so far have been physical necessities to put across safety in the cement plant. They are all essential and should be maintained to the highest point of efficiency, but there is still another phase that is far more important. This phase is the education of employees in the safe method of working and getting their cooperation to apply these safe methods at all times so they do not get hurt or hurt someone else.

This we have accomplished best by holding group meetings and getting the suggestions of the men present at these meetings and, as far as possible, carrying out their suggestions.

Our system is to have each department in its subdivisions hold meetings. Foremen usually preside and seldom over twenty men constitute the group present. Items of interest are brought up and any accidents that have occurred, or are known about, are discussed. The Portland Cement Association report on "Significant Accidents" is read at these meetings, as well as the report of any accidents that have occurred at any of the other plants of our company. Suggestions are asked for and as many as sixty suggestions have been received from one of these meetings. We insist that each department hold enough of these meetings so that each man in the department attends at least one of these meetings each month.

A general safety committee composed of all foremen meets once a week to discuss safety problems. Here any suggestions brought up at the group safety meetings, that cannot be taken care of in the regular routine of operation, are discussed and decision made as to their disposal.

A special group of selected men known as safety officers, about one for each twenty employees in the mill, meets, one-third of them, each week so each turn has its representation, and I talk to them concerning safety and any items of general interest that should be brought up at the time. Items they have to report are listed and answers made to any questions they or anyone in the group they represent send in concerning why something has or has not been done in the interest of safety. In addition to mill safety, stress is placed on community safety and no meeting is ever adjourned without the request for each member to "Take Their Safety Home."

Safety is also discussed at the superintendent's meeting. A chart is always on display at this meeting showing the number of accidents, trivial or lost time that have occurred in each department for the previous week and the subject is regularly discussed at its proper time.

Each item reported at any of these meetings is written up on a form provided for that purpose. This form is made in triplicate, the original for the assistant superintendent's office, second copy given by head of department receiving it to workman who signs it on completion of job and returns it to his head of department, and the first copy is signed by head of department and returned to assistant superintendent who has it filed as a record of job completed.

An idea of the number of items reported at the various meetings is obtained when I say that 2,125 were written up for 1927—89.6 per cent were completed, and this year items have been reported at the rate of 2,500 for the year.

In addition to the various meetings, with their groups constantly reporting items to be taken care of, a special committee of picked men is assigned to the job of making a thorough inspection of the entire plant each spring and fall; they report on conditions affecting safety, cleanliness, structural conditions, painting and, in fact, everything that is necessary or will improve the safe operation of the plant. Usually three days is required for this committee to complete its inspection and its reports have sometimes had three hundred items.

Other things we feel have a bearing on safety are good locker rooms; periodic physical examination of all employees in addition to physical examination of applicants; a nurse on duty every day who investigates all cases of employees reported off account of sickness and does considerable community welfare nursing; a doctor who spends one hour each day at the emergency hospital and is subject to call any hour of the twenty-four, all in addition to a well equipped first aid hospital that is completely manned at all times.

To maintain interest in safety we try to have our employees attend safety schools and safety lecture courses whenever possible. Several schools are run by the Western Pennsylvania Division of the National Safety Council, at Pittsburgh, about fifteen miles from the plant. We post the schedule of the meetings and with a little personal advertising are able to get about twenty employees to regularly attend these Pittsburgh meetings. For the last couple of years there has been a

group of meetings held at New Kensington, about 10 miles distant from our plant. We made a special drive for these meetings and provided bus transportation for those not having their own cars who were willing to go. For the seven meetings held last year we had a total attendance of 2,150—average attendance 307—maximum 386—and a total of 697 employees attended one or more meetings—233 attended the banquet and 211 received diplomas for attending at least five of the seven meetings.

This year we intend to hold a series of meetings at Universal. The number of our employees willing to attend a safety lecture course of this type has become so great that we can better arrange to bring the lecturers and entertainers needed to them than to safely transport the great number to other community meetings. We also feel that by holding a set of safety meetings in our own town we will better promote safety throughout the entire community.

We have had over 50 present at each of the meetings and dinners of the Portland Cement Association Regional Safety Meetings held in Pittsburgh the last two years. A representative of our plant has been present at the last four National Safety Congresses and has also attended the Portland Cement Association Regional Safety Meetings held in Allentown and state meetings held in Philadelphia for the last two years.

For the promotion of safety in the community we have each year interested all local organizations in the November Thanksgiving No-Accident drive, and have distributed great numbers of posters for conspicuous display and have seen that each school child in the district has a small picture of the general poster with an explanation of the purpose of the drive given by the teacher or someone from our organization. Occasionally we go through our files and pick out any safety posters that we think would be of use to school children and give them to the teachers to distribute or use in any way they desire to supplement their regular course of studies.

To obtain new ideas for the promotion of safety we encourage the visiting of other plants of our company or of other companies by leading foremen or heads of departments whenever possible. By this means they can see how the other fellow guards his machinery, conducts safety meetings or runs competitions to promote safety and come back with the ideas so they can be worked into our system or make some improvement upon what we are already doing.

Each part of this elaborate system to put safety across in the cement plant, we think, is necessary and has contributed to whatever success we have had; but the one point we feel is absolutely needed is foreman responsibility. The foreman is held responsible for his group. He must be in sympathy with the safety movement and see that every man under him is in sympathy with it. He must be an example to them in safety; order them to work in a safe manner, and then be sure they carry out all the safety knowledge that has been imparted to them. The foreman must see that his group meetings are held; that every trivial injury no matter how slight is immediately reported; encourage participation in all outside safety movements, and lead his men by being present at all outside meetings himself. The success or failure of any group regarding safety is entirely in the hands of the foreman.

"Putting Safety across in the Cement Plant" is not an easy job or one that can be done spasmodically, but it requires the effort of everyone in the organization to be everlastingly at it. That it pays, there can be no doubt, as is easily shown by the results published by the Portland Cement Association and the satisfaction to each of us. "And the end is that the workman shall live to enjoy the fruits of his labor; that his mother shall have the comfort of his arm in her age; that his wife shall not be untimely a widow; that his children shall have a father, and that cripples and helpless wrecks who were once strong men shall no longer be a by product of industry."

CHAIRMAN TOWN: I think Mr. Cline's paper has been exceptionally interesting. In fact, having gone very definitely into detail, he has undoubtedly given us a great many points that are of interest and great value to us.

Going back to unfinished business just a minute. Mr. Fortuin, will you please read your report of the Poster Committee for the benefit of the Cement Section?

Report of the Committee on Posters

By R. B. FORTUIN

Chairman

I was appointed chairman of this committee at the national meeting in Chicago, and in turn invited the following men to assist in the work of the committee:

Messrs. David Adam—Lawrence Port. Cement Co.

Fred Hunt—Nazareth Cement Co.

Paul Sandt—Edison Port. Cement Co.

Chas. Benner—Lehigh Port. Cement Co.

Chas. Roth—Plant No. 6, Penna.—Dixie C. Corp.

The chairman of the committee wishes to express appreciation for the fine cooperation of the members of his committee.

A form letter was sent to every member plant on the mailing list of the National Safety Council, asking suggestions for posters. Twelve replies were received, and acknowledgments made to these companies.

The committee adopted a policy that all cement posters should be made up from actual photographs of significant accidents that occurred in the past in the cement industry. To date a total of eleven suggestions, together with photographs, have been sent to Mr. Lee Gardiner, in charge of the Poster Division of the National Safety Council—two more suggestions and photographs will be sent in, in a few days, thus completing the work of the Committee for the past year.

It is very difficult for a small group of men to make up posters that are applicable to the industry throughout the entire country, and the committee would like to suggest that the member plants of the National Safety Council be more liberal in the future with their ideas of how posters should be made up, which will be entirely pertinent to accidents and hazards in the cement industry.

The chairman has considered it a pleasure to carry on the work during the past year.

MR. FORTUIN: I would like to say an additional word to that, gentlemen. It is very hard for any group of men to make up posters that are entirely pertinent to the cement industry and which are of particular interest to your individual plant. The committee sent out these form letters asking for, I believe, five suggestions from each member plant; and out of the 160 members of the cement industry we received only 12 replies. That indicates possibly a small interest on the part of executives in the cement plants, or it may indicate that the form letter did not get to the proper person in the organization.

I would like to ask for this committee that each one of you gentlemen here today make it a point to have some one in your organization send to Mr. Lee Gardner, of the National Safety Council, or to myself personally, suggestions for posters for the coming year.

The posters in the past have covered a wide field. Some of them have not covered the field adequately, and others in possibly the wrong manner. What we would like to do is to pick out the real hazards and significant accidents of the past and have them portrayed on a photograph and then have that made up into a poster. During the past year you have seen a number of the posters that we

made up as appeared in the *National Safety News*. Possibly these posters are not entirely in accord with your ideas, and if not, we certainly will welcome constructive criticism on your part.

The committee gave their time freely and willingly. I know that the members with whom I worked were very pleasant men to work with, and they did all they could to further the work of this committee, but their work is at an end and we need your help to give us further suggestions. I hope that all members will endeavor to let us know what ideas can be made up into posters this coming year.

CHAIRMAN TOWN: I wish to thank Mr. Fortuin for his report of the Poster Committee.

If he will permit, I would like to add a word. Any of you who have had anything to do with active work in the Council know very well that there must be time or energy spent in addition to your regular routine work with the company which employs you; and frankly after you have been looking after those odds and ends or those extra details of work absolutely outside of your regular company business, you realize at the end of the year that you have spent considerable time, with patience sometimes exhausted, and it seems at times like almost an uphill business, as it would be if it were not for the loyal support of active committees.

Two or three men should not endeavor or undertake to do all the work of a section. They haven't in the case of the Cement Section, but it has been delegated to altogether too few, and an important trend in our Section has been to expand. Add a committee once in a while, and now we are in the hopes that these committees by reason of the experience they have accumulated year after year are going to be able to function all the stronger in the succeeding years to come.

Knowing the efforts that Mr. Fortuin and his committee have put forth in this poster work, and also knowing something about the inside work of the National Safety Council I want to suggest that you take everything that Mr. Fortuin said strictly to heart, because the work of the poster committees of the Council depends almost entirely upon the individual efforts of the unit sections of the Council. If each Section is not able to pass in its ideas and suggestions in posters, then the work of the Council is going to be all the more handicapped.

Whenever you are appealed to for this type of work, it would be a splendid thing if you could plan for a competition within your own plant to see what can be done for the cause of this poster work.

I have just received a telegram which speaks volumes. There were three or four of the cement plants who sent word from the Pacific Coast that they regretted very much being unable to have any representative attend any of these meetings of the National Safety Council, because they are having a regional meeting or two out on the Coast this week. They are having one in San Francisco today, I believe, which includes all of the plants of the Northern Pacific District, and they send their regrets that they were unable to come on account of conflicting dates. However, I think the Cowell-Portland Cement Co. feel that they are here.

They have sent us a telegram addressed to this meeting which says:

"Today this company's plant completes 847 days without a lost-time accident.

Cowell-Portland Cement Co."

I say they are entitled to a glad hand.

R. C. FRAME (Alpha-Portland Cement Co., Easton, Pa.): I am going to ask (and you may take it upon yourself to call on me for money if necessary) that you send a telegram to the Cowell-Portland Cement Co. from the Cement and Quarry Sections combined, extending congratulations. I think the fact that they have thought of us and wanted us to know of their good success entitles them to our consideration.

CHAIRMAN TOWN: If you will do that, Mr. Frame, I will appreciate it.

Now we come to that part of our meeting that is always lively with interest and I am going to turn it over to Mr. S. Henry Harrison, Assistant Superintendent, Vulcanite Portland Cement Co., Phillipsburg, N. J. I hope nobody will find it necessary to leave because we want suggestions, ideas and good points from everybody in this part of the meeting.

Round Table Discussion

Led by **S. HENRY HARRISON**

Assistant Superintendent, Vulcanite Portland Cement Co., Phillipsburg, N. J.

I think we will all agree that mental causes of accidents are a problem of great importance and they are the most difficult to correct even to a comparatively small degree. A man goes to work burdened with domestic cares caused by sickness, financial troubles, or what not. Sooner or later his attention is divided, he is less alert or preoccupied, and as a consequence an accident occurs; for the same reason a locomotive engineer fails to see the danger signal set against him—he drives his train into a block into which he is forbidden to enter and frightful consequences ensue. This phase of the safety question is one of extreme difficulty to correct and one which is well worth our attention.

In starting the round-table discussion we will discuss the various other problems in connection with the safety first movement awaiting solution by the various member companies. Aside from the humanitarian phase of this question, and this is of very great importance indeed,—we find that no matter from which angle we approach the subject of safety first, we are always confronted with the same problem—How can we reduce the great non-productive expense—Compensation?

In the State of Pennsylvania alone for the first six months of this year the total compensation award was \$6,003,183.00, and the total for the year 1927 was \$13,329,557.00.

When one stops to consider the vast sums of money expended each year over the entire United States due to this vast economic loss, it is little wonder that the Executives in various industries have taken a united stand to reduce this item which necessarily must enter into the cost of manufacture of all the products of industry.

One of the large insurance companies has found that in analyzing 75,000 accident cases fully 98 per cent were preventable, and that if the industrial accident frequency could be reduced fifty per cent there would result an annual saving of \$5,000,000,000.00 to say nothing of the misery and hardship which would be avoided.

The splendid results which have been obtained by the Portland Cement Industry promise to be even more gratifying due in no small measure to the fact that the industry at the present time is in the transition stage. Mills that were using machinery of an inferior type are gradually replacing it with equipment of modern design.

Some one has said that the number of accidents on a railroad system is directly proportional to the length or mileage of the system. Such being the case it is only fair to assume that the number of accidents in a factory is directly proportional to the amount of machinery installed and also to the number of men employed.

In some of the older plants in the Cement Industry where the units were designed for comparatively small output per individual machine, it is natural to suppose that more men were required to operate a plant so designed. Today the small units are being rapidly replaced by larger units,—as for instance—Mills of the roller type turning out—say 140 bbls. of cement per day are being replaced by Mills of the Tube Mill type turning out over 2,000 bbls. per day.

The old reciprocating engine driven plant is rapidly fading from the picture.—In its place we have the modern steam turbine with its direct connected electrical generator. In a great many instances the power plant is entirely eliminated—the power being furnished by one of the great electric systems which are rapidly spreading their net work of wires over the entire United States. The old Cement Plant with its multitude of pulleys, belts, shafting, gears, chains, rope-drives, clutches, etc., is being modernized and in place of this hodgepodge of power transmission machinery we have the electric motor drive connected to its load direct or through a gear reduction device.

With the substitution of the wet process for the dry the screw conveyor is largely eliminated, and the centrifugal pump with its attendant pipe lines has taken its place.

The rotary kiln of small size is being replaced by kilns two or three hundred feet and over in length.

Even in the department where dry pulverized material is conveyed the screw conveyor is being replaced by pneumatic conveying systems.

All these changes cannot but produce beneficial results in so far as reduction of accidents is concerned. Incidentally, they also tend to show how much more difficult it is for a cement plant of the older type to come through the year with a clean accident record. Contrast one of the older plants in the Lehigh Valley with one of the modern plants in the Birmingham district and this fact becomes evident at once.

There is another question which it might be well to discuss, and that is the increasing number of low voltage electrical accidents. By low voltage I mean voltages of 220 volts and under. There seems to be a prevailing opinion among electrical workers that a circuit of 220 or 110 volts is harmless. Such is certainly not the case. With the increased use of electrical energy it is surprising that we do not have more industrial as well as more domestic accidents due to this agency.

Recently several fatal accidents have been mentioned in the press. In this city a few weeks ago a man was killed while carrying a bundle of wet hides in a meat packing house. The floor of the packing house was wet—the unfortunate man's clothing was moist, and in carrying the bundle of hides they accidentally struck an incandescent lamp which was broken—the hides came in contact with an electrical conductor with the result that the man was instantly killed. The voltage was 110 volts in this case. Other cases have occurred where men have been killed while working in the interior of boilers or other steam vessels. Death was due to contact with low voltage electrical conductors.

I am bringing this matter to your attention because there are innumerable places, especially in the basements of engine rooms, also in the vicinity of raw material blending tanks where if electrical extension cords are carelessly used fatal results are sure to follow. There have occurred too many cases of this kind where persons have been fatally injured to warrant us in treating this subject lightly.

In discussing this subject with one of the insurance companies their opinion was asked regarding a 35 volt line to be used as a special low voltage circuit in cleaning boilers,—they remarked that they were not prepared to regard 35 volts as harmless. It is all a matter of electrical contact. Perhaps it would be well to treat all electrical circuits as dangerous and have no one enter a boiler with an electrical extension cord, but to use a pocket flash light battery instead, as is the practice with most boiler inspectors.

One of the most difficult problems for the Plant Safety Committee to solve is the problem of converting the confirmed safety skeptic into an active enthusiast in Safety First. I believe that even the most obstinate cases can be cured by keeping everlastingly at them.

Another problem confronting Safety Committees is the problem of fake accidents. For instance—a man reports to work with a pain in his back,—what really ails him is, we all say, Lumbago, but he attributes his trouble to heavy lifting at his work. In this deception his physician often innocently aids him. Many a fine no-accident record has been shattered by this practice.

Perhaps the most hazardous department in a Portland Cement Plant is the Fuel Mill where pulverized Coal is prepared for burning in the Rotary Kilns. As is well known the pulverized fuel is introduced into the Kiln by means of a fuel feeding device and an air blast. Suppose while the device is functioning properly, for some cause or other there is a failure in the air supply *through* the air blast, the Coal will continue to enter the Feeder, the air blast having failed the Coal will be forced out of the Feeder and spilled on the floor in front of the Kiln where it may become ignited by the hot clinker dropping from the discharge end of the Kiln. Such cases have occurred and disastrous results have followed.

Would it not be well to automatically cut off the Coal supply immediately upon failure of the air blast.

Where the Waste Heat System is employed there is always more or less danger of back firing in front of the Kilns should the Exhaust Fans in the rear of the Boilers cease to function. Here too, in this case it may be well to automatically cut off the pulverized fuel supply due to failure of the Exhaust Fans.

It may not be out of place while we are discussing the danger due to pulverized Coal, to consider the subject of "skylarking." I have in mind where a workman while passing from one building into another was struck with a paper bag filled with pulverized Coal, a lighted torch placed on the ground nearby ignited the powdered Coal causing painful burns to the workman's arm and neck. The Coal was thrown from the upper platform in the fuel grinding room and was, doubtless, intended not to injure the man but to give him a dose of coal-dust. It is hard to understand why men indulge in such silly capers, but they do now and then. Needless to say a case of this kind should be treated as a criminal act and the offender dealt with according to law.

However, in a properly supervised Plant "skylarking" does not exist, or rather it is reduced to such an extent that it may be said to have almost entirely ceased. This I suppose is the case with most of the Cement Companies, and is, I believe, one of the beneficial results of no-accident campaign drives.

Before closing these few remarks I would like to dwell for an instant on the question as to the best method of securing reports of injured persons—I refer particularly to accidents which for the moment are considered as insignificant and unnecessary to be reported, as for instance slight cuts or scratches which later develop into infected cases. No reports having been made out in the first case it is difficult to determine whether the injured was really injured at work or at home, or another place outside of working hours. In this case a dishonest workman could claim compensation and the payment of his bills for medical attention, etc.

There are representatives here from many Cement Companies located in different sections of the United States, and we should be able to obtain some valuable opinions regarding the subjects to which your attention has just been called, as well as on subjects which I have not mentioned.

MR. HARRISON: We will now go on with the discussion, but please confine yourselves to three minute talks.

DR. PARLETTE (Pittsburgh Limestone Co., Pittsburgh, Pa.): With reference to fraudulent claims, the Pittsburgh Limestone Co. has a check-out board, and one side has a sign reading, "Check out uninjured" and the other side, "Check out injured." There are blanks there which have to be made out, and if the man has

been injured during the day the first-aid station will report on that patient during that day. When he checks out injured, providing he has not been taken to the hospital, his superintendent or foreman visits his home and that is followed up.

If he comes to work the next day and he claims that he was injured sometime during the day without having checked up as he should, his claim, of course, doesn't go.

I think that is probably the best scheme that I have ever heard of.

MR. HARRISON: I would like to call on Mr. Frame, of the Alpha-Portland Cement Co., and hear what he has to say.

R. C. FRAME (Alpha-Portland Cement Co., Easton, Pa.): This, I think, has been another of the very splendid discussions of safety problems which have been put on for a number of years by the joint session of the Quarry and Cement members of the National Safety Council.

The Alpha-Portland Cement Co. has made wonderful progress in the reduction of accidents at their many plants. We don't have to look back very far before we can clearly recall where we had something like 300 to 400 lost-time accidents in one year. When looking at the records the other day the best that we could count for the first eight months of this year is 24. This remarkable reduction, gentlemen, has only come about through the intense interest of the management in enlisted cooperation, enthusiasm, genuine all-around good work respecting accident prevention and every phase in which it appeals to us.

It seems to be a rather easy matter, after the superintendent of the plant or foreman and safety committees all get started in this work, to post a record of each plant from month to month. Each plant sees what the other one has accomplished, they realize more their own shortcomings and they wonder why they cannot do as well at their plant as their neighboring competitor has done. After all when they start thinking we can look for results.

Mr. Brown told you this morning that the Alpha Co. last year won two trophies from the Portland Cement Association. One of the plants was at Ironton, Ohio.

I give great credit to the telegram which our chairman read a few moments ago from the Cowell-Portland Cement Co., in California, who had their last lost-time accident in May 1926, and I have every confidence in this Cowell organization from what we have learned of them that they are going to continue the splendid record through to December thirty-first.

Alongside of that wonderful performance the plant at Ironton, Ohio, had their last lost-time accident in December, 1926. They won a trophy last year and so far this year the record is clear. Of course, we hope the god of luck and goodwill are with us in our continued effort and that we too will join with Cowell, and that there will be still some other Portland Cement plants that will come through on December thirty-first, so that we will not only have two, but we may have six or eight or possibly more that will win this wonderful trophy for the second year.

Aside from this record-breaking performance at our Ironton plant we have still other organizations to which we can point, such as Bellevue, Michigan. This Bellevue plant some years ago, had their long string of lost-time accidents, permanent injuries and fatalities, but once they started in earnest, they quickly demonstrated that they could cut their safety program off the same pattern. This Bellevue plant has not had a lost-time accident since April, 1927, with every indication that they are going to be a trophy winner this year.

We have been operating a plant at Manheim, West Virginia, since 1908. They have had many problems down there, the principal one being due to mining operation. They have driven columns into the side of the mountain, which brings a problem peculiar to that line of work. With improved conditions, transportation, and light, and all the other elements that go into it, Manheim, not to be outdone

by her sister plants in the Alpha organization, is working heart and soul to attain their trophy for 1928. Their record, as it stands today, shows the last lost-time accident occurred in August, 1927. So they have already finished 365 days without a lost-time accident, but according to the Portland Cement Association code, nothing brings you the prize until you do the calendar year.

It has been felt by those in charge of the Portland Cement Association activities that it is better to set a measured time in which to make this record. Something like a horse race when they all start from a given point and finish at a given point. It seems to me that it takes a little more effort and the record means a little more to us when we get out to accomplish something within a definite period of time.

It may be of interest to you to know the viewpoint of our management at Ironton. You may ask the question, I wonder what is back of this Ironton Organization? I wonder what they are doing out there? How do you go about to produce this wonderful safety record? And it is a wonderful safety record for this reason: Instead of having the ordinary quarry from which many cement plants obtain their rock, they have a mining proposition; no ordinary job. If I remember correctly, their shaft is something in the neighborhood of 600 feet deep, from which they lead out into the rooms, take out the stone, blast the load, bring it to the shaft and hoist it to the surface. They employ some 80 men in this mine.

The records on mining have shown you gentlemen long years ago that it is of a hazardous nature. I venture the open quarry has many advantages over the mining operation, and when this mining operation at Ironton has done so well, in fact has kept pace with the plant operation on the outside, I think we should give them a certain amount of credit for their help in putting over the results.

I am going to read you just a few lines that come, I might say, from the heart of the plant management at Ironton.

Letter from the Alpha Co. Plant at Ironton, Ohio

We trust we are right in assuming that the majority of the plants represented here are members of the 1928 Trophy Club and hope they will be able to complete the year without an accident and win a trophy.

The Cement Association Trophy is a thing of beauty and means so much to those who fought for it that it is only fitting that no expense be spared in providing a suitable dedication. The Ironton plant's trophy was dedicated on May 9, 1928, and this day will be long remembered by the plant employees and the men, women and children of Ironton.

While making arrangements for our dedication we did not lose sight of the fact that accident prevention pertains not only to the cement industry but to the country as a whole, so with this in mind we decided to throw the dedication open to the public at large. Special invitations were sent to the various civic clubs as well as to our neighboring industries. Arrangements were made with the local high schools, both public and parochial, whereby the students were dismissed at noon with instruction to report back at the school at 1:30 p. m. At this time the entire high school student body, about 1200 in all, were formed in parade formation and, headed by the school fifty-piece band, marched to the plant. The day was ideal and our ceremonies were honored by the attendance of five or six hundred little fellows who had heard that there were to be "free eats" at the plant. They began to arrive about noon and immediately captured all the strategic places around the refreshment stand, which they held from noon until the refreshments were served at about 4 o'clock.

The speakers of the day included Mr. Barbazette, manager of operations; Mr. Brown, president; Mr. McKelvy, vice-president, all of the Alpha Industrial Commission of Ohio; Mr. Butler, terminal superintendent, Chesapeake & Ohio Railway

Company, and Mr. Morgan, C. & O. Y. M. C. A. secretary. All of them touched on the wonderful record the plant made and also on the value of safety not only in the mill or work shop, but in the home, on the streets and everywhere. There is no doubt in our mind but that many safety converts, if we may call them such, were made as a result of the stirring speeches.

The refreshments which followed the speaking consisted of the following:

- 2500 packages of Cracker Jack
- 2000 packages of Pop Corn
- 2000 packages of Peanuts
- 120 gallons of Orangeade
- 120 gallons of Lemonade
- 1500 bottles of Pop

Everybody had plenty to eat and drink and left the grounds hoping that the plant will be able to go through another year without a lost time accident.

The question is continually being asked us, "What did you do to win a trophy?" and we will briefly outline our method of handling the job of accident prevention although we feel sure that you find it very similar to the methods used in other plants.

Successful accident prevention is the result of cooperation between every member connected with an organization. We of the Alpha Company point with pride to the cooperation that exists within our company and we doubt whether there is a greater safety enthusiast in the country than our president. The spirit of safety is contagious only when it starts at the top and works downward. If the president of a company is a believer in safety the general manager will be also. Once the general manager is converted the superintendents will not be far behind and you will find before you hardly realize it that the foremen and men are right in line. The management must show a willingness to spend money for things that produce results. Guard rails, etc., should be installed wherever needed as we have found that men can't be convinced of a management's interest in safety if they see on all sides of them unguarded gears, etc., just waiting for a chance to bite them.

Some safety engineers argue that the installation of guards tends to make a man careless and less on the alert than he would be if the guards were not there and he would realize that the slightest sign of forgetfulness on his part meant injury or death. We cannot, however, agree with this point of view and make it a practice to guard everything or place that may cause trouble.

Our safety committee, composed only of foremen or heads of departments, is similar, we believe, to the majority of other committees. We did considerable experimenting before so organizing our committee, but found that the foreman is the logical member of a safety committee.

Regular meetings are held once a month with special meetings added whenever necessary. At these meetings the condition of the plant as a whole is discussed and various recommendations considered. Especial attention is given to the reports issued by the Portland Cement Association and in our opinion the monthly report on "Significant Accidents" is one of the most valuable bits of information put out by this organization. This report is given a thorough study in our committee meetings and an attempt is made to visualize each accident mentioned or in other words we imagine the injured man as being one of our men. If we then find that a similar accident is liable to occur at our plant we take immediate steps to head it off.

Each foreman is given a copy of those "Significant Accidents" and in addition to this we make out another report of the accidents which are peculiar to his department. The latter are first read and explained to the men and then posted on the department bulletin board.

The Alpha Management made its plant committee's work easier when it started direct advertising by paying a safety bonus. Under this plan 1 per cent of a man's

earnings is added to his check whenever the plant goes through a month without a lost-time accident. While this bonus does not amount to much for each man still it means quite an outlay for the company in a year's time for all of our plants. The average monthly bonus for each man at our plant would be about \$1.25, but it is surprising how our men count on this addition and how they appreciate it.

Prior to 1925 we were having a great number of eye accidents, men were being struck by flying chips of stone and steel and three men each lost the sight of one eye. The committee realized that something would have to be done and done quickly if we did not want the nickname of being a one-eyed plant. So a compulsory goggle rule was put in effect in April, 1925, and each man was given a pair of goggles and a letter explaining the reason for giving them and also instruction as to when they must be worn, as well as the penalty for not wearing them.

These goggles were purchased by the company at \$1.10 a pair and this amount was deducted from each man when he received his pair. The company keeps the goggles in repair free of charge and when a man leaves the service his \$1.10 is refunded to him, providing he returns his goggles, no deduction being made for the condition of the goggles when they are returned.

At the beginning we had some trouble getting the men to wear them and we were given all the stock excuses, such as, "I can't see through them, they give me a headache," etc., but we kept driving away and each time a man turned in a pair of goggles the glasses of which were shattered by a flying chip or were covered with exploded metal we put them on our bulletin board with a full description of just how near so and so came to losing his eye sight. Such advertising proved a big help and now it is a rare case to have to call a man's attention to his goggles. We cannot say just how many eyes or lost-time accidents have and are being saved by this rule, but we do give the goggles a big share of the credit for reducing our accidents.

It is impossible to place too much emphasis on the part played by the plant doctor in holding down the number of lost-time accidents and the record we have made could not have been accomplished had it not been for our doctor.

It is a rule at our plant that every new man must be given a thorough physical examination before he is given a job and each old man is given a periodical examination. By this arrangement the unfit are kept out of our plant and a line is kept on our employees so that if anything develops which might make them unable to take care of their regular job as they should, we can transfer them to another job which they can handle with safety.

The real company doctor is one in whom the men have confidence. He should be a ready and sympathetic listener to all their troubles, both real and imaginary so that the men will be anxious to come to him for treatment. Most men think it effeminate or babyish to run to the first aid room for every little scratch, but the doctor can do more to correct this idea than anyone else. Infection, which may follow the most innocent looking scratch, is responsible for more lost time than any other one thing and will continue to be so unless the men can be educated to the importance of first aid.

In conclusion I might say that the record we have made was not due to any elaborate program carried on in the plant. The methods we use are similar to those used in most plants, but the success of any safety drive is a matter of cooperation and education, convince your men that they are the real beneficiaries of this safety movement. Inculcate in them a determined winning spirit so that they will point with pride to their personal safety record, the record of their department, of their plant and of their company as a whole.

We have won a trophy and have gone 657 days without a lost-time accident, but they only serve as an inspiration for even greater accident prevention effort in the future and we are going to prove to the world that our adopted plant slogan, "Accidents are Unnecessary," is something more than a mere pretty phrase.

In short gentlemen, what I have outlined is only a very brief review of the safety activity that is being carried on in many plants belonging to the Portland Cement Association. The wonderful record that Chairman Town mentioned this morning very ably supports this and I feel certain that the work is going to grow.

The district safety meetings as well as those of the National Council are being well attended, and the free discussion of everything pertaining to the prevention work has been the means of putting Portland Cement where it stands today.

MR. HARRISON: I see we have Mr. Fred Hunt with us, of the Nazareth Cement Co., and we would like to hear from him on the electrical side of the safety first question.

F. B. HUNT (Nazareth Cement Co., Nazareth, Pa.): This is unexpected, but I want to emphasize that whether you fellows know it or not approximately 20 per cent of the accidents occurring in the cement industry last year were due to electrical causes, and at least six—I am not familiar with the number that have occurred since June—but during the first four months of the year six of the fatalities in the Portland Cement Co. were from electrical causes. As Mr. Harrison has brought out in his report, it doesn't necessarily mean when you speak of electrical hazards that it refers to high voltage. In fact several of the accidents this year have been due to low voltage, down as low as 110.

You folks are all familiar with the accidents that occur in the home, such as a person coming in contact with the water line and electric socket at the same time. Well, get in direct contact perhaps with some high tension side or high side of a transformer which you know absolutely nothing about. You may think there are only 110 volts in there, but maybe there are 22,000 or 33,000.

No doubt you know that last evening the papers carried an account of a joke that was intended for a fraternity initiation down at the University of Texas. This is entirely out of the cement line, but you can see what it may lead to.

For a fraternity initiation down there they took two bedsprings and connected the two sides to 110 volts and put a resistance in there. They put the first four men on these springs and gave them a little shock. That was funny. All the other fellows got a big kick out of it. But when the fifth man went on the springs, it wasn't quite so funny. That man died just four hours later from the shock received from those springs. That was supposed to be 110 volts.

Going further into the boiler question, a number of plants have considered the installation of a transformer, dropping a line from 220 or 110 down to 32 for using an extension while cleaning boilers. I believe that is also wrong. Just as Mr. Harrison said, the insurance companies will not agree to even a 32 volt installation.

Go into your boilers with high powered flash lights. It may cost a little more for batteries, but it will be a saving of human lives in the long run.

Just before closing I would like to ask some of the men, especially Dr. Corlett, regarding plants that have gone into the physical examination and examining every man in the plant, what results they have obtained, and whether they have any definite information or definite figures showing what those physical examinations have done?

DR. CORLETT: I just don't know how to answer that. I examined 1,700 men and I found heart conditions 28 per cent, 13 per cent hernia, 78 per cent pyorrhea, and I have forgotten the other figures.

Last week I examined quite a number of men between the ages of forty-five and sixty, rather above forty-five years of age; and 98 per cent of those men had high blood pressure, valve leaks and hardened arteries.

The Carnegie Steel Co. has put on a drive to have men in the high places physically examined at least once a year, and those over sixty years of age examined twice a year, and I think that is entirely proper.

Those with hardened arteries and high blood pressure who have to climb to high places may become dizzy, and they even suffer strokes of apoplexy if required to climb to those high places. It is very hard to tell some times whether the man has died as a result of a fall or the result of apoplexy.

MR. HARRISON: While we are on the subject of electricity, I saw it stated somewhere that a current of about one-tenth ampere, going to the vital parts of the body, is sufficient to kill the person.

DR. CORLETT: That is a question. I was talking not long ago with quite an electrical expert and he told me that 110 volts certainly would kill if the person didn't happen to be in normal physical condition. I am not prepared to say.

It may be possible for us to tell whether a man is in perfect physical condition from the standpoint of the salts in the blood stream, valvular leakage, which uncompensated makes very little noise, and from other standpoints. I do know, however, that 110 volts have killed a sufficient number of people in the United States that we should consider 110 volts hazardous on all occasions.

MR. HARRISON: I have seen it stated also that in judicial electrocutions where 1,500 volts were applied to the head and the lower extremities, a current of ten amperes passed through the criminal's body would indicate that his bodily resistance was only fifty ohms. If such is the case, a 150 volt circuit, if properly applied, would produce one ampere and that surely ought to be sufficient to do away with anyone.

R. C. FRAME (Alpha Portland Cement Co., Easton, Pa.): Some years ago I visited Dr. Lauffer, of the Westinghouse Co., who is an authority, I think, on the resuscitation of those electrocuted. He showed me the apparatus and told me of some experiments he had made to determine the resistance of a person's body. He found the resistance varied with different men's measurements, such as testing a man through the body by his two fore hands, by putting on gloves soaked in brine, etc.

He was able to get resistance as low as 60 ohms, and in his opinion one-quarter of an ampere would kill any man. In other words, I think the evidence is very definite that a man not in the very best of physical condition, if he gets the right kind of contact can be killed easily.

I have personal knowledge of a man being killed on as low as 56 volts direct current. The man got in contact with a large plate of zinc when he was standing in water to his knees, and the current passed through him. He was so cramped that he was not able to get away from it. We don't know how long it took him to lose consciousness—he probably lost consciousness gradually—but he was dead when we found him.

We must regard any voltage above 50 as undoubtedly dangerous under the right conditions, and so handle our low voltage work that we can avoid this condition as much as possible.

MR. HARRISON: I haven't the names of the gentlemen in the Quarry Section but we would like to hear from some one in that Section.

A. C. GOOD (American Limestone Co., Belfont, Pa.): The matter of extension cords is a very vital subject to practically every plant, and I would like to inquire whether anyone has ever used or whether there is such a thing on the market as a cord totally shielded? There are a number of cords which have a ground wire strung through them intended to ground the socket at the end of the cord, but I wondered whether a cord had ever been developed which had a shield around both the conducting wires?

H. W. FRAZER (Charles S. Warner Chemical Co., Wilmington, Del.): One of the greatest difficulties of the quarries is to get a good ground. In cases where the stone deposit has only one or two feet of dirt, one of the hardest problems is to get a good safe ground.

MR. HARRISON: We would like to hear from Mr. Fortuin, of the Pennsylvania-Dixie Co.

R. B. FORTUIN: (Pennsylvania-Dixie Co., Nazareth, Pa.): There is one point I would like to bring out, but before going into that I would like to give you an idea of our experience this year.

In our seven plants we had approximately 50 lost time accidents in 1927. To date in 1928 we have had exactly 10, which I believe is a very good reduction.

During the last three months we conducted a three months' No Accident Campaign among our four plants in the Ludington Division, in addition to the Hercules Cement Corporation, the Nashua Cement Corporation and the Lone Star Cement Corporation, all those plants being located in the Nashua Division. In 1927, we had 20 lost time accidents in those plants, and in 1928, we have had exactly three.

Now the point I want to bring out is this: I firmly believe that our success in accident prevention work is entirely due to bringing out the old idea in new clothing. Each year and each month we bring out the old idea of safety work and accident prevention in entirely different form.

The first of July, for example, we were at a loss to know what we could start or what we could change to make it new. So we started what is called our "Good Housekeeping Campaign." Each month a man is drawn from each of the plants in another division (there are four in number), and that committee goes to each plant and thoroughly inspects it from start to finish. They inspect for sanitation and safety hazards and then cleanliness; and I don't believe there is any single thing that we have ever done that has given greater impetus to the reduction of accidents than those inspections each month.

Cleanliness naturally takes into consideration cleaning up all sorts of debris around the plant. Tidiness takes into consideration the storing of machinery parts throughout the entire mill. Fire hazard takes into consideration the fire hazards in the various departments such as waste paper baskets and the accumulation of combustible rubbish. Sanitation takes into consideration rotten apples and milk bottles that still hold some milk, and all sorts of garbage that may be distributed through the plant by the workmen. Safety hazard takes into consideration those machines where guards have been supplied and are not in place at the time of inspection.

The committee does not recommend new guards or new safety arrangements no matter where it may be.

This inspection runs in competition between departments in the individual plants and in competition with the other plants in the organization, and I want to say that the interest is very keen and no one department wants to have a lower percentage than any other department. Our superintendents are here today and they will vouch for that statement.

Another thing we created this year was a three months' No Accident Campaign running through the months of June, July and August, and had in addition the three independent plants; and the campaign has an appeal not only to our own organization but to the members of the independent organizations. It was something that had never been carried forth before and it created an interest which was unheard of in the past.

When we started the campaign, we had a mass meeting of the employees of all the plants and we finished the campaign in the same manner; we had as speakers men who talked the language of the men in the mill. Our main speaker for the opening of the campaign was Mr. Thomas Quigley. We ended the campaign with the executives of the cement plants only and we awarded a trophy to each plant completing the three months without a lost time accident.

For next year we have in mind our campaigns and also to go into the matter of physical examination. We are preparing that now and expect to put it into

effect on January first. It is the old ideas that we are trying to bring out in new clothing, and that I believe is the reason for the interest that we have carried along in our organization since the inception of the Pennsylvania-Dixie Cement Corporation.

MR. HARRISON: We would like to hear from some of you gentlemen in the Quarry Section. I haven't a list of your names so I cannot call upon you individually.

The Industry in Pennsylvania is Praised

THOMAS J. QUIGLEY (Department of Labor and Industry, Harrisburg, Pa.): By invitation of Mr. Fortuin, I got up here. I want to say that I feel at home in this meeting because looking around me I see so many Pennsylvania people here.

When it comes to accident prevention work, not because this is the cement meeting or joint cement and quarry, I want to say that no industry in the state of Pennsylvania is doing more for accident prevention work than the cement industry of Pennsylvania. They tell you about the wonderful records that some of the steel mills have established in Pennsylvania, the railroads in Pennsylvania, and other industries; but I say that the cement industry doesn't take second place to any industry in the state of Pennsylvania for accident prevention work.

During the No Accident Campaign in the month of June, it was my pleasure to attend about 44 different safety meetings in the interest of the No Accident Campaign. Not only did I attend meetings of the general quarrying industry, but limestone and everything else. For the first eight months of 1928, as compared with the first eight months of 1927, we have shown a reduction of 25 per cent in fatalities in the state of Pennsylvania. For the first eight months of 1927, we lost 28 lives in the quarry industry, that is quarries of all kinds, and for the first eight months in 1928 that number has dropped to 21. In 1927, we had 2,483 lost time accidents in the quarrying industry and for the first eight months of this year, we have dropped down to 1,318.

If we can continue in the quarry and cement industry for the balance of this year as we did for the first eight months of 1928, the cement and quarry industry of Pennsylvania, I believe, will lead all other industries in percentage of reduction in accidents, fatal and nonfatal.

To accomplish that we have had the most wonderful cooperation from all of the quarrying and all of the cement industries. Last week I attended eight meetings in the Western part of Pennsylvania. I went into a new field, into virgin territory to preach accident prevention work.

I went in among the refractory corporations. Never before had safety meetings been held; never before had any person attempted to talk safety to them or to show them how accidents could be prevented in refractory industries. Every plant that I visited had closed down their plants for one hour, paid all the men for their time and some of them even paid the contractors for their loss in the day's earnings to attend the safety meeting. When you get that kind of cooperation, gentlemen, whether it is in Pennsylvania or in Texas, in Missouri or Michigan, you cannot fail to have real, honest-to-goodness results. You are bound to make a success of it. You certainly cannot fail when you get that kind of cooperation.

But to the Cement Association in Pennsylvania belongs the credit for getting all the other quarrying industries working for safety. We can point with pride to the record made by the cement industries and they never failed to come with testimonial and information whenever we called upon them. I say that the records made in accident prevention in the state of Pennsylvania this year and the reduction which we have shown have been accomplished only through 100 per cent cooperation from the cement and quarrying industries; and I am satisfied that our new program which goes into effect January first for a continuous drive for

twelve months in 1929 will put Pennsylvania on the map and we will make the most remarkable showing for accident reduction that has ever been accomplished in this country.

MR. HARRISON: We would like to hear from Mr. Adam of the Lawrence Portland Cement Co.

D. A. ADAM (Lawrence Portland Cement Co., Northampton, Pa.): I just want to say a word this afternoon about something I have talked on before. That seems mighty easy, because if you repeat a thing several times, the sub-conscious mind comes into play and you don't need to care. But I do this because I see today, quite a number of new faces. Not new in accident prevention, but new in our cement and quarry meetings.

Interpreting Safety in Simple Terms

Some three years ago the idea occurred to me: Do the men grasp and know thoroughly what it is the foremen tell them? We all appreciate that the foreman is the key to the accident prevention work in a plant. I thoroughly agree with that; but when we place the responsibility on the foreman we put him in a position that he must answer for every man under his control.

Now, as I said, three years ago the idea occurred to me: Do the men in our particular industries know exactly what the foreman means or what he says? It puts me in mind of a story that illustrates the point.

It was at a dinner party and it was very quiet. One of the guests, to break the monotony, said to the hostess, who was a wonderful piano player, "Would you play for us?"

She played a selection of the great Wagner's and when she finished there was a dull lull. You all know. You have been in circumstances, where a dull silence comes over a company, and anything might happen. Well, that happened there. The lady who had been playing the piano said to the gentleman on her right, who was rather deaf, "Would you care for another before your dinner?", and he said, "No thanks, I had two before I came in." So I think the men sometimes do not really know just what is being said.

So, I decided to call the men together at twelve o'clock just after the dinner hour is over; I sit down and just talk for half an hour. I try to show those fellows why the foreman tells them to do certain things and why they should do them and also the reason why the foreman tells them to do them.

I also ask ever so many of our men questions about the regulation of our plant. "Do you know why you are asked to do that?" "No, I don't know. The boss said to do it."

That is the wrong attitude. If you tell a man to do a thing mechanically, you are certain to get results to a point, but you do not get the full cooperation that you ought to get and must necessarily get to put safety across.

It is the man who does the work that is apt to get hurt and not the foreman, and I felt that I was doing in my humble way a service to help the foreman, on whom we put the responsibility. I don't know whether it is these Thursday talks, but our accidents have tumbled down faster than ever before.

Ladies and gentlemen, we often hear people say, "Well, what is the good of going to a safety meeting? There's nothing new." I agree there, and I feel that when I come to a safety congress, I don't come with the intention of taking something new back to my plant in the way of ideas. But I do feel that I want to come to these meetings to go back with the encouragement and the endorsement given me by those meetings which are sponsored by the National Safety Council and those meetings which are sponsored by the Portland Cement Association.

I feel that when I go back I am on the right road, and it is up to you and me

MR. HARRISON: Will Miss Weeder, of the Jay & Portland Cement Co., tell us something of the welfare work they are doing?

MISS J. A. WEEDEE (Jay & Portland Cement Co., Egypt, Pa.): I have nothing special or exciting to add to what has already been said. We are not members of the trophy club but we hope to become so during the coming year. We are gradually coming down from a rather high record to two in 1928, and we are going to make every effort to get one of those trophies.

MR. HARRISON: Mr. Cline, of the Universal Portland Cement Co.

J. R. CLINE (Universal Portland Cement Co., Pittsburgh, Pa.): We give every man in our plant a physical examination. This week we have just finished the second examination for the second year. It pays. The men like it and there have been a number of them benefitted by the suggestions given by the doctor. The first few of them who knew they had physical weaknesses of some kind, tried to keep from being examined, but they have come around with suggestions of how they can be benefitted.

We also have group life insurance.

MR. HARRISON: Is Mr. Switzer present?

E. C. SWITZER (Petoskey Portland Cement Co., Petoskey, Mich.): Our experience has been that in 1925 we had a very bad year in lost time accidents and one fatality. We have since that time been improving our record; in 1926, we had three lost time accidents and in 1927 two, and we have had one so far this year, so that we are making progress. We hope to get in the trophy class. Our expectations are to keep at the thing and work until we do. The contest for the trophy has been a very great incentive to progress in safety work with us as with all the other plants of the Association.

Accident Frequency the Important Guide

H. W. HEINRICH (The Travelers Insurance Co., Hartford, Conn.): I want to say just a word in regard to the value of the so-called lost time accidents as a guide to effective accident prevention work in the quarry and cement industries.

It is inspiring to hear man after man get up and recite the experiences in his particular plant. I have no quarrel with that. Surely the reduction of lost time accidents is a very good measure of effective safety work. It is the result we hope to attain, but as a guide to accident prevention and lost time accidents, it is, not so good a point to use. It is not so good for instance as frequency of all accidents.

In the very interesting meeting the Metals Section had this morning, one of the speakers referred to the common type of traffic accident where a man driving an automobile across a railroad grade crossing is injured by a passing train. It was referred to in one sense as an unavoidable accident. I want to use that as an illustration in regard to the value of lost time or serious accidents.

In the case of that kind, it is possible of course that a man may, the first day he buys a car, the first mile he drives it, and the first railroad grade crossing he passes, be struck by a train; but it is much more likely that he has driven across railroad crossings many times without stopping to look or listen and is finally struck.

The point I wish to make in connection with that is that the one accident that finally results from a long series of unfortunate mishaps is merely the result of a great many setups of the same situation, and so when it finally does occur, a man is hardly justified in saying that this is the first time I have ever driven across a railroad grade crossing without stopping to listen. He has done it many times before. An effort has been made to determine how many times a man does the same thing that finally results in an accident, or finally results in injury (let me put it that way), and it has been estimated to be from 30 to 40 times.

The point is that there are 30 or 40 opportunities for a good live supervisor who has accident prevention work at heart to see and to control and to observe and to correct these conditions that run along so many times before they finally result in accident.

To go back to my first point, as a better guide to effective accident prevention work, I would take any accident, because not having an accident is nothing but luck and cause is nothing but luck. The accident, however, is not luck. The accident is controllable, but whether through inattention or through some extraneous circumstances, whether the accident results in a serious injury or minor injury, is purely a matter of luck; then why choose the one accident out of 30 or 40 as a guide to prevention instead of 30 or 40 all of which are the same and all of which may lead to a serious accident?

If a man slips and falls or drops something or knocks against an obstruction, those are so-called causes of accidents. A man fumbles something in his hand and lets it drop; it may result in only striking the foot, it may strike one toe and cause a slight injury, and it may strike his instep and cause a lost time accident; but either there is no accident, a slight accident, or a serious accident, and all three of these are a better guide than the one accident which happens to result in lost time.

Improper Use of Electricity Causes Accidents

In this meeting reference has been made to electrical apparatus as a cause of accident. I want to point to the fact that electrical current is a friend to industry if properly used. It is a powerful, effective and useful giant, and a friendly giant. Far from being the cause of accidents, if properly used, electricity might be easily considered the reverse. I understand thoroughly the position of the gentleman who made the remark about 20 per cent of the accidents in the cement industry being caused by electrical current, but he used the term "caused" and although the mere matter of words is of little moment, yet it means something in so far as we use causes in order to correct the conditions that promote injuries.

Electrical current in the instance that he cites was properly not the cause at all. If, through mishandling, electricity causes injury, then the mishandling is the thing that we want to drive at and we needn't necessarily be afraid of current. If the wiring was improper, if sufficient ground was not provided, or if the installation was imperfect, those things of course through the medium of electricity may cause injuries; but I assert that the cause is something other than electricity. And so again in closing, I want to say that the value of any accident, the value of minor accidents, the value of all accidents is a much better guide than is the lost time accident.

The result that we are aiming at is, of course, the reduction of lost time or the serious accidents which we can achieve through concentrating our efforts upon all accidents.

CHAIRMAN TOWN: Mr. Harrison, has anyone any suggestions that he can give to help us out concerning the screw conveyor accident? We all know that the screw conveyor constitutes one of the greatest hazards in the cement industry, probably around some of the crushing plants and quarries, but certainly around cement plants. Has any one anything favorable to offer on the proper avoidance of accidents due to screw conveyors?

WILSON W. RITTER (State Workman's Insurance Fund, Harrisburg, Pa.): Being quite familiar with conditions from an accident and frequency standpoint throughout Pennsylvania, if I were to leave this meeting without saying a word of commendation to the cement industry in the Allentown district, I would really feel condemned.

My friend Mr. Cortell, from Pittsburgh, has said quite frequently that there is more safety per square foot in the Pittsburgh area than any place in the United States. I cannot agree with him. I want to say that there is more safety per square foot in the Allentown district than any place, I believe, in the whole world.

Now, why are they obtaining such remarkable results? Briefly, simply because every man from the general manager on down to the fellow in the ranks is 1,000 per cent strong for safety always. They are obtaining these results by proper safeguarding, by education, proper medical facilities, etc.

A. E. SNODGRASS (Louisville Cement Co., Louisville, Ky.): We are not members of the trophy club but we have a record of thirteen months without an accident. The reason why we are not in that bunch of plants is because we endeavor to get it within a calendar year.

We have our regular monthly meetings and discuss the near-accidents, and it is very amusing to hear the men talk about those accidents which might have been serious but which got by without hurting anybody.

One of our men spoke about putting three or four tons on a one ton chain block, and they put it up to the foreman: "If you saw your men putting a three or four ton block on a one ton block, what would you do?" The foreman said, "I'd tell them to go ahead this time but don't do it any more."

This gentleman's remark impressed me that we are playing in mud rakers. In other words it's the frequency that we should work on. We had 608 accidents in 1926 and one lost time accident; and in 1927, we had 354 accidents of all kinds and one fatality. So it is the number of near-accidents or minor accidents that is the barometer. In other words we had 354 chances and killed one man, and we had 608 chances in 1926 without killing a man. So, I think, as the gentleman who preceded me says, it is the number of chances we take rather than the severity that measures our progress.

An Exception to the Word "Luck"

G. E. DAVIS (Universal Portland Cement Co., Chicago, Ill.): I cannot help but take exception to the word "luck" being used in accident prevention. If we are going to accept it as luck, we had better stop right now. Accident prevention and the reduction of accidents must be the result of work. We must get behind this movement. We must reach the working man.

We all realize that we must start at the top, with the management. We have been doing that for the past twenty years in the United States Steel Corporation. Start right at the top and go right down through the superintendents and the foremen. That is the key to success, but you must get down to the man himself, and that is the question and the problem today—how to keep interesting the man in safety?

I often tell our men that there is a right way to do everything. There is a right way and there is a safe way, and we keep working to that end, working to prevent all accidents no matter what they are.

H. W. HEINRICH (Travelers Insurance Co., Hartford, Conn.): May I reply to that gentleman? I know that I have difficulty in expressing my thoughts, but I am quite sure that the audience in general hasn't taken the same interpretation of my remarks that the gentleman has. However, it may be so and I would like to repeat again I most certainly agree with this last gentleman who has spoken.

Accident prevention is not luck, not by any means. Accident prevention is not luck, not by any means. Accident prevention is a science. It is based upon known laws, and boiled down to its simple fundamentals, it is nothing but finding the cause of a certain trouble and removing that cause if possible.

What I did say about luck, however, was just this: That once the accident happens, which we gentlemen are here to prevent not through luck but through work

—once that accident has happened, its degree of severity is largely a matter of luck.

A. J. EALES (Bessemer Cement Corporation, Bessemer, Pa.): With regard to that, I take exception. I think there is such a thing as luck. While we want to cut out accidents and are working for that, the only accident we have had this year in the cement plant was when a laborer from outside came in to work on the fountain. He put in some cast iron pipe and there was a small piece on the pipe that we wanted out. We just knocked that chip off and it struck one of the workmen in the eye and laid him off for a month. I might call that a luck accident. It was done by an outside man entirely. It loses us a chance for the trophy this year, and that might be luck.

A year or two ago, I saw a safety film showing the method of grating and chaining a hole as we used to do in our quarries. That is take four pieces of fusc and a stick of dynamite on the end and drop it into the hole. That was shown as a safety practice. Until two years ago, we had a man doing the same thing. He had been doing it for six or seven years when one day something attracted his attention and he didn't drop the stick of dynamite in the hole and it went off in his hand and killed him.

We have changed that now. We have a small battery to lower the charge down in the hole and then set it off.

In the early part of the discussion, the mental attitude of the workers was mentioned. We don't know the mental attitude of the worker in this particular case. After he was killed his fellow workers said, although he had been handling that job for six or seven years, he was always afraid of the dynamite. He always figured that he would be knocked off with it. We never knew that or we might have changed it.

A short time after the accident occurred we had a man in the packing department who was riding a car down to the packing house and he sideswiped another car and the man claimed that he had his one leg crushed between the two cars. It did not show any bruises or any damage to the limb at all, but yet he would not put the foot to the ground at all. Feeling that the best thing to do was to have an x-ray taken, we loaded him in the car and took him to the doctor to have an x-ray taken. He screamed when we carried him in the x-ray room and put him on the table to have the picture taken. I waited for the picture to be developed and it showed no break at all. I said, "There are no bones broken and you are all right." He got off and walked to the car and went right back to another car. This shows the mental attitude of the men which you must take into consideration. There are some men whose mental attitude is strange.

The fellow is an excellent worker and we kept him on the job. About two weeks ago he got some cement dust in his eyes. It was taken out locally but still he claimed there was some in his eye, and so I said, "We'll load you in the car and take you to town to an eye specialist." We took him to an eye specialist and he said there was nothing there. He put a few drops in his eyes and the man went back on the job satisfied.

So there are mental attitudes that we must take into consideration. Otherwise, we will get some real lost time accidents.

We have been very fortunate in the accidents in our quarry although we have had some fatal ones. We have been trying hard for the trophy and we rather seem to have a different spirit entirely. Last year we had one accident which cut us off from the trophy. We had one this year that cuts us out.

We had a case where the local doctor said he could not get the chip out of the eye. We took the man downtown to the doctor and the steel wasn't magnetic enough and we couldn't get it out with the magnet there. So we took him over to Youngstown where they have a larger magnet, but they weren't able to get it out either. The eye specialist suggested taking the eye out and said that was the only thing that could be done. This was over twelve hours later and no infection had

set in so I wouldn't let them take the eye out. That afternoon we took the man to Pittsburgh. They put him under an anaesthetic, turned the eyeball out and took the particle out and that man has his eyesight today.

MISS J. A. WEEDE (Jay & Portland Cement Co., Egypt, Pa.): I am awfully sorry to have to get up, but I see the doctor isn't here. You have to know all the inside story of a case in order to appreciate it.

The eye is a very delicate organ, and while the one eye may be all right, there is such a thing as having an injury in the other eye and by sympathetic action it is possible to lose the sight of both eyes simultaneously.

An Unfortunate Accident in the Quarry

G. W. BROWNELL (North American Cement Co., Hagerstown, Md.): I just want to say a word in connection with the element of luck. We have three cement and lime plants, and after plugging mighty hard for safety in 1925, we were awarded the safety trophy. In 1926, our Berkley quarry operation was awarded that trophy, and then again in 1927, our Security Mill operated from January first until November sixteenth without a lost time accident. The accident that made it impossible for us to finish the year as a member of the trophy club was undoubtedly due to bad luck. Again this year we went up until July thirteenth. It was Friday, July thirteenth, without a lost time accident.

In the case this year it was the safety man who lost his life. The first thing in the morning, about six-thirty just before the pillars and shuttle operators went to work, this man being accustomed to go over the place and look for dangerous spots in stone, was at a place where there were several over-hanging stones. He was standing above them prodding down with about a ten foot rod in, I believe, the most approved safety manner, and the stone he was standing on slipped.

About three or four ton of material, of clay and stone, dropping from above, wouldn't have been a hindrance had he been over a little ways and only thirty feet up the face, but he went down with that slide and a small stone, comparatively small—probably a cubic foot—hit him and gave him internal injuries and he died five hours later. I contend that was luck. The man had a reputation for safe working. He was doing a safety act and doing it in an approved manner. I think that was bad luck that kept our Security Mill from finishing any year to date as a member of the trophy club.

MR. HARRISON: One November, we ran 27 days without an accident and the engineer one day stuck his finger in the releasing lever. That ruined the November accident record. We thought we could obtain a clear record during December but on the second of December in going through the engine room, I asked the chief engineer how the accident had occurred and he stuck his finger in it and we had one more accident and one demonstration.

I have read Mr. Heinrich's paper on the Origin of Accidents, and I think anybody reading that article will thoroughly agree with Mr. Heinrich.

(Chairman Town resumed the chair.)

CHAIRMAN TOWN: I think that we will all agree that these discussion periods are highly interesting and educational. It occurs to me that we may possibly have fallen short in a measure from the amount of good we might have obtained, had we laid out our lines of discussion in certain definite directions, and possibly appointed a man to start a discussion along certain definite lines which had been causing the greatest trouble and perhaps been conducive to the greatest number of accidents around the plant, and then drawing out of the discussion ways of preventing those accidents. That possibly could have been worked out in a satisfactory manner and may be something for the Program Committee to think of for next year's session.

A. J. EALES (Bessemer Cement Corp., Bessemer, Pa.): Where we have a free open discussion we hear the other fellow's accidents and they logically come one from the other and I think we get further ahead that way than assigning subjects.

CHAIRMAN TOWN: Just the way they have done this afternoon. Then there is one other thing that occurs to me—one afternoon is far too short for discussions. They are certainly very interesting and much good can be derived from them.

A. C. GOOD (American Limestone Co.): I would like to voice a protest which I understand was made at your meeting this morning, and that is that the future meetings of the Quarry Section and the Cement Section not be held at the same time because there are many of us who want to attend both and we cannot.

CHAIRMAN TOWN: I think that is a very timely remark. As you say, it was mentioned this morning and I believe it will be possible for the Program Committees of the two sections to confer with each other and concur in the program arrangements which will enable those of either section to attend interesting parts of the meetings of the other section.

Is there anything else to be brought before the meeting adjourns?

I feel that this has been a very helpful session and we look forward each year to making the program more and more interesting.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Refrigeration Section

Section Officers

Chairman—V. WAKEFIELD, City Ice Company of Kansas City, Kansas City, Mo.
Secretary and Publicity Committee Chairman—E. H. FOX, National Association Practical Refrigerating Engineers, Chicago, Ill.
Poster Committee Chairman—G. H. WEBBER, Consumers Company, Chicago, Ill.
Membership Committee Chairman—WM. M. OLER, JR., American Ice Company, New York City.
Statistics Committee Chairman—A. C. GENTRY, Atlantic Ice and Coal Company, Atlanta, Ga.
Engineering Committee Chairman—A. J. AUTHENRIETH, Middle West Utilities Company, Chicago, Ill.
News Letter Editor—F. L. McCANDLISH, Southern Ice & Utility Company, Texarkana, Texas.
Executive Committee: THE OFFICERS AND
B. B. McCULLOCH, Bureau of Safety, Chicago, Ill.
E. G. HITT, Chicago Ice Producers Mutual Liability Company, Chicago, Ill.

October 2, 1928

VINCENT WAKEFIELD, Chairman

Treasurer, City Ice Company of Kansas City, Kansas City, Mo.

The session of the Refrigeration Section at the Seventeenth Annual Safety Congress, was called to order at two-fifteen o'clock by the chairman, Mr. Vincent Wakefield, Treasurer, City Ice Company of Kansas City, Kansas City, Mo.

CHAIRMAN WAKEFIELD: The Chair takes a great deal of pleasure in welcoming all of you to this session. It is the first time in the history of the National Safety Council that those who are vitally interested in refrigeration, and those industries using refrigeration, have had the opportunity under the auspices of a meeting of their own to sit down together and discuss a common problem. Therefore, the Chair takes a great deal of pleasure in not only thanking you for your presence but in expressing the hope that this is merely the forerunner of meetings that will be repeated at sessions of the National Safety Council to come.

This meeting has been organized by the Committee so that those of you who are using refrigeration would have some idea of what can be accomplished through an organization of a section within the National Safety Council. It was felt, therefore, that it would be the wisest thing for some one who had had a great deal of experience in organizations such as this, and for some one who had a great

deal of experience in organized safety to come and tell us something of what it has been possible to do in other industries.

A man we all had in mind when this subject was proposed was Mr. Charles B. Scott of the Bureau of Safety of the Middle West Utilities System, president of that organization and a past-president of the National Safety Council. When I asked Mr. Scott if he would make this address to us today, I found that he had turned down already many requests to address this Congress. Nevertheless, in his kindness of heart, he consented to do it. I think that we are extremely fortunate in having the opportunity to hear Mr. Scott today. I know of no one who is more capable of pointing the way in the refrigeration industry or any other branch of safety than he. I, therefore, take a great deal of pleasure in introducing Mr. Charles B. Scott of the Bureau of Safety, a pioneer of safety work, and my personal friend.

Address

By CHARLES B. SCOTT
Bureau of Safety, Chicago

I was constrained to accept your chairman's invitation, notwithstanding the fact that I preferred not to do so, for several reasons. The first was the personal friendship to which the chairman referred, and the fact that it was difficult for me in view thereof to decline. The second was that I doubted my ability to do justice to the subject assigned me. The third was my desire, in attending the convention, to be more free to enjoy the advantages that many of you have of listening rather than being listened to. All these things considered, it seemed rather unfortunate that I should be selected to discuss this subject.

It occurred to me however, that perhaps I could tell you some of the reasons why a refrigeration section of the National Safety Council should be organized, and that I might be able to point out to you some of the advantages of such an arrangement. My sincere conviction is that this industry, the refrigeration industry should have such an organization as is contemplated by this first meeting.

The reasons for that feeling are: First, that it would be beneficial to your industry as a whole to have some organized arrangement by which you and those less fortunate than you, who have not had the opportunity of coming in contact with an organization such as the National Safety Council, could be helped in a work that I know they would like to carry on. The companies with which I am associated are interested in the refrigeration business, and from that point of view, I can realize the necessity for such an organization as is proposed.

In this period of new development in industry, in this age when we no longer think of industry as we formerly did, there is hardly a necessity for anyone to say to you that the efforts which you are making should be well organized. There is no successful industry but that has some machinery or channel of procedure by which its activities and work is correlated and standardized. There is hardly a successful company or corporation, that does not feel the necessity for contact with organizations engaged in similar work. This is a day and age when this fact is recognized, and when people engaged in a particular business, or men engaged in any particular work, realize more fully than ever before the advantage of knowing what the other fellow does.

My company has a very liberal policy with respect to association activities. During the past sixteen or seventeen years, I have spent about twenty per cent of my time, aside from the regular duties of my job, in helping along the organization work of industry, particularly the work of the National Electric Light Association, our company being engaged mostly in the power generation and distribution busi-

ness. For thirteen years my employers have insisted that I should keep the chairmanship of the Accident Prevention Committee of that national organization.

During that same time, and concurrently with some of the thirteen years, I was chairman of the Accident Prevention Committee of the American Gas Association and the American Electric Railway Association; and through the entire history of the National Safety Council I have been one of the representatives of our company in that organization and have served on its Executive Committee.

If my employer should ask me today if he and his stockholders received proper compensation for the money that has been spent in all those years my traveling over the country attending meetings, and the time that I have spent in these activities, I should honestly, frankly and conscientiously say to him, "Yes, a thousand fold; a thousand fold have you been paid."

There are occasionally those who accept responsibilities in these national organizations, prompted by pride, ambition, and the fact that they get before the public, but they are very few. The men in the National Safety Council have given years of their time, much of their energy, and expended from their own personal funds a large amount of money. They were not prompted by the conspicuous place they might get in the organization, nor by the personal pleasures that would come to them from such activities. These men have done these things for the advancement of the cause which the organization represents.

The present standing of the National Safety Council, the work it is doing and this Congress here today—all is due to the influence of the volunteer workers who have put their energy, their time and money into this work. What I have said of this organization is also true of these other organizations. If the executives of our companies, and if the industry at large knew the real spirit that permeates these national organizations and these national efforts, there would be an even greater support of these organizations by all companies. If these executives and these companies knew of the benefits that accrue to themselves and to the interests which they represent by reason of group meetings, they would get together and see to it that this correlation of ideas and this interchange of opinion is greatly enlarged.

You ask me how I, charged with the accident prevention work of a group of public utilities, was justified in spending so much time and so much money with the National Electric Light Association. You may ask in your own minds whether or not the experience I had there really and truly was of benefit in my own job. Let me refer you to just a few accomplishments of that organization to prove what I have said.

My mind first turns to a book that was prepared by some six or eight gentlemen from different parts of the country. It was designed to teach linemen how to do their work safely. This was prepared as a textbook, and it serves the purpose of a textbook on the properties where groups of linemen are brought together under the direction of their foremen and their line superintendent. They take a course of training in the proper methods of construction and maintenance of distribution lines. The book was prepared so that there would arise within the mind of the student or of the reader, questions as to whether some of the methods of procedure were correct or whether they were safe. The book was purposely written to bring up this interest and discussion on the part of linemen. That booklet has been adopted on all of the properties with which I am connected. Every winter, linemen's safety schools are held all over the country in which the foremen or the superintendent is the teacher, and the linemen are the students. They are taught safe ways in which to do their work.

In 1922 we made a calculation from the records of our company, which showed that 75 per cent of the fatalities and 75 per cent of the accidents in the electrical industry were due to electric current. This booklet and these classes have enabled us to lower the severity record until today instead of electric current causing 75 per cent of the fatalities and serious accidents, it is down to perhaps less than 60

per cent. That course of instruction was prepared by representatives from different companies coming together, correlating their own ideas, and developing this book of instruction, which has been of great benefit to us in lessening the number of serious and fatal accidents.

If the whole thirteen years had resulted in the saving of only one lineman's life out of the group I represent, my company, and I myself, Mr. Chairman, would have been justified in spending the time which was spent on this work.

This same committee, during the thirteen years of my association with it, also developed the proper type of gloves for linemen to wear. Prior to that time a miscellaneous lot of gloves of questionable value were used. These engineers made a study and a laboratory test and succeeded in getting out specifications for gloves that would fit the hands, gloves that resisted the current and gloves of proper length. Now every firm in the electrical industry knows the standard specifications for gloves. If the committee in the thirteen years had only developed that protection for these men, a protection very much needed, this electrical industry would have been justified in spending the money and the time expended in that development.

I also had the honor and privilege to serve on the Committee on Resuscitation for the gas and electrical industry of this country, that was conducted under the auspices of these national organizations. If the gas business and the electrical business had had no national organization, this resuscitation method never would have been developed.

Only a few years ago on our own properties there were hundreds of men, in fact, hundreds of locations, where they had never heard of the Schaefer method of resuscitation. If my companies want to measure the value of my services, I am perfectly willing that they measure it only by the work that has been done on resuscitation and the results of that work. In the thirteen years we have saved the lives of 100 linemen because of the knowledge that our people had of resuscitation, knowledge which they got through these national organizations.

If time permitted I could tell you much more. Here is a list of a whole page of the outstanding accomplishments in accident prevention made through the National Electric Light Association, any one of which would have fully justified the time and the money expended by our company in this work.

You might say, "That is all right in the electrical business, but the refrigeration business is a different business. We do not have electricity to contend with." (Perhaps some of you fellows will think this is a wild statement I am going to make.) There is not in my opinion a refrigeration manager who knows the comparative hazardousness of the refrigeration business as compared with other industries.

Yet the National Safety Council, notwithstanding it has had no refrigeration section, has kept a record as to the dangers of the refrigeration business. They have worked out a comparison of your business with other businesses as to the hazards of it. When I read these figures you are all going to be very much surprised. The accident frequency per million hours of work in the ice industry (that is, the frequency of accidents per million hours work in the ice industry) is 81.48. In the public utility business, the accident frequency per million hours work is 31.11, or about one-third of your own accident frequency. Your accident frequency is 81.48 per million hours of work and the accident frequency of all other industries combined is 26.82. That surely says that the refrigeration industry should get busy on the question of accident prevention.

You might say, "Well, I believe that; we do have more accidents, perhaps, than any other industry, but they are all trivial accidents. They are mostly caused by a piece of ice falling on somebody's toe or by the tongs slipping out." Let us put it then on the basis of severity. The severity per one thousand hours of work in the refrigeration industry is 3.22. In the public utility business, that dangerous business where men handle electric current and where the current kills and injures

in 75 per cent of the accidents, it is 3.59 as against your 3.22. And in all the industries combined it is only 1.76 as against your 3.22.

You gentlemen who are in the refrigeration industry don't know how you stand as compared to these other industries, and you don't know the possibilities of what can be done by organized efforts to reduce these ratios. If this refrigeration section is organized and if the same intelligent, earnest interest is given to the ice problem as has been given to the steel industry and to the electrical industry, I stake my reputation as a prophet that in two years from now you will have reduced that severity rate 50 per cent. By doing what? By getting together the men in your own industry that are interested in the saving of the lives of your employees and delegating to those men the duty of providing methods by which accidents can be prevented.

If there is any indictment against the industry of this country of which it ought to be ashamed, it is the indictment of the loss of life of workers in that industry. And any industry that does not take an active interest in doing that, is not worthy of the sympathy it should have and the cooperation it should receive, because it is neglecting one of the most important phases of industrial life.

I hope the talks that will follow this feeble effort of mine will convince the men that are here to such an extent that they will go back and convince the men who sent them here that this ice industry needs the support of the executives of these refrigeration companies—not a passive interest but such interest as will influence them to do the things that my chief executive had me do; namely, that they will give their men and spend their money in developing plans for the control of the accidents that you are having. They are just as easily controlled as they are in any other business and perhaps easier than in some of the other industries.

Do you know what safety work has done for the companies with which I am associated? Do you think that about all the benefit I have contributed to the companies with which I am associated has been to devise some papers, specifications and rules that have resulted in fewer accidents, more safeguards on our properties and such things as that?

The big men in our industries have yet to see this safety matter as it really is. In the public utility field, the big men, the chief executives, have yet to take into consideration the effect of this work on the public relations, on the good opinion of the people, their customers and the people with whom they come in contact. I don't believe they yet know the motorman on the street car has through safety work been transformed from a gruff, impudent, uninterested employee to a gentleman, with kindly feelings, with a sense of regard for the lives of the riders. They do not know as yet the true value of the training that these men have had through the avenue of safety work by which they have been taught to appreciate the bigger things in their job.

These men, these motormen, these linemen, fully appreciate the value of safety work. They think of it in terms of whether or not they have been injured or whether they have a good safety record. They fail however to take into account some of the things that safety work has done for them, that have made them better fathers and better husbands and better citizens in the community in which they live.

We who are engaged in the work have not yet learned to measure the true value of the thing we are seeking. We who have spent our lives at it have not learned the true value it has been to us as an individual in making us better fathers and better husbands, better men, better friends, better citizens, more upstanding men. These are some of the by-products of safety work that are going to come to us, if you want to value them as company assets. These are some of the values that are coming to these men back home that are having these accidents and these foremen that form your family in the company with which you are connected.

These are some of the benefits that come to you as individuals for taking a part in doing the thing you ought to do.

There is another measure, perhaps not so important and not so productive of good results, and that is the measure of increased efficiency. We have better people working down in the valley of Texas than we had five years ago. We have more efficient men. Our losses are less. The upkeep expenses are less. The quality of our ice is better than it used to be. That is partly due to the spirit that produces better work and better things and by the men doing their work right. The increased efficiency is a by-product of safety work and should not be lost sight of in estimating the value of it.

There are other benefits, there are other reasons why you should go into it. I said a while ago that the industry of today is not the industry of ten years ago. It isn't. I don't know how long I will be permitted to continue my services in the field of industry. I don't know what test will be applied to all I have tried to do when the time comes for me to step aside. There is one test I want those men to apply to my services, and by that test I am willing that the justification for my employment shall be made, or it shall be unjustified. I want them, when they measure my worth to my company, to ask this question: What did he do to humanize the industry? And by that test, and that test only, am I willing that I should be judged. If by these years of effort through national organizations such as the National Safety Council, they are able to say, "He did contribute to the humanizing of industry," my years of service shall have been justified.

When Mr. Wakefield persuaded me to make this appeal to you I made up my mind that I would base it on business reasons; that I would stay away from the thing I am now touching on. I thought I would. A few minutes ago, when I came up to the hotel, I took a kind of a hitch on myself and said, "I am going to keep away from the other things that I am always preaching." Now, I am tempted to do the thing that I said to myself I wouldn't do.

But men, listen to me, forget your business for the moment, forget the economics of it, forget the strivings that you are making to develop your industry along the lines of efficient operation, forget those things just for a moment, and then ask yourselves this question: If I interest myself in this, can I contribute to the welfare and the happiness of my people back home? Just put it on that basis. Say to yourself, "Can I save one of the fellows that works for me; can I contribute to the happiness of one of the families that form my industrial local service; can I do something for Jim Jones, his wife and his children back home if I interest myself in this?"

Let the answer to that question tell you what you are going to do about having your industry come to the front and join the other industries and take a part in this work. And whether or not it pays, whether or not you develop standards and regulations and rules, if it saves the life of one of those working with you, it is worth all the effort that you put into it.

I hope that your industry, the refrigeration industry, will join hands with these other industries and say to the world, "We believe in the human side of this industrial question; it means something to us. We are going to line up with you and do what we can to carry on this work."

CHAIRMAN WAKEFIELD: I am sure that all of you who listened to Mr. Scott cannot help but have one striking thought as a result of that address. I know that the Chair feels that he has been participating in an industry that in the face of the figures that Mr. Scott has laid down indicts us as a careless and thriftless industry, when we can run frequency and severity records greater than a dangerous business, such as the power and light business.

Before Mr. Scott leaves the room, I want to extend to him on behalf of the Section our very heartfelt thanks for that address.

We have heard from Mr. Scott on what organization can do, and in looking around over some of the industries who have felt their way along by individual effort and without directed effort from this headquarters of safety, we found there was a large organization in the City of New York known as the Knickerbocker Ice Company that had done considerable work. Therefore, we felt it would be interesting to you to have an executive from that organization talk to you and tell you why he believes in a safety organization in his company. I am, therefore, very pleased to introduce to you at this time, Mr. Wesley M. Oler, Jr., Vice-President of the Knickerbocker Ice Company.

Why We Believe in Safety in Our Company

By WESLEY M. OLER, JR.

Vice-President, American Ice Company, New York City

I can't help feeling like the Irishman who knew he would get ahead in life, because he started off as a conductor and now he's a motorman; for it is certainly quite a step forward from the garages, stables, coal yards and dressing rooms of our plants, where I do most of my speaking, to this handsome room in the Hotel Pennsylvania. Talking to the boys in our own organization is more in my line than public speaking, but when the invitation came to tell why we believe in Safety in our Company it struck a chord so close to my heart that I just couldn't turn it down.

Lord Tennyson said in one of his famous poems: "I would that my mouth could utter the thoughts that arise in me." If the great poet had difficulty in expressing himself, you can imagine my feeling in tackling a subject that has played such a tremendous part in industry, and that, up to the present, at least, has received such criminally scant attention.

Safety is such a simple word, and yet I know of no single word that embraces as broad a field as that one word "Safety." It is larger than what is commonly termed "Industrial Relations" because it includes it; it goes way beyond accident prevention, that is part of it; the development of loyalty, efficiency, interest in the job, all have their place in safety; and the vital happiness of every family is wrapped up in it. Safety is no appendage to any organization. It is no side-show to the circus. It is the big white tent that shelters all under it and makes possible the constant running of the whole show, no matter what the stormy conditions are outside.

That sounds like a sweeping statement, and yet the results gained from experience, together with the reports you are hearing at this convention, if thoughtfully scrutinized, must convince you that it is no exaggeration.

I am asked to tell you "Why We Believe in Safety in Our Company." The shortest and most complete answer is that we look upon safety as a distinct obligation; and we believe in discharging our obligations.

Having spent some time and effort running here and there trying to prevent accidents of one kind or another by the installation of various kinds of mechanical devices, by scolding or discharging offending employees and apparently getting nowhere in particular, we decided we had better sit down awhile on the old log and think things over. Remembering from boyhood that the only way to get rid of a lot of bees was to hunt out the nest and tear it down, instead of getting all out of breath chasing the individual bees all over creation, we began to take a witness-box examination of what it was all about. As a result, we discovered the following startling facts, each of which though apparently unrelated to the others, yet has an important place in the whole scheme of safety.

First: The Department of Commerce told us that \$800,000,000 is lost to industry annually through accidents. Second: We knew from experience that our injured

employees draw only part pay when on compensation and that this works a distinct hardship on them and their families. Third; Roger W. Babson's statistics showed that at the age of 50 years over half our male population is down and out through laziness and indifference. And finally: The National Safety Council told us that over 20,000 little children lose their lives every year through accidents of one kind or another.

These facts alone ought to appeal to the imagination of most business executives and ought to open up a pretty broad field for thought.

The staggering loss of 20,000 little lives a year with the attendant anguish and heartaches to twice as many unhappy parents certainly should become the personal obligation of every individual. Even to suggest such a thing strikes me as a travesty on the intelligence of every thinking person, and yet it is surprising how little real effort is being made to check this terrific loss. But it is clear that if something isn't done, as traffic conditions grow worse, this unfortunate "Legion of the Condemned" is bound to increase.

The Department of Commerce has done a great piece of work in saving to industry millions of dollars annually through the elimination of waste and duplication. Now it tells us that \$800,000,000 a year is lost because of accidents and that much of this loss may be prevented through treating the problem of safety as seriously as we have treated the problems of waste and duplication.

It is even questionable whether the combined loss through duplication and waste approaches the vast sum lost through accidents, and yet, while we strain every nerve in our quest for efficiency to eliminate the former, we allow safety to go merrily on unchaperoned. Are we going to continue pouring at the top of the barrel and allowing it to run out at the bung hole, or are we going to strive to keep as much as possible of this 800 million dollars where it belongs, in the treasuries of our companies? Stepping over dollars to pick up dimes is what business, as a whole, has been doing in this respect.

The progress that safety has been making up to very recently is comparable to the old darkie who was striving along a country road in a very rickety old buggy with large wobbly wheels and a raw boned, emaciated old horse named Maggie. He was apparently in unknown territory and seeing a stranger inquired:

"Say, boss, kin you all tell me how far it is to Centerville?"

"About 14 miles," replied the stranger.

"Thank you, sah!—git up, Maggie!"

About an hour later he met another stranger and made the same query.

"About 14 miles straight ahead," was the reply.

"Thank you, sah!—get up, Maggie!"

At the end of still another hour he asked a third man:

"Boss, kin you all please tell me, sah, how far it is to Centerville?"

"Yes, it's just about 14 miles straight ahead."

"Thank you, boss, well git up, Maggie, and never you mind, old horse, we's holdin' our own anyhow."

It's high time, gentlemen, that safety did a little more than hold its own in industry today.

It strikes me as a mighty shocking reflection on us as a nation when we are told that only one man in 50 in America ever thinks, that only one out of 500 ever originates anything, and what is still more startling, that at the age of 50 years, 53.5 per cent of the male population of America are down and out because of laziness and indifference.

We can't take much pride in the knowledge that at 50 years, the best time in any man's life, over half of our male population are down and out because at no time during that 50 years did they ever give a damn. And therein, gentlemen, lies the crux of this whole subject.

Old John Burroughs, the great naturalist, once said: "Men may stagnate as truly as water may stagnate; and just as motion and activity are the remedy for one, so are purpose and direction the remedy for the other."

We expect our employers to be cheerful, loyal, conscientious workers and blame them if they are not. But our experience has been that you can't get something for nothing in this world and that the responsibility for the lack of these qualities in our employees, and for the fact that so many men are down and out at 50 years of age, rests squarely on our own shoulders.

The world doesn't owe any of us anything, a fact that many fail to appreciate. On the contrary, the higher up we get the greater our obligation. As executives, the opportunity to see beyond the day's work and to vision the future lies open to us; and as executives, part of our obligation is to grasp this vision, but an equally important part is to carry that picture to the rank and file.

Safety is one of the bright spots on the highway of the future. It stands out as a beacon; and to those who are willing to follow its rays far enough will be shown this picture of future industry, an industry clearly characterized by the absence of careless workmen; an industry where this class of men has been eliminated along with waste, duplication, and obsolete machinery by the sheer force of necessity in the struggle for economic existence.

Is this elimination to be a "driving out" of the indifferent and untutored through the survival of the fittest, or is it to be a "lifting out" through education and guidance? That is the question that we have to answer.

The Greatest Asset in Industry

Gentlemen, "the greatest asset we have in industry today is an able bodied man, and the most neglected asset in industry today is that man's attitude toward his job." One of the most important phases of safety is the opportunity it offers executives to encourage their men to make friends of their jobs. The man who realizes that his job is the best friend he has in the world and that it does more for him than all the rest of his friends put together is not bumping his truck along over rough roads, he is taking it slowly to avoid wrenching his chassis. The contented workman is not rushing headlong down the street leaving it to pedestrians and children to look out for themselves, he is giving the others some rights on the street too. The contented workman is not quarreling with his fellow workers or with our customers, he is unconsciously spreading cooperation and good will. "Safety," gentlemen, "is a by product of interest in the job, so is efficiency and so is loyalty."

It takes a lot of hard tireless work to educate men, to change their mental attitude toward their work and their company, but it pays big dividends. Just as honesty is the best policy regardless of the moral issue, so safety is the best policy. It is simply good business sense.

Our task in solving this problem of safety will be much simplified if we will just recognize two fundamental facts.

First, that in the majority of cases both the cause of accident and the cure lie in a man's mind. The involved employee is either a new man who is nervous and not properly instructed, he has sickness or trouble at home, he is sore at his boss, or he just doesn't like his job anyway. And, second, if this is true (and statistics indicate clearly that it is), then the cure lies in correcting this condition of the mind, turning this man from a discontented to a good humored and contented workman. As mentioned previously, it is not the employee with a smile who is neglectful of equipment, heedless in the matter of accidents, and quarrelsome with his associates and customers. But it is the same old story. In politics it runs: as Maine

goes so goes the Country. In Business it runs: as the boss goes, so goes the organization. We can't have a happy, contented organization with a thoughtless, inconsiderate, short-sighted administration.

This contagion of contentment is well illustrated by the first half of that old axiom, "smile and the world smiles with you." The other half, "cry and you cry alone," doesn't prove out, for one is just about as contagious as the other. My small daughter taught me a lesson in this respect one day recently when she was curled up in my lap having a little heart-to-heart talk. She said to me: "Daddy, I'm always glad when you come down to breakfast smiling and happy in the morning because when you do everything seems to go right all day long, Mother is happy and the nurse and the cook and everybody seem to have a good time all the rest of the day; but when you come down cross, then Mother gets impatient with us and everybody and everything in the house just seems to go all wrong all day."

Human Nature Always the Same

If that is true in my house, I guess it is true in every other house, and it doesn't much matter whether it is in the home or in the office. Human nature is about the same the world over, and this gospel of a cheery smile is right at the bottom of the whole safety movement.

But very seriously, the one thought that I should like to leave with you this morning is that safety is a broad gauge, comprehensive proposition. It is playing a much greater part in the business of each one of us than we have any idea of. It is playing a helping part or a hindering part according to the importance we are attaching to it.

It is not alone the humanitarian appeal, although this should be ever uppermost in our minds; it is not even this appeal together with the economic loss in dollars and cents, which might well be saved, that makes safety so important; it is the tremendous influence that this work brings to bear in the building of morale, in the development of efficiency, and in the making of the employee not only a loyal, conscientious, careful workman for his own organization, but a more thoughtful and a more valuable citizen in this broad land of ours.

CHAIRMAN WAKEFIELD: We surely appreciate that very much indeed. If there are any questions or any discussion you would like to go into on any one of these papers, I want everyone of you to feel entirely free to stand up and claim the floor and give us the benefit of your comments.

A Good Registration Is Shown

Very probably you will be interested in knowing that there are some 135 members registered at this meeting. They come from the following States: New York, New Jersey, Pennsylvania, Illinois, Maryland, Massachusetts, Missouri, Indiana, Wisconsin, Ohio, West Virginia, Delaware, Connecticut, Florida, Michigan and Oklahoma. That territory is represented in this room at the present time. It is rather a hopeful sign; I thought you would be interested in it.

I want to introduce to you for a brief paper at this time, Mr. F. E. Matthews. Mr. Matthews is Chairman of the Refrigeration Safety Code Committee sponsored by the American Society of Refrigerating Engineers. Mr. Matthews has been working on an angle of safety for quite a while along the lines that we are considering this afternoon. I take pleasure in presenting Mr. Matthews.

Address

By F. E. MATTHEWS

Chairman, Refrigeration Safety Code Committee

I welcome this opportunity to speak to an audience genuinely interested in the subject of safety in refrigeration. There has been too much reluctance to speak of safety in the past for fear of suggesting its antonym, danger.

Now, lest I be considered a terrorist for advocating means of promoting safety, I wish to state that, in the nearly thirty years of active connection with the refrigeration industry, a large part of which had to do with large refrigerating and ice plant operation in seven of the largest cities of the United States, I have personally witnessed only one really serious accident.

While such experiences speak eloquently for the care that has been exercised by plant owners and operators in the past, accidents do occasionally occur, resulting in loss of life, limb and property and sometimes entailing precipitate and ill-advised legislation, which until it can have been made practicable through long experience attained through effort at enforcement, often works undue hardships on both machinery manufacturers and plant owners.

Naturally enough, demand for regulatory legislation in this connection first sprang up in the more congested centers where the effect of such accidents is likely to prove most severe. Demand for a municipal safety code for refrigeration appears to have arisen first in New York City. This was in 1914, at which time a small committee of four was appointed by the American Society of Refrigerating Engineers to assist in the formulation of such a code.

In the fourteen years that have elapsed there has been a code committee constantly maintained and the original American Society of Refrigerating Engineers code, the outgrowth of that formulated for New York City and adopted in 1915, has been repeatedly superseded by other codes from time to time to meet the constantly changing demands imposed by progress in the art. In fact such action is now required by the rules of procedure of the society which, while revision may be made annually, require that the current code be considered for revision at least every three years, during which time either the main committee or a small standing committee, appointed for the purpose, continues active to look after current public requirements.

A newly revised code developed under the above procedure has just been reported to the council of the society and presumably will be offered for approval by the American Engineering Standards Association at an early date. During the revision of this code, a number of the committee cooperated with the Bureau of Fire Prevention in the City of New York in the preparation of its revised code which was passed by the Board of Aldermen this year.

In the time that has intervened since the formulation of the first New York code, thousands of copies of the A. S. R. E. code in different stages of development have been distributed gratis to interested parties, especially for the guidance of prospective law makers by whom it has been embodied in whole or in part in many state and municipal measures.

The movement still suffers for want of proper publicity channels and to some slight extent, unfortunately, from adverse advertising on the part of its enemies. This is to be expected, however, as it is impossible to satisfy demands in radically different directions. We still have to depend largely on the inherently slow process of percolation, by which means only, unfortunately, much valuable engineering as well as other technical information finally reaches a more or less lethargic public. With the rapidly broadening outlook on national safety being created by the National Safety Council and to be supported, it is hoped, by publications in all

fields, progress toward safety in refrigeration should become soon greatly accelerated.

As to just how this can be best realized, probably no two men would offer the same answer, when it comes to details. From the speaker's standpoint, however, it would appear that all must agree that it can come only through the elimination, so far as is possible, of both the personal and the mechanical weakness factors involved in the machine and its operation. This calls, in plain language, for safety designed and fabricated refrigerating apparatus, safely installed and safely operated. This is purposely an all-including formula which in turn indicates the only theoretically all-inclusive (but practically limited) means for its realization a highly developed national standard refrigeration safety code. Admittedly in the class of "cure-alls," there appears to be no other nostrum having like possibilities.

Whether or not, when, and to what extent, this unattainable ideal is realized will depend, as do most things, on ability to sell. To sell a national standard refrigeration safety code will require:

1. A realization on the part of the refrigerating machine user of the need for some code. The urge for protective measures in this class, unfortunately, comes only locally and spasmodically when the user, or some of his immediate associates, suffers an accident in his plant. It is also promoted to some slight extent by the ever present insurance rate.

2. A realization on the part of the refrigerating machine builder of the advantages to be gained by a standard code. Here the urge comes most forcibly via his selling and erecting staffs as they encounter widely varying as well as rapidly increasing regulations in different states and municipalities. The builders of large machines have long since come to this realization. Some of those of the infant small machine industry remain yet to be convinced.

3. A realization on the part of advisers to law makers that the national standard code prepared by the best talent that can be brought to bear on the subject, operating under the highest authority having general jurisdiction is worthy of embodiment in their laws. Many states and municipalities are now coming to this realization.

More specifically, the authors of the national standard code are the members of the sectional committee organized and now functioning under American Engineering Standards Association authority and procedure and American Society of Refrigerating Engineers sponsorship. This committee now comprises 41 delegates with alternates duly appointed by 29 member organizations all interested in the art of refrigeration. Under American Engineering Standards Association rules a proper balance of representation of various interests is assured at all times and under American Society of Refrigerating Engineers rules either the main or a proper sub-committee must be always available for such matters as interpretation of the code, temporary rulings on new situations and exceptions. Periodic revisions of the code are mandatory, thus capitalizing the experience of the standing committee to keep the code proper abreast of the art.

It is believed that a movement so organized and functioning for so important an end is worthy of your full endorsement.

I just want to say that practical means for the capitalization of accidents for their subsequent prevention are proposed in the author's discussion of the paper of L. C. Smith entitled "How Can Individual Refrigerating Plant Operators Learn from the Experience of Others?"

SECRETARY FOX: You have just heard the speech of Mr. Matthews. Mr. Matthews has given this subject very close study. It is a subject that is very close to his heart. I know that as the new refrigeration section of the National Safety Council goes along and progresses that we will hear more from the codes committee through Mr. Matthews. That committee will be of great service to the furtherance of safety in the refrigeration section.

It now falls my lot to introduce Mr. Wakefield. Mr. Wakefield spoke about the time that I had given to the preparatory work that was necessary for the calling of this section, but I can assure you that the little I have done is far outshone by the immense amount of work that Mr. Wakefield has done. I take pleasure in introducing to you Mr. Vincent Wakefield, Treasurer of the City Ice Company of Kansas City.

How to Install a Safety Organization in a Refrigerating Plant

By VINCENT WAKEFIELD

Treasurer, City Ice Company of Kansas City, Kansas City, Mo.

In speaking of the subject assigned to me for discussion this afternoon, I would draw your attention to the fact that I, necessarily, labor under some difficulty because of the different nomenclature used across the country as a whole when referring to positions held by supervisory employees. Therefore, in so far as I may refer to specific positions, I ask your indulgence to the end that you will mentally substitute the title obtaining in your territory for the one that I may use.

I would also draw your attention to the fact that it is not possible for me to lay down a definite ironclad procedure that is capable of being utilized in any industry using refrigeration in any part of the country, for the reason that there may be, necessarily, vast differences in the methods of operation and the number of plants operated, and I can only outline, therefore, a rather loosely-knit organization, the underlying principles of which, however, will be adaptable to your local situation.

In approaching the subject of organizing for safety, it has been my experience that it is better to separate your employees into two divisions, namely, those serving in supervisory capacities on the one hand, and those of the rank and file on the other. Having done this mentally, or on paper, whichever will be the most convenient for you, I suggest that you select from the supervisory forces a committee of either three or five men from each plant you operate. I would then take occasion to talk individually to each of the three or five men that you have selected on the importance of organized safety in industry and of the benefits that can be derived therefrom. In short, in your personal conversation with these men, try, without showing too clearly what you are doing, to instill in their minds the necessity for and benefits obtainable from organized safety.

About a week or ten days after you have had the last of these conversations, I suggest that you call these groups of three or five men into your office and tell them that, after giving the matter very careful consideration, you have decided that it would be a very beneficial thing to have a safety organization in your plant, and that you have selected them as the safety committee. You should place upon their shoulders the responsibility of organizing themselves by electing a chairman and secretary, and the chief executive should not take any official duties on that committee or even accept membership thereon. This committee should be charged squarely with the responsibility of all safety activities within the plant and should be known as the "Plant Safety Committee."

If you operate more than one plant, this plant safety committee should be organized at each one of the plants that you operate and, as I have mentioned before, should consist of three or five of the supervisory forces. In the smaller plants, where you may not have enough supervisory forces to draw upon, it will be permissible to put in one of the older and what you might term key-men

of the rank and file. So much for the organization of the plant safety committee, which you will note has been done, with the exception of the preliminary educational work, practically by executive order. The committee should be required to meet regularly and on company time, not less than once a month.

Now as to the employees—these should be organized separately; should have their own separate officers, chairman, vice chairman and secretary, but the method of organization should be exactly reverse to the method employed in organizing your committee, that is to say, let the men themselves request permission and assistance in organizing, rather than have you tell them they must do so.

We have found that you can, through the plant safety committee, infiltrate through the ranks of the employees a constant flow of safety propaganda, emphasizing benefits that accrue to the employee and employer as a result of organized safety effort, and so, by the force of suggestion, imposed upon some of the natural leaders within the forces of the rank and file, after a short period of time, it is comparatively easy to insure their approaching the management with the request that they be allowed to organize the employees for safety. By getting this action from the employees themselves, who, naturally, think that it is their own idea, you will find the movement will be more enthusiastically embraced and it will start off with far greater chances of success than if you arbitrarily ordered them to organize themselves and hold meetings regularly. This body can be styled the XYZ Plant Safety *Organization*, as distinct from the XYZ Plant Safety *Committee*.

In order to make it easy for the safety organization to function, they should be given a charter and by-laws, which they should follow and which provides the usual regulations for such types of organizations. If any of you would care to have a copy of the Constitution and By-Laws we use in the City Ice Company of Kansas City, we shall be glad to send them to you on request.

We now have a safety organization, taking care of all employees, a plant safety committee, consisting of supervisory forces, and if you have a very large company operating in a number of different places, it will be found desirable to add what may be termed a "Central Safety Committee," who should meet regularly and pass on matters referred to it by the various plant committees, and also to formulate safety policies and pass down to those committees so that they may be put into effect. The central safety committee necessarily must consist of executives, and it is most heartily recommended that the president or chief executive of your company be the chairman of that committee.

Having thus set up your entire safety organization, it cannot be said to be organized until there is a reasonably clear understanding in everyone's mind on the work that is to be done and the method that is to be followed in doing it and, with your permission, therefore, I will outline briefly some of the major activities of each of the groups I have suggested.

Starting at the bottom, and considering the work that should be done by the employees themselves, it is suggested that they should be furnished with a copy of all accident reports and that at each one of their monthly meetings, these reports should be read and discussed by those present, with a view to determining the cause of the accident. In this way, the cause of accidents becomes more generally known and employees warned against that particular type of accident. They should have an inspection committee which, at periodical intervals of less than one month, should go over every part of the plant and make a report on a printed form provided for that purpose. This inspection should have as its object three purposes, namely:

- (1) General cleanliness or, as I have heard it better termed, good house-keeping. This is important from the fire prevention angle, as well as the accident prevention angle.
- (2) Physical hazards of either structure or machinery.
- (3) Improper performance by employees of their duty, thus exposing themselves or others to injury.

The written report of this committee on the form referred to should be before the body for their consideration, so that they can feel that they are taking an intelligent part in managing the safe conduct of the plant and themselves.

The chairman of the plant safety organization should assign to two or more of his men the job of reading a paper, lasting two or three minutes, dealing with various phases of accident prevention in relation to specific hazards of your particular plant. Each one of the papers should be followed by discussion.

The organization should also elect one member to serve for a suggested period of three months, whose duty it shall be to maintain in a clean and orderly condition safety bulletin boards, which should be provided by the management. This individual must be responsible for the posting thereon of safety bulletins, which should also be furnished by the management and which are obtainable from the National Safety Council. It has also been found practical and desirable to have a committee of three men, whose duty it shall be to see that first aid kits, gas masks and other safety appliances are maintained in good order and fully stocked. This committee can also be charged with part of the educational program in educating employees in the use of the appliances and first aid kits. It will be found that a greater success will be achieved if the safety organization has a committee of three or five members, which shall be known as the program committee and whose duty it shall be to prepare at least one week in advance of the meeting an attractive, well-designed program. In this connection, particular attention is drawn to the fact that it is usually possible three or four times a year, or even more often, to obtain an inspirational address by some speaker who is not connected with the company, but a man of some prominence in your locality. The local Safety Council of your city will, I am sure, be delighted to assist you in locating men of this type.

By following these suggestions, your meeting will have definite business in front of it and will proceed in an orderly way. It is suggested that the meeting should not be permitted to last longer than an hour and a half, and it will be better if it can be conducted in an hour. An opportunity should be given at each meeting for any individual in the audience to draw to the attention of that body any hazard that he feels exists. The body should be permitted to legislate by passing resolutions, after carefully considering a hazard, said resolutions making specific recommendations wherever possible to cope with the hazard under discussion.

As to the plant safety committee, it will be found to be wise to hold them in much the same relation to the safety organization that the United States Senate is to the House of Representatives, in that every resolution and recommendation made by the safety organization must come before the plant committee for its approval or disapproval. If it is disapproved, it is returned with an explanation as to why it is disapproved, and if it is approved, it goes on up to the chief executive officer for his attention, and may I say a word here that, if, when your chief executive receives that recommendation and does not approve it, should promptly return it, assigning his reasons for disapproval. It is very important that safety organizations making recommendations should be advised that they have either been approved or disapproved; otherwise, it will undoubtedly promote a loss of interest.

The plant safety committee is also charged with seeing that the safety organization and the activity of the safety organization is functioning properly; of

staying behind the scenes, as it were, and yet, actually steering the work that is being done; seeing to it that the meetings are held regularly and making sure that when those meetings are held, a regular program is ready and that it is followed in proper order and properly handled.

It is also the duty of the plant safety committee to take every opportunity that they can to constantly preach the safety gospel among employees, and show its practical application from day to day.

Another, and one of the most important duties of this safety committee is to make certain that new employees are educated on how to do the work that is assigned to them in a safe manner.

There are, of course, many activities of both the safety committee and safety organization which time will not permit me to touch upon here. If, however, you will follow the procedure I have outlined, you will have at each one of your plants or, if they are too small, at each natural geographical group of plants, a safety organization of all employees, a safety committee of three or five supervisory forces, and, possibly, a central safety committee to steer the whole. I know from experience in my own company that this type of organization, provided its work is carried on regularly and with enthusiasm and enjoys the enthusiastic support and approval of the management, will give most amazing results of cutting down accidents of all types.

CHAIRMAN WAKEFIELD: Gentlemen, the next and final number on this program is to be presented to us by Mr. Leslie C. Smith. Mr. Smith has been sitting here in the corner listening to these various papers. He is going to talk to us on a very appropriate subject, "Where Do We Go from Here?" In introducing Mr. Smith, I do so with a great deal of pleasure because we who have been in the ice business for any length of time regard Leslie Smith as the father of the ice business.

Where Do We Go from Here?

By **LESLIE C. SMITH**

Secretary, National Association of Ice Industries, Chicago

We have been told how this movement can be done, how it has been done; we have been told about the success which has followed it, of its impression, vital and strong; about the men who have fostered this movement, of the clear thinking and analysis which these men have brought to it and of the sanction of their expenditure of time, energy and capacity in promoting it. We have heard capably analyzed for us its economic soundness, its justification, first of all, from the material side. None of us could hear that analysis and not wonder why we were not organized thoroughly to promote that type of cooperation in business. Then, we have had told us both by Mr. Scott and Mr. Oler this vital thing that is growing more potent in American business every succeeding year.

There is an old adage that the tendency of mankind is toward a race of friendly men. It has been rather difficult to follow the reasoning, I confess, over much of history. It is none the less difficult to follow its reasoning in some branches, some industries, in our great American commercial life. The obstacles established against it have been, first of all, the indifference; and secondly, the greed behind business.

I can bring this to no man who knows of my position in my work, long established and constantly poured out, who will not understand exactly what I mean. There is nothing the matter with my business. There is nothing the matter with my industry, except the greed of the men in it. These men are thinking in terms

of friendly men; human interest is commanding attention today as it never has before in business. The interest of the mass, the interest of the composite whole has now begun to transcend the interest in the individual or in the personal success.

With that progress before us, with this thorough knowledge of the fact, we repeat that it has been done successfully with full compensation in every particular, with the idea of its economic soundness, of its human interest; and then instances such as our excellent chairman has just recited of the simple ways and means for putting it into effect; it strikes me, we have one serious weakness, and that is, where shall we turn in this multi-scattered phase of our industry, where shall we turn for guidance in these matters? My 6,382 plants have not heard Mr. Wakefield's establishment of methods. Most of them know absolutely nothing

about it. I think that applies in very large measure, particularly in those of greater number, in all the ramifications or branches of the refrigerating industry.

Isn't the next sound step for us to take the organization of that source of authoritative information to which we may turn for guidance in this work? I have discovered long since that if I want to put a proposition across to my people, I have to carry them a concrete plan. If I do not, it is lost in the maze of individual thinking. I believe that is true here. Nor can I find the slightest possible prospect of conflict, howsoever we may establish these points of interest. In other words, a safety code is perfectly sound and should be there, but it should offer no obstruction or no cross-current to the man who is out on the platform or in the storage house or out on the street. So, when that becomes thoroughly understood and in larger practice, we shall find it as Mr. Fox has said, entirely of assistance to the major thinking; for after all, it is doing the thinking that is right both for ourselves and for those who in large measure are dependent upon our direction both for their safety and physical return.

My conclusion is just this: I shall take this project back to my industry in its entirety; I shall bring to that presentation the best I can find, to make it clearly

understood to them exactly what we are trying to do; and then I shall persistently insist that it is a normal, natural, proper step in the evolution of the ice industry of America.

There is my concrete plan. We are discussing drawing ourselves together under the guidance of this organization which so long and in so many ways and ramifications has proven its capacity to direct, has proven its authority for information which we may need—then what other things, I repeat again, does there seem for us to do than put our interest, put our determination behind this movement and forward it with all the driving power we can?

Many of us are responsible to groups, I to a very large one, you perhaps to an individual company; and yet, if you are a member of my organization, you will be very glad indeed to know that you can be made directly helpful to what other people might do.

I said it is growing to be a race of friendly men. May I give you an illustration of that? Sixteen years ago, a man who recently came into this business in an executive capacity, seeking information, went to one of the very large successful companies in America. He was told that what they had amassed in information about making, handling and distributing ice had cost them a lot of money and they didn't propose to give it away to anybody. That was sixteen years ago. Today, I doubt very much if there be a plant or company that would not even go so far as to open its books to any sincere, unselfish inquirer. The secrecy in business, in industries, is rapidly passing out, and should pass out. And so, it is the being helpful, each to the other, that is binding us together.

In the organization and by and through it, we shall rapidly learn where some one can find information of direct importance to him, which he can make productive of the big interests involved in bringing it into application in his own contact. I can find no reason, I have heard none, which should not make all of us richly eager to get into this movement and to do what we can to bring Mr. Wakefield's better success, Mr. Oler's broader vision, Mr. Scott's wide scope of experience and observation, back to the thing for which you and I are responsible.

Resolution to Found a Refrigeration Section

F. S. ARMSTRONG (Central Illinois Public Service Co., Springfield, Ill.): At this time, with your permission, I would like to offer the following resolution:

Whereas, On this second day of October, 1928, there are in meeting assembled a large number of people who are vitally interested in organized safety for those industries using refrigeration; and

Whereas, At this meeting there has been clearly shown the great need for the establishment of a Refrigeration Section; now therefore be it

RESOLVED, That this meeting does hereby recommend to the Executive Committee of the National Safety Council to officially authorize the establishment of a Refrigeration Section of the National Safety Council.

I move the adoption of this resolution, Mr. Chairman.

CHAIRMAN WAKEFIELD: You have heard the resolution. Do I hear a second? (The motion was seconded and carried.)

C. B. RYAN (Northern Indiana Power Co., Indianapolis, Ind.): May I present a resolution?

BE IT RESOLVED, By the Refrigeration Section that the organization committee which functioned in 1928 be hereby authorized to continue its functions with full power to elect officers until the annual Safety Congress of 1929.

I move you the adoption of the resolution.

CHAIRMAN WAKEFIELD: You have heard the resolution. Do I hear a second to it?

(The motion was seconded.)

CHAIRMAN WAKEFIELD: The resolution is to the effect that the committee which organized this section should be empowered to carry on its activities, if the Executive Committee of the National Safety Council approves this section; and if necessary it will have authority to elect officers of this section until the next convention next year.

(The question was put to a vote and carried.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Rubber Section

New Section Officers

- General Chairman*—M. A. QUIRK, Morgan and Wright Plant, United States Rubber Company, Detroit, Mich.
- Vice-Chairman*—E. R. LAWLER, United States Rubber Company, Hartford Plant, Hartford, Conn.
- Vice-Chairman*—PAUL VAN CLEEF, Van Cleef Brothers, Chicago, Ill.
- Vice-Chairman*—E. A. HOENER, The Firestone Tire and Rubber Company, Akron, Ohio.
- Secretary and Publicity Committee Chairman*—S. MANSFIELD, The Goodyear Tire and Rubber Company, Akron, Ohio.
- Poster Committee Chairman*—J. T. KIDNEY, The Goodyear Tire and Rubber Company, Akron, Ohio.
- Program Committee Chairmen*—A. L. VILES, The Rubber Association of America, New York City; and
C. E. OTT, Seiberling Rubber Company, Akron, Ohio.
- Slide Committee Chairman*—R. H. COCHRAN, Kelly-Springfield Tire Company, Cumberland, Md.
- News Letter Editor*—J. E. LYNCH, The Fisk Rubber Company, Chicopee Falls, Mass.
- Membership Committee Chairman*—P. M. WOODEN, The Mansfield Tire and Rubber Company, Mansfield, Ohio.
- Statistical Committee Chairman*—HOWARD W. LOW, The Miller Rubber Company, Akron, Ohio.
- Health Committee Chairman*—L. J. D. HEALY, Federal Division, The Fisk Rubber Company, Cudahy, Wis.
- Engineering Committee Chairman*—C. L. HUNGERFORD, Firestone Tire and Rubber Company, Akron, Ohio.
- Safety Contest Committee Chairmen*—E. W. BECK, United States Rubber Company, New York City; and
A. D. KUNZE, The Rubber Association of America, New York City.
- Advisory Committee*—H. T. MARTIN, The Fisk Rubber Company, Chicopee Falls, Mass.
E. W. BECK, United States Rubber Company, New York City.
W. L. SCHNEIDER, The B. F. Goodrich Company, Akron, Ohio.
R. C. SALISBURY, The Fisk Rubber Company, Federal Division, Cudahy, Wis.

Retiring Officers.

Chairman, R. C. SALISBURY, The Fisk Rubber Company, Federal Division, Cudahy, Wis.; *Vice-Chairman*, M. A. QUIRK, Morgan and Wright Plant, United States Rubber Company, Detroit, Mich.; *Vice-Chairman*, PAUL VAN CLEEF, Van Cleef Brothers, Chicago, Ill.; *Vice-Chairman*, E. A. HOENER, The Firestone Tire and Ohio Railroad Company, Richmond, Va.; *Publicity Committee Chairman*, E. R. LAWLER, Hartford Rubber Works, Company, Hartford, Conn.; *Poster and Slide Committee Chairman*, HOWARD W. LOW, The Miller Rubber Company, Akron, Ohio; *Program Committee Chairman*, HARVEY WILLSON, The Rubber Association of America, New York City; *News Letter Editor*, L. W. DURKEE, The Goodyear Tire and Rubber Company, Akron, Ohio; *Membership Committee Chairman*, R. H. COCHRAN, Kelly-Springfield Tire Company, Cumberland, Md.; *Statistical Committee Chairman*, S. MANSFIELD, The Goodyear Tire and Rubber Company, Akron, Ohio; *Health Committee Chairman*, DR. J. NEWTON SHIRLEY, Hood Rubber Company, Watertown, Mass.; *Engineering Committee Chairman*, T. F. HOUSTON, The Firestone Tire and Rubber Company, Akron, Ohio. *Advisory Committee*: H. T. MARTIN, The Fisk Rubber Company, Chicopee Falls, Mass.; E. W. BECK, United States Rubber Company, New York City; W. L. SCHNEIDER, The B. F. Goodrich Company, Akron, Ohio.

October 1, 1928

R. C. SALISBURY, Chairman

Manager, Health and Safety, The Fisk Rubber Company, Federal Division
Cudahy, Wis.

The first session of the Rubber Section at the Seventeenth Annual Safety Congress was called to order at one-thirty o'clock by the chairman, R. C. Salisbury, The Fisk Rubber Co., Federal Division, Cudahy, Wis.

CHAIRMAN SALISBURY: We are fortunate in having as our speaker this afternoon a man who is vitally interested in the safety movement, a man who is known not only in Wisconsin but in other States as well as an authority on the subject of safety. He is a man of broad sympathies and splendid understanding.

Mr. Knutson is a commissioner of the Industrial Commission of Wisconsin and, as such, is brought into close contact with thousands of persons who have had the misfortune to be injured.

He has reviewed thousands of accident cases and from those cases he has been able to draw conclusions which give him a fund of valuable ideas in all that pertains to industrial accidents.

He has addressed many meetings of the National Safety Congress in former years and safety conferences in many parts of the United States. He always gives his audience his best. I take great pleasure in introducing Mr. R. G. Knutson.

Safety Moves Forward and Why

By R. G. KNUTSON

Commissioner, Industrial Commission, State of Wisconsin, Madison, Wis.

We have come to a point long past the time when the employer and employee worked side by side, when their relationship was that of neighbor and comrade. Then their interests were practically identical. They were engaged in small industry and their hazards relatively small. With the advent of "big business" and mass production, now we have on the one hand, management

with its primary interest in mass production and its accountability to its stockholders for profits; and then on the other, the workers who have become more or less a part of the big system used in production.

Employer and employee are no longer neighbors and their interests are no longer identical. To accomplish its end, industry to be profitable has made necessary the use of large numbers of men working in one building of huge and rapidly moving machinery. These factors in turn have created hazards to working men which have resulted in many injuries with their resultant losses in earning power, followed by suffering and anguish.

It is well recognized that this condition which modern industry has produced, must be carried by industry as a cost of production. Such cost of production is then, in turn, borne by the public, the consumer, which constitutes the state. Upon this hypothesis, what should be the proper attitude of the state in accident prevention work?

The state is interested in the development and maintenance of a high standard of living. Its ideals are assured only when its citizens are strong, virile, independent and self-respecting. The state must, not as its right, but as its duty, do that which is necessary to build the strength and wealth of its largest class, the worker. It cannot by indifference permit itself or its institutions to be jeopardized by poverty, devitalized labor and the economic wants of manpower which are the result of industrial accidents. To accomplish these aims and purposes, a state department of labor has a real job before it.

Compensation laws, in a measure, softened the results of injury, but the most important field in which a state, or its agency, the labor department, can engage is in the promotion of industrial safety. I use the term promotion of safety rather than accident prevention because it conveys the idea that the state should be actively engaged in positive and constructive work.

First of all, and as a base from which to operate, the state must declare by law that all places of employment shall be reasonably safe and require that an employer shall not permit or allow dangerous practices to be used. The primary obligation as to safety should be upon industry. Upon this declaration of principle, the administering body should act as much as possible in a helpful and advisory capacity. Its purpose should be not that of a police officer having in view prosecution for a violation of a law, but rather that of a salesman, selling the idea that compliance with the law promotes safety and avoids the harrowing results of an injury.

There are two kinds of investigation, which a state department should make, first, general inspections of places of employment, and second, special investigation of particular accidents.

In general inspection work it is very essential that it be done thoroughly and cover the entire state. If the work is not thorough, that is, if not all violations of law are discovered, it follows that some dangerous points have been overlooked and perhaps the employer lulled into a false sense of security. An incomplete inspection is worse than none, because it leaves a cause of injury uncorrected, gives the opportunity to shift the responsibility for making places and practices safe, and if an accident occurs, furnishes an alibi to the employer who is apt to assert volubly that the inspector should have discovered the dangerous condition.

This kind of work should likewise be state wide and apply to all industries to avoid a charge of discrimination. All employers in a given field should be required to comply with the law and to correct like dangerous conditions. To do less in any case, gives the competitors just cause for complaint. The intent of safety regulation is to set up minimum standards for all and to raise the level of competition so that the "good employer" is not subjected to the cut-throat competition of the unscrupulous.

General inspections should be made periodically and written reports made to point out to the employee those conditions which are dangerous and which do not comply with regulations. In making such inspections, the state official should insist that a competent person representing the management accompany him. After the inspection is completed, the items enumerated should, if possible, be discussed with the management. A copy of the report should, of course, be left with the employer.

Proper completion of such inspection necessitates a follow up, conveying to the management the idea that the department is interested in getting the conditions remedied.

The second type of inspectional work is the investigation of all accidents, particularly serious ones, with a view of avoiding similar accidents in the future. It is then much easier to convince an employer that machines and practices be changed after one of his employees has been hurt. Personal experience is always more eloquent than impersonal knowledge gained from other sources as to particular causes of accidents, and therefore the occurrence of an accident furnishes the opportunity to deliver a master stroke in the promotion of safety even though, as one contemplates the results of injuries, it seems like a rather sad commentary on human relationships to think one must wait sometimes to "lock the barn after the horse is stolen."

Of course, from a practical standpoint, all accidents cannot be individually investigated, but reports of accidents can be analyzed as to causes and a letter written making inquiry as to what steps have been taken to prevent similar accidents. Furthermore, it is desirable that the field representatives be advised of such matters. Recently in the reports received in one day, fourteen were sent in by a tie treating plant, nearly all indicating injuries to feet due to the dropping of ties because of their slippery condition. It was found that no inspection had been made of this plant and therefore a list was sent to the field representative. He was well received and steps were taken immediately, trying out several methods which should prove helpful in preventing accidents.

While the primary obligation to provide safe places to work and to avoid unsafe practices is with the employer, he frequently is required to give so much attention to production that he is not able to get the same viewpoint as an outsider as to how certain accidents can be avoided. In such cases, as well as when "safety is a stranger," there will be no great difficulty in having recommendations carried out if the inspector "knows his stuff." The responsibility for the proper promotion of safety, for welding the idea, must be placed squarely on the shoulders of the inspector. By acquainting himself in his district, both as to conditions and persons, by personal visits to plants with proper words of advice and compliment when and as deserved, he can build up a spirit of confidence, so that employers will invite advice and counsel.

It is well recognized that a very important phase in the promotion of safety is educational. In this field the state can and should play a leading role. It can maintain an information service so that employers may have the advantage of expert assistance in remedying unsafe conditions and practices. Perhaps a state that has done most along this line is New Jersey, under the leadership of Dr. McBride. This state maintains a wonderful and elaborate safety museum wherein are shown the latest practical devices for guarding machinery and parts and also the proper means of avoiding and preventing dangerous conditions. Here is a practical demonstration to employers as to how things can be done to make work safe. Such work is really construction. It developed a better attitude on the part of the employer by showing that the state is more interested in helping him solve his problems than in merely detecting violations of law.

As important as discovering unsafe conditions and practices, is the bring-

ing home to both employers and employees knowledge of what constitutes unsafe conditions and practices and a development in their conduct, particularly as it relates to co-workers, of a safety consciousness. Judging from the sudden and great increase in accidents since 1920, it would seem that the most important factor in safety is psychological rather than mechanical or technological. In other words, accidents are due to carelessness and thoughtlessness of persons, manifested chiefly in the way they do their work rather than in the way machines are constructed and guarded. An analysis of the accident experience in Wisconsin, or any other state, discloses the fact that only 15 to 20 per cent of all accidents are machine accidents, as compared to the 80 to 85 per cent caused by falling objects, and the like. Many, if not all, such accidents can be avoided, but only by an active living mental alertness on the job and a knowledge of how to work safely.

A very effective means to attain this end is the promotion of regional safety conferences. These conferences can be held in those localities where the employers themselves are willing to get behind the movement and actually put it across. In Wisconsin we have found it desirable to give such conferences regional names as Fox River Valley Conference, Wisconsin River Valley Conference, Rock River Valley Conference, rather than the name of a city. Cities conveniently located are grouped with a view of bringing together employers and employees known to each other and who therefore are more apt to exchange experiences freely and take to heart the information they receive.

It is probably better to hold one day conferences so that men will not be away from home over night and will lose not more than one day from the plant. At the first meeting a single program is most desirable. In the Fox River Valley, where the fourth annual conference was held on June 6, four sectional programs were held in the forenoon simultaneously, namely, wood-working, metal trades, paper and pulp and public utilities. At each of these, problems were presented pertaining to the one particular industry. In the afternoon and evening the program was general and of interest to all. Such conference may be made self-supporting by charging a registration fee.

Such conferences are valuable in themselves, but our experience has been that they serve as a means to a great end and that is that they are usually followed by Foreman's Safety Schools. These schools are usually sponsored by various local organizations and are aimed to bring together the key men in various plants one evening each week for from seven to ten weeks. So successful have these conferences and schools become that employers in other localities have requested and urged similar organizations for themselves.

To be effective, whatever is done by a state department must be predicated upon an existing body of safety laws or orders. In Wisconsin the department is charged not only with administering safety laws, but also with formulating safety regulations. The legislature has established the general standard requiring all places of employment and all practices to be safe and has placed the responsibility upon the department of defining within such rule what is and what is not a safe place or a safe practice. Within this power various regulations have been adopted and are known as safety orders and are collected into various codes.

In the process of developing these codes, the department must of necessity give recognition to the interests affected and therefore advisory committees are organized consisting of representatives of industry, labor and the public and are also made to include experts. After careful study, investigation and agreement, such codes are recommended to the department in the form of regulations and are usually adopted. Such orders then have the full force and effect of law. The advantage of such a system is that regulations are

adopted upon expert advice and may readily be changed to meet changing conditions and new methods and processes.

When a state department is fortunate enough to be charged with the administration of the workmen's compensation act as well as with safety regulations, it can do much more effective work in the promotion of safety. This is true because it has available all the experience which comes from compensation cases. Such experience not only furnishes a wealth of information as to the causes of accidents, but also gives a strategic opportunity to do effective safety work. The accident is an object lesson and with proper investigation the lesson may be brought home more thoroughly.

Two features of law are effective in the promotion of safety. These are first, that when an accident occurs because of the violation of a safety order, the employer is required to pay 15 per cent increased compensation, which obligation he cannot insure; and conversely, if an employee is injured because of willful failure to use a safety device, furnished by his employer, compensation is reduced, and second, that he is given credit in his compensation premiums for the record in his own plants. By these two provisions of law, for purely selfish reasons, the employer and employee both are urged to comply.

After all, a state department can do only that which, under a wise expenditure of money, its budget permits it to do. The attitude of the state, however, should be that sufficient funds should be appropriated to make possible those efforts by way of investigation, inspection, study of safe processes and practices, demonstration and education that will produce a safety rule and a safety consciousness that will reduce accidents to a minimum, that will save to the state a strong, virile, citizenship unhampered by deformities, that will save millions of dollars and will assure to workers and to their families, life and happiness, rather than the pain, suffering and anguish that comes as the result of avoidable accidents, but in all its work recognizing and maintaining the principle that the primary obligation to make places of employment safe is with industry.

P. M. WOODEN (Mansfield Tire & Rubber Co., Mansfield, Ohio): You spoke a moment ago about sudden drafts coming in on the men. How would you determine what the result was from a sudden draft coming in on the men?

MR. KNUTSON: Usually pneumonia.

MR. WOODEN: There would be no question as to when a man has pneumonia. Suppose he had a stitch in his back that laid him up for a couple of weeks, five or six weeks?

MR. KNUTSON: The back injuries, the back aches are about on a par with hernias.

MR. WOODEN: I agree with you.

MR. KNUTSON: Because I have made inquiry of several doctors who reside in rural sections wherein there are no industrial centers, and they tell me that they never have any of these back injury cases, which indicates to me that about the best cure for those, in so far as the individual is concerned, is the gold cure, and he takes compensation as a means of trying to get it.

E. W. BECK (U. S. Rubber Co., New York City): I would like to ask the Commissioner how his State handles the aggravation of pre-existing conditions?

MR. KNUTSON: If you have in mind a specific case, perhaps I could enlighten you more.

MR. BECK: I have in mind individuals who may have worked in, say, a coal mine or a slate quarry and are employed in a certain plant may be exposed to draft, fumes or what not, and then the case comes up as an aggravation of a pre-existing condition, which is compensable in some States.

MR. KNUTSON: Tuberculosis, for instance.

MR. BECK: Yes.

MR. KNUTSON: We are in a rather unusual situation with respect to that identical question in our State today. I will tell you how this came about. We had a case of tuberculosis of a man who had been employed for twenty-six years as a stone polisher. At the time (I don't recall the dates now) of his disability, there was an insurance company on that risk who had been on that employer's risk for three months. The previous insurance carrier had been on for two years, and the one preceding that for several years. At the trial of this case before us, the parties at interest stipulated that this man's disease was the result of his injury. So, the only question left then was which insurance company was going to pay for this fellow's disability?

Up until that time, we didn't realize that we had no provision in our law to take care of that, no specific provision to take care of a case like that. However, in the discussion of that case between the members of the Commission, it was my opinion that the insurance company who was on the risk during the period of time when this man could have quit that particular employment and gone into some other employment and not have become disabled as a result of tuberculosis, should not be held liable.

MR. BECK: Which employer, the last employer?

MR. KNUTSON: There was only one employer but three insurance carriers on that same risk.

My argument against that was this: That this employer had complied with the provisions of compensation by having had his risk insured; he had paid his premium for this compensation or protection as fixed by the State, and that it wasn't just to hold him responsible after having complied with the law and then sue these insurance carriers, to recover the damages that were involved. The decision went against the employer, not the insurance carrier.

The case went up to our Supreme Court. Our Supreme Court held that the insurance company that was on the risk at the time of disability was liable. This man had been in that same occupation for twenty-six years for this same employer.

A short time after that decision by the Supreme Court, we had a case come before us of another stone cutter who had been employed by another employer for practically the same period of time and became disabled from tuberculosis six weeks after this employer had filed a non-election not to be subject to the compensation law. Do you see the difference in the situations you have there? Now, if we were to abide by the Supreme Court decision in the first case, this poor devil wouldn't get a cent of compensation after having worked in that industry for twenty-six or twenty-seven years.

I want to tell you that I am not an attorney; I don't profess to know anything about legal technicalities, but my guess is that our Supreme Court is going to reverse themselves on that first case and lay down some new laws that will take care of these situations.

With that litigation pending, I am unable to answer your question definitely, because we are absolutely at sea now.

The aggravation of an old condition you get in a number of different instances. Take, as an illustration, a man who is infected with syphilis. Oftentimes they are ignorant of the fact. As I understand it, the syphilitic germ for some reason, or other, affects certain individuals in different ways. In some cases I have known where they have gone blind from it. Others die of what they call heart disease, syphilitic heart. Others become insane. Why it affects different individuals in different ways I am unable to explain. In still others, it affects the bony structure of the body. We had a case one time where a fellow while pushing a truck fractured the clavicle in the shoulder. The doctor set it and prescribed the usual course of treatment. After they removed the splints, there was no union. They took a Wasserman test, which showed 4-plus. That man receives compensation.

If a man comes in on the border line of tuberculosis—we have had a couple of those cases where men have just been on a job a few weeks and become disabled with tuberculosis. Of course, their cases are dismissed, because we do know, as a result of actual experience, that that type, at least, of tuberculosis does not develop within the course of a few weeks; it is usually a period of months and oftentimes a period of years that it takes the disease to develop.

Apparently there are different types of tubercular germs. In some cases, I have been told by doctors who have made a life study of it, tuberculosis can sometimes produce death within the course of two or three months from the time of its inception.

MR. BECK: My thought, Mr. Commissioner, was along the line of a man who may have worked in your stone quarries for twenty years and then he should come to Akron or Detroit and we should hire him, and then after an exposure of eighteen months or two years in our plant, his condition is aggravated. He may claim it is due to the dust or fumes or draft.

MR. KNUTSON: Regardless of which way you handle a case of that kind, in my opinion, it is ultimately evened up, because you may be sending another man from Ohio into Wisconsin, where the same thing occurs.

MR. BECK: Mr. Commissioner, the State may. I agree with you from a State point of view. They have limestone mines in Indiana and they send the men up to the grinders of Connecticut. But in the rubber industry we haven't those particular hazards that will aggravate a condition, that will really cause tuberculosis. We are employing those fellows who are already in the second stage of pneumoconiosis.

MR. KNUTSON: If they become disabled under those circumstances while in your employ, they must establish some definite conclusive evidence that there actually was a hazard in the employment you gave them that could readily have aggravated the condition to the extent that they became disabled from it. There must necessarily have been some hazard there, some additional hazard than that which we usually honor, that would actually have some direct bearing on the case, otherwise I would say he is not entitled to compensation.

W. F. KEOHAE (Beacon Falls Rubber Shoe Co., Beacon Falls, Conn.): Under the laws of Wisconsin, would a worker developing a duodenal ulcer come within the scope of the compensation law?

MR. KNUTSON: No.

E. P. MCHUGH (Mechanical Rubber Co., Cleveland, Ohio): I would like to ask the speaker if in this typhoid case, the plant purchased the water from the city?

MR. KNUTSON: No. Had they purchased the water from the city, there would have been a typhoid epidemic in the city.

MR. MCHUGH: Suppose they did purchase it in the city and found there wasn't any more cases in the city?

MR. KNUTSON: There would be no liability, because then the hazard would have been just as great within their homes as within the place of employment.

If you had seen the source of this water supply you wouldn't have wondered. I don't think they are entitled to much consideration when any person could have actually seen that water supply, the source of their water supply. It is a wonder to me that they all didn't die from something or other.

A. M. DIETZ (Pennsylvania Rubber Co., Jeannette, Pa.): I want to get back to that hernia question. Unfortunately, or fortunately, we are one of the companies that have to take care of 90 per cent of our cases. I got a thorough understanding of your demonstration, but I want explained this question: Is it possible through a man's work that there is some condition that he can develop hernia through some lift or something?

MR. KNUTSON: My answer to that is this: That you can best determine from the story that the man himself tells as to whether or not he actually got that hernia at the time he alleged to have received it. I think, at least I tried to illustrate to you, that the bulk of these fellows have an incomplete hernia to start with.

MR. DIETZ: Do you mean at birth?

MR. KNUTSON: I say, all these hernia cases, outside of those resulting from direct trauma, are the result of a predisposed condition that was there at the time of birth. By that I don't mean to say that it is impossible to produce a traumatic hernia. But, the bulk of these fellows have that predisposed condition there, either weakened abdominal walls, flabby muscles, or they have enlarged rings, depending upon the type of hernia that develops.

MR. DIETZ: With those conditions you are speaking about, is it possible to bring them about by the work they do?

MR. KNUTSON: Do you mean over a period of time?

MR. DIETZ: Yes.

MR. KNUTSON: Well, I don't know. We have allowed compensation for occupational hernia, but have allowed very few of them, where the testimony showed that this individual had a job that required excessive physical exertion extending over a period of some years.

MR. DIETZ: If you have a doctor examine a new employee and he does not find any hernia developments, could you feel assured that the company is responsible for that hernia?

MR. KNUTSON: The examination after he had it?

MR. DIETZ: When we employ a man we have a doctor examine him. If he comes into our plant under that doctor's examination all right and a hernia develops, should we feel reasonably assured that we are responsible?

MR. KNUTSON: Not necessarily. I don't think that should be the determining factor. However, I think an examination at the time he enters your employ would have been highly beneficial. If that doctor is honest in the making of that examination and gives an honest record and in addition keeps a record of the man and the man is given a copy of the results of that examination so that the man, if he isn't satisfied with it, can go and be examined by his own doctor, too.

MR. DIETZ: If after the doctor defines his condition can the man waive his rights and be hired under those conditions if hernia develops?

MR. KNUTSON: Not in our State. The only exceptions in our law are in cases of people who are blind, both eyes, or subject to epileptic fits. He may file a non-election absolving the employer from paying compensation resulting from injuries directly traceable to the handicap that he has. For instance, if the epileptic was standing at a machine, at a press, and it repeated and cut off his hand, certainly he should receive compensation the same as the other fellow. On the other hand, if while standing around or doing something, he got an epileptic fit and fell, struck a piece of moving machinery and was killed, of course the condition of the man there is responsible for the injury. They can only non-elect for those injuries that can be directly traceable to the handicap.

W. T. MEAD (U. S. Rubber Co., Providence, R. I.): Upon a doctor's examination showing a man having a very lax ring, could a hernia be produced if a man was pushing an object and his foot slipped?

MR. KNUTSON: I don't know. Perhaps it could; but if it did occur at that time, I could tell you in ten minutes by asking that man some questions. I would be interested in what he has to say as to what happened immediately following that, because if he actually did get the rupture at that time, there are certain things that must necessarily follow. If he didn't get it at that time, why, of

course, he doesn't know about these things and you can determine that by the way in which he answers those questions.

MR. MEAD: What are some of those things?

MR. KNUTSON: I wonder how many of you men here have ever had a boil or carbuncle that bursts as a result of having applied poultices?

I had a carbuncle on the back of my neck one time. I applied poultices to that. We were living away out in the country, about twenty-five miles from any doctor. At the time that carbuncle burst, I want to tell you men that I was so sick that honestly I would have welcomed some one coming around there and shooting me. All that carbuncle had to burst through was the tender skin on the back of my neck. I am telling you I thought I was within an inch of my grave. Having in mind a hernia, whether that protrusion goes down through the canal or whether it comes out through the abdominal wall, you have, I think it is, three layers of muscles across your abdomen, and if you are going to get sufficient intra-abdominal pressure to shoot a bunch of your intestines out through a hole there, in my opinion, you are absolutely done working right there, the pain would be so severe that at least the bulk of us would cry out with pain and agony.

The usual story you get is, "I went into the toilet, took down my trousers and here was a lump the size of an egg. I came back and went to work again." Another story is, "When I got home I discovered a lump; when I laid down in bed, the lump disappeared, and when I arose again the lump reappeared." All of those things are important in determining these hernia cases.

C. A. OSTBY (U. S. Rubber Co., Bristol, R. I.): I would like to ask if you don't experience difficulty in laying the reason or the blame somewhere as to what causes eye troubles?

MR. KNUTSON: Do you mean a loss of vision or some disease of the eye?

MR. OSTBY: That ultimately happened in one case, but it must have been some disease to cause blindness, I should say.

MR. KNUTSON: I think we are fortunate in Wisconsin in having what, in my opinion, are some of the best eye specialists in the country. The eye men have learned more definitely about what causes eye conditions than the general practitioner has been able to determine in so far as the other parts of the body are concerned.

Oftentimes we have cases of injury, we will say a direct blow to the eye. The man comes in afterwards and claims as a result of that blow his vision has been affected. These eye men, men that we have learned to trust, because we are satisfied their only mission in coming before us, whether at the request of the insurance carrier, the man or the employer, is in giving us an honest opinion. Those eye specialists can determine by examining that eye whether or not this 50 per cent loss of vision the man has is the result of that injury or whether it was a condition existing prior to the injury. They can determine that accurately and definitely.

When you speak of eye diseases, that, of course, would depend largely on what the man had to start with. First, you should have a definite diagnosis of his condition by a competent man. Second, you have to go into that man's history, his experience in that particular employment, and whether or not it can to any degree of reasonable probability be said that there was some condition in connection with his employment that produced this. We know that you can by wiping your eye with a towel, if there is some bacteria there, set up an infection.

I think you must have in mind quite definitely what the man's actual condition is, a diagnosis of his case. I am telling you frankly, eye cases are the least of my worries as far as compensation is concerned.

GEORGE A. HOLMES (U. S. Rubber Co., North Canton, Ohio): In Connecticut, one of the provisions for hernia compensation is that the man is unable to work after he receives an accident. Is that also true in Wisconsin?

MR. KNUTSON: Yes, in accidental hernias.

MR. HOLMES: Are there any exceptions to that?

MR. KNUTSON: Personally, I cannot conceive of anyone being an authority on compensation. If I were working in Connecticut and wanted to slip something over on you and read that law over, surely if I had a pain in my side I would go home.

MR. HOLMES: We thought along those lines, too. I was wondering if that was one of the provisions on which you make your decision. Is it necessary that a man receive a traumatic hernia? Do they always have to quit work? Can a man continue his work?

MR. KNUTSON: No.

E. R. LAWLER (U. S. Rubber Co., Hartford, Conn.): I was very much interested in Mr. Knutson's remarks on hernia. I have learned a lot today. In connection with Mr. Holmes' remarks, I have a clipping that might interest those particularly from Hartford. For a long while we have had a lot of trouble with hernia laws. Last year, in July, they changed the compensation law. The Supreme Court has just rendered a decision. It was in *The Times* in Hartford last Saturday night. The Chief Justice dissents from the opinion of the other four judges. The whole thing hinged on the word "immediate." The four judges approved of the Commission throwing out the case, stating that it meant "at once," and the Supreme Justice himself said that that was an inhuman clause in the law and should be changed. That is for the information of those that live in Connecticut; you have got to watch your step because there is going to be a change in the law.

I think Mr. Knutson's remarks have helped us all considerably in getting a better view of the hernia law.

MR. KNUTSON: About eight or nine years ago, our Supreme Court rendered a decision on a hernia case that has been known ever since as the Meade case. Our court set forth definitely what the necessary requirements were in a case of hernia where a man was to get compensation. We followed that decision. Here about a year ago we dismissed a hernia case and the applicant took an appeal and went on up to the Supreme Court with it; and in this last decision the Supreme Court said that, in their opinion, the members of the Industrial Commission were far better able to determine whether or not this man received an accidental hernia than the court. That is in substance what they said. We are, as a result of that decision, free lancers.

About three years ago, an insurance man came to me and wanted to know what I thought about their publishing in pamphlet form to distribute among their insured, the contents of the Supreme Court decision in the Meade case. I said to him, "In my opinion, that would be the most foolish thing in the world for you to do."

He said, "Why?"

I said, "Because every one of those fellows who has a hernia or gets one afterward is going to come in before our commission, and he is going to testify absolutely according to the decisions in that case." And he would. That is why I say I don't think you ought to have that provision in your law.

P. M. WOODEN (Mansfield Tire & Rubber Co., Mansfield, Ohio): I would like to relate a personal experience or observation. I had occasion to look over our files the other day. I found that in that period there were 67 men who had an existing hernia that they didn't know anything about. That is absolutely true, gentlemen. You can see from that that some men don't know when they have a hernia.

C. S. CHING (U. S. Rubber Company, New York City): I think this body owes Mr. Knutson a vote of thanks. I therefore move that we extend him a rising vote of thanks.

(The members arose and applauded.)

MR. KNUTSON: Gentlemen, I appreciate your courtesy very much. I was glad of the opportunity.

CHAIRMAN SALISBURY: I am going to pass among you a list that has been compiled, and comprises the answers to the questionnaire, sent to you about four months ago and to which 28 companies generously replied. There are results here that will be well worth going over. I am confident that this questionnaire will provoke a good discussion which will be beneficial to all of us. I am going to pass out only ten of these. You may divide them up. I want to have them all returned until I have your permission that they may be given to you permanently. In other words, I am using material here that has not been authorized by our Executive Committee.

We want to cover just as much ground as we possibly can. With that in mind, I am going to get right into this. I want to tell you again that 28 companies replied to that questionnaire. It shows that 12 of those 28 companies conduct departmental contests, that six of them conduct interplant contests, that five of them have bonus plans. It shows that 27 of these companies issue safety rules and enforce them, 25 by reprimanding their men and one by lay-offs. There are 19 of the companies using foremen's safety committees, six exclusively worker's committees and nine worker's and foremen's committees combined. There are 22 of the companies who claim to have a systematic method of instructing new workers and 16 claim that they instruct their transferred workers into the hazards with which the employee is unfamiliar. It shows also that 12 companies conduct safety mass meetings, that 12 hold courts of inquiry with management, and only four with management and workers combined; that 12 companies classify their accidents by basic cause, and 16 who state that their foremen in some manner or other list the various hazards by operation in the departments in which they work.

The other information asked was in connection with bulletin board material. I find that seven of the companies are using Elliott Service in addition to that of the National Safety Council; one uses the Mather Service and numerous and practically all of us use the home-made type of bulletin.

I am going to skip at random to start this discussion, because this is your three-quarters of an hour. It is entirely up to you to get something out of this. I shall endeavor to get something for my own selfish self. Is there a representative of the Overland Trail Rubber Company, of Omaha, Nebraska, in the room? You will observe that they hold a court of inquiry of the management and workers combined. Is there a representative of the U. S. Gutta Percha Rubber Company in the room? The Pennsylvania Rubber Company state that they hold courts of inquiry with management and workers combined. There is a representative of that company in the room. I am going to ask him to tell us just what they do.

A. M. DIERZ (Pennsylvania Rubber Company, Jeannette, Pa.): We take our lost time accidents for a complete month. At the safety meetings, we call the individual workers in one at a time. It takes us sometimes all day to do this. We ask him how he was injured, and if he has a method to prevent it or if he can offer some suggestion to safeguard himself and his fellow workmen. After that procedure is over, we immediately appoint him on the safety committee for three months in that department. He has to report at each meeting something that he has done. If he does not have a recommendation we send him his card back and ask him for it, and we invariably get it. We believe it is doing the company a lot of good.

CHAIRMAN SALISBURY: Are there any other representatives present who will talk on courts of inquiry?

Mr. Schneider, you are listed here as conducting courts of inquiry; will you tell us your plan?

MR. SCHNEIDER: We follow practically the same plan as the Pennsylvania Rubber Company. Of course, each case is decided on its own merits. Some of our groups employ different methods. We don't use the same method in every department. I find that the complaints have to be adjusted to the various men we have to deal with. Some foremen have peculiar ideas. I think the result is better than fixing one set plan all the way through our plant. I have found that that is true. We call a man in for violation of a rule, or if he has had more than one accident. The foreman must bring him in. The inspector must also accompany him and explain how the accident happened, and how it could have been prevented; and if there is any need for discipline, it is dealt out at that time. No man can report to work without first reporting to the superintendent under those measures; his clock card is pulled. The foreman has instructions that he must be sent to the superintendent's office. In some cases we have exacted pledges from the men. In other cases we have appealed to them for their cooperation. We have no general plan, as I said before. We use various methods, whichever we feel works the best.

CHAIRMAN SALISBURY: This sheet conveys to me the only known methods of educational accident prevention work. There appears to be nothing added to the questionnaires that were sent out. We have in front of us then a list of every known preventive educational measure. It strikes me that we could have a real discussion in connection with this phase of safety work if you probably had had a little more time to peruse the sheet.

This sheet shows that 12 companies out of 28 conduct some form of contest, interdepartmental or interplant. Six of them conduct an interplant contest. Is there anybody here that would like to have some information about contests?

MR. DIETZ: We tried to run our factory and the various departments of it in the contest for six months. We found that the shipping department and the receiving department and some of the other departments where the hazards aren't so great were always sitting on top. In our curing department, where 75 or 80 per cent of our accidents occur, they were at the end of the list. We talked to those men. They told us that they could cut their accidents but couldn't get away from the end of the list. We discarded that competition throughout the factory and put it on shifts, and that department cut its accidents about 65 per cent in three months. Sometimes we gave a bonus, sometimes we gave a box of cigars. The foreman ran the contest himself.

E. R. LAWLER (U. S. Rubber Co., Hartford, Conn.): In Hartford, we gave each department a base rate. We took the previous twelve months' lost time accidents and minor accidents and gave each department a base rate. So, you see, if those departments have had a fine record they have to do unusually well in order to improve that record. We found that the departments that have the most hazards are the ones that generally win the prize.

You will find invariably if you base it upon their past record, they will improve their record. In your receiving and shipping departments, they don't show a lost time accident sometimes for two years. In one case, we had in one of our departments not a single man reporting to the hospital for two years. When they get a scratch out there they never pay any attention to it, because they don't want to mar their department.

MR. SCHNEIDER: There is another way that can be handled, I believe, and that is to set your departments up into groups, and pit one group against another. We are doing that. We find there is a great deal of rivalry, because you will have

that many more prizes; you will have a group prize and an individual prize for the individual departments.

I think the method that our good friend Mr. Lawler told us about is perfectly just and fair.

C. E. OTT (Sciberling Rubber Co., Akron, Ohio): What kind of prizes do they give out?

CHAIRMAN SALISBURY: What do you do, Mr. Beck?

E. W. BECK (U. S. Rubber Co., New York City): Mr. Chairman, I have an address to give on that very subject this week.

The question of prizes is one that has stumped me to a certain extent for some time. I feel that you want to give a prize that is practical, you want to give a prize that does not require a great deal of attention to keep it looking good, you want to give a prize that will last, something not perishable.

We have tried to get the opinions of others on the question of prizes. We this last year gave four bronze trophies which were cast at the Gorham Company in Providence. They are beautiful plaques that can be fastened on the inside or outside of a building. On that plaque is the name of the company winning the prize and the reason for their winning it.

We take as a base rate the three previous years, and the prize is given to the plant that shows the greatest percentage of improvement over their average experience for the previous three years.

To answer this gentleman here, we base each of our severity cases according to what we believe is the importance of each factor. Severity we weight 50 per cent, the frequency of lost time accidents 5 per cent, the frequency of minor accidents only 5 per cent and the cost factor 20 per cent. The cost factor is the cost per thousand man hour's work, not the cost per hundred dollars of pay roll. We use the thousand man-hour's of work, because it gives us a cost per exposure to accidents, while the pay roll figure is not a fair figure, because in a State like South Carolina, you have an entirely different wage rate than in a State like Michigan or Massachusetts.

In the year 1926 we tried a new scheme of taking the original hand paintings that are used for the National Safety Council calendars and we gave those original paintings as prizes to the factory showing the greatest percentage of gain over the previous three years. Those paintings are not only pieces of art but they tell the safety story. I might say that they have been very well preserved at the factory that won them. They have been placed in a conspicuous location where the employees will see them.

The paintings can be had from the National Safety Council today. Each year the National Safety Council has 12 paintings and those paintings, while I know what they cost, sell for about one-fourth of what the original cost is. They are a bargain. They are beautiful pieces of art.

MR. CHING: If you will exclude the U. S. Rubber Company from answering, I would like to know what the other companies do in the way of prizes?

CHAIRMAN SALISBURY: I want to give an experience. A number of years ago when safety work was in its infancy and when I was serving an apprenticeship, we used to give prizes to departments, or run a departmental contest and award prizes to every man in the department. We gave as prizes six-foot rules, cuff links of more or less inferior quality, whetstones, etc. We deviated and gave two cigars to each man in a winning department and five cigars or ten cigars to the foreman and assistant foreman in charge of those departments. That plan was worked very successfully over a two-year period by the Joliet works of the Illinois Steel Company. They today have an enviable safety record. I don't know whether they are doing that sort of thing today or not. I presume they are not. I have often felt such a plan would stimulate a lot of interest in some of our departments.

I am going to ask some other of the companies to answer Mr. Ching's question and relate their experiences.

C. L. HUNGERFORD (Firestone Tire & Rubber Company, Akron, Ohio): The Central Alloy Steel Company are giving out as prizes certificates which give the winners either \$15 or \$20 worth of anything they want from shoes for the baby to new parts for their Ford car; they can buy anything they want, but they have to take it in goods from some of the local concerns. We at the present time are running a contest, and we are going to give out cash awards, money.

MR. CHING: To each man in the department?

MR. HUNGERFORD: No, just to the individual.

MR. CHING: How much will they get?

MR. HUNGERFORD: It is a safety slogan contest, and the winner will be given \$20. There is also an award to be given to the department showing the greatest percentage of slogans.

MR. CHING: Then, you are going to have two prizes.

MR. HUNGERFORD: Yes.

MR. BECK: What are you giving the department?

MR. HUNGERFORD: We are planning to give them \$50.

MR. BECK: I was talking about interplant contests. We have 20 to 30 plants. What kind of a prize is best to give to the twenty or thirty plants?

CHAIRMAN SALISBURY: That is rather difficult to answer because none of us have that many plants.

I have a suggestion that may be worth something to you, Mr. Beck. We conducted a divisional contest in our own plant on a weighted proposition. At the start of the contest, we gave each employee in the department a card with some pertinent wording on the back relating to safety and on the front the information relating to the contest, and a detachable part of the card in the form of a lottery ticket. In the division winning the contest based on lowest frequency of all accidents every employee is entitled to drop his card signed with his number into a box and we drew a raffle for \$100. We divided that \$100 into five prizes graduating down from \$30 to \$10.

We found that plan very good because everybody in the plant received one of those cards that told the safety story. When the contest was over, we announced the division that won and we had all the men congregated and see for themselves that the drawing was fair. Only five men received prizes but it had the desired effect.

I want now to go to basic causes of accidents. I have a list here of accidents that are basic causes. I will refrain from using names until I get permission on this thing. One company classified the causes of its accidents as follows: machine accidents, conveyors and gears, belts and pulleys, piling machines and other machines as basic causes of accidents. I don't think for one moment that those constitute basic causes of an accident. I have more lists.

Another company reports the following as their basic causes: handling material, handling tools, chips from tools, falling material, tripping. Those, to me, are not basic causes.

Most of you know that the Travelers Insurance Company has done considerable recently in bringing out genuine basic causes. I want to know if those are basic causes or if these are. The insurance company lists the following as basic causes: (1) Instructions—none, faulty and not enforced. That is, in my opinion, a basic cause of an accident, a possible basic cause of an accident. (2) Disobedience to instructions; improper discipline; interference by others; use of unsafe short cuts or improper practices; chance taking and haste. I don't altogether like chance taking as a basic cause. The man simply took a chance and he was hurt probably by some other condition. It is in here as a basic cause. (3) Inattention; attention distracted; inexperience; ignorance; lack of skill; poor judgment; improper

mental attitude of employee. It would be rather difficult to ascertain that that was a basic cause, but it certainly, in my opinion, is a basic cause. (4) Fatigue, mental or physical. I don't know whether we are going to be successful in establishing a number of accidents as a result of mental fatigue or physical fatigue, but we are going to try and do it.

(5) Mechanical exposures unguarded. That is not a very difficult basic cause.

(6) Poor housekeeping; congestion; improperly piled or stored material; unsafe layout of machinery or of operation; unsafe building conditions; improper fire protection or exits; improper lighting, sanitation or ventilation; goggles, masks; lack of proper equipment; conveyors, elevators, tools. I don't altogether approve of the elevators as a basic cause. There may be elevators combined with one of these other conditions.

(7) Defects in tools, equipment or materials; unguarded, partially guarded or hazardous electrical steam, chemical or other physical exposures. I was in hopes that Mr. Martin of our eastern plant would be here to talk on this, because he has an experience now of six months of foremen listing the predominant causes of the accidents on these forms. When this was first presented, I rather objected to it on the ground that no foreman would consistently or continuously report that accidents were occurring in his department as a result of lack of instruction, because if he did he would be simply reporting on himself. But, in taking it up in our regular meetings with our foremen, I believe we are really going to be able to get them to report these conditions, if they exist.

I would like to hear from somebody in connection with this, if for no other reason than to satisfy myself that we are on the right track.

MR. HUNGERFORD: We have been using that for the past three months. It has been received very well by all of our supervisors. Just before I came away, I finished an analysis of the reports. By the way, we are getting the foremen to list every accident no matter how trivial it is. They didn't like to do that at first. They thought they would have to spend too much time in the office. The managers like it very well, because it is giving them a view or a picture they never had before.

The trouble I find is that 75 per cent of our foremen are putting down checks where they shouldn't, that is, putting a check opposite "didn't follow instructions" rather than "instructions were not given." However, that is being corrected by personal investigation on my part and by the superintendents. It is getting results that we have never had before. I think it is due to the fact that we are taking the basic causes. You forgot to mention there that eighty-eight per cent of those causes were directly supervisory.

CHAIRMAN SALISBURY: Yes, that is true.

MR. HUNGERFORD: We like it.

P. M. WOODEN (Mansfield Tire & Rubber Co., Mansfield, Ohio): Poor judgment—doesn't that cover a multitude of sins?

CHAIRMAN SALISBURY: That would come under the main caption of "inexperience." Where you have an inexperienced operator, there is the possibility of poor judgment being used. The foreman might check off "inexperience" as well as "poor judgment."

MR. WOODEN: Also the caption of "more intelligent" and the man "taking a chance."

CHAIRMAN SALISBURY: Yes. I have also a more simplified list of basic causes.

M. A. QUIRK (U. S. Rubber Co., Detroit, Mich.): After you get all these lists, what do you do with them? Do you compile them and look them over afterwards?

CHAIRMAN SALISBURY: We haven't had enough experience with them, as yet. The system, as I understand it, at our eastern plant is to compile it and use it regularly. If there are too many causes of one condition, the foreman is called in and checked up on it.

MR. QUIRK: Take a plant that is giving instructions. They know they are instructing their new employees. That is the first job they have to do. Let us say that you have sixty-seven accidents in your tool department in one month due to falling objects and so forth. At the end of the month are you supposed to look over the classifications and centralize your efforts on the accidents that are giving the most trouble? As I see this thing, when you get all finished you don't know what the real causes of your accidents are other than issuing proper instructions.

CHAIRMAN SALISBURY: Take our curing room as an example. The majority of mechanical causes of accidents are conveyors. There may be a falling or dropping hazard or something of that sort. We know those conditions in a curing room. We know our conveyors are guarded properly, that is, the driving mechanism. We know that our presses in many instances have been the cause of a lot of accidents. What are the causes of the majority of your accidents? Let us say, for example, conveyors and probably overhead equipment. Now, get down to a basic cause in that department, that your foreman has "failed to instruct" his men properly or they are not following instructions or there has been inattention. Your final monthly report will show the basic cause plus the condition responsible, such as "falling objects."

C. A. OSTBY (U. S. Rubber Co., Bristol, R. I.): You asked for an answer as to whether those are basic causes or not. My opinion is that the equipment that we have (I am talking from rubber experience) is not the basic cause of accidents. It is very seldom that a piece of equipment falls and causes an accident. I think it is needless to say that all accidents or ninety per cent of them surely are caused by either carelessness on the part of the foreman or in not telling the employee where the hazards are, or carelessness on the part of the employee after he has been told. The equipment you name are the hazards and not the causes of accidents.

CHAIRMAN SALISBURY: I think so.

MR. WOODEN: Is it true in all cases?

CHAIRMAN SALISBURY: What would be the cause, in a safety stop failing to work?

MR. HUNGERFORD: That would be the cause of the injury and not the cause of the accident. That is the point I think should be brought out. We get mixed up on the cause of an injury and the cause of an accident. If a man falls over a ladder and breaks his arm, what caused him to fall over the ladder is what we are anxious to get at so we can stop it.

CHAIRMAN SALISBURY: That is what we are endeavoring to do with this basic cause list.

MR. HUNGERFORD: Is anybody willing to tell me how they discipline supervision that is on salary?

MR. CHING: How do you do it?

MR. HUNGERFORD: Let me give you a specific case. A man was taken off as a foreman and put back on a piece work job. That was pretty serious. There was a lot of other things involved besides the safety feature.

MR. CHING: How would they discipline you?

MR. HUNGERFORD: The safety department fortunately so far is not responsible for accidents. We hold the foreman absolutely responsible.

A. M. DIETZ (Pennsylvania Rubber Co., Jeannette, Pa.): There is one thing I would like to know. The Pennsylvania Rubber Company is only a baby in this safety work. Only within the last eighteen months has it been given any serious thought at all. Everything we have is pretty crude. What I want to know is how do you start your man after he is injured; what is the procedure? What do you require your men to do? What form do you have in making up the report is what I would like to have some information on.

HOWARD W. LOW (Miller Rubber Co., Akron, Ohio): As I understand the question, you mean after a man has an injury and he is unable to work any more that day or do you mean a little minor injury?

MR. DIETZ: A minor injury.

MR. LOW: At Miller, a man with a minor injury reports to the hospital without any pass whatever. He orally tells his inspector or the first man in authority above him that he is injured and is going over to the hospital. He goes over there and receives treatment and goes back to the job. I think what you are trying to drive at is how we can get the men into the hospital without reporting. The hospital makes a notation on their registers of any man who does not report an injury the same day it is received. We go to the hospital register every day. I report such cases immediately to the department head. I am glad to say they go back at them. We charge the injuries to the departments. We have our division heads sold on the fact that a man who develops an infection in a minor injury will run up the expense on his department \$100 where a minor injury would be fifty cent charge to that department.

MR. DIETZ: Where do you start? Does the injured man give the nurse the cause of the injury?

MR. LOW: The man gives the nurse the cause of the injury. We don't keep any track of the causes of minor injuries. The nurse writes down that he got his finger bruised or something of that sort. All cases are reported to the State. There is rather a complete record made of the nature and cause of injuries that we report to the State. In every case of that kind the foreman makes a written report to the safety department showing the cause of the injury and usually what can be done to prevent it.

CHAIRMAN SALISBURY: I want to bring up one point here. According to this questionnaire, 25 companies enforce their safety rules by reprimand. I am wondering if there is any record made of the reprimands in any way, shape or form to show you have disciplined employees. I have in mind this: In Wisconsin there is a 15 per cent penalty clause in our act that works both ways. The employee may be penalized 15 per cent through his wilful failure to comply with the regulations. If we furnish a man a pair of goggles and say, "Wear them," and he does not wear them, we cannot penalize that man 15 per cent of his normal compensation because we must show conclusively that we do enforce our safety rules. Merely to put a rule on the wall stating all men working at emery wheels must wear goggles and satisfying ourselves that we have complied with the rule by giving him a pair, does not necessarily follow that that rule is enforced. But, we are now, particularly in our machine shop, enforcing our rules through reprimand, discharge and layoffs, and recording them on our employment records; so that in the event a man should sustain an injury through the failure to comply with reasonable precautions, we may have a record on that man once or twice or three times, where he has been laid off, reprimanded or discharged and our case would be ever so much stronger. I am wondering if anybody has any system of recording such violations of the safety rules in the employment records.

MR. HUNGERFORD: Regardless of what the suspension is for, a suspension slip must be immediately sent to the employment department where it is filed as a permanent part of his record. We don't simply say, "suspended for carelessness," or "suspended for poor workmanship;" we insist that a very definite story of the exact offense is stated fully.

ADJOURNMENT

October 2, 1928

R. C. SALISBURY, Chairman

Manager, Health and Safety, The Fisk Rubber Company, Federal Division
Cudahy, Wis.

The second session of the Rubber Section was called to order at 9:30 o'clock by the chairman, R. C. Salisbury.

CHAIRMAN SALISBURY: Gentlemen, I want to make a few remarks concerning the activities of the Rubber Section—what they have been, and probably what they should be.

The Executive Committee during the past year met twice, once in Akron and again in New York. The Akron meeting was very successful. There were sixteen members present and we met at the Goodrich and Firestone plants—two-day session. Then again in New York in April we were the guests of the U. S. Rubber Company and there were eleven present, with six visitors, also a two-day session.

Various chairmen of the committees have been very active and, if you will remember, last year when I was given the honor of becoming your chairman I stated then that my success would be assured because I was surrounded with a splendid executive committee, and that proved to be a fact. All members have functioned wonderfully well and have cooperated to their very best extent. Special mention should be made of the *News Letter* Committee. We were unfortunate in the early part of the year in having to accept the resignation of Mr. Schreiber, of Goodyear, due to a change in his position, but he immediately filled that position for us through Jimmie Quirk (the vice-chairman in charge of *News Letters*), by providing Mr. Durkee, also of Goodyear. You have read some of Mr. Durkee's *News Letters*, and I am sure they proved very interesting and instructive.

The Membership Committee has rendered an excellent report, as follows:

Report of Membership Committee

By R. H. COCHRAN
Chairman

Number of Members in Rubber Section 10-1-27.....	48
New Memberships During the Year.....	10
Memberships Cancelled During the Year.....	5
Total Number of Members in Rubber Section to Date.....	53

List of New Members	No. of Employees	Date Received
E. M. Smith Company	125	9-30-27
The Lima Cord, Sole & Heel Company.....	48	11-24-27
Johnson & Johnson	1,600	12-13-27
Corduroy Tire Company	365	3-19-28
Avon Sole Company	150	5-10-28
Cambridge Rubber Company	1,500	5-22-28
Johns-Manville Corporation	4,500	7-18-28
Ohio Rubber Engineering Company.....		7-30-28
Michelin Tire Company	1,900	8- 9-28
Utility Manufacturing Company	35	9- 6-28
List of Memberships Cancelled:		
Essex Rubber Company		10-28-27
McCreary Tire and Rubber Company.....		4- 7-28
Bickett Rubber Products Company		12- 7-27
Mason Tire and Rubber Company		8- 6-28
Canadian Johns-Manville Company	200	8- 8-28

Several other companies seem favorably impressed with the National Safety Council and its activities and probably will join in the near future if they are properly urged. They are:

The Gates Rubber Company, Denver, Colo.
 Manhattan Rubber Company, Passaic, N. J.
 Belmont Packing or Rubber Company, Philadelphia, Penna.
 S. S. White Dental Company, Prince Bay, N. Y.
 Quaker City Rubber Company, Philadelphia, Penna.
 Lambert Tire and Rubber Company, Akron, Ohio.

During the past year, five committeemen were appointed to assist in the membership campaign. They were: Messrs. Reed B. Harkness, Cupples Company, St. Louis, Mo.; L. J. Glascock, Dunlop Tire and Rubber Company, Buffalo, N. Y.; J. M. Hunter, U. S. Asbestos Company, Manheim, Penna.; Wm. T. Mead, U. S. Rubber Company, Providence, R. I., and R. A. Bullock, Corduroy Tire Company, Grand Rapids, Michigan.

In the early part of the year I received a list of non-member rubber companies from the National Safety Council. A circular letter was written and, together with some pamphlets from the National Safety Council, was sent out on our company stationery and envelopes to all the different non-member rubber companies. Mr. Bushnell made this suggestion and I thought it a very good one. Seven replies were received from different companies—most of them favorable.

My intention at that time was to divide the United States into five sections and give each member on my committee a list of those companies located in his section and then about three weeks after I sent out my circular letter, have them write to each company in their particular section. Then in about a month I planned to have the National Safety Council send out another letter. The lists were not sent to the members of the committee on time but were sent out to them about two weeks ago and, of course, this does not give the committeemen an opportunity to do very much before the convention in New York. However, the National Safety Council, and especially Mr. Bushnell, has been corresponding with the non-members and cooperating with this committee in an effort to get new members.

The number of new members for this year was ten, but the number of cancellations was five, so we have only five new members—equal to that of last year. However, as stated before, the companies mentioned in the first part of the report seem very favorably impressed with the National Safety Council and the new Chairman of the Membership Committee should or may get started early this year securing these companies to become members before starting a campaign for other new members; that is, he will have something to work on, and should get an early start.

CHAIRMAN SALISBURY: That speaks well for your Membership Committee.

I took the time to read that report because I do know that Mr. Cochran has been very active in his efforts to secure new members. It is only through the enlargement of this section and the bringing into it of the other companies that we are going to get the best results.

The vice-chairmen of the section were all active and carried out their work to the best of their abilities.

The Health Hazards Section has some very good information lined up and you will get the benefit of this work tomorrow.

It is necessary to get right down to business. Our time is limited.

Mr. Smith, the speaker at my left, has asked that a change be made in the program, because of the fact that he must provide for a Wisconsin dinner, and he has asked to make a switch. Mr. Cook, who is the first speaker, has consented, and we will have Mr. Smith.

Ramifications of Safety Interest

By WALTER S. SMITH

Manager, Safety Division, Milwaukee Association of Commerce, Milwaukee, Wis.

I feel highly complimented in being called before your Section today. I would be very proud, indeed, if I could give you such a message that when you went back to your respective manufacturing establishment you would be able to banish accidents forever. That, of course, I cannot hope to do, but I do hope that some word of mine may be the means of inspiring you to greater efforts along safety lines so that when another year has rolled around you will be able to say that you have accomplished bigger things in accident prevention.

I believe we have reason for self-congratulation. The fact that we are present today and the purpose for which we are here are indications that we are tending toward a higher civilization.

In the days gone by, when the cavemen or the jungle jumpers found an injured man, they immediately got busy with their war clubs and put the unfortunate person out of his misery, saying perhaps: "That's one less competitor." I doubt if any of you gentlemen would do that. In the first place, you haven't any war clubs—you have golf clubs but no war clubs. War clubs are not nice little play-things anyway, but in the old days no home was complete without one. Domestic peace and felicity were maintained by whoever got to the war club first.

Today we are experimenting with civilization. I say experimenting because it is far from perfect. No civilization even approaches perfection in which many thousands every year needlessly are killed and injured.

I have been much impressed by reading the transactions of the Rubber Section of other years and note the high quality of the men who addressed your various meetings. It is an inspiration to read what they said to you. It seems to me that it would be time well spent for every safety man to have access to the printed transactions of the National Safety Congress so that he might draw on the splendid safety gospel therein shown.

Many of the addresses are well worth reading a number of times, which reminds me that Paderewski said "repetition makes reputation," so if we wish to rank high as safety men we can very well repeat on the reading of the transactions of the congresses in years gone by.

There are perhaps six thousand people in attendance at this safety congress and let it be hoped that every one is intensely interested in taking back home with him the enthusiasm that he will so much need during the coming year.

Every speaker, in making a public appearance, would like to be witty, would like to be effervescent and make a hit with his audience. I regret that I cannot be that way for the simple reason that I am depressed because I know that today, while we are assembled here to discuss safety, 69 people will be killed in automobile accidents, 63 will die by accidents in industrial plants, 41 will be consumed by fire, 22 by drowning, and 63 will lose their lives in home accidents.

It seems to me that we have not sufficiently popularized safety. We have not made a fad of it as yet. There are any number of men in the United States who watch very closely the styles worn by the Prince of Wales and are very quick to imitate him in their dress. Of course, that is a fad, but if we could make safety a lasting fad, which may seem somewhat paradoxical, perhaps we could get greater results than we have so far attained.

What we need, also, is to get more big men interested in safety. If the most noted business man in America were to say tomorrow, "You business men had better get behind accident prevention right away as a matter of good, common

sense," it would be one of the best things that could possibly happen to the safety movement.

As an illustration, if I say "No matter how we juggle the figures, two and two added will always make four," no one will pay any attention to that, because the statement seems trite and the person making the statement is perhaps not widely known. But let President Coolidge say that and the newspaper wires all over the country will burn up with a story that the President renews our faith in the infallibility of mathematics as an exact science.

I imagine that if we were to ask each one of you safety men here present, you would tell me that when you left your home city your plant was in as good a condition as it was humanly possible to make it and yet, undoubtedly, there will be accidents while you are away.

You have analyzed your accidents and you have kept statistics so that it would seem almost impossible for the same accident to happen twice, and yet, it does happen. Perhaps it is because while we have been able to safeguard machinery, we have not been able to fully control the human element.

Speaking of the human element reminds me of a report I received from the "Roads Department" of the Province of Quebec.

The department up to July 25 had cancelled 150 drivers' licenses for various infractions of the rules of the road.

One driver's case in particular interested me. His license was cancelled "for stopping his car on the railway track at the approach of a train with the object of daring and frightening the engineer."

Of course that is an extreme case, but it goes to show how far some persons will go in flirting with death.

We are trying to find all of the ramifications of safety interest. In our search we are sure to find a great deal of indifference. It's your job and my job to batter down that indifference and to get all with whom we come in contact enlisted under the banner of safety.

A report of accidents in the rubber industry for the State of Ohio, June, 1928, shows one fatality—cause given is miscellaneous.

There were 621 non-fatal accidents reported.

The causes are as follows:

Hand trucks	31
Falls of persons	38
Hot, corrosive and poisonous substances	40
Falling objects	51
Slipping upon or striking against objects	72
Hand tools	78
Machines	93
Handling objects	161

The last named is the largest number. Most of the accidents named cannot be prevented by mechanical guards. Many of them can be prevented by the only means left and that is safety education.

I wonder if many of these accidents are not due to the fact that persons are placed on jobs for which they are not physically and mentally fit.

In endeavoring to discover the ramifications of safety interest, I found what we always find when we start to do this sort of thing. When we discover that accidents are increasing in spite of an immense amount of safety work being done, we try to pin the reason unto some person or persons.

In preparing this talk, I had access to a recent report of the American Engineering Council which is published in book form by Harper & Brothers, New York. I am going to quote you a few paragraphs from this book, which is entitled "Safety and Production."

After quoting a number of cases where accidents were materially reduced and remarkable increase in production made, the report says this:

"These examples not only conclusively answer the query whether accidents are controllable, but the results are so remarkable that they definitely raise the question whether the new safety movement, when it really gathers momentum, may not quite eclipse the older movement and bring results that have scarcely been deemed possible heretofore.

"Apparently there are hidden sources of strength in the safety movement that have hardly been tapped. The common outstanding feature of all the cases cited is the thoroughgoing interest of the executive. In every one of these cases the result has not been casual and accidental; it has been the result of long continued careful effort; it has been obviously the carrying out of an executive policy. The executive had not only an interest but a vision of safety and the growing belief in the possibility of realizing it, and he went to work to attain it through the peculiarly effective ways that are known to executives. In other words, these are simply further examples of the ability of an executive to impress his point of view upon industry and the significant feature of these cases is the demonstration that this power of the executive to influence action carries over into the accident field.

"This then raises the question: Is not the key to the safety movement of the future the chief executive himself? Up to the present time the safety movement has in general been essentially a second rank movement. It has had the knowledge and approval of executives but it has not entered into the consciousness of most executives as a matter demanding their personal interest and attention.

"The point of view underlying and motivating this present undertaking is, as a matter of fact, a belief that the time has come when safety in industry must become a matter of first-rate and first-hand executive importance. Frankly, the primary purpose of this study is to interest executives in the subject. It is believed that the success of the safety movement of the future, a movement that must stem an industrial tide that is running not only swiftly but dangerously, and ever more swiftly and dangerously, can be had only when safety is recognized as a major executive objective."

There are many of the largest executives of the United States that are doing a first-class piece of work in safety. Some of them are attending this congress. There are cases on record where the chief executive has shown a very decided interest in the safety of the plants under his charge. But there are many more cases where safety is being well taken care of where the responsibility has been delegated to men who are perhaps known as minor executives.

I recall a large manufacturing plant where there used to be a constant stream of men going to the first aid room to have their injuries cared for or to be sent to the doctor when the injuries were serious. Everyone there seemed to take it as a matter of course.

Yet that plant went from the first of May last year to the first of July with only one lost time accident. They had no accidents in July and in August they had two.

And these splendid results were achieved because the chief executive got busy and determined to have no more accidents. And they were successful because they got the co-operation of all the men in the plant. Everyone began to believe in safety. There weren't any ifs or ands or buts. Everybody got on the bandwagon and the result was perfect harmony and almost no accidents.

You will remember that the Spanish-American War took place during the administration of President William McKinley. Before the war with Spain started it was necessary for the War Department to deliver some very necessary information to General Garcia in Cuba. And it was imperative that some one go to Cuba with it. No one expected that President McKinley would pass up all his other duties and, as Commander-in-Chief of the army, go to Cuba with that information.

But he was able to select a man who knew how. This hazardous task was delegated to Major Rowan who went to Cuba and returned safely with his task accomplished.

It occurs to me that this is one of the most remarkable cases on record where a task was delegated to a minor officer; and so I believe it will be, no matter what new developments we may have in the safety field, the minor executives who will continue to have the greater part of the burden to bear. But perhaps you don't agree with me—that may come out in the discussion.

One of the ramifications of safety interest took me into the University of Wisconsin. The President of the University, Glenn Frank, has written one of the finest articles on safety that I have ever read, "Safety for the Body and Adventure for the Mind." I believe that President Frank delivered this safety talk at the Fox River Valley Conference at Oshkosh last June.

You will find a printed copy of the address in the National Safety News for September. Among other remarkable statements, President Frank said this:

"If I did not think enlightened self-interest was making for such an end, I should join the men who despair of our civilization. But our machine age is going to cure itself of its own sins without either the assistance of outside reform or any internal reform of the characters of business men, simply because the steady advance in technical progress and business intelligence is making it daily plainer that most of the things about our machine age that the critics condemn are bad business."

Now, gentlemen, I thank you for your patience and your kind attention. May you go forth to your endeavors with fresh determination to surmount the difficulties that beset your tasks.

May you be filled with the spirit that wavers not, and that you may be spared many years in which to make America a safe place in which to work and to live.

WALTER S. SMITH (manager of the Safety Division of the Milwaukee Association of Commerce, Milwaukee, Wisconsin): I would like to tell you something of my work as manager of the Safety Division of the Milwaukee Association of Commerce. Part of this work is to conduct a foremen's school, a fire prevention school and a first aid school. In our foremen's safety school we registered 6,360 people. They didn't all attend at once. Sometimes our attendance at one meeting will run as many as 4,000 people. We have the school divided into eight sections: electrical section, machine shop, all-trades, etc. We registered something like 1,700 people in the fire prevention school. They don't all attend at once, but we have attendances from 800 to 1,000 persons. While I have been engaged in a large number of different kinds of work, I think the thing that I am now doing is the most interesting. It brings me in closer contact with human beings. Mr. Salisbury is chairman of what is known as the All-Trades Section. The attendance in that section is made up of a variety of industries, those who won't fit into some of the other sections. The attendance will run as high as 1,300 at one meeting. The average for last year was 915. He is also a member of what is known as the Operating Board, consisting of 22 men that represent the leading industries for the city of Milwaukee.

CHAIRMAN SALISBURY: Thank you, Mr. Smith. We will defer discussing your paper until we have gone through the rest of the program.

The next speaker on the program appears as Mr. F. J. Hoxie, but we are going to put that over to the last subject and go right into the paper of Mr. Cook. It became necessary to make a change in Mr. Cook's paper. You will note he was to discuss vulcanizers, but Mr. Cook stated that he had already discussed vulcanizers in the rubber industry some years ago and with slight modifications the copy can be brought up to date, and he didn't feel it would be worth while coming here and repeating a subject that has already been properly covered. At the end of his paper, if there is anything on your minds in connection with heaters and

vulcanizers, I am sure he would be glad to give us the benefit of his experiences and his knowledge. I am sure that the paper he will give us will contain many valuable ideas and possibly some new thoughts. I now have great pleasure in presenting to you Mr. G. W. Cook.

Methods of Accident Prevention

By G. W. COOK

Supervising Engineer, The Travelers Insurance Co., Hartford, Conn.

Since the organization of the Rubber Section of the National Safety Council about fifty speakers have appeared before you. The safety problems of the rubber industry have been treated from many angles and the proceedings of the Rubber Section now form a valuable reference work on accident prevention in the rubber industry. You will recall that most of the speakers, who have addressed you, were men actually engaged in the rubber industry. It may be, then, of interest to you to hear the ideas of one who deals with all industries.

It is dangerous to proclaim anything new in safety. We do many things as a matter of habit and many of these methods we use today, are worthy of scrutiny. After examining some of these methods critically, we have developed certain progressive ideas which are being applied to industry in general, and it is only fitting that we examine them and test their applicability to the rubber industry.

It is almost unnecessary to say that to prevent an accident we must know the cause of the accident. If you will examine the list of accident causes, by which you classify your accidents, you will find that the list is made up of classes or kinds of accidents, but not causes. For some unknown reason the practice has grown up in practically all safety work of listing, as the causes of an accident, a description of the accident. Your foreman, when reporting on an accident, puts down under the caption Cause, "Hand caught between halves of a mould," or "Hot water splashed on man." Almost every report made by a foreman, or even a safety inspector, investigating an accident, will show under cause of accident, a description of what happened, but not why it happened.

We speak of cause and effect, and in describing accidents, almost invariably, effect is given as the cause. What caused the man to be caught between the halves of a mould? What caused the hot water to splash on the man?

This all seems absurdly simple, but try to get your foreman to report causes. Try to get your safety inspector to report causes. Take the reports of accidents which come over your desk and assign causes yourself. You will immediately find yourself in difficulty. It is easy to tell what happened. It is generally easy to tell how it happened. The difficulty arises when we try to tell why it happened; what caused it to happen.

If you analyze accidents to cause, it will mean that you will have to scrap your present charts of accident causes, with items on them, such as, hand tools, bumped against, burns, etc., and to substitute such items as, instructions not enforced, unskilled employees, ineffectually guarded, or improper planning. It would be interesting to see a comparison of experience of the members of the Rubber Section on such causes as, incomplete instructions, disobedience of rules, or congestion.

We speak of basic causes of accidents, the primary and secondary cause of accidents, the principal and contributing causes. Several people analyzing an accident may each assign a different cause. It is not always essential to find what we might designate as the basic cause. Find any cause and cure it. If you educate your organization to do that clear fundamental thinking necessary to really analyze accidents to cause, you will develop an entirely different approach to your accident

You are always much concerned over the severity of your accidents. Your first efforts are to keep down compensation accidents and, next to compensation accidents, the lost time accidents. Seldom is any serious attention given to, no lost time, or at work accidents. There has been an opinion, more or less prevalent that no effort should be made to keep down minor accidents. An increase in minor accidents has been accepted as an indication of the efficiency of the safety department in getting minor injuries to the hospital. There is a well established theory that if any effort is made to cut down minor accidents, injured employees will be driven away from the hospital and an increase in infections develop. It is an idea that was probably founded purely on theory and not on fact. In plants where a drive on minor injuries has been tried, this "bugaboo" of increased infections has not materialized.

Every accident has a cause. The severity of the physical result of an accident has little, if any, relation to the cause. The physical result of an accident is purely a matter of chance. The same cause may produce a fatality, a compensation accident, a lost time accident, a minor accident, or a near accident. From this viewpoint and, if the accident problem is to be treated as a whole, every accident is of equal importance.

We might say that all accidents are minor accidents and major accidents are only minor accidents which, due to chance, or unfavorable physical result, have become major accidents and, by the same reasoning if we stop minor accidents, we cannot help stopping major accidents. The causes of major accidents and the causes of minor accidents are the same causes. If we stop minor accidents by eliminating the cause, we can anticipate the major accidents.

This all means that we must approach the problem from a different angle, to forget the severity, and treat all accidents with equal concern, and try to eliminate all accidents regardless of the physical result.

One of the oldest safety sayings we have is, that the foreman is the keystone of safety, or the key man in safety. Later we have developed the idea that the foreman should be held responsible for the safety of those under his supervision. We endeavor to accomplish this foreman's responsibility in various ways. We hold foreman's meetings. We require them to investigate the report on accidents. We charge the cost of their accidents against the cost budget of their departments. We incorporate accident prevention into the bonus system, and we discipline them through their immediate superiors for unfavorable experience.

We have found plenty of ways of placing the responsibility on the foreman, but it is a question of just how much of this responsibility he has accepted. Is his cooperation the result of discipline from his superiors, or does he willingly accept the added burden cheerfully with a real desire on his part to incorporate it into his conception of foremanship? Most foremen look upon the safety department as an organization with which he cooperates to prevent accidents. He does not yet look upon it as primarily an organization to assist him in preventing his accidents.

The time has passed when your safety department needs to sell the safety idea to the foreman. You are now holding him responsible in his department, and you now have another obligation with respect to this foreman. Most foremen were workmen yesterday, and in many ways he still thinks with the mental attitude of a workman rather than from the standpoint of management. He should understand the economic significance of accident prevention. He should be taught how to go about it to prevent accidents, to analyze accidents, and how to solve his own safety problems.

Your safety departments have a further duty to perform with respect to the foremen, whom you hold responsible for accidents, and that is to educate them, to school them, in the business of preventing accidents. They should be taught to come to you to discuss their problems with you, and not your problems with them.

If you will recall the unexpected, extremely serious, accidents which have oc-

curred in the rubber industry, you will also recall that they were mostly accidents on machinery or engineering equipment. An elevator falls—a vulcanizer door blows off—a man is caught in a calender or wind-up. Each kind of these accidents happens so seldom that they can hardly be said to have any frequency. Grouped together, however, these engineering accidents do have a frequency which, coupled with their unusual severity, have a marked effect on the plant experience.

In every plant in the rubber industry there are two safety organizations—the one we usually recognize, and the one maintained by the Engineering Department. Your maintenance engineer is the head of a safety organization whether he knows it or not. You depend upon him to keep a vast amount of engineering equipment safe. He is tolerably successful in doing this. He has inspectors, testers, etc., testing stops, gauges and inspecting elevators, chains, hoists, etc. The fact that these accidents do happen indicates that there is still room for further improvement.

Your designing engineers are supposed to design safe machines and generally do so. When a machine is installed, safeguards are provided before it is put in operation. Unfortunately many of the hazards surrounding a machine only develop as the machine is operated. In fact, some of the most serious machine accidents in the rubber industry have happened while the machine was being developed for production. There are two ways of correcting this condition. One is to make a study of the machine in operation from the standpoint of safety and provide the safeguards. The other way, the one most always used, is to have the accident first and provide the remedy afterwards. Recall, if you will, the accidents on the rimming presses, the bead wrapping machines, and some of the tire building machines,—accidents which happened on new machines before they were properly safeguarded, but after they were put into production.

I know of no industry where there has been such a turnover in equipment as there has been in the rubber tire industry in the last few years. You have made such rapid progress that your engineers have been exceedingly busy keeping up with this progress. The job of the engineers is to design and install equipment for the production department, and keep it in operation. Safety must always be incidental to the main job of these engineers, and as it works out it is the incidental job to several different engineers. We know that to get a job done well, the responsibility should be concentrated under one man. Is it unreasonable then to say that the safety of engineering equipment should be concentrated under one man, an engineer whose first job is safety?

I know that in every plant you have what you call a safety engineer. These men are seldom engineers and their duties are not those of an engineer. They investigate accidents, hold meetings, compile statistics, make inspections, post bulletins, draw charts and do many other things. They fill a real job in the accident prevention program, but it is not an engineer's job.

There is a need for the concentration of responsibility for the safety of engineering equipment in use under one head, and responsibility for studying new equipment and seeing that it is safeguarded before these accidents occur.

Whether such an engineer should be under the works engineer, assigned to the safety department, or independent of either, I am not prepared to say. This much is certain. In the average plant one very important function, that of controlling safety of engineering equipment, is in the hands of various individuals. The responsibility is scattered and the definite control uncertain.

One of the oldest forms of safety work is plant inspection. We inspect a plant for safety. By that we mean that we make a tour of the plant and observe unsafe conditions. There are some plant operations that can be taken in at a glance. There are some others which require several hours to complete the cycle which can be termed one operation. Starting up, feeding and running a batch in a calender is such an operation.

There are other operations which are intermittent and are only performed at

intervals. Milling a batch for the cement house is such an operation. A plant inspection will disclose only a portion of the first kind, and may miss entirely the second kind of an operation.

It is evident then, that if we are going to disclose all the hazards of a plant, we must make a study of each operation from the start to the finish. We must take each department in turn and trace the operations through the department, just as a time study man analyzes operations.

We designate this as job analysis. We analyze the job from the standpoint of safety. If we have the benefit of accident records properly kept, we can allocate the accidents which have occurred to the departments where they have occurred, and possibly to the operation, and study the operations in view of past experience. Also, from our knowledge of accident causes we can develop the possibilities of accidents which have not yet occurred on the specific operations.

In some plants where job analysis has been practiced, a set of detailed safe practices has been built up for each operation. It then becomes incumbent upon the foreman, to train new employees in safety on these operations, and no further excuse for ignorance of employee can be used if the foreman has done his part.

Job analysis requires careful detailed study. It requires time and a thorough analysis of operations. The results are well worth while, and far more valuable than plant safety inspections as usually conducted.

If you in the Rubber industry will practice Safety Job Analysis, you will develop a far better picture of accident producing conditions, and in time be able to provide your foreman with detailed material for instructing his help.

If you will concentrate the responsibility for engineering safety under one head, an engineer, you should expect a decrease in the severe unexpected engineering accidents which have had such a marked effect upon your accident costs. If you will school the foreman in the fundamentals of practical accident prevention, you will be doing your share towards fitting him to carry on the responsibility which you have already placed upon him. If you will ignore severity, and treat all accidents with the same degree of seriousness, make a drive on minor accidents, you will undoubtedly have a marked effect on all accidents. And, lastly, if you will analyze all accidents to cause, you will find a much more effective method of approach to this problem of accident prevention.

CHAIRMAN SALISEURY: I think it would be well to discuss Mr. Cook's paper right now while the subject matter is fresh in our minds. I would just like to make one or two remarks concerning the Rubber Industry accident experience for Mr. Cook's benefit. It fits in somewhat with his paper. Of the 17 companies reporting their accidents during the year 1927, the rubber industry stood in ninth position with respect to the frequency rate, and third with respect to severity. In your talk, Mr. Cook, you touched on the low frequency-high severity accident—that is to say, in the paper you emphasized one or two points in connection with reduction as controlled by engineering supervision. I agree with you considerably and I just wonder if we can't discuss this phase of Mr. Cook's paper for the next ten minutes with some advantage.

C. L. HUNGERFORD (Division of Safety and Hygiene, Firestone Tire & Rubber Company, Akron, Ohio): With respect to machine accidents, and not being able to do anything until we have an accident—one of the methods that we use in our plant is this: Before a new machine is turned over to the production department it has to be okayed by the safety department. Of course, if it is a pressure vessel it has to be given the hydrostatic test. We also expect it to be seen that the state laws are complied with, such as providing necessary guards for gears, and one of the things we have found out on new machines is that very often not having just enough or too much clearance between revolving rollers causes a lot of accidents and that is a matter of education with the engineering department, but we always try to get our roller sufficiently far apart so as not to form a grip-

ping action, should a hand become caught. In other words, if it is only an inch apart, we try to get it three or four inches apart, or else right up close together, and that method has prevented a lot of accidents that never came to the attention of the management until after the machine was placed in construction and going full blast. We have had no trouble there in a year and a half and I think that is one of the reasons—inspection, study of the machine before it is placed in production for regular operation.

CHAIRMAN SALISBURY: Are there any questions you would like to ask Mr. Cook?

I have one in mind, if you don't mind my monopolizing the meeting. You made reference to proper discipline. In just what manner do you think we should hold foremen accountable and responsible for accidents? And in just what manner do you think a foreman should be disciplined? Could you answer that question?

MR. COOK: You are asking one of the oldest questions in the safety game. I have seen several different methods tried and I think you have to bring into consideration two things—the way in which a plant is managed, first of all. I recall a large electrical manufacturing concern who refused definitely to penalize the foremen or to do anything to discipline the foremen. On the other hand, they were perfectly willing to put in the budget allowances for prevention methods. It seems in this plant each department has a cost budget for operating and they were perfectly willing to charge the cost of accidents in the department to the cost budget of the department. Strange as it may seem, cost was one of the things in this plant they were disciplining the foremen on, and by adding this they got as good results in disciplining through the cost budget as by any other means. I am not prepared to say, Mr. Salisbury, how foremen should be disciplined in any plant. I think that is the job of every plant to decide.

One of the most serious accidents we had in the rubber industry occurred last spring on the in-running rolls, where they were about six inches apart. That means that in-running rolls are always dangerous. Unless a man could go clear through between a pair of in-running rolls and not get hurt at all, we consider them dangerous, and if you will discover in your plant all the in-running rolls, you will find a lot of them, and if a man can get a hand or leg or anything else in the rolls, you have a dangerous condition and it should be watched. Very often, when we see a pair of windup rolls for example, we think they have plenty of room between them. That means there is no pinching hazard, no chance of a hand being squeezed, but he can get in there in a good many ways, besides getting his hand in.

MR. McHUGH (U. S. Rubber Co.): Mr. Salisbury, I would like to find something out. Quite frequently this discipline of foremen and employees comes up at meetings. I would like to ask if they have disciplined a foreman at any time and if they would do so would they have the courage to recommend his discharge if they thought the accident severe enough to warrant it.

A MEMBER (Chicago, Ill.): I know of several plants where the foremen are participating in the bonus system and about two out of three plants charge on 20 per cent of the cost, and the other charges all of it. Now, the foremen are vitally interested because every bit of accident cost that is developed under their supervision is deducted from their bonus, and I think that is quite a severe manner of discipline.

MR. McHUGH: When you are giving him a bonus you are giving him something outside of his salary. I refer to cases where a man is on a salary and where you deduct part of his original salary, or else lay him off, where he loses that or loses part of his job. You are not touching his regular salary that way; you are touching something that is being given to him. What are we going to do about discipline?

MR. COOK: I can't speak for the rubber industry, and I wouldn't want to be

in the position of violating confidences, but I can tell you frankly that I know of cases—plenty of them—where foremen have been discharged, laid off, demoted and also in some organizations have been fined for violation of the rules that have been laid down to them.

W. L. SCHNEIDER (Goodrich Rubber Company): I happen to know of a number of cases, and I may say that this happened in some other plants, where usually the management does not have a good safety man to watch it; or else he is not one himself. This is due to a lack of effort in production. You will find that is generally true. The foreman who is not a good safety man himself lacks the essentials of a good production man. He is usually out of it.

MR. WOOD (Mansfield Tire Company): I think I sense the gist of the situation. We have been up against the same proposition. It resolves itself right back to the type of management which is sold 100 per cent on the theory that you can't interfere with the foreman. "We would like to do so, but we can't."

MR. HENNECK (The Safety Cable Company, Bayonne, New Jersey): I happen to be a living example. I am a foreman, and the method in our plant is to make the foreman realize that accidents have to be prevented at any cost, especially those that can be attributed to neglect on his part. One of the methods is to publish his name in the department on a great big conspicuous board on the entrance to the plant, showing accidents and how prevented. Another method is to have a meeting of the foremen each month to impress all of them that accidents must be stopped, by deducted bonuses. He receives no bonus for that month. The third measure of prevention was to make every foreman an inspector in the plant with regard to safety. He devotes two days a month in all departments studying conditions.

MR. McHUGH: The reason I started this discussion was the fact that in my experience we come to these meetings and we are interested and talk of safety and we want to go back and put it across. But my experience has been that we have had foremen in our plant that are good production men. If you say, "We recommend that you lay this fellow off without salary for a month," your management is not sold on that idea. We have to go out and sell that idea to the boss back home if we are going to put across discipline. You have to do it right. I don't think there is a man here this morning who has done anything.

MR. HUNGERFORD: I don't want to tell this, but I will have to. An inspector slipped in the shower room and broke his clavicle, and the safety department was criticised for having a slippery shower room. It is always slippery. The colored men settle it by wearing sandals; but in checking up we found that horseplay was the cause. Another inspector splashed cold water on this fellow. He jumped and fell and broke a bone. The foreman criticised the medical department before he found it out. It took an hour to get this case to the hospital. The foreman still insisted on telling the organization what terrible treatment he was having. The management was criticised for not having sent someone in to find out what was the real cause of the accident. Another thing he stated was this idea of holding foremen responsible for horseplay in the shower room was all the bunk and furthermore if a man was fool enough not to carry out the instructions that were posted on our bulletin board he wasn't going to do much about it. The next day he was not a foreman, and still isn't. We did keep him, but he was reduced to piecework rate basis on the job from whence he started. That is the only specific case I know, but that happened four months ago. He was the full shift foreman.

MR. McHUGH: Was in charge of a department?

MR. HUNGERFORD: He was in charge of a department; he had full range. He was first, second and third shift foreman, and responsible directly.

CHAIRMAN SALISBURY: Isn't it a fact that the necessities for disciplining foremen would be very rare? Of course, there is one example, of another foreman in

our Eastern plant losing his position not only because of the bad safety record that he had, but as Mr. Schneider said, that safety record was closely allied to a bad production record and he was discharged. But those cases are rare.

MR. McHUGH: He simply wasn't a good production man.

MR. J. T. KIDNEY (Goodyear Rubber Company): How long had he been with you, Mr. Hungerford?

MR. HUNGERFORD: Fifteen years.

MR. KIDNEY: I think the gentleman has answered his own question when he said he was foreman for fifteen years. We have had that condition, and we find it among our men who grew up with us twenty-three years, and we find that men who have been holding jobs so long are the hardest to bring into safety. We actually did bring a twenty-three year man around on the 1st of July. It was done by the State Inspector. He had six men chipping, and then one received a bad eye. The State Inspector came in and looked at the machine and saw two men in the back working without goggles. The foreman said that they didn't need goggles, that they were not chipping. The inspector said, "Chipping is going on here about them and the laws require that those in danger of the flying chips have to wear goggles, too." Well, the foreman said he couldn't see that. He said, "You have to put goggles on those men." He came back and ordered us to post bulletins out there about it. We had to put a bulletin board above the chippers that they would have to wear goggles all the time. Shortly after that he had another accident and the inspector said he was going to arrest him. The boss said, "You can't do that." The inspector said, "You leave him there and we'll take him out."

MR. McHUGH: I'd never let a twenty-three year man go on that account. We don't do that.

MR. KIDNEY: I don't think any foreman ever lost his job just because he wasn't a good safety man, but it is used as a measure of disability as a foreman and I think that the whole question is answered there. I know men in our plant that are being turned out. They may be important men, but are poor safety men, and that is one of the items that went into the yard stick with which they were measured.

CHAIRMAN SALISBURY: Gentlemen, I take pleasure in introducing to you a genuine authority on static electricity, Mr. Hoxie.

A Personal Peculiarity of Workmen—Common Cause of Accident and Fire in Rubber Factories

By F. J. HOXIE

Associated Factory Mutual Fire Insurance Companies, Phenix, R. I.

In 1921, at the Boston meeting of this organization, I gave a paper entitled, "Fire Hazard of Rubber Factories, Dependent on Humidity." In that paper I mentioned a case in which a physiological peculiarity of a man employed in a rubber spreading room was the cause of many fires. Since that time other cases have occurred which clearly demonstrate the danger of employing people about combustible volatile solvents who do not give off much moisture from the surface of their bodies.

There was an article in the "Factory Mutual Record" of November, 1924, entitled "Human Spark Plugs," which described the case of a young woman who was employed in Endicott Johnson's Shoe Factory, in passing shoe soles between rollers which applied rubber cement to them. The cement took fire from static sparks five times in one winter. In one of these fires she was so severely burned that she was under medical treatment for three weeks. Dur-

ing this time another girl carried on the work, and no fires occurred. When the first girl recovered and returned to work in the morning she had been at work but fifteen minutes when another fire occurred. It was then recognized that some personal peculiarity of this girl was the cause of the fires.

In recent years, in inspecting factories in which volatile combustible solvents are used with rubber, pyroxylin, or other substances I have made careful inquiry as to whether any people are employed about these combustible solvents who have dry skin. This can generally be determined by shaking hands with such people. The skin on their hands feels dry, and due to the fact that little moisture is given off from the surface of their bodies their clothing remains dry and they retain any static charge which is communicated to them, with the result that a spark will pass from their fingers to any grounded or large conducting object which they come near, thereby igniting nearby volatile combustible solvents.

Generally such people are not themselves aware of the fact that they are different from other people, attributing the fires which may occur about them from time to time to mere chance. In the above mentioned case, as well as the one I mentioned in the previous paper fires were of frequent occurrence, so that if this fact had been recognized it would have been at once seen that it was a physiological peculiarity which caused the fires, which might at any time cause a serious accident, not only to the persons themselves but to their associates.

In the use of humidity for preventing fires from static electricity the question at once arises as to what is the most convenient way to get the humidity and how much is needed. Several rubber factories have now been using this remedy for some years and have made careful observations which will answer these questions. Among these are the Hood Rubber Co. of Watertown, Mass., and the Firestone Tire and Rubber Co. of Akron, Ohio. A gentleman from these factories will discuss this paper and give their experience.

Several years ago I recommended humidity to prevent fires and explosions in grinding metallic magnesium. At first it was thought that the humidity would blacken the magnesium powder but it was found that the small amount required to keep down the static did not have a seriously detrimental effect.

Recently a representative of the research department of a large explosive manufacturing company wrote me, asking if I could suggest a remedy for static in the handling of dry nitrated cellulose. I mentioned the cases cited above and suggested the use of humidity. This gentleman has been asked to discuss this paper and give any experience he may have on this subject.

I have found it useful in studying the effect of moisture on static fires to plot all of the fires reported according to the month of the year in which they occurred. The Factory Mutual Insurance Companies have so little experience with dry nitrated cellulose that this method of study cannot be applied, but doubtless the manufacturers of nitro cellulose, either for explosives or pyroxylin plastic could throw useful light on this question.

As a means of getting humidity in cold weather I have frequently recommended a small open pet cock on the steam heating appliances, as these heating appliances will only be used in cold weather when the air is dry and when there is the most danger from static.

Thorough grounding of all metal parts of machines and providing a well grounded metal plate to stand upon is frequently recommended for preventing static fires. This is excellent if the grounding is effective, but frequently the operatives wear new shoes in which the metal nails do not come in contact with their feet on the inside or the metal plate on the outside, therefore the maintenance of a humidity of about fifty per cent relative or not less than five

grains of moisture to the cubic foot of air in the room in which the volatile combustibles are handled generally proves most effective.

Our experience has been that more fires are caused from static sparks from the fingers of the operatives than from the machine itself.

Another department of a rubber works in which several fires and explosions have been reported is an apparatus in which flowers of sulphur are passed through metallic sieves. These sieves serve as condensers and accumulate enough electricity to cause a spark sufficient to ignite the sulphur. I have never heard of any cases in which the static capacity appeared to be an important factor in the ignition of flowers of sulphur, although I see no reason why it should not be so if the atmosphere is dry enough.

CHAIRMAN SALISBURY: We are indebted to you for the valuable information you have given us. It is listed in the program that Mr. W. T. Runals, Assistant Superintendent of Engineering, The Firestone Tire & Rubber Co., Akron, Ohio, would discuss Mr. Hoxie's paper. He can't be here, but Mr. Hungerford has consented to give us the benefit, not only of Mr. Runal's experience, but also some of his own.

MR. HUNGERFORD: This discussion wasn't written by myself, but by Mr. R. R. Jones of my company. It is somewhat of a reinforcement of what Mr. Hoxie has said.

Discussion of Mr. F. J. Hoxie's Paper

I do not believe there is any subject more vital to the Safety and Fire Protection Engineer in a rubber factory than the subject of static electricity. Static is generated as a sort of by-product in practically every operation performed, while at the same time, the conditions surrounding that operation are more conducive to fire than is usually the case in other lines of work. The most interesting tool which any safety engineer can make for himself is a gold leaf electroscope. He can find all the information necessary in any High School book on Physics and with this tool he can make many experiments and settle some questions not otherwise soluble. With such an instrument I have repeatedly shown that some persons, for some reason, are "Human Spark Plugs," as Mr. Hoxie states. A small percentage of women operators working under identical conditions will show a charge where their associates will not show a charge. I have never discovered this property among men although it may be that it exists. It is needless to state that the best interests of safety are served when these "spark plugs" are transferred to an operation where the conditions surrounding are not conducive to fire hazards.

With this electroscope also it can be shown that the evaporation of an ordinary rubber solvent will generate static electricity; that the vapor is one polarity, the containing vessel the other. In the absence of sufficient moisture in the air, the charge is liable to build up on the containers so that a grounded object such as an operator approaching them will induce a spark with the usual results. The answer is, of course, sufficiently high humidity to provide leakage past, or direct grounding, or both. It might be well for the safety engineer to take notice in the plant of another condition which caused us some trouble before the answer was found.

It is, of course, a rule that paddles, scrapers, etc., used in handling rubber cement, or similar materials shall either be non-metallic, or some non-ferrous metal such as brass, copper or aluminum. One of our operators made a very beautiful paddle consisting of an aluminum head and blade, but he made a mistake by mounting this on a wooden pole, the net result being that the head would accumulate a static charge such as a body in free space, and brought near a grounded object such as the inside of the masticator, would give off a spark in

absolutely the worst possible place. At least two fires occurred in this manner and a metal handle stopped the difficulty.

As to the use of humidity in preventing fires from this cause, I might say that so far as I am aware we have never had a fire which might be attributed to static where the humidity in that particular part of the room where the fire occurred was above 50 per cent. In our control work, we require an average humidity of 40 per cent and require the supervision to obtain these readings, using a Sling Psychrometer, and working out the results with a Parks-Cramer Humidity Slide Rule. This method of obtaining humidity is admittedly the more accurate and with the above equipment, a slight amount of discussion which we have had, there is no difficulty in securing accurate and consistent results.

As to the method of obtaining the increase of humidity, the escape of steam is usually as simple as anything and since the winter time is when the most correction is needed, the heat liberated in the room will not be detrimental. Where air washers are used in connection with ventilating systems they can obviously be used for humidity control.

It is the custom in some plants to use a moisture of carbon tetrachloride with various inflammable solvents to reduce the danger flash. It can easily be shown that such moisture, even containing as low as 20 per cent of carbon tetrachloride, are not as hazardous as poor solvent. They are not, by any means, safe under all conditions until the amount of carbon tetrachloride is sufficiently high that its toxic effects begins to be apparent. These mixtures again are often made by men who do not realize the difference in the specific gravity of the ingredients. If the mixture is not thoroughly stirred, there will be surely some surprise parties and taken altogether the little moisture in the air is less expensive, less toxic and quite often safer than the usual mixture of this kind.

Safety and fire protection engineers should also be on the look-out to separate fire causes reported to be due to static from those which undoubtedly occur from this cause. If an operator spills solvent in an electric switch or breaks an electric lamp, or an extension cord, or does a lot of other foolish things from which a sudden fire results, it is very liable to be charged up to static. By separating the causes, the Safety Engineer will prove whether or not his precautions against static are adequate and will find many cases where the matter is one for ordinary discipline and not a revision of his method of static control. The matter is a very interesting one and, at the same time, a vital one to the rubber industry. As a matter of fact, our work here was made necessary due to the fact that we are using in our gum dipping plant often as high as 15,000 gals. of benzol per 24 hours per day, in addition to the usual hazards of a rubber tire fabric.

MR. HUNGERFORD: Though it may be that that exists now, I may be responsible for that, but he is not familiar with the exact situation, because I just happened to mention a case where we had an operator, a young man of about twenty-one, and every time he reached for his shears he shot a beautiful spark until he almost became a nervous wreck. We didn't know what to do about it. Suddenly I noticed he had on some beautiful crepe soled shoes.

Another time I was standing and watching another operator of a horizontal spreading machine. He was spreading a frame flap which had a fleecy line and this was the first shift operator running the machine. The second shift operator had gone to his locker room, and returned. It was raining outside terribly, and there had been some water coming through the window on the floor. I imagine the humidity was around 80 degrees anyway. And all at once, a light flew out and shot along the length of the room! Of course, we all left immediately, but right behind me came the operator of the third shift wearing his rubbers. He had gone down and put on his rubbers, generating a beautiful charge and letting it on to the spreaders.

The electroscope is a very handy instrument. It is amusing to take around and get up near some person and watch it act. Some people it will not affect and others it will straighten out. And it is certainly peculiar to watch the people with empty looks on their faces when you carry it around, especially from October to May. Some of them can't understand what it is all about, though we try to educate them along that line.

I will have to admit, Mr. Hoxie, that we have been very unsuccessful in using the hygrometer due to the fact that the wick must be exposed to the atmosphere and in the dusty conditions which the rubber industry is not entirely free from, the wick becomes soiled and we have proven that by taking a new wick and placing your hands around it, the moisture of your hands will affect your hygrometer reading, so we bought several automatic recording devices and we have bought also the simple wet and dry bulb and tried them out and have discarded them, due to the fact that we have found them unreliable.

MR. HOXIE: Have you used the Cramer Hygrometer that depends upon the stretch of a hair?

MR. HUNGERFORD: No, I haven't.

MR. HOXIE: I use them very generally in my work in cotton mills. You see, a cotton card-room is about as dusty as any place you can get. The advantage these have is that they have a direct reading. You don't require any wick. You can read right off on percentage.

MR. HUNGERFORD: Is that a recent development?

MR. HOXIE: No, they have been used a long while and are common in cotton mills, where they want a direct reading apparatus.

MR. HUNGERFORD: We find that the sliding rule makes it simple to do that. Another thing that comes under the head of static, which I mentioned at the end of my paper, is the use of your powdered coal systems. Not only is that particularly hazardous in itself, but there has been some bad explosions due to the use of powdered coal. We have had several fires. One was very serious. However, we find that good housekeeping is the real preventative there. We have installed a very complete vacuum system and under no condition would we permit the cumulation of dust throughout the building. The final analysis in one fire was the static that was caused by the powdered coal dust and we have since been very strict about housekeeping in the coal dust plant. I am very sorry that neither Mr. Jones nor Mr. Runals was here because they have done a lot of work on the subject, and have worked very closely with Mr. Hoxie.

E. W. BECK (U. S. Rubber Company): I would like to ask Mr. Hoxie if he knows of a very simple device for testing grounds.

MR. HOXIE: Do you make your own electricity?

MR. BECK: Yes.

MR. HOXIE: You can ground in sight of your circuit and pass it on the other side but there is a little danger attached to that. A magneto is very effective indeed. That has always been used in electrical work.

MR. BECK: Do you recommend a magneto—a megometer?

MR. HOXIE: That has always been used in electrical work. Why, yes, you have the same thing there only you have gone further testing them. You have measured them. You know that you may have ground of a very high resistance, then if you get equally high voltage it will go through. I did quite a lot of work one time in measuring grounds in reference to some study I was making of electricity, and I buried around my house plates of lead a foot square and then connected the transformer with currents of various voltages and put on a millimeter and determined how much current I would get through.

You will find very frequently the grounding of transformers is a means of safety, for the reason that you can drive a pin in the ground where the soil is sandy, and it will conduct some electricity, but not very much, and the conduc-

tivity comes from the little bit of water carried on the outside of the grains of sand. You let a ground current pass through there; the heat of the current itself will advance in a little while. We, in the insurance rules, now say a good way of getting ground for a ground detector on a switch-board is to drive a pin in the ground. Well, you know that different soils conduct electricity very differently. I put in some discussion one time in a paper that was read before the Society of American Electrical Engineers, in which the author had said that you could get a very good ground by driving a pin five or six feet into the ground. I think that was around Chicago, but you know that the ground water through the middle West is charged with lime and conducts quite differently than along the Atlantic Seaboard, so you can't gamble on that at all.

One time, in Rhode Island, lightning struck a power line on the Blackstone River, and it ran for several miles and burned all kinds of farms and did lots of damage. Yet, take this very case—that circuit was grounded at every pole through a piece of post three-quarters of an inch of pipe driven right along the edge of the river. But you know that was because water that is comparatively pure is a poor conductor, whereas water containing a small amount of salt, lime, or anything else like salt will conduct very well. But, as far as static is concerned, most any kind of water will carry that. And the chief thing in the static in rubber works is that moisture on the surface of your body counts for a lot. You know that if, as some people do, you get up in the morning and don't air your beds out, when you go to sleep that night, you find the bed is very cold. That is due to the fact that those bed clothes were moist from the moisture which had come from your body and you can't sleep warm if you don't dry that moisture out of them and your clothing. Your underclothing, and other clothing also contains moisture, and that all contains salt which conducts electricity very greatly. It is very effective indeed. But there are some people that don't have it and those people are dangerous to have around any volatile solvent.

To get back to that human spark-plug that the Endicott-Johnson people wrote about, I will cite you another instance. In a factory where I was employed, they carried this test on in a room with a number of steam taps. They leaked a little. They were going to move it to another building where there was no leaking steam. I told them to go slow. My guess was that those eighteen steam taps were doing a lot of good there and if they put that into a normal building where there was no leaking steam they would get into trouble; so they put in methods of blowing steam into it and they have had no trouble as yet. The only test I have found necessary is simply to shake hands with the people, but I have found no doubt that a more exact test could be used by putting them in a small room with a recording hygrometer. You will find that people who are apparently quite normal will surprise you by their registration.

ADJOURNMENT

October 3, 1928

R. C. SALISBURY, Chairman

**Manager, Health and Safety, The Fisk Rubber Company, Federal Division
Cudahy, Wis.**

The third session was called to order at ten o'clock by the chairman, R. C. Salisbury.

CHAIRMAN SALISBURY: We are nearing the end of the Rubber Section meetings this year and we have a very splendid program arranged for this morning. You will notice that we are to hear reports of the various committees, but I believe it would be better to call upon our speaker, Mr. L. J. D. Healy, of the Fisk Rubber Company, who is going to give us his continued talk on "Health Hazards in the Rubber Industry—Organic Accelerators and Anti-Oxidants." It is not necessary to introduce him, but rather to present him.

Health Hazards in the Rubber Industry—Organic Accelerators and Anti-Oxidants

By L. J. D. HEALY

**Technical Superintendent, Federal Division, The Fisk Rubber Company
Cudahy, Wis.**

This paper is a continuation of a similar paper on the health hazards of compounding materials used in the rubber industry and presented by the writer before the Rubber Section at the last annual safety conference.

In the latter paper the various compounding materials used in the rubber industry were classified into four groups:

- 1—Accelerators and dry organic compounds.
- 2—Dry inorganic compounds.
- 3—Gums, resinous materials and waxes.
- 4—Liquids and gases.

The method of classification and description of these compounds was taken up in detail and complete description of a considerable number of the organic compounds listed under Group No. 1 was completed. The data presented at that time has since been used as a basis for compiling a Safe Practices Pamphlet, the work having been continued by the Health Hazards Committee upon recommendation of the Rubber Section, and the pamphlet issued by the National Safety Council.

This classification may not be the best possible one, although with many years of experience with them it seemed like a logical classification. Yesterday I played hookey from this section and attended the Chemical Section where they were having a discussion on "Health Hazards in the Chemical Industry." The rubber industry is essentially a chemical industry and I thought possibly I could pick up something of interest in that section. In a discussion of manufacturing, I was very much interested to hear Dr. Gehrmann of the DuPont Company, Wilmington, say that our knowledge of most of these organic compounds, especially the newer ones, is really deplorable. I think that Dr. Shirley here will agree with that statement, as he and I have both worked on this problem during the past year, and it is a fact that there is practically no reference in either American or European literature to the greater majority of these compounds. There are only a few of them, such as aniline oil, benzol and a few of those which have caused serious disturbance in the rubber industry that have been covered. This is only a small minority. It is a big problem to classify these substances in an intelligent manner and know just what to expect from their toxic and irritant properties. This

tivity comes from the little bit of water carried on the outside of the grains of sand. You let a ground current pass through there; the heat of the current itself will advance in a little while. We, in the insurance rules, now say a good way of getting ground for a ground detector on a switch-board is to drive a pin in the ground. Well, you know that different soils conduct electricity very differently. I put in some discussion one time in a paper that was read before the Society of American Electrical Engineers, in which the author had said that you could get a very good ground by driving a pin five or six feet into the ground. I think that was around Chicago, but you know that the ground water through the middle West is charged with lime and conducts quite differently than along the Atlantic Seaboard, so you can't gamble on that at all.

One time, in Rhode Island, lightning struck a power line on the Blackstone River, and it ran for several miles and burned all kinds of farms and did lots of damage. Yet, take this very case—that circuit was grounded at every pole through a piece of post three-quarters of an inch of pipe driven right along the edge of the river. But you know that was because water that is comparatively pure is a poor conductor, whereas water containing a small amount of salt, lime, or anything else like salt will conduct very well. But, as far as static is concerned, most any kind of water will carry that. And the chief thing in the static in rubber works is that moisture on the surface of your body counts for a lot. You know that if, as some people do, you get up in the morning and don't air your beds out, when you go to sleep that night, you find the bed is very cold. That is due to the fact that those bed clothes were moist from the moisture which had come from your body and you can't sleep warm if you don't dry that moisture out of them and your clothing. Your underclothing, and other clothing also contains moisture, and that all contains salt which conducts electricity very greatly. It is very effective indeed. But there are some people that don't have it and those people are dangerous to have around any volatile solvent.

ADJOURNMENT

October 3, 1928

R. C. SALISBURY, Chairman

Manager, Health and Safety, The Fisk Rubber Company, Federal Division
Cudahy, Wis.

The third session was called to order at ten o'clock by the chairman, R. C. Salisbury.

CHAIRMAN SALISBURY: We are nearing the end of the Rubber Section meetings this year and we have a very splendid program arranged for this morning. You will notice that we are to hear reports of the various committees, but I believe it would be better to call upon our speaker, Mr. L. J. D. Healy, of the Fisk Rubber Company, who is going to give us his continued talk on "Health Hazards in the Rubber Industry—Organic Accelerators and Anti-Oxidants." It is not necessary to introduce him, but rather to present him.

Health Hazards in the Rubber Industry—Organic Accelerators and Anti-Oxidants

By L. J. D. HEALY

Technical Superintendent, Federal Division, The Fisk Rubber Company
Cudahy, Wis.

This paper is a continuation of a similar paper on the health hazards of compounding materials used in the rubber industry and presented by the writer before the Rubber Section at the last annual safety conference.

In the latter paper the various compounding materials used in the rubber industry were classified into four groups:

- 1—Accelerators and dry organic compounds.
- 2—Dry inorganic compounds.
- 3—Gums, resinous materials and waxes.
- 4—Liquids and greases.

The method of classification and description of these compounds was taken up in detail and complete description of a considerable number of the organic compounds listed under Group No. 1 was completed. The data presented at that time has since been used as a basis for compiling a Safe Practices Pamphlet, the work having been continued by the Health Hazard Committee upon recommendation of the Rubber Section, and the pamphlet issued by the National Safety Council.

This classification may not be the best possible one, although with many years of experience with them it seemed like a logical classification. Yesterday I played hookey from this section and attended the Chemical Section where they were having a discussion on "Health Hazards in the Chemical Industry." The rubber industry is essentially a chemical industry and I thought possibly I could pick up something of interest in that section. In a discussion of manufacturing, I was very much interested to hear Dr. Gehrmann of the DuPont Company, Wilmington, say that our knowledge of most of these organic compounds, especially the newer ones, is really deplorable. I think that Dr. Shirley here will agree with that statement, as he and I have both worked on this problem during the past year, and it is a fact that there is practically no reference in either American or European literature to the greater majority of these compounds. There are only a few of them, such as aniline oil, benzol and a few of those which have caused serious disturbance in the rubber industry that have been covered. This is only a small minority. It is a big problem to classify these substances in an intelligent manner and know just what to expect from their toxic and irritant properties. This

idea is not original with myself, but the credit for the suggestion of compiling this information belongs to our Chairman, Mr. Burt Salisbury.

Mr. Salisbury realized the need of more definite information in regard to these compounds and unfortunately for myself, he dragged me into this. I found it was a pretty deep subject and I just had to keep on swimming and haven't seen land yet. By the time I get one list complete and written up, along will come two or three more new organic substances on the market and these have to be studied. To keep this work up to date means that the Health Hazard Committee of the Rubber Section will have to continue working on it from year to year.

The work thus far has dealt only with the organic accelerator group. Of the four groups or types of compounds, the organic accelerator group consists of a comparatively new series of substances used for rubber manufacture. As a group, they are the least understood and most dangerous to handle from the health hazard standpoint.

With the presentation of this paper, the writer completes the classification and description of the accelerator group. Several new accelerators have been developed during the past year and put into commercial production, and these have been added to the list as prepared in the previous paper.

New chemicals for use in rubber manufacture are being continually developed with the result that an increasing number and variety of organic substances are being offered on the market, often to the confusion of the rubber manufacturer and due to conflicting claims of the distributors. In this present age of competition, the accelerator manufacturer is only too anxious to get a promising accelerator on the market, often before adequate data has been obtained either as to its value for rubber work or as to the health hazards involved in the handling of the material. On the other hand, the rubber manufacturer, being only too anxious to improve his product, is often tempted to accept the exaggerated statements of accelerator salesmen, and jumps into production with an unknown and untried substance resulting in untold factory trouble, as well as possible injury to the health or comfort of the employees using these materials. Numerous cases of the latter have occurred during the past few years with the advent of organic accelerators and softeners.

A recent issue of an *English Rubber Journal* contains a report of the chief inspector of factories and workshops of Great Britain for the year 1927, which shows an increase of dermatitis amongst rubber workers of 96 per cent in 1927 as over the year 1926. Nineteen of these were caused by the use of accelerators, whereas these agents were held responsible in only seven cases in 1926.

While the writer has no definite record of this kind for American factories, he believes that dermatitis and illness caused by accelerators is decreasing in the United States rather than increasing due to the more intelligent use of accelerators.

Referring back to the meeting which I attended yesterday, Dr. Gehrmann also brought out the fact that very often trouble arises from the use of these compounds, of which very little knowledge is obtainable. It is very difficult to get at the bottom of some of these troubles at all. For instance, he cited one case where a department superintendent was requested to report as to whether or not a certain organic compound was causing any trouble and he reported no, none whatever. He then asked him what percentage turnover he had, and the superintendent replied, that he had a very large turnover there; he had 40 per cent turnover. That looked rather peculiar, so some of the men who had been in that department the longest were examined and it was found that a great majority of them were suffering from certain disorders due to the use of this material. This shows that the men who quit, had more sense than the employer in that they realized their health wasn't good on that job and they quit and went to some other work. I think you will find the same thing true where many of these compounds are used. The

manufacturer takes very little interest in how toxic some of these compounds are and the men just leave and go somewhere else.

When we say some of these compounds are safe to handle and that there is practically no health hazard involved, it must not be understood that they are entirely non-toxic because some of them are relatively toxic in one sense of the word; that is, it is a degree of relativity. Experiments have shown that most of these compounds are toxic to an extent when taken internally through the digestive tract. While many of these are toxic in large quantities taken internally, it must be remembered that so also are many of the products which we consider entirely innocuous, and if taken in large doses, would be toxic.

In setting a safety factor, we must take into consideration the time and the manner of injection. This is a question of continuous or discontinuous exposure to such compounds. The time and amount are really the important factors. Thus it can be readily seen that the method of handling in many of these cases is a deciding factor as to whether or not the material is or is not a health hazard. I think most of the medical men here present will agree that many of our every day substances and drugs would be likewise classed, if taken in large overdoses, as toxic, but in the ordinary handling of the same could not be classed as such.

Other factors to be considered in the handling of such substances are, first: Is the substance a liquid or a powder? If it is a liquid, is it volatile; and if a powder, does it fly or create a dust? Second, whether liquid or a powder, does it decompose into toxic gases during process?

For illustration, aniline, a liquid, is exceedingly toxic in small amounts; it is a volatile liquid which makes it doubly harmful. As it goes into the different compounds in the factory it becomes subject to heat, and the volatility is greatly increased. It does not decompose, but the volatility is such at the calenders that it comes off in considerable volume and becomes a very dangerous material to use. So you can readily see that the method of handling these compounds is exceedingly important. In handling anything such as aniline, it goes without saying that it likewise must not come in contact with the flesh during handling. Some means of handling must be worked out which will prevent contact and in subsequent operations wherever volatility occurs, there must be strong suction hoods to remove these vapors and prevent the men from inhaling them. It happens to be a compound which is not only absorbed through the skin, but can be taken internally through the respiratory organs, as well.

As against the strictly toxic compounds which are toxic upon being taken internally and which can get into the system in the form of dust and so on, or through carelessness in handling by men getting material on their hands and later without washing partake of food, we have another class of compounds which are very prone to cause dermatitis. Some of them are powders. In handling the latter, each manufacturer seems to have a problem of his own. One of these compounds handled in one plant will cause no trouble whatever, whereas used in another plant, will give all kinds of trouble. I think I can mention one which you will all recognize, Hexa methylene tetramine, or "Hexa." I have seen this material used by the ton in one climate and amongst certain groups of workmen, causing absolutely no trouble. I have also seen it used where it has given no end of trouble. There are several reasons for these peculiar conditions. First, we have susceptibility of the individual, some persons being much more susceptible than others. As with poison-ivy, some people can pull it up by the roots and are immune, and others cannot come near it without being poisoned. Personally, I can handle Hexa without a sign of a rash, while I have seen other people who will develop a rash through just handling stock in which there was about three-fourths of one per cent present.

Then, too, we have climatic conditions, which contribute to these troubles. Climates which are very humid and warm, probably give us more trouble in han-

dling these accelerators than those which are cool and dry. Again we have conditions under which the laborers are working when handling these materials. So you can readily see that unless some of these compounds are better understood, there is danger of the rubber industry running into quite an epidemic of occupational diseases.

Most of these dermatitis cases are not serious and usually respond quite readily to treatment, provided the employee is taken away from that particular department and placed in another department. However, we must not lose sight of the fact that some of these skin eruptions are liable to other secondary infections. Blood poisoning might develop and we would have a very serious case on our hands, and while not necessarily due to the dermatitis, the initial cause was the dermatitis. Some of these eruptions are very itchy and a man, if not careful, is going to scratch himself and infection is very likely to follow. So it goes without saying that we should make every effort possible to reduce the hazard of using these materials, not only for the health of the working man, but also for his comfort.

This classification will practically complete the organic group. I will not attempt to read a description of these substances, but I will just go over the lineup as to their relative toxicity.

With reference to the paper presented by the writer at the National Conference in 1927, it has been suggested that the rubber compounds be arranged according to their degree of toxicity rather than alphabetically. The writer still believes that for reference work it is desirable to group all compounds alphabetically, but in order that the more toxic compounds can be readily recognized, he suggests that an indexed grouping arranged according to the degree of toxicity, preface the description of the compounds.

The writer further suggests that the index be arranged in four groups:

Group A will contain all the highly toxic compounds.

Group B those involving only slight hazards.

Group C those compounds involving no hazards provided they are handled according to recommended procedure.

Group D those which involve no hazard and which can be handled more or less promiscuously.

According to this grouping the organic compounds would be indexed as follows:

Group A—Highly Toxic or Irritant

Aniline Oil
Hexamethylene-tetramine
Ortho-toluidine
Para nitroso-di-methylaniline
Para phenylene-di-amine
Para toluidine

Group B—Slightly Toxic or Irritant

Alpha naphthylamine
Beta naphthylamine
Formaniline
Lead oxidation products of di-methyl-di-thio-carbonic acid
Methylene aniline
Methylene di-tolyl diamine
Methylene para toliudine
Tri methyl trimethylene-triamine.

*Group C—No Hazards With Proper Handling
Somewhat hazardous with promiscuous handling.*

Aldehyde ammonia
Di ortho tolyl thiourea
Di-phenyl thiourea
Heptaldehyde aniline
Methylene dianilide
Methylene diphenyl diamine
Quinodine
Thiocarbonilide

Group D—No Hazards

Dimethyl ammonium dimethyl-di-thio carbamate
Di-ortho-tolylguanidine
Diphenylguanidine
Ethylidene aniline
Mercapto benzo thiazole
Phenyl-tolylguanidine
Piperidonium pentamethylene-dithiocarbamate
Tetra methyl thiuram disulphide
Tetra methyl thiuram monosulphide
Triphenyl guanidine
Xanthates
Zinc oxidized salt of dimethyl-di-thio-carbamic acid

In these Safe Practices Pamphlets prepared by the Health Hazards Committee of the Rubber Section, and issued by the National Safety Council, we have endeavored to show the composition of these accelerators, their probable toxicity or irritant effect, and wherever possible suggestions of handling which will remove all hazards. We believe that if these suggestions are followed, but little, if any, hazard will be experienced in handling these compounds. In a few instances, the use of very toxic accelerators has been discouraged since with the large variety we have to choose from at the present time there can usually be found a suitable substitute.

It has been very gratifying to note that a number of the large reputable chemical companies are now making a study of the toxicity of their accelerators and organic compounds before offering them to the trade, and in many cases guarantying them to be non-poisonous and non-irritant. This practice is to be commended. The more knowledge we have concerning the materials we are using, the more intelligently can we handle the same.

The classification and description of accelerators appended hereto will therefore complete the list of most of the organic accelerators in common use today. As new accelerators come into general use, the Health Hazards Committee can add these to the list from time to time and thus keep the latter up to date. The committee will be glad to receive any information concerning unusual conditions or symptoms of trouble arising through the use of accelerators. It is hoped that the various manufacturers will send in to the committee any information which they think will be of interest to others in avoiding troubles. We are especially interested to learn of any trouble developing from the use of rubber compounding ingredients.

I will now take up a new group of organic compounds, which has invaded the rubber manufacturing field since the writer's first paper was prepared. This group of compounds consists of the so-called anti-oxidants for preserving the life of rubber.

Since the discovery of vulcanization by Goodyear in 1839, practically no advance had been made in the vulcanization of rubber until the discovery of organic accelerators about a decade and a half ago. Previous to the use of accelerators,

the normal life of most vulcanized rubber goods was comparatively short. With the extended use of accelerators during the past ten years, it has been noted that certain of these accelerators not only greatly cut down the time of vulcanization but they also greatly improved the physical properties of the rubber goods and in addition made them more resistant to deterioration.

The principal factors contributing toward the deterioration of vulcanized rubber are: light, heat and oxygen. Rubber may be protected against the action of light by storage in darkness or by compounding in such a way as to prevent excessive absorption of the actinic light rays. Resistance to heat may also be obtained to a considerable extent by proper compounding. Atmospheric oxygen still remains to be the most destructive factor.

Certain types of accelerators have appeared to offset this oxidation to a considerable extent and has led to an intensive study of those particular organic groups which best resist oxidation. The search has resulted in this new body of organic compounds which have been named "anti-oxidants," and which promise to offer the next great advance in the vulcanization of rubber goods. They have been given considerable publicity and have come into quite general use during the past year. A canvass of the various rubber companies indicates that most of the latter are using or at least experimenting with one or more of these compounds.

These anti-oxidants are organic compounds similar in many respects to the organic accelerator group. There are approximately about a half dozen of these compounds in quite general use. They are sold mostly under various trade names. Some of these compounds are derived from toxic bases and others are of such composition that those using them should be on the lookout for dermatitis. In general they are substances which can be safely handled with reasonable precautions. A study is being made of their toxic and irritant properties and as soon as this is completed, these substances will be classed as a sub-group under the accelerators and dry inorganic compounds. Sufficient data has not yet been accumulated in order to complete the anti-oxidant group in time for this meeting. However, for the benefit of those using these substances, the following list comprises those in most general use, together with their basic composition and probable toxic or irritant properties:

Age-rite powder

A gray powder melting at approximately 100° C. and consisting of phenyl-beta-naphthylamine. Probably slightly toxic and should be handled according to instructions noted under the naphthylamine group of accelerators. No hazard with proper handling.

Age-rite resin

A red resinous substance, brittle when cold and liquid at milling temperatures. Contains adol-alpha naphthylamine. General precautions as noted for the age-rite powder should apply.

Antox

A tan colored powder containing para-amino phenol. A combined accelerator and anti-oxidant. Used only to a limited extent. No trouble reported from its use. Possibility of slight dermatitis.

Neozone

A purplish gray waxy compound containing phenyl-alpha naphthylamine with meta toluine diamine and some acid wax. Quite safe to use with ordinary precautions. Probably slightly toxic. No danger of dust.

Oxynone

A light brown powder, oxidizing in moist air. It is an amine derivative, which should be handled with some care to prevent staining of the flesh or possible dermatitis. Should not be inhaled.

Resistor

An aldehyde condensation product in the form of a pinkish buff powder. No data as to toxicity but its general composition would indicate no hazard involved in its use.

Stabilite

A yellowish compound readily turning purple upon exposure. Consists of di phenyl ethylene diamine. Probably somewhat toxic but involving no hazard with careful use.

V. G. B.

A brown resinous powder consisting of acetaldehyde alpha naphthylamine. Only slightly toxic. Has been used in large quantities. No trouble other than slight dermatitis reported. Should not be inhaled.

A description of these compounds will later be issued to be appended to the accelerator and organic group.

The Health Hazards Committee gladly welcomes any criticisms or suggestions concerning this work.

✓ **Lead Oxidation Product of Dimethyl-dithio-carbamic-acid**

Origin and Constitution:

The lead oxidation product of dimethyl-dithio-carbamic acid is prepared by oxidizing the lead salt of dimethyl-dithio-carbamic acid, $[(CH_3)_2N-CS-S]_2Pb$. It is one of the very powerful ultra accelerators and for this reason is seldom put on the market in the pure state, but usually in a diluted form on a clay base. In the latter form it consists of a very fine gray to yellowish-white powder and with only a slight odor. It has a specific gravity of 2.50.

Uses:

This material is used commercially as a rubber accelerator. It is used principally in dark-colored goods in conjunction with litharge, finding a quite extensive use in mechanicals, footwear and dry heat stocks. It reacts at low vulcanizing temperatures the range being from 250° F. to 280° F.

Litharge is required to activate the accelerator. It has a tendency to scorch on the mill, and temperatures must be carefully controlled.

Health Hazards:

Being a dry powder, this accelerator is usually weighed out in the compound room in the usual manner and added directly to the rubber on the mixing mills. It is a lead salt but is relatively insoluble and comparatively little danger is involved in its use. However, it is invariably used in conjunction with litharge and the same precautions should be observed when handling this accelerator as noted under the use of lead compounds.

The compound weighers and mill operatives should avoid handling with bare hands and be careful not to inhale the dust. Such small amounts of the active ingredient are used that the danger from poisoning is slight. The real danger is from the litharge, which is invariably used in conjunction with this accelerator. No cases of dermatitis have been reported.

Methylene-ditolyl-diamine*Origin and Constitution:*

Methylene-ditolyl-diamine is the reaction product of formaldehyde and two molecular portions of para toluidine. It has the formula $(CH_2.C_6H_4.NH)_2CH_2$ and is similar in properties to methylene para toluidine, the latter being formed when formaldehyde reacts with one molecular portion of para toluidine.

Uses:

Methylene-ditolyl-diamine is a mild accelerator for vulcanizing rubber. Due to its low accelerating power it is now practically obsolete as an accelerator.

Health Hazards:

The health hazards of this material are about the same as for methylene para toluidine. It is non-poisonous except as traces of formaldehyde or para toluidine are present as impurities. No ill results of its use have been reported.

Methylene-para-toluidine*Origin and Constitution:*

Methylene-para-toluidine, also known as anhydro formaldehyde para toluidine, is a grayish or yellowish white powder with faint aromatic odor. It has no definite melting point but softens between 80° and 100° C. It is not a definite chemical compound but a mixture of two isomers having the formula CH_2 . C_6H_4 . $\text{N}=\text{CH}_2$. It is prepared by the action of formaldehyde upon para toluidine in equi-molecular proportions.

Uses:

This material is used quite extensively in many lines of rubber manufacturing including mechanical rubber goods, tires and tubes. It is used both as an accelerator and a rubber softener. It is also an excellent plastisizer and anti-scorching material and for this reason is often used in conjunction with more powerful accelerators to counteract the scorching tendency of the latter. It is used up to 2 per cent on the weight of the rubber present. Zinc oxide is usually used with it as an activator.

Health Hazards:

Methylene-para-toluidine is handled in much the same way as other dry powders, being weighed out in the compound room and the powder either added directly to the rubber or mixed with the other powders. The powder does not fly excessively and no special precautions need be taken in weighing out. It is non-poisonous if pure and causes no skin rash. However, the commercial product may contain traces of aldehyde or toluidines and for this reason it is advisable for the weighers to refrain from handling the material with the bare hands.

During the mixing and calendering operations some volatilization takes place and pungent aldehyde fumes cause irritation to eyes and respiratory organs. Mills and calenders should accordingly be hooded, with suction to remove these vapors.

This material has had an extensive use in the rubber industry and when above precautions have been observed, no ill effects have been reported.

Para-nitroso-dimethyl-aniline*Origin and Constitution:*

Para nitroso dimethyl aniline is a green crystalline substance with a melting point of 88° C. and having the formula $(\text{CH}_3)_2$. N. C_6H_4 . NO. The commercial dried product contains about 2 per cent moisture and 95 per cent para nitroso dimethyl aniline on the dry basis. The latter is soluble in both rubber and water and melts at about 80° to 85° C. The dried product absorbs moisture very rapidly from the air and undergoes decomposition when exposed to air. For this reason the material is also marketed as a paste containing a definite amount of water, usually 40 per cent.

Uses:

Para nitroso dimethyl aniline is used as an intermediate product in organic synthesis and as a rubber accelerator. It is a fairly powerful accelerator and has been used quite extensively in the hard rubber and pneumatic tire industries.

It readily disperses in rubber exercising a pronounced softening action with little

danger of scorching. It may be used in the proportion of from $\frac{1}{2}$ to 1 per cent of the rubber. It may also be added to the rubber by soaking the latter in a water solution, previously to adding the compounds. It cannot be used for white or light colored goods since it has a discoloring action.

Health Hazards:

This material may be weighed out as a powder or paste, or dissolved in water. There is a certain amount of danger from handling this material by any of these methods. The material is poisonous and has a decided tendency to cause disagreeable skin eruptions. Care should be exercised in handling, and the material should not come in contact with the skin.

During mixing and calendering it gives off a disagreeable odor but does not fume seriously. The mill and calender operatives should avoid handling the hot stock with the bare hands as far as possible since it is conducive to dermatitis. Since it is almost impossible to handle stock of this nature through the plant without danger, its use has been discontinued by some manufacturers. It is advisable to use less poisonous accelerators wherever it is possible to do so.

Phenyl-tolyl-guanidine

Origin and Constitution:

Phenyl-tolyl-guanidine is a white crystalline powder having the formula $C_6H_5.NH.CH_2C_6H_4.NH.C:NH$. It is slightly soluble in rubber.

Uses:

Phenyl-tolyl-guanidine is used commercially as a rubber accelerator, but to a lesser extent than many of the other accelerators. It is a relatively active accelerator, comparable in most respects to diphenyl guanidine.

Health Hazards:

Being a dry powder this material can be handled conveniently in the compound and mill rooms. It can be weighed out in the usual manner and added directly on the mills. It does not fly excessively nor does it fume during mixing. It is a safe accelerator to use. No cases of poisoning or of dermatitis from its use have been reported.

Quinoidine

Origin and Constitution:

Quinoidine is a dark brown resinous substance having no definite melting point. It softens between 80° and 100° C. It consists of the uncrystallizable portion of the extract of cinchona bark. It is obtained from the latter solution after all the crystallizable alkaloids have been removed. The commercial material is put on the market in a very impure form, often being contaminated with appreciable quantities of foreign matter.

Uses:

Quinoidine is used in medicinal preparations and as an accelerator for rubber. It is no longer popular as a rubber accelerator since it has the disadvantages of imparting a disagreeable odor to the rubber and has a tendency to scorch during milling. It is only a mild accelerator requiring from 1 to 2 per cent upon the weight of the rubber. Zinc oxide is necessary to activate the accelerator.

Health Hazards:

It is a comparatively safe accelerator to use. It does, however, give off a strong penetrating and disagreeable odor during the milling and calendering operations. Its use in the rubber industry is now almost obsolete.

Tetramethyl-thiuram-disulphide*Origin and Constitution:*

Tetramethyl-thiuram-disulphide is a grayish crystalline substance having a melting point of 150° C. and a specific gravity of 1.29. It belongs to a class of organic accelerators known as the thiuram disulphides. They are prepared by oxidizing the corresponding dithiocarbamates. The tetra methyl salt is the one best known in the rubber trade and is prepared by oxidizing the reaction product of dimethyl amine and carbon disulphide. The commercial product is prepared as a fine powder. It is insoluble in water but soluble in benzene or carbon disulphide.

Uses:

This material is used quite extensively as a rubber accelerator in all types of rubber goods. It is an extremely powerful accelerator and one of the best known low temperature ultra accelerators. It is used in proportion of from 1/8 to 1 per cent on the weight of the rubber. It is usually used in conjunction with zinc oxide as an activator.

Health Hazards:

This accelerator is a dry non-hygroscopic powder and non-poisonous. It can therefore be weighed out in the compound room safely and added directly to the rubber on a mill or put up in the form of a master batch. There is no fuming on mills or calenders. No ill results of its use have been reported.

Tetra-methyl-thiuram-monosulphide*Origin and Constitution:*

Tetra methyl thiuram monosulphide is a yellow crystalline powder having a melting point of 103° C. Its chemical constitution is represented by the formula $(CH_3)_4NCS.S.CS.N(CH_3)_2$. It is similar in many properties to the thiuram disulphide but does not react at as low temperatures as the latter. For this reason it can be handled to better advantage than the disulphide for many types of rubber compounds.

Uses:

Its principal use is an accelerator for the vulcanization of rubber. It is an extremely powerful accelerator and is used quite extensively for many classes of rubber goods. It is usually used in comparatively small quantities, of from 1/10 to 1/2 of 1 per cent on the weight of rubber.

Health Hazards:

Being a dry non-hygroscopic powder it is easily handled. It is non-poisonous, non-fuming and no hazard has been encountered in its use for rubber work.

Triethyl-trimethylene-triamine*Origin and Constitution:*

Triethyl-trimethylene-triamine (T.T.T.) is a brown viscous liquid having a boiling point of approximately 207° C. and a specific gravity of 0.89. It is quite soluble in rubber. It has the formula $[(C_2H_5.N:CH_2)_3]_x$.

Uses:

T.T.T is prepared for use as an accelerator in the vulcanization of rubber. It is a very active accelerator, especially in the presence of zinc oxide. While not used to as great an extent as many other accelerators, it does find considerable application in certain lines of dry heat vulcanization and is adaptable for sheet goods and for boot and shoe work.

Health Hazards:

T.T.T is classed as a safe material for accelerator purposes. It should be carefully handled however. A number of cases of dermatitis caused by its use have

been reported. Certain persons appear more susceptible than others. Persons who have previously suffered from "Hexa Rash" will often develop dermatitis from handling T.T.T stocks. If reasonable precautions are observed to prevent direct contact with the hands and clothing, no serious difficulty should be experienced in its use.

Triphenylguanidine

Origin and Constitution:

Triphenylguanidine is a white crystalline substance having a melting point of 145° C. and specific gravity of 1.10. It is prepared by the action of aniline on thiocarbanilide and has the formula $(C_6H_5NH)_2C:NC_6H_5$. It is insoluble in water but slightly soluble in rubber. It is a very stable material being unaffected by exposure to light or air.

Uses:

Triphenylguanidine is used quite extensively as a rubber accelerator. It is a mild accelerator, but is adaptable for white and light colored goods and in compounds requiring a long range of cure. It can be used for nearly all classes of rubber goods and due to the fact that it has no tendency to cause scorching it has been very popular with the rubber trade. Its use as an accelerator is falling off in favor of newer and more powerful accelerators.

Health Hazards:

Triphenylguanidine, if pure, is non-poisonous and odorless. It does not fly badly and can be handled easily in both compound room and mill room without danger. The material is non-volatile and causes no danger from fuming at the calender.

Several impurities may be present in the commercial product, the most dangerous one being free aniline. A careful check should be made to detect any undue excess of aniline. It is a very safe accelerator and no health hazards are involved with ordinary care.

Xanthates

Origin and Constitution:

The Xanthates are extremely powerful accelerators being amongst the most powerful of the ultra accelerator type. There are several commercially available Xanthate accelerators, namely, zinc butyl xanthate, zinc ethyl xanthate and zinc isopropyl xanthate. They are white powders, finely ground and quite stable. They do not readily take on moisture from the air. The zinc salts are prepared by the reaction of zinc sulphate upon the corresponding sodium xanthate and their general

formula is $Zn(S:C \overset{S}{})_2$.
OR

Uses:

The zinc xanthates are used as rubber accelerators but their use is decidedly limited due to the fact that they react at very low temperatures and cause scorching, especially if used in conjunction with zinc oxide. They are used for the most part in quick curing cements and specialties which are cured either very rapidly or at low temperatures. A xanthate cement will cure in less than one minute. Wherever used special precautions are required to prevent premature setting up of the rubber stock.

Health Hazards:

The zinc xanthates are dry powders which can be easily handled in the weighing and milling departments. Comparatively little data has been accumulated relative to their toxic properties, but their chemical grouping would indicate that they are relatively harmless for rubber work, especially where used in such small quantities.

Zinc Oxidized Salt of Dimethyl-di-thio-carbamic-acid**Origin and Constitution:**

The oxidized zinc salt of dimethyl di-thio carbamic acid is one of the very powerful ultra accelerators used for low temperature vulcanization. It may be obtained either in the pure undiluted state or in a diluted form in which the oxidized zinc salt is mixed with an inert clay base. It is a fine gray to yellowish white powder having a slight not unpleasant organic odor. It has a specific gravity of approximately 2.00. It is decomposable upon heating.

Uses:

The material was developed for use as a rubber accelerator. It is very active at low vulcanizing temperature and is very difficult to handle on mixing mills without scorching of the rubber. Due to this difficulty it has not found extensive use in the rubber industry. Its use is confined largely to specialties and vulcanizing cements.

Health Hazards:

This accelerator is non-poisonous and causes no disagreeable or harmful fumes during mixing. No ill effects from its use have been reported.

CHAIRMAN SALISBURY: Perhaps there are some questions that occurred to us as Mr. Healy read the more simplified part of the paper that you would like to enlighten yourself upon. Anything in connection with the usual dermatitis or skin eruptions that comes to your mind, Mr. Healy and Dr. Shirley are here.

C. S. CHING, (U. S. Rubber Company): I would like to ask Mr. Healy, in the use of aniline, take this kind of a situation: If you had a plant that was throwing off aniline fumes into the air, I don't know in what way, or at what distance from that plant. Could you get any bad effects from it? Have you any idea?

MR. HEALY: The aniline fumes couldn't come off in any great volume. The amount of aniline used in the rubber industry, based on the percentage to rubber milled is very small, probably less than 4 per cent.

MR. CHING: I mean where they use aniline dye.

MR. HEALY: That is a case of concentration. If that was blown through a stack at a considerable height, it would be lost unless in tremendous volume.

MR. CHING: If you could get a discoloration in the course of an hour, if that sheet of paper would turn absolutely yellow, would that be dangerous?

MR. HEALY: That would be dangerous.

MR. McHUGH: We had a case of dermatitis. A man working in a compound room had it, what would you say to keeping him in the plant where he would be susceptible to it?

MR. HEALY: He could be placed in departments where he couldn't come in contact with those compounds. There are several departments where you wouldn't want to put him, where he was handling the raw stock, for instance. Even after the stock is calendered and goes either to the tub or tire room or mechanical department, there still might be danger with certain types of accelerators if he handled the raw stock. It is not alone in the mill or calender where you have the hot stock that they contract dermatitis. If they are susceptible they get it from the cold stock also.

MR. WILLIAMS (R. & H. Chemical Co.): I'd like to ask this meeting if they have ever formulated any test they would like to have the manufacturers make before offering to the public. As a manufacturer, we do a great deal to determine toxicity and its causes. We have spent a great deal of money and time on the Hexa rash. We have made blood tests and sweat tests on acidity. We have a man who has ground Hexa for ten years and has no more rash on him than anybody in this room. He is covered with dust from morning to night. But we want

suggestions as to how to get at this thing because we don't want to send out a material that is going to come back and give us a bad reputation. I believe if this committee could establish some kind of cooperation between users and manufacturers it would help a great deal. If our materials get out and there is a difficulty, why we want to know it immediately so that we can investigate it. We usually test a material a year before it is put out to the public. We have men assigned to it daily and if nothing turns up we naturally assume that it is comparatively safe, but in a rubber mill you have a combination of sulphur fumes coming off and that, with this material whatever it may be, may give dermatitis or some other ill effect that we don't know and I would like to see some cooperation established by which we could predetermine the ill effect which may be produced.

CHAIRMAN SALISBURY: I will be glad to refer that to the Health Hazards Committee, both your problem and the proposal that you make and possibly during this coming year they will get in communication with you.

MR. HEALY: I think that it is a fine attitude to take, to determine the toxicity of these compounds. I think, however, that will have to be handled through the research department of one of our universities, not only one, but probably several. Mr. Schneider, of the Goodrich Company, has had some very fine work done at the Western Reserve. So probably that will have to be handled through the research department of one of our universities.

MR. MEADE (U. S. Rubber Company, Providence, R. I.): I would like to ask a question regarding aniline fumes that are thrown off to the atmosphere, whether the weather has any effect upon the amount or weight, or what I could call concentration on objects that are exposed? I have known instances where, when the wind is blowing in the right direction and the weather might be called a misty rain, a newspaper hung out of a window became thoroughly saturated and every drop that fell on the newspaper, inside of half a minute turned perfectly yellow. Is there any way in which the amount thrown off can be gathered and located as to quantity?

MR. HEALY: Referring to the first part of that question as to weather conditions, that is another case of concentration of the aniline in the atmosphere. It goes without saying, of course, that the diffusion of the aniline in the air is much more rapid and is scattered more rapidly at certain times than others. Now, on damp days the atmosphere is heavy, there is very little wind stirring and the aniline does not diffuse or get away rapidly and being heavy and water soluble, probably disperses very close to where it is discharged into the air, and concentration can become very great. I believe your chemical laboratory can probably make that test for you to determine the concentration. It would mean absorption apparatus, especially rigged up, and you would have to absorb the aniline and then test for concentration per meter or cubic yard.

P. M. WOODEN (Mansfield Tire Company, Mansfield, Ohio): As a matter of information, I would like to ask the members present if they have had any experience with boils? I have had an epidemic of boils lately and they think it comes from the rubber stock. In the last three weeks we have had twenty-five or thirty men with boils, as many as twelve or fifteen boils.

DR. SHIRLEY (Hood Tire & Rubber Company): I think this time of the year they are likely to have boils, but from what you have said, I should think it was a contamination from one worker to another. I have seen that happen very often in my experience.

MR. WOODEN: But I have had it all over the plant.

DR. SHIRLEY: I often think we should blame the compounds but I can't link it up. I think you will find that with the change of season you will have them. In the spring and in the fall they are more prevalent.

MR. WOODEN: I don't have that always. It didn't happen last year, Doctor.

DR. SHIRLEY: Maybe one individual started it. I think you get them more in the spring than in the fall, but at the change of the season, as I say, you may get it. You will see that in your plant dispensary. It follows pretty true year after year, you get your two waves, the spring wave being heavier than the fall wave.

MR. DIETZ (Pennsylvania Rubber Company): Would you advise educating the worker in handling these ingredients as to the health hazards?

MR. HEALY: I believe that it is not altogether necessary to instruct the worker as to the nature of the compound he is working with, but you should give him the tools to work with. If there is danger in handling, you should see that he is given gloves and goggles and so forth for the proper handling of the materials. Likewise, if you have trouble in mixing, you should have your mills hooded. You must give him the tools to work with and provide the rooms with the necessary circulation of air to prevent excessive fumes or dust. A man doesn't care what he works with so long as he knows that no harm results from the use of that material.

CHAIRMAN SALISBURY: We have been unusually fortunate at this convention in having two particularly outstanding speakers, one the other day, Mr. Knutson of the Industrial Commission of Wisconsin, whom you will remember as big, and also the speaker of today, Mr. C. S. Ching, who is also big physically, and equally big mentally. Mr. Ching is permitted to come on to our program and we may well congratulate ourselves.

C. S. CHING (U. S. Rubber Company, New York): Mr. Chairman and gentlemen, I want to thank you for your very complimentary remarks. I am here simply as a pinch-hitter for Mr. Thacher, our vice-president. I will present his paper. I assure you I will not handle the chemical terms as fluently as Mr. Healy did.

Safety as Management's Responsibility

By S. P. THACHER

United States Rubber Company, Detroit, Mich.

Management and Industrial Enterprise work with and through the four M's—Men, Materials, Machines and Money. Nobody will deny that in the battle for industrial supremacy men are the deciding factors. Management can get money; can buy the most efficient machines and the best of all materials, but it has to train men—workers and executives. The degree of efficiency to which management is able to carry this training largely determines the results.

In this training modern management goes further than teaching speed and quality or production. We have recognized the need for teaching safe practice in our productive methods and processes. We have gone even further than this and are training our employees to practice Safety First off the job as well as during working hours. In other words, interest in the employee has gone beyond the purely economic stage.

Experience in the past decade has conclusively proven that the work of accident prevention is not a "one-man job;" that satisfactory results can be secured only through the highest measure of cooperation between employer and employee. Management must be vitally interested in the work if it expects to educate men to share the responsibility. The workers must be given a part to perform in it if their interest is to be aroused and maintained, and it is only through organization that this is possible, whether the plant be large or small.

Management cannot expect workers to be interested in safety work if it does not give consideration to the guarding of dangerous machines and conditions and follow it up by *action*. While it is true that the greater percentage of injuries can only be eliminated through the care of men following safe practices, at the same

time, the fact that physical safeguarding is being taken care of serves as a good basis for argument that the men must do their part.

Human carelessness cannot be quickly corrected, but physical safeguarding in a plant, in many instances, can be completed in a short time and have an important bearing on reduction of injuries.

It depends finally on the measure of cooperation from the workers and this cooperation cannot be expected unless the workmen have the proof and belief that management is sincere and willing to do its share in the joint effort which will inure to their common benefit. The tangible evidence given by safeguarding, promoting safety education and spending money to remove or lessen hazards is the best possible guarantee of its good faith.

The employer who does not see that accident prevention is a duty cannot fail, if the facts are properly presented, to appreciate that it is his responsibility and duty and an economic and humanitarian necessity.

I do not believe that anyone questions the fact that all this is management's responsibility—and by management is meant the entire executive staff from the president down to those on the firing line—the foremen and assistant foremen.

A glance at the organization chart of any modern manufacturing concern will surely disclose a safety supervisor and usually he is shown as reporting direct to the factory manager.

Safety must be given a dignified position in the organization. Management must get back of it and stay back of it so unmistakably that every foreman and workman will know what the officers propose to do to make the plant safe and what they expect the foremen and workmen to do. Without this backing from the management a safety supervisor can do little in reaching the workmen and in awakening the real safety spirit.

It is a pleasure to pay a well earned tribute to these men. Their work is not easy and oftentimes they do not feel that they are accomplishing very much. But day in and day out, they have been carrying on until today if an audit could be made of their combined efforts it would show many millions of dollars of economic and human waste saved in industry.

Accident prevention is of major importance to a plant, whether it be in a time of high or low production. In rush production it is easy to overlook accident prevention or welfare of the workers. In our efforts to meet schedules and orders a few, or, perhaps, many of our workers in industry are sometimes killed or maimed, which may appear to be excusable. Every time there is a serious accident there is that interruption to industry. It means much to modern industry. What it means in dollars and cents I cannot say, but the mere consideration of it establishes definitely that fact in the mind of any manager who cannot otherwise be interested in safety work.

The worker is oftentimes censored for his carelessness and for crippling the working force, especially if he is a valuable worker. Management can overcome this in a large measure by not forgetting the fact that increased production necessitates increased supervision and guidance. This increased supervision or guidance will pay for itself without question, for it is that sort of supervision that makes for greater interest among the workers and develops accident prevention as well as better methods of production.

Education, discipline and supervision are paramount in accident prevention. My personal experience leads me to believe that there are two types of safety education—first, that type of safety education where we depend too much on safety propaganda or mere talk; second, that type of education where educational effort is directed to the development of skill rather than caution. To achieve the desired results, I believe we should direct our efforts and energy to make our workers thorough and skillful. It is that type of mental training, discipline and inspiration

which makes a man carefully grasp his tools and think safety at all times. Exactly the same process is involved as that which takes a slovenly workman and raises him to the class of a craftsman—the most productive industrial machine and industrial human unit that we have in the whole world—and work of that kind, discipline, training and inspiration, expended in safety work, must automatically have as a corollary a training in increased care and pride in work and greater productive capacity on the part of the workman. This, of course, is undeniably true of the new worker.

In the past, and even today, too many major accidents and lives have been lost in industry as the result of new employees being improperly instructed or misplaced for the jobs they were expected to perform. Management has learned to exercise care in selecting men physically and mentally fitted for the jobs they are hired to fill, and has come to realize that in making a good first impression on the new man a distinct advantage has been gained in his willingness to learn and his general attitude toward production and safety. Courteous treatment, careful explanation of work, follow-up and the right kind of supervision are important. This right kind of instruction and supervision not only makes workers quicker producing units but also safe workers in any plant.

I am inclined to believe that our troubles do not come from failure to accept these principles so much as from failure to use judgment in their application.

Another angle concerning the question of responsibility is the manner in which safety is handled or introduced into a plant by management. Safety can be made a part of business production, operation, or what not. It can be treated as a frill or a fashion. Whatever way it is introduced or handled, it will be received by the workers accordingly. There is only one way that management should insist that it be handled and that is that every man in the organization, from the president down, make safety a part of business production.

To the pioneers of this great safety movement and to men present who are engaged in this important work, I pay my respects, because I think it is one of the greatest movements ever instituted in that its effects are so far-reaching. It is perfectly all right and good business to talk about dollars and cents; that is primarily one of the purposes of accident prevention, but if we expect the results that you men are so arduously working for management must not forsake the humanitarian side of this problem by considering dollars before men. Just as soon as the workers sense that the matter of preventing accidents is being carefully planned and becoming an integral part of their work to save money they will refuse to cooperate.

In my opinion the correct viewpoint that management should have on safety is summed up very beautifully on the trophy our company presents each year to that one of its plants showing the greatest improvement in its accident experience:

“And the end is that the workman shall live to enjoy the fruits of his labor; that his mother shall have the comfort of his arm in her age; that his wife shall not be untimely a widow; that his children shall have a father, and that cripples and helpless wrecks who were once strong men shall not longer be a by-product of industry.”

MR. CHING: I am now going to take a minute of your time to tell you gentlemen engaged in safety work to have a measuring stick for your work. Unfortunately the position I occupy in the company prevents me from applying the measuring stick in the work I do. I may be sent to Washington or Cleveland, and I talk the matter over with Ed McHugh or in Detroit with Jimmie Quirk, or in Hartford with Ed Lawler, so I am moving around in a circle. There is no way of measuring or handling employer-employee relations where you can apply a measuring stick and get down to a dollars-and-cents figure. But in safety work there is an absolutely accurate way of applying the measuring stick, and one of

the reasons why Mr. Beck in our company has been able to do what he has done to stimulate the interest in the higher officials of our company is because he has had his figures and statistics in such shape that nobody could contradict them.

You must prepare your statistics and figures in the same way. If you do not do that, you are certainly not going to stimulate and arouse the interest of your company officials as you ought to. I think Mr. Thacher is absolutely right and we all agree, of course, that we must think of that other side of safety, the humanitarian side, of the suffering that is caused as a result of industrial accidents, but the difficulty is that we are so remote from the scene of the accident that we don't see the blood or bruise of the injured limb, and it becomes merely a record. If you want to impress your officials with it, if you want to leave an impression upon them, you have to make it in either black or red figures. Sometimes red figures have as great an effect on a man who is removed from an accident as a drop of blood. It means that somebody has to take notice. So much for that phase of it.

The relations between all the departments of a company are so intricate, so complicated, that it is extremely difficult for each one in the organization to know what is in the back of the other's head and what he is trying to accomplish. That goes for members of your organization, your supervising force, as well as for the worker, and the job of the safety man in endeavoring to get everybody in the plant thinking in terms of safety, is a tremendously big job, because you haven't the time. You can't get the people together and impress them with your point of view or get them to see all phases of it. If you have possibly a contract or a special occasion job, and a certain way is set up to do a quick job on it and the customer has been promised this thing next Thursday morning at nine o'clock, the thing that is running in the minds of your production organization usually is: "We have to get this out. He has been promised this and it has got to be shipped at nine o'clock." A safety man comes along and then says, "See here, why this is dangerous. You mustn't do that and that and that . . ." And immediately the production man may get to thinking: why that is going to block the wheels of progress. If we could just get this pest out of the way we would have a perfectly lovely time here and do things.

The big job is to get that fellow to see that you can't do the job right except with safety; that one small accident will delay that job more than doing it right in the first place. I don't know how many of you have had experience with some kind of employees' committee. I assume that you all have had some kind of safety committees operating in your plant. Safety committees are good things. They are not worth a tinker's damn if you are just going through motions; if you are going to say, "Some one made a speech at the National Safety Council, and we ought to have a safety committee." So the safety man goes home and tells the manager about it and that it is the latest fad, and they go out and get Bill and John and Tom and they have a safety committee. The first two or three meetings they don't make any suggestions, they just go along and make speeches and gradually it dies out. Then some fellow who has never had an accident in his life will say, it is a fashionable thing to spend money on safety, but it is really not important.

Now, I want to say that safety is but one phase of production. Safety is but one phase of employer-employee relations. Believe me, until you get to talking to your employees about everything affecting that relation, when you have a system of committees that will talk to your management back and forth, so that they know every phase of production and just what you are driving at, so that the management and employees are cooperating all over the plant to make it a safe place to work with low labor and high wage—if you are getting that, your safety is going far.

There is another thing, a thing that you have got to hammer home and realize, and that is this: You can't have proper labor relations in any plant that is not efficient. If you have an efficient plant, waste of any kind in your plant, if it is not operating efficiently in regard to the number of men in the plant, the number of men on the job, the proper safeguarding of materials and all of those things, you never can have proper employee relations in that plant. And my hunch is you never can have a safe plant if it is inefficient. I don't care how many speeches the manager makes at the Chamber of Commerce meeting, you can't have a safe plant until you clean house and have the proper number of men on the job, until their earning capacity is unhindered, and until you are getting no waste in the plant. That is the only way you can have a safe plant because it fits in with every other phase of proper production.

We are hearing a lot about the foreman being the keyman of the job. I have heard it so many times I am sick of it. Even the Y. M. C. A. is talking about it now and the foreman is quite a fellow, but the fact that you call him a foreman doesn't change him very much; he is still about the same as he was before. You can't get very far in preaching to him either. I believe that the foreman in your plant may not be the same kind of a fellow as the one in our plant, but he must be a good all-around production man first of all. I know that comparing men occupying similar positions with our plant and others we find the foreman classed as a superintendent or an overseer, or a general foreman or assistant foreman, or what-not; so when you talk about foremen you are talking about a lot of different grades of supervising forces. We have to give our foremen absolutely reliable statistics that are comparable to accidents in their departments; then we will accomplish a great deal.

I assume we are all making our comparisons in the same way and the interchange of information is what helps. We say, "Here is the Fisk Rubber Company and the U. S. Rubber Company, and our comparisons with Fisk are so and so." We hand that to the vice-president and he will say that you are either good or rotten, depending on whether you are talking about one or the other. That should get to the foreman in his particular plant and his department. Don't hesitate to spend a little money on typewriter ribbons. Get our statistics and figures. Keep them before the eyes of your management. I can't emphasize that too strongly. I worked with a young fellow once who later became an official of a big company. He told me three things to remember: (1) Always make all the friends you can; (2) Be sure to keep your boss posted, whether you are right or wrong, especially if you are wrong; (3) Don't be afraid to do a little judicious advertising.

CHAIRMAN SALISBURY: I am sure, gentlemen, speaking in your behalf, that we are greatly indebted to Mr Ching for his inspiring address and we are grateful to Ernest Beck for helping us secure Mr. Ching.

Report of the Nominating Committee

Before proceeding with the balance of the program, I wish to submit for your approval the recommendations of the Nominating Committee. They have named the following officers to carry out the business of the Section during the coming year.

For Chairman—Mr. M. A. Quirk (better known as Jimmie Quirk), U. S. Rubber Co.

Vice-Chairman—E. A. Hoehner, E. R. Lawler, U. S. Rubber Co.

Treasurer—P. Van Cleef, of Van Cleef Bros., Chicago.

Secretary—S. Mansfield, Goodyear Rubber Co.

Posters—J. T. Kidney, Goodyear Rubber Co.

Slides—R. H. Cochran, Kelly-Springfield Co.

Programs—C. E. Ott, Seiberling Co.
News Letter—J. Lynch, Fisk Tire & Rubber Co.
 Membership—P. M. Wooden, Mansfield Tire Co.
 Statistical—H. W. Low, Miller Rubber Co.
 Health—L. J. D. Healy, Fisk Tire & Rubber Co.
 Engineering—C. L. Hungerford, Firestone.

Advisory Committee:

H. T. Martin
 E. W. Beck, U. S. Rubber Co.
 W. L. Schneider
 R. C. Salisbury

The recommendations were regularly moved and seconded.

CHAIRMAN SALISBURY: Mr. Quirk, will you just give us about two or three minutes?

MR. QUIRK: Gentlemen of the Rubber Section, two minutes are a long time for me. All I can say is that it will be indeed a pleasure to serve the Rubber Section and you men next year, and the only thing that I am going to ask for is that one big word, cooperation. The coming year we have a lot of work and I realize that the chairman has a big job ahead of him, and will absolutely need your support and in a very short time you will receive some message from me asking for your help, so, in closing, I just want to say that I want to serve you to the best of my ability and I will conscientiously carry out the duties of Chairman of the Rubber Section.

MR. MARTIN: Mr. Ching gave me the idea of the yard-stick for measuring statistics. That called to my attention a class of statistics that I think is very much overdone sometimes. We have a statistical committee and I would like to give this thought to them for consideration. We are talking a great deal about lost time accidents. That means, to my mind, accidents due to loss of time. We consider a lost time accident, one where the loss of time extends beyond the day or shift after the man is injured. I know a great many concerns that have gone to unreasonable limits in caring for lost time accidents. I think it is of no great importance whether you have loss of time or not. Any accident that comes to your hospital is a loss of time and should be cared for whether it takes seven or ten days. We are making a lot of liars out of ourselves, if you will permit the frankness. We go to ends that are some times questionable to prevent lost time accidents. I am entering a plea for honest statistics, minor injuries, this differentiation between classes of accidents that causes men to work in a guard house that never happened before, on a job that is created for no other purpose than that of beautifying statistics. Let's come clean.

CHAIRMAN SALISBURY: The balance of the time is to be devoted to a discussion of Safety Kinks as used in the Rubber Industry, and as compiled by our friend and co-worker, Mr. C. L. Hungerford, who is going to put this on for us in his usual good form. I am sure that it is going to be beneficial and after showing the pictures, we want to use a little time for a general round table. One or two questions have been sent up on cards and we want them answered.

Safety Kinks

By C. L. HUNGERFORD

Division of Safety and Hygiene, Firestone Tire & Rubber Company
 Akron, O.

Just as Mr. Quirk has already stated, all of this work is due to the cooperation of members. We are paid primarily to do our job in our company but we do give a lot of time to the National Safety Council Rubber Section because

we know that by giving we secure a lot of valuable ideas that will help us in our work. Now, on the Safety Kink Slides that will be shown is material that was given to me by various companies and you can use these any time you like by merely writing to the headquarters office of the National Safety Council. The cooperating member's name appears on the slides and I thank them. We have not only endeavored to show mechanical guards, but will show a few things that are kinks or methods of putting safety across to the man who is on the job.

The first picture, furnished by the Fisk Rubber Company, is a truck for carrying a large calender roll. It is a cradle truck, cut away to conform to the contour of the roll, which prevents it from falling off. We are using the same type at our plant. Before we put it on a flat truck with wedges. You can visualize what happened when the wedges were not placed properly.

Slide 2110—Danger of falling eliminated by window bars. (Fisk Rubber Co.)

H. W. Low (Miller Rubber Company): May I ask the author how they take care of the different sizes of rolls? Do they have different trucks for various sizes?

MR. HUNGERFORD: The sizes don't vary greatly.

MR. LOW: In this connection, I may add, we had a similar type of truck four years ago. All plants don't work the same, but we made the storage at that particular place. We take the calender roll from the calender and sling it on an overhead track. We have the same cut-out stand that will fit the contour of the roll. It eliminates entirely the trucking and the handling of the calender roll. We have a section of the corner of the room set off and the men just place them in the overhead track. We consider it more efficient.

MR. HUNGERFORD: The next is a picture (slide 2110) of where the windows are low and there are possibilities of the employee or material falling out. The bars here prevent that possibility. There has been a lot of close calls of employees leaning out of windows with low sills. Just the other day a girl was leaning out of the window to look at the clock in the tower. If anything had scared her or if anyone had pushed her, it would have been possible for her to have fallen five

stories. It is the simple things that often go unnoticed that sometimes create fatal accidents. They use this in the Fisk Rubber Company.

MR. LYNCH: It is always very valuable too for keeping material such as rolls of stock that are used in the Rubber Industry from falling out or from falling on a truck which is passing by.

MR. HUNGERFORD: Another thing, we have in our plant a conveyor which passes our windows, and the bars are for the same purpose.

MR. BECK: Mr. Chairman, in that particular connection, in certain warehouses where they barred up windows, they often stack supplies. It is very poor practice from the point of view of fire prevention. Do not store goods against windows or walls where you have an outside exposure. In event of fire it handicaps you.

Slide 2115—Mould press. (Fisk Rubber Co.)

MR. HUNGERFORD: Here is pictured another simple kink, and yet very effective. How many of your millmen are continually cutting their hands while sharpening knives on stones? This stone holder is fastened to the housing of the mill. It remains there permanently.

MR. SCHNEIDER: I wonder how many companies have their knives dressed at one central point rather than by each individual, eliminating a certain amount of danger or localizing the danger?

MR. HUNGERFORD: I don't think that is always practical for millmen. We are doing it, however, in some divisions and it seems to be working successfully. A man takes his old knife back and gets a new one; it saves a great deal of time.

Here is shown a conveyor with a span mill guard around the gears. The hooks are protected with just ordinary rubber hose which prevents anyone from being injured seriously if they should happen to walk into the conveyor. This rope around here is a safety rope which stops the conveyor in case of emergency. We had safety ropes installed on our conveyors and they are not only a wonderful thing to prevent physical injury to men and women, but every once in a while

something may go wrong with the equipment. By being able to stop it quickly, it prevents further damage.

This is a truck for transferring large rolls of calender stock, the idea being that it carries two rolls, one on each side. That prevents a bale from over-rolling.

Mr. Low: Is that a portable foot?

Mr. HUNGERFORD: It is removable.

Slide 2118—Safety Bar on warm-up mill. (Firestone Tire & Rubber Co.)

Mr. Low: Suppose it is not used, what happens?

Mr. HUNGERFORD: Well, sometimes they get along all right without them, but we have had examples where they fall over. If we find they are not using them, we dress them down for it.

Mr. HUNGERFORD: There is another thing here, a hanger to prevent the bars from slipping out. It is especially designed and is a little hard to see. We wanted to carry the same bar all the way through from the wind-up on the calender to the wind-up on the pocket building table. We found that the bars were continually dropping out so we just welded a piece in the end of each hanger and it keeps the hook from shifting and allows plenty of chance for the bar to drop in but not to drop out.

Slide 2119—A ladder that will not slip; O. K. for high ceiling. (Firestone Tire and Rubber Co.)

MR. MCHUGH: It is simply a skirt on the bottom of your hanger, is it not?

MR. HUNGERFORD: Yes. Mr. Lynch will explain the mold press, please?

MR. LYNCH: (Slide 2115). I imagine everybody has had trouble with presses

the same as we have had. This we have worked up. It is the best thing we have put in recently for safety. Rather than have a storage of rings alongside of your conveyor table, you leave one ring on the bottom half of your mould. The tire is placed in there and the top ring which is traveling along immediately between the bottom half and the top half of the mould, drops down, goes under this press and is automatically pressed. You don't have to stop the conveyor

Slide 2122—Lugs prevent car plate from slipping. (Firestone Tire & Rubber Co.)

at all. It has proven a very favorable thing from every standpoint. Needless to say, it is a wonderful thing for safety.

MR. BECK: Have you ever had anyone caught between the rolls and the top case of the mould on that type?

MR. LYNCH: No, we haven't. There is a man who doesn't show on the picture, who sits directly behind that mould and operates it by hand; as that mould passes through, he releases the hydraulic valve and raises and then lowers it. It isn't in that position all of the time. That is just in the closed position.

MR. BECK: Does that give you an absolutely perfect center?

MR. LYNCH: Yes, it does.

MR. BECK: You don't have to use your spring presses?

MR. LYNCH: No, except on the big tires.

MR. BECK: Does that eliminate your clasp and ring press operation? Does it eliminate it entirely?

MR. LYNCH: Yes, and incidentally, in five years we lost 324 days in ring press accidents and in compensation about \$1,000.

MR. HUNGERFORD: This next picture illustrates an elevator safety switch. When the operator leaves he throws it off and makes it impossible for anyone to start the elevator. This was suggested by an elevator operator who got off to help a trucker on and in some way the truck handle started the elevator. The operator grabbed a stick, reached under the gate and shut off the power. Of course, that prevented any further damage. Now these safety switches are on all elevators and the rule is that no operator can leave without pulling the switches. It is quite an interesting feature. They were going to publish this man's picture and name in the Non-Skid and commend him highly for the wonderful headwork he used in stopping the elevator. On second thought it was suggested that he certainly didn't use head work in getting off the conveyor and leaving the power on, so he was reprimanded instead of commended.

MR. SCHNEIDER: Isn't there a tendency for them all to want to assist people in getting on and off.

MR. HUNGERFORD: We have elevators where that is the rule.

The next slide shows a simple thing on a ladder and yet a very effective device. How often do we have a man on a ladder where the safety shoes slip or are not effective? We have had a ladder where the man at the bottom of the ladder was not 100 per cent safe either. It is very easy with the hooks at the end of the ladder, as shown, to hook it on to anything.

Here (in slide 2118) we have a safety bar on a warming mill. This bar is put across the front and the difference between that bar and the roll is twenty inches. It prevents the millman from getting too close to the mill and it gives him something to lean against. The millmen like it very much. I want to call your attention to the fact that the mill is not as low as it looks. It is fifty-four inches from the floor.

MR. MARTIN: How high is your bar?

MR. HUNGERFORD: About 24 inches.

MR. HUNGERFORD: I might tell how and why we installed that.

We had a safety inspector from the State come through our plant one day— We had beautiful safety trip-tables and about three inches under each safety trip table we had a rigid bar which was to prevent the rubber from snapping loose from the mill. That worked fine. This was called to our attention by the State Safety Inspector. The objection was that the safety would be tripped by the rubber sling being loose. Incidentally, this bar prevented that. It slips over very tight and there is no trouble. Of course, you only get that on your rubber stock.

MR. BECK: How close do you say the bar is to the rolls?

MR. LYNCH: The distance is twenty inches on the average.

MR. BECK: Are you using the center bar on your trip?

MR. LYNCH: Yes, it is about eighty inches above the floor on all our mills. You can't reach it. It is too high. We haven't a man in the place that can reach that bar. These are all hooked up with your safety. It has to be reset.

MR. HUNGERFORD: Here (slide 2119) is a ladder that will not slip, and that is excellent for high ceilings. We had a man who fell off a ladder, the ladder slipped, and he fractured his skull and died. Our Vice President asked for a ladder that could be adjusted, something that would not slip and cause such accidents. We thought we couldn't get anything that we could put through the doorways and so our Safety Department and Engineering Department got together

and got a company to manufacture this for us. It has only a two-foot wide base. The adjustable outriggers support it. The platform, toe board and standard railings, giving a man a place to work with perfect security. It will support a weight of 300 pounds, that is, an ordinary man, with proper tools and motor can stand on it. It is being used a lot by our mechanical division.

MR. LOW: Do you have a climbing ladder?

MR. HUNGERFORD: No, it is part of the structure and is telescoped.

MR. LOW: What actuating medium have you there?

MR. HUNGERFORD: It is a hand crank with an automatic friction brake which prevents the platform from coming down too fast.

MR. LOW: What is the approximate cost of that?

MR. HUNGERFORD: \$750.00.

MR. LOW: Do you have it manufactured?

MR. HUNGERFORD: That was the only one. That is what makes it so expensive. The vice president wanted it and O. K'd it. These are also used by big department stores. We found that in New York City every big department store has this type. They have an awful lot of ceiling work and have had a lot of trouble with accidents on account of ladders falling, so it just shows you what effort in one instance will influence another. We don't care whether you make rubber tires or sell silk cloth.

MR. KIDNEY: At the exhibition on the roof of the Pennsylvania there is a scaffolding being exhibited and you might be interested in it.

MR. HUNGERFORD: I noticed that. It is a good line, but the huge platform that is necessary for transporting that makes it impossible for us to use it.

MR. QUIRK: A week ago in Detroit there were planks across a ladder on the seventh floor of a building and the scaffold was two months old. They are now testing to see whether it is the acid used in the window cleaning that caused the scaffold to break. The front frame broke on the seventh floor. They thought a ladder two or three months old would be O. K. Two men strapped to the different ends of the ladder fell down. We should find out what is being used in cleaning windows. I wonder if they are watching that or not. It is being investigated in Detroit.

MR. DEITZ: How long have you had that ladder?

MR. HUNGERFORD: A year ago last June a man was killed and we got the ladder about four months later.

MR. MCHUGH: Would you need an engineer to operate it?

MR. HUNGERFORD: No, it is very simple; one man can handle it. It practically folds up. These adjusting wheels below here can take care of any uneven surface and the standard toe-board and railing lands on the base. I have seen one man on the job take care of it. It is very easy to pull. It is all operated from the ground.

MR. MCHUGH: What is the height of the ladder when it is extended?

MR. HUNGERFORD: Eighteen feet to the top of the platform. It is not designed for four or five men. It is designed to support the weight of 350 pounds. Of course, it is all structural steel.

MR. MCHUGH: How long does it take to set it up?

MR. HUNGERFORD: Five minutes is a long time. The rigging trips and sets the foot down on the ground just like a regular transfer. I know we are glad to have it. I am sure the manufacturer would be glad to supply them. It is economical, a money saver, because one or two men will go out on a job that took four men.

MR. MCHUGH: Can you take a motor on it?

MR. HUNGERFORD: Yes. Originally we could take a motor up and couldn't get it down. Now, we can take it up and bring it down very easily. We will be glad

to give you whatever dope you may want on this at any time by simply asking for it.

MR. DIETZ: How do you take care of the varying returns? These are worrying me.

MR. HUNGERFORD: The cleats are close enough together that we haven't had any trouble with that at all.

The next is from the Miller Rubber Company. At this corner persons would come around with a large roll of bead wire and—bing—somebody would get a foot smashed or something else. They cut out the partition and put in a screen which enables clear vision and eliminates the blind corner. Now, there are a lot of places in any organization where that can be done, either by cutting out the partition and putting in screen ornaments, or whatever you desire. They haven't had any trouble since this has been installed.

MR. LOW: That enables the stockroom man and pedestrians to see into the stockroom. They are not so used to the fact that there is danger there and don't always look, but the stockroom men and people coming for the stock look out for it every time. Our pipe storage is also in that room. Once in a while a fellow would come out carrying a piece of pipe over his shoulder. He now is given a chance to see anybody coming along.

The next (slide 2125) is a window prop. The rods are slotted on the end and we found that after awhile the slot would bend. Then the men would stand a milk bottle or something to hold the section of the window open. We have had a lot of trouble, no injuries, but several close calls, by a piece of pipe or milk bottle dropping out of the windows. We went around and took all these window rods and spot welded them across the end of the slot so they can't get away. Welding makes it one piece now like the links of a chain.

MR. HUNGERFORD: This is an extended lip on the truck to prevent your mould from slipping off or out when being transferred from one point to another. I think it is a very good idea.

MR. LOW: It is as heavy as boiler plate. It is not welded on, but it is fastened on with bolts.

MR. HUNGERFORD: We often wonder what kind of bulletin boards other companies are using. Here is one being used by Fisk. Part of their success is getting their statistics before the eyes of the men, bearing on what Mr. Ching said about letting them know what is going on.

The next slide shows an accident report that every foreman makes out. This is a combination of the report used by U. S., Goodyear, Goodrich and Fisk. It shows the history of the injury, how long with the company, etc., but the important thing is to state the cause of the accident and what is being done or could be done to prevent it. The only thing an accident report is good for is to find out what you can do to prevent it. We pay a lot of attention to what has been done and is being done, to prevent it. This lets the department heads know just where accidents occur, and what is being done about them. It also shows the immediate supervisor. We often find out that the supervisor is having more in one department than the supervisor in another.

I have never been to a Safety Congress but what the question has come up regarding the lunch room of the mill. We have installed as shown in this slide this portable cafeteria in our millroom and we serve a hot meal to the men at a reasonable cost. These lunch wagons were made by our mechanical division. We serve meat, soup, coffee and dessert from ten to twelve, and from four to six. It isn't used on the third shift because the men usually eat before they come on, and they don't have any lunch period through the day. This is very popular with the men, giving men who do heavy work a hot and heavy meal.

This next—Accident Score Board—is used by the B. F. Goodrich Company

in presenting to their men just what they are doing. It seems to be self-explanatory. If a score isn't marked up daily I get a telephone call on it.

Mr. Low: Does the Safety Department do its posting or the departments themselves?

Mr. HUNGERFORD: The departments themselves post it because we want every foreman to know his experience.

Mr. HUNGERFORD: Another Safety Kink. "Open these doors and see the best safety device known." "I Am It." Would you mind telling us something about that, Mr. Salisbury?

CHAIRMAN SALISBURY: That is a simple and inexpensive method of making the employee realize that he is an integral part of safety. The truck is portable and can be taken from one department to another. The employee opening the doors sees his reflection in the concealed mirror.

Mr. HUNGERFORD: If you have got any good out of these Safety Kinks we are glad, but I want to bring out this. If you have received any good from it, please bear in mind to help whoever is in charge of safety kinks for next year. Send in your ideas, photos, etc., because the receipt means an awful lot in the way of helping it along. The success of the program depends on the cooperation of every member—new or old.

CHAIRMAN SALISBURY: I want to get into the record of this meeting the following question that was sent up on one of the cards: "What is the opinion of the value of installation of mills higher than 46 inches from floor line to top of rolls? Is there any objection to 54 inches?" That was sent in by W. L. Schneider, of B. F. Goodrich Co. He also adds, "If not, has it any additional safety value?" I want to get that into the record and unless someone can answer it now, we will just keep it there for future records.

Mr. SCHNEIDER: The point I had in mind there was: We are talking about newer methods of safety. Some people have used low or squatting mills for years and we have an engineering standard now that recommends 46 inches. I wanted to get the opinion of some of our body here as to what constitutes a good installation of height from a safety standpoint under a new method.

W. F. DOWN (U. S. Rubber Company, Cambridge): I wonder if anybody present at this group could suggest to me where I could have made a glass roll, solid four inches in diameter, approximately 46 inches in length. Have you ever had anything like that made?

Mr. DIETZ: Try McGee Glass Company, Jeanette, Pa. They will make it up for you.

CHAIRMAN SALISBURY: I am going to ask the new Chairman to close this meeting.

Mr. QUIRK: It is customary for a chairman to announce the additional part of the slate for next year, the men who are going to serve on the different committees. The following men have been selected to serve. Will they just arise when called:

Mr. Lawler, Vice Chairman, U. S. Rubber Company.

Mr. Mansfield, Goodyear Rubber Company, Secretary.

Mr. Wooden, of Mansfield Tire Company, Membership.

The others have already been announced, so I won't repeat them.

I just want to say that with your efforts and mine, we will accomplish something. There are many new faces each year. As I look around me now, there are a great many faces that I do not know and I think before we leave we had better get better acquainted. I would like to shake hands with you all. If there is anything you would like to present this coming year, I shall be happy to hear it.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Steam Railroad Section

New Section Officers

- Chairman*—J. E. LONG, The Delaware and Hudson Company, Albany, N. Y.
Vice-Chairman—C. F. LARSON, The Missouri Pacific Railroad Company, St. Louis, Mo.
Secretary—A. W. SMALLEN, Chicago, Milwaukee, St. Paul and Pacific Railroad Company, Chicago, Ill.
Program Committee Chairman—C. E. HILL, New York Central Lines, New York City.
Membership Committee Chairman—C. T. BAILEY, Oregon Short Line Railroad, Salt Lake City, Utah.
Accident Causes and Remedies Committee Chairman—T. H. CARROW, The Pennsylvania Railroad, Philadelphia, Pa.
Poster Committee Chairman—L. G. BENTLEY, The Chesapeake & Ohio Railway Company, Richmond, Va.
Publicity Committee Chairman—D. H. BEATTY, Southern Railway System, Washington, D. C.
Prevention of Highway Crossing Accidents Committee Chairman—C. L. LAFOUNTAINE, Great Northern Railway Company, St. Paul, Minn.
Public Relations Committee Chairman—(United States & Canada)—J. L. WALSH, Missouri, Kansas, Texas Lines, Dallas, Texas; W. A. BOOTH, Canadian National Railways, Montreal, Quebec, Canada.
Present and Future Activities of the Section Committee Chairman—A. V. ROHWEDER, Duluth, Missabe & Northern Railway Co., Duluth, Minn.
Engineering Committee Chairman—A. N. REECE, The Kansas City Southern Railway Company, Kansas City, Mo.

Retiring Officers

Chairman, E. R. COTT, The Hocking Valley Railway Company, Columbus, Ohio; *Vice-Chairman*, J. E. LONG, The Delaware and Hudson Company, Albany, N. Y.; *Secretary*, C. F. LARSON, The Missouri Pacific Railroad Company, St. Louis, Mo.; *Past Chairman*, J. D. WHITE, Illinois Central System, Chicago, Ill.; *Accident Causes and Remedies Committee Chairman*, T. H. CARROW, The Pennsylvania Railroad Company, Philadelphia, Pa.; *Poster Committee Chairman*, L. G. BENTLEY, Chesapeake and Ohio Railroad Company, Richmond, Va.; *Publicity Committee Chairman*, A. B. HOFF, Erie Railroad Company, New York City; *Prevention Highway Crossing Accidents Committee Chairman*, C. T. BAILEY, Oregon Short Line Railroad Company, Salt Lake City, Utah; *Public Relations Committee Chairman*

(United States and Canada), J. L. WALSH, Dallas, Texas, and W. A. BOOTH, Canadian National Railway, Quebec, Canada; *Program Committee Chairman*, D. G. PHILLIPS, Wabash Railway Company, St. Louis, Mo.; *Special Committee Chairman on Present and Future Activities of the Section*, T. P. BRENNAN, The Long Island Railroad Company, New York City; *Membership Committee Chairman*, A. V. ROHWEDER, Duluth, Missabe and Northern Railway, Duluth, Minn.; *Engineering Committee Chairman*, W. L. ROLLER, The Hocking Valley Railway Company, Columbus, Ohio.

October 2, 1928

E. R. COTT, Chairman

Supervisor of Safety, The Hocking Valley Railway Company
Columbus, O.

The first session of the Steam Railroad Section at the Seventeenth Annual Safety Congress was called to order at nine-fifteen o'clock by the chairman, E. R. COTT, Supervisor of Safety, The Hocking Valley Railway Co., Columbus, Ohio.

CHAIRMAN COTT: The Seventeenth Annual Safety Congress of the Steam Railroad Section of the National Safety Council will now come to order. I will thank you all to rise while Mr. W. L. Roller gives the Invocation.

W. L. ROLLER (Chairman, Engineering Committee, Hocking Valley Railroad Co., Columbus, O.): We feel grateful to Thee, our Heavenly Father, for this privilege of meeting together again to consider the many questions which have to do with the welfare of our fellow men.

We thank Thee, Heavenly Father, that thou hast put it into our hearts to get into this great movement that means so much for our fellow men. Be with us through the entire session of this Congress for our sake and Jesus Christ's sake. Amen.

We start the program out while we have Mr. Roller on the floor, to call on Mr. Roller for the report of the Engineering Committee.

Report of Engineering Committee

By W. L. ROLLER
Chairman

The chairman of the Engineering Committee, Steam Railroad Section, wishes to report that on account of other activities he has been unable to carry forward the work of preparation of Safe Practice Pamphlets as outlined early in the year. A number of such pamphlets have been reviewed and suggestions forwarded thereon. Chairman wishes, in lieu of definite accomplishment, to recommend for the ensuing year the following:—

First—That in all cases where technical knowledge of material and equipment, the use of which affects the safety of the railway worker, the matter be referred to the Engineering Committee for study,

Second—That the "Repair, Redressing and Sharpening of Maintenance of Way Tools" be made subject for Safe Practice Pamphlet. Our experience shows that a considerable proportion of accidents and personal injuries, especially in the Maintenance of Way Department, arise from faulty or neglected repairs to small tools which might be avoided by proper repairs and proper inspection.

Third—That the "Care and Operation of Gasoline Motor Cars" be made subject of Safe Practice Pamphlet. With the tremendous increase in number of such motor cars on the railways each year, it is vastly important that some reliable data be made available looking toward greater care in the maintenance and operation of this equipment. This is especially important in that this equipment is usually entrusted in their operation to men more or less lacking in the knowledge of fundamentals of their construction and proper operation.

Fourth—Would also recommend that the committee be assigned the subject of "Safe Methods of Handling Steel Rails." This pamphlet should embrace not only the matter of mechanical methods and devices but should also approach the matter of laying rails by hand and also report on recommended practice in loading rails at the mill to insure greater safety in unloading on the site of the work. This phase of the maintenance workers job is fraught with more hazard than almost any other class of work he is called upon to do.

CHAIRMAN COTT: We wish to thank Mr. Roller for his work during the year and he has laid out a program at least which we recommend to our successor. I wonder if next our chairman of the Program Committee, Mr. D. G. Phillips, will come forward and make his report.

D. G. PHILLIPS (Wabash Railway, St. Louis, Mo.): The Program Committee; about the only report they can possibly make is to call your attention to the written program you have in your hands. There is just one part of that program to which I call your special attention. While it is not more important than any other part, yet this year we have stressed that part and that is the Round Table Discussion tomorrow afternoon. Now, as you look at that program you will find a number of subjects, five I believe, suggested; but that does not mean that those are the only subjects that are expected to be discussed at that time. It simply means those subjects were selected to sort of start the thing off, to give us a running start. So, think up any subjects you possibly can that you want discussed, get up on the floor and get the rest started and we will do the rest.

I want to express my thanks to Mr. Walsh and Mr. Larson of the Missouri Pacific and incidentally to Mr. Cott, who did most of the work of getting this program together. We hope and feel sure you will be interested and profit by the things you hear and you yourselves say and do during the rendering of this program.

CHAIRMAN COTT: Thank you.

Mr. Hoff of the Erie, chairman of the Publicity Committee, will be called on next for his report.

Report of the Publicity Committee

By A. B. HOFF
Chairman

In presenting my report as chairman of the Publicity Committee, I regret to state that circumstances over which I had no control have rendered my activities far short of what I had hoped for.

What has been accomplished is this:—

1. A committee was formed.
2. A bulletin outlining a policy on publicity, was sent to the safety representative of each member road.
3. Articles suitable for publicity were solicited from railroads. Some usable material was sent in and used.

4. Relations were established with the editors of two brotherhood magazines in Cleveland, and two shop crafts magazines in Washington. These gentlemen agreed to cooperate and were furnished by me with safety articles by members of their craft or brotherhood. Some of these were published.
5. Press articles from time to time.

It is perhaps pertinent, in this report, to inquire just what functions a Committee on Publicity can cover. It is clearly impossible to establish a Publicity Bureau. This requires a continual supervision, an adequate staff, office room and financial assistance.

The question therefore resolves itself into possibly two functions:

1—A channel of publicity for such National Safety Council committees as desire, or find advisable, to use the committee for any special publicity purpose of their own.

2—As much casual publicity as is possible to put over featuring more particularly the work of the National Safety Council, Steam Railroad Section.

In commenting on these two functions, which may be considered distinct in character from publicity put out by the American Railway Association, or any individual road, it must be observed that the Publicity Committee is merely one more agency in the vast number of railroad publicity organizations which are now at work.

Every road has one, every railroad association or publication has one. They are chiefly interested in such a form of publicity as will serve their ends and the ends of safety.

It is with these thoughts in mind, therefore, that I have the honor and privilege of presenting this report. In conclusion, I wish to thank all those present and absent who have so cordially and cheerfully cooperated with our committee.

CHAIRMAN COTT: Thank you, Mr. Hoff. Mr. Bailey, I will ask you to report for the Highway Crossings Committee.

Report of the Highway Crossings Committee

By C. T. BAILEY

Chairman

It has seemed hardly necessary for the chairman of the committee assigned to the subject of Committee work to make a report in view of the very excellent accomplishments of a similar committee in the American Railway Association Section. However, the National Safety Council has a distinct place in the program of the Accident Prevention on Street Crossings. I believe it is the real organization for contact with the public. They have done a lot in assisting this great movement. They have assisted a great many ways in the distribution of posters and publicity. That is a big thing as we do it in propaganda, educating automobile drivers as to the hazards of grade crossings.

We did not prepare a formal report but we have assembled some statistical data that will be of interest. It will be recalled by action of the Executive Committee and the Committee of Direction, the work of both committees would be coordinated and we have striven with that point in view. The American Railway Association, as you recall, is putting out the posters and booklets. I am advised by the secretary of that section, in carrying on this general propaganda, that there were 596,000 posters distributed throughout the country and 542,000 booklets. Of this portion, the National Safety Council distributed through their local councils and other agencies not available to the committee of the American Railway Section, 10,000 posters.

There were 1,600 periodicals and messages broadcast over 100 radio stations last year. Editorials and articles written in the *National Safety News* covering the Grade Crossing situation were re-printed in many magazines and publications throughout the country.

Getting down to the Grade Crossing Accident Prevention propaganda you no doubt all were furnished with statistics covering these corresponding accidents in 1927, which shows a very great decrease in view of the increase of automobiles in the country. In 1926 there were over 23 million automobiles registered and there were 2,371 killed and 6,613 injured, a decrease over 1926 of 121 persons killed and 373 injured with the increased use of motor vehicles. For the first six months of 1928 there is shown a slight increase in this type of accident.

For the first six months of 1927 the Interstate Commerce Commission indicates there were 2,561 accidents resulting in 1,062 fatal injuries and in 1928 there were 2,634 accidents occurring with 1,097 fatal injuries and 2,934 other injuries, an increase of 73 accidents, 35 persons killed and 33 persons injured.

Of course we realize that exposure to this type of accident is governed largely by the use of motor vehicles. As the use of motor vehicles increases we are confronted with that type of accident. I want to urge upon all members of this Section to cooperate fully with the propaganda being distributed through the country. We can not give it too much publicity. You would be surprised at the opportunities that are afforded to talk on this very important subject at clubs and other places and the newspapers are anxious to get material for news items—nothing that is old stuff—but something new all the time.

I think if the representatives of the American Railroads will do their best to get into contact with the newspapers' representatives in their community and distribute this propaganda, the accomplishments will be great. The Committee has nothing much further to report other than to urge your continued support of this matter and cooperate with the American Railway Association which we are going to do. We are going to continue to carry on as we have in the past.

CHAIRMAN COTT: Before calling on Mr. Rohweder for the report of the Membership Committee I want to call attention to the fact that I received a letter a few days ago informing us that the Boston and Maine Railroad has recently become a member through the help of Mr. Charles E. Hill, vice-president of the National Safety Council. I wrote Mr. Hill thanking him for his interest, which all of you know is great, in this Section, in securing this new member.

Mr. Rohweder, will you please make a report for the Membership Committee?

Report of the Membership Committee

By A. V. ROHWEDER

Chairman

The report of the Membership Committee is a report very much similar to the report of the sales campaign. A year ago we had 98 members and today we have 102 members. Among the new members you might be interested to know are such railroads as the Boston and Maine, Great Northern, Northern Pacific and the Chicago, Milwaukee, St. Paul and Pacific; adding materially to the mileage of the Section and very materially to the section in bringing some of the men who have been very active in this section in years gone by and for some reason or other had dropped out.

The work of the Membership Committee is a work which should not be left to the chairman of the committee alone. Every one of you in your respective territories throughout this country should assist the Membership Committee. We find in talking to a number of executives who have refused to join the National

Safety Council that they know little or nothing about the work the National Safety Council is carrying on.

The fee paid by any railroad in the National Safety Council is brought back to them a million times over in direct and indirect service, in the work that is done in the industrial organizations along the line of their railroad, and in the schools, in the homes and on the streets and highways, that these roads pass through. I mention that just as a thought and a suggestion that there may be a railroad in your territory or someone on that railroad you can get to and suggest to them the advisability of their supporting the National Safety program to a membership in the National Safety Council and add to the 102 members we now have in the Steam Railroad Section.

CHAIRMAN COTT: I want to thank you, Mr. Rohweder, for your activities which have been most helpful.

Mr. Walsh, will you please report for the Public Relations Committee?

Report of the Public Relations Committee

By J. L. WALSH, Chairman

The Steam Railroad Section, National Safety Council, has as great a need for the approval, sympathy and close cooperation of the public in its accident prevention work as any of the various sections and probably has since its organization, put as much time, effort and money in interesting the general public in the necessity of an organized safety campaign as any other single agency.

The interest of the Steam Railroad Section in this, might by some perhaps be called a selfish interest, but this is not true as safety in the home and safety on the streets and playgrounds has always been stressed in the numerous contacts made by railroad men in their talks to the public in schools and in club meetings of various kinds.

That you may visualize how many people are annually addressed in this effort to interest the general public in accident prevention work, I might mention that, on inquiry, 25 railroads advised me that during the year 1927 representatives of their safety departments personally addressed 2,028,974 school children and 267,700 other persons on the subject of safety. If all the Class 1 railroads were canvassed, this number could no doubt be multiplied by two or three.

In January, 1928, as chairman of the Public Relations Committee, I wrote to the National Secretaries of the Parent-Teachers Associations, International Association of Rotary Clubs, International Association of Lions Clubs, The Kiwanis International, and to the chairmen of fourteen of the various A. R. A. Sections, offering to provide a capable speaker for a short talk on safety at their annual meetings. I find that in most instances the program committees of these sections are in the same position as is the program committee of this Section, that is, not bothered so much about a shortage of speakers as they are about finding time for those that want to talk.

Every reply expressed approval of the safety campaign the railroads are conducting, and gratification with the result obtained; also expressed the importance of cooperation by the various agencies. The campaign resulted in placing speakers as follows:

For the Freight Stations A. R. A. meeting in Niagara Falls in June, addressed by Mr. J. E. Long of the D. & H. Ry.

For the Freight Claim Division A. R. A. meeting at Detroit in June, addressed by Mr. Frank Wenter of the C. & N. W. Ry.

For the Protective Section A. R. A. meeting in St. Louis in June, addressed by Mr. D. G. Phillips of the Wabash Ry.

The Parent-Teachers Association advised me that their program already provided for a round table discussion on safety conducted by the Educational Division of the National Safety Council and the Medical and Surgical Section A. R. A. advised that arrangements had already been made for a representative of the Safety Section A. R. A. to address them on the subject of safety.

The attitude of the public toward the railroads in accident prevention is important and no opportunity should be overlooked or neglected to post them on what the railroads have done and are doing to prevent accidents and injuries of all kinds. Their aid and cooperation should be solicited, especially that of the National, State, County and Municipal office holders, the schools, churches and newspapers, the Fraternal, Civic and Industrial organizations and associations.

CHAIRMAN COTT: Mr. Walsh has been ill for some time and we are glad he is here.

Without detracting for one minute from the work of various chairmen I want to say that Mr. Walsh took his work seriously, worked earnestly throughout the year, was a good man to tie to throughout my administration and he has done in your interest a considerable amount of work that will be reflected later on in lowered accidents throughout the country.

Mr. J. E. Long, Mr. Bailey and Mr. Walsh are appointed a Committee on Resolutions. Mr. Long, Chairman.

I call your particular attention to the death of Mr. Brennan and I will expect them to produce a resolution later on in this section acknowledging our loss. I presume most of you know of Mr. Brennan's passing. I was fortunate enough to be able to attend the funeral as a representative of this Section.

J. E. LONG (Delaware & Hudson Railway, Albany, N. Y.): Mr. Chairman, might I ask you to include Mr. Bentley on that Resolutions Committee?

CHAIRMAN COTT: I am very sorry, Mr. Long, I will have to refuse your request. Mr. Bentley has been chairman of the Resolutions Committee for the last twenty-nine years and made me promise I would not put him on a Resolutions Committee this year.

Chairman's Address

By E. R. COTT

Supervisor of Safety, The Hocking Valley Railroad, Columbus, O.

Gentlemen, it now comes to that time when the chairman is supposed to make his address. Had I thought of it a little earlier I would perhaps have had the program changed, to show, not an "address" but a "talk" by your chairman. An address presupposes that the subject will be exhausted, usually accompanied by an exhaustion of the audience, but one who talks may say that only which he knows and then stop. This is a time, as I see it, not to make an address but talk things over among ourselves and talk them over frankly.

I have always been more or less a direct actionist and sometimes we have been advised to soft-pedal this and that; but when, if ever, can we talk things over among ourselves except here? So, for a while you and I will talk things over that are in my mind and perhaps in yours and leave you to be the judge as to the worth of the subjects that come to my mind at this time.

Without thought of trespassing on the reports of these various committee chairmen, I want to make some mention of their work and accomplishments. Mr. Phillips, in preparing this program had in mind both the safety officer and the railway employee attending a safety convention for the first time. The program, I believe, is a balanced one. It will provide food for thought for the

safety officer, education and inspiration for the railway employee, and in preparing such a program we must keep in mind these two audiences which we have here. Sometimes some of us are bored, we think we are at least, because we hear some things over and over again; but we must always recollect there are with us men to whom the subject is new.

Mr. Walsh and Mr. Booth, Mr. Booth in Canada and Mr. Walsh in America, have opened up several new avenues of contact which, if followed up by succeeding chairmen, will produce a relationship with various organizations that will be helpful both to this Section and to them and to the Safety movement in large.

Mr. Hoff of the Erie has had that thankless task that any chairman of the Publicity Committee has. The most difficult thing in the world to obtain is publicity, at least at long range. We must and should find some publicity channels that have not yet been opened to us. Here is a work for which we bequeath to our successor in the hope that he can find and secure some avenues which were not opened to us. I do call attention to the fact that the National Safety Council headquarters, with their staff of 85 or more employees, and public relations channels, have not been fed. We have not fed them the amount of real news that all of us have at our finger's ends, which might be spread out over the network.

Mr. Bentley, Past Master of Bulletins, has done a splendid work as chairman of the Poster Committee of this Section. Unfortunately the work that he has produced has not been purchased in quantities that work justified. Only recently a new cooperative plan between the American Railway Association and the National Safety Council was worked out. It has not been given trial long enough yet to prove its practicability. The members of this section are entitled to bulletin service. This Section must furnish bulletin service. It is part of the membership service and a plan must be worked out and it is a difficult one since the American Railway Association has gone into the bulletin service and produces such splendid bulletins. This also I bequest to my successor and he and time will tell whether our present plan will work out.

Mr. Bailey, of our Highway Grade Crossing Committee, was a member of the same committee of the American Railway Association. That committee by right is taking a lead in this work and our thought in having Mr. Bailey, in addition to his ability, was that knowing what was going on in the other section he might be in a position to cooperate and help through this section of the Council, the work being done by the American Railway Association.

Mr. Thomas Holmes Carrow, late of Europe (you will learn more about that later), will give you a report today which is instructive and timely; namely, a report upon the trespassing situation in America. The American seems to think he has a God-given right to go when and where he pleases; exercising that divine right, he occupies our right of way at any point which he wishes to, resulting as you know if you are watching the statistics, in a tremendous loss of life about which the nation itself is indifferent. Your special officers who are making an attempt to reduce this evil are getting very little support from public authorities. Let your officer arrest ten men in the average State in the Union, take them before the Judge and he gives them fifteen minutes to get out of town and they go down to the station and take the next train out. In my section of the country we have complaints from the trespassers saying the train is late delaying them from getting from one point to another.

We had a wreck on our railroad and a delegation of hoboes came to our trainmaster and wanted to know how soon the wreck would be cleared up. If your trains do not stop at the point which they want to leave they are very clever about knowing how to open an angle cock and they can get off if they have to knock down the conductor in the caboose doing it. The trespassing situation is getting away from us, Gentlemen. It is time we looked into it, time we acquainted

the public with the true situation so earnest steps and efforts can be made to handle it. I recommend after you receive Mr. Carrow's report, you take it home, see that it is broadcast and use it in an endeavor to handle this situation on your own individual railways.

Mr. Roller, a first engineer for a number of years to the chairman of the Engineering Committee, has told you a lot of the things an Engineering Committee should do and which he has not done. We forgive him, however, because of the fact that at least we have a program laid down to us by an engineer which we may follow. His recommendations, I believe, are worth while and succeeding chairmen should make a study of that report, establish a contact with the safe practice men of the National Safety Council and work toward the end suggested.

Mr. Rohweder, chairman of the Nominating Committee, had I believe, Mr. Larson or Mr. Walsh and Mr. Phillips as his assistants. Their report will be given to you tomorrow. It is based upon a long acquaintanceship in the section, precedence and a thorough study of our own situation. They are absolutely unbiased in their opinion and had only in mind the welfare of the Section when they selected the officers whom they will present to you tomorrow. So much for this part of the Chairman's talk.

You are all, no doubt, familiar with the fact that recently the National Safety Council at the request of the Steam Railroad Section, introduced a system of medal awards and in January, 1928, seven metal plaques were presented to the seven individual railroads making the lowest accident rate over a period of years. When we did this we eliminated from the contest those who were awarded medals for 1927. You have a fair and open field for all of the other railways in the country. There are no favorites. Work and endeavor alone will put one to the top and we hope that all of you have an interest in this contest and have an ambition to see your road receive one of these plaques. This work is confined entirely to employee accidents. There is no weighted basis used such as in the Harriman award and the Interstate Commerce Commission figures are the only figures used in computing your rating. There was, at first perhaps, some little suspicion and misunderstanding as to what was intended. Nothing more or less was intended than a stimulus, recognition of work done, and I am sure that the railroads will welcome this additional public recognition of their efforts. Paraphrase: We live, Gentlemen, in a world of progress. I think it was Elbert Hubbard who said: "If you stand still you go backwards."

That is true. You recall the Roman Empire; master road builders built their far flung highways away from Rome and after getting so far, set their figure of a God, at the end of the roadway. The name of this God comes down to us now in the word "Termina." As long as Rome expanded, as long as Rome grew, as long as she reached out for other empires there was strength. There was power. But, after a while, she became satisfied, she set up this God "Termina" and instead of being interested in what was over the hill, what was on the other side, began to stop and look around and then look backward, back from whence it came and gradually retreated and decay and rot set in.

And so it is in Life. In any movement as long as we are looking ahead, as long as we have a desire and ambition to see what is on the other side of the hill, we progress but whenever we become satisfied to stand and look around, then we are going backwards.

I had a grandfather, not an unusual thing for one to have, but a rather exceptional grandfather, one of whom I am greatly proud. He was one of these men as he grew older was interested in the things that were around him. I believe it was Shakespeare said, "Man is a creature that looks before and afterwards," and Carlisle in commenting on it said, "It is a wonder he didn't look around a bit."

My grandfather kept mentally young. He was interested in what was going on and things ahead, and it was my custom as a lad to go to his home every Saturday

evening. I remember they had a light meal of tea and toast. I always hated tea and I didn't care particularly for toast but I sat through the meal because I would have the privilege for an hour or so after of listening to my grandfather talk.

There were two magazines always found in his room. The *World's Work* and the *Scientific American*. It was his custom to bring out one or the other of these magazines and select some topic he had read and discuss it with me. I recall going to his home one Saturday evening and finding grandfather excited about something, and after the meal was over he took me into the library and he told me in rather strong words he was cancelling his subscription to the *Scientific American*. He was done with it. He was through with it, no longer interested in it. He said for years he had had confidence in the *Scientific American*. If they were expounding or reciting about a theory they so stated if the matter had not been proven the reader was told, but now for some reason they had gone off into the realms of fiction with a story in the last issue of the magazine—not only was it fiction but they deliberately lied and introduced photographs to prove a thing which any man with reason knew was impossible. He then exhibited to me a photograph of the Wright Brothers flying their first aircraft at Kitty Hawk, N. C. Grandfather had reached the limit of his road.

From then on, as I see it now, he began to lose interest in what was around him and go back over the road he had traveled.

Now that, gentlemen, can be true of the safety movement, but it must never be true. Those of you who have in the past led the way, those of you of today who are showing the way, those of you tomorrow who will be responsible for that movement, must always have a vision that looks beyond; and God help this movement whenever we stand still and look around and become satisfied with the things being done.

The safety movement has made a definite progress, step by step, if you will trace its movement; but it is only recently I believe that we have realized that safety is, after all, not a thing of itself but rather a by-product of other things. Safety is a by-product of correct engineering, efficient and economical operation, and those things of themselves are but by-products of correct mental attitude.

A number of years ago in the interest of fire-prevention, the railroads of the country ordered good housekeeping. Bulletins were spread about; rules were made, orders issued with more or less indifferent success and then it was that someone discovered that good housekeeping in itself was nothing more or less than the outward indication of the character of men in charge; that good housekeeping in a shop or a building was nothing more or less than a bulletin that told to the passing world the character of men in charge of that building. If I wanted to know what kind of an agent you had at one of your stations I would only have to go there, ask no questions but look inside. If he was a bluffer the waiting room would be clean and the rest wouldn't be fit to be seen. If the place was disorderly, poorly cared for, dirt in the corners, records thrown about, I would know he was a poor agent. I would know his reports were not on time or accurate, that the superintendent or dispatcher did not like his work because the conditions surrounding that particular station indicated the kind of man that was there. To order him to clean up was of no avail, but to clean that man up mentally and morally would sooner or later be reflected in the character of housekeeping that prevailed in that particular station.

I have seen it time and time again proven, that the traveling auditor would say, "What happened to John Smith in his accounts?" When the chief dispatcher tells me John Smith is a better operator than he used to be—when the traffic manager is better satisfied, it is not because he cleaned out, but because we cleaned him up mentally and the house and his work showed the result. That is absolutely true of the safety movement. You cannot talk safety first and secure safety; you cannot issue orders that will make him and his men safe; but when you change

the mental attitude, you will have changed the surroundings, because habits change and then economy, order, cleanliness and safety follow.

The safety record of any shop is but the sum total of the mental and mechanical qualifications of that particular shop. Poor railways do not have good safety records. Low production is reflected always in high accident rates. Inefficiency is no kin to safety, and uneconomical operation is followed always by high accident costs. The railways that are making safety records and good records today are efficiently operated railroads, and safety is merely a reflection of the efficiency that we find in the operation of those railways.

The safety man of today and the future must be a student of personnel work. He must intimately acquaint himself with operating details because today to get farther down the list than we have he must get into the matters that only are reflected later on in safety records, because he must have his fingers on the pulse of the entire movement of a railway. The safety officer is not asking for greater authority. He is asking for larger opportunity, opportunity to serve; and recently the safety officer on the American railways is securing his place in the sun, the place which he deserves. I don't think there is a finer body of men existing on our American railways; that elsewhere you can find a group among which are so great a number that will subordinate personal ambition to the love of their work. Greed, selfishness, personal ambition and self desires, hatred, suspicion—these cannot be in the heart of a safety man who expects to get the results we want and the road wants. So I am proud of the safety men I know, who go on day after day asking little for themselves only to be of greater service to their fellowmen.

Wonderful things have been accomplished since Thomas Holmes Carrow took the floor at Salt Lake and talked about the 35 per cent goal. Lewis R. Palmer has prepared some statistics for us that will be given to us today or probably tomorrow, which will show you what has been accomplished since that time and these statistics I speak of are brought clear up to date through the six months of 1928. Those of you who are not thoroughly familiar with the statistical end of this work will be amazed and surprised at what has been accomplished. We must be frank and acknowledge that part of this reduction is due to the fact that we are no longer being charged with accidents due to the facts that hurts can no longer be dignified by the term "injury" and thus charge us with carelessness. The indifference of reporting officers, physicians and supervising officers is now a thing of the past and the result is that there have been chalked off of our record, a mark of carelessness that was after all a matter of nothing more or less than indifference. We are getting down to the point now where to reduce accidents hurts but there is a group out here in front of me who are big enough to carry the job on and it will be done.

I want to sound to you a note of warning which I believe it is my right and privilege to do: that we keep our balance; that we do not make of safety work a thing sublime now, ridiculous later; and that we ourselves do not degenerate into claim preventers but always be accident preventers, which is our job. That note of the warning I sound.

I want to say a word in speaking of records about whispers. Perhaps it might be better for me not to have mentioned what I speak of now but when one gets his head up and over the top it is a good target. Prominence subjects one to exposure and there have always been tales going around from time to time about the methods of reporting on certain railways. Not one but a number. Only recently the Interstate Commerce Commission made an examination of a number of railroads and inspection of their method of reporting and gave them a clean bill of health, all of which I think you will be glad to know.

The Interstate Commerce Commission has a rule that we must report accidents under certain circumstances and there is a stiff fine for failing to do so;

and if any one knows of a specific instance, it is their right and privilege to so report the facts, but, gentlemen, we are all working together friendly and happily. Let us leave the whispers out, let's work together; let's strive to reach the goal. Let's not take into our heart any envy, only the envy of ambition to reach the goal.

I want to welcome the Boston & Maine, a new member and our old friends who have come back into the National Safety Council. I think it is now time that we no longer put the question to ourselves: What do we get out of membership in the Council? but rather to put it on the basis of what our membership does.

First, it makes possible this Congress and this Congress will carry a message of safety to the far corners of this nation and perhaps the world. Our memberships make possible missionaries that go into the field to make Safety Converts.

Our membership makes it possible to carry to the public and industry our problems and their relations to it. In the interest of greater Safety both for them and ourselves it makes possible helpful contacts and associations that reflect in lower accident rates throughout the nation, and it carries and makes possible the carrying of a Safety message to schools and homes where live and where are women and children, whom all men love. If you will think of the movement in that way, I believe you will never ask, "What do we get out of our membership?" but "What does our membership urge us to do in the interest of Safety?"

Now, when I look at you men, you safety men, I don't see you but I see beyond you and through you. I see homes, sheltering roofs, trees and gardens and flowers, and there, happy in his task, a father. There also, secure in the love of a mother, are little children, safe in the home. Above I see the vision, a cloud by day and a pillar of fire by night, the guardianship of safety.

Mr. Palmer, will you escort the Doctor to the Chair? We are having a slight change in our program in item three on Wednesday morning. It will now be given in order that the Doctor who intends to leave for Europe tomorrow may present his paper.

Gentlemen, I take pleasure in introducing to you Dr. Arthur Geiringer, M.D., Associate Medical Director, Equitable Life Assurance Society, New York City.

Preservation of Health

By ARTHUR GEIRINGER, M. D.

Associate Medical Director, Equitable Assurance Society, New York City

It is certainly the experience of life that irrespective of riches or poverty, fame or obscurity, happiness or sorrow, yes, even in health and in disease, the great hope and the great conscious and subconscious desire of mankind is to continue to live. No one but the individual with perverted reason can deny that the basic urge in man is "I want to live and I want to live long." Of course he wishes to live happily and comfortably but above all and despite all, with rare exception, man's cry and prayer is to *live* and to prolong this life.

If this desire to live is the fundamental and basic wish and determination of man, what more noble or worth while effort can one conceive of than any agency which will, by means of any degree of intention, advice or practice, help him accomplish his aims; and it is exactly that which numerous forms of Health Preservation Units throughout the world are doing with rapidly growing and progressively increasing effort and success.

This great health conservation movement started with the advent of modern medicine but it was not until after the Great War that the work was seriously and practically organized and actually applied. This renewed activity, or health renaissance, was stimulated by the numerous instances of disease and suffering

which resulted from the many intentional and unintentional brutalities of the war but more definitely the need of energetic health preservation was emphasized by the astounding evidence of physical unfitness which was shown by the records of recruiting camps throughout the world. It seems extreme and yet is absolutely true that almost half of the young men, the apparent flower of the nations, showed upon preliminary examination a state of health and a condition of body clearly below the normal standard and also clearly *far below* the *possible* standard of near perfection. Now if this was the picture of health of the young man what must be the physical condition of the middle and old age groups. Relatively much worse!

*Based on first six months' experience.

We say emphatically and without qualification that the general physical condition of mankind is pitiful. Pitiful because it is definitely and positively avoidable.

The more profoundly we study the human body the greater is our respect for it. The more intensively we go into the details of this subject, the more definitely convinced are we that the mass of facts developed by science represent only the alpha of the secrets which are yet to be exposed. Yet, despite our profound ignorance of so many features of human structure and function, it is undeniably true that the relatively slight degree of knowledge which we have is of great significance and value. Indeed it is of such great value that if the human race would apply this knowledge and use it, even to a moderate degree, easily one-half of all physical ills would be definitely relieved and furthermore, if this definite knowledge were applied from a preventive standpoint, few of the numerous ills of mankind would ever see the light of day.

If this short talk conveys to you and impresses upon you these two following thoughts I shall be more than gratified. First, the great majority of mankind enjoy only a fair degree of health. Good health is just around the corner and humanity

may have it whenever it takes the trouble to reach for it; and secondly, the proper approach to good health and a longer life is the prevention of disease primarily, not its cure or treatment.

Time will not permit me to prove to you by statistical data the truth of my apparently severely drawn picture of the low standard of the average human physical condition. That the picture is true however, and not at all exaggerated can be very easily proven by reference to the great mass of medical data developed, as I mentioned above, during the war and further accumulated since the war, by all kinds of health units and by the thousands upon thousands of physical examinations in the records of Life Insurance companies, which records, incidentally, present a perfect cross section of health of the individuals of the leading nations over a period of fully a hundred years.

Admitting then, as a result of such study, that the average physical status of men and women is such that improvement is definitely indicated, may we ask by what means can we accomplish such a result? I believe that educational methods in the form of lectures, newspaper articles, magazine articles, bulletins, pictorial presentations, teaching in schools, and the family doctor are very important and effective means of contact and achievement, but it is my opinion that in the last analysis these methods will not be fully satisfactory unless they all emphasize that the basic, the essential procedure, is specifically the Periodic Physical Examination of all individuals and particularly and positively those of the ages of 40 years and older.

We are of course, interested in the sick man or woman. The whole effort of curative medicine exists for him, but on the other hand, the whole idea and purpose of periodic physical examination and the whole idea of health preservation and life prolongation in this newer sense were not evolved for the purpose of helping the individual who is obviously ill, who knows that he is ill, and who knows that he should receive medical advice and treatment. Quite the contrary. The idea was developed for the benefit of the large number of people who *appear healthy, feel healthy, and believe that they are healthy* but in whom there may exist an abnormal condition which has neither manifested symptoms nor made itself felt in any manner, a condition which is a potential source of trouble. The defect may be described as a weak link in the chain of an individual's physical well-being.

It might here be argued that if a person appears well and feels well it is better to leave well enough alone; that it is better not to seek trouble; and that to suggest illness is to create a thought or state of mind toward ill feeling. Quite true at first glance or upon superficial and shallow thought, *but not true at all* upon even slight reflection or elementary analysis.

There is no more justification for such reasoning than there is to say that the man who exercises foresight in saving part of his income for a "rainy day" is wrong; or that a railroad engineer is in error who from time to time inspects the important bolts, brakes, and other vital adjustments of his engine to avoid breakdowns and resulting accidents. No one could possibly criticize such practices or a host of other similar procedures of foresight which are common to all of us in our daily life. To take a contrary stand is illogical and will lead to a sad and cruel awakening. Failure to face facts is a policy which is usually definite, positive, and unrelenting in its penalties.

Despite the fact that the science of medicine is not complete or infallible it is well enough equipped at the present time to detect and to check up on the early signs of mankind's common ills. It is possible by means of a simple examination to discover the "weak link" which we mention above. This can be done with astonishing accuracy and certainty. Why ignore such an important possibility? How little material success, fortune, position, and accomplishments mean during the sad days, months or years of ill health? How often have we all heard "I would give

anything or sacrifice anything to be healthy and physically happy again!" How distressing are the thoughts and experiences of the "might have beens!"

Will the periodic physical examination change this picture? Positively! Without going into the technicalities of the question, we can cite a great number of instances where men *thought* they were healthy but in whom physical examination revealed vital defects or impairments, abnormalities which extensive experience teaches would have meant a shorter life and certainly a very unhappy one. Of these, we can tell of numerous cases where these impairments were entirely cured or eradicated with little effort through intelligent medical supervision. We have in mind several particular instances illustrative of this experience.

A policyholder of a large insurance company which is extending health conservation service to its policyholders sent a specimen of urine to the company stating that he was in perfect health and that therefore he did not desire full physical examination. "Still I have received so many of your circulars that just for interest I thought it might be well to have you do a urinalysis for me." A small percentage of sugar was found and the man was advised "that this single finding does not mean that you have diabetes but it should certainly act as a suggestion that you consult your physician, show him this report, and request the necessary further study to eliminate or confirm the possibility involved." To this there was no early response. About four months later, however, the policyholder wrote as follows: "Your finding disturbed me greatly and I was sorry that I sent the specimen to you. I was healthy and happy until I received your report. Still there was no way out so I went to Chicago, the nearest medical center. There further specimens were examined under various conditions and a quantitative blood sugar test was made. The results proved that I was indeed an early but true diabetic. I am now under periodic observation and treatment and I am convinced that I shall live many years longer than I would have lived if I had started treatment perhaps a few years later, when this disease would have made itself manifest by serious and hopeless symptoms. I am therefore more than grateful to you."

There are, without a vestige of doubt, thousands upon thousands of such cases going around entirely oblivious of a diabetic condition which a simple examination would determine but who unfortunately will not know their condition until it is too late. The same is true of Bright's disease, high blood pressure, heart impairments, early pulmonary tuberculosis, and many other ultimately fatal pathological changes. Few of these in the early stages cause striking symptoms and because of this insidious onset which may actually exist for years the sufferer has no other means of detecting and correcting his condition than by a careful periodic examination. On the other hand, if he does learn of these impairments while they are still incipient it is remarkable how readily most of them will respond to proper treatment.

Periodic examination is growing rapidly in popularity and yet not rapidly enough. No man after forty has a right to deny himself or his family this important aid to live a longer life. We prophesy that in the not far distant future Periodic Physical Examination will be the rule and not the exception among intelligent people.

And now, in addition to that aspect of this question which is the desire of man to live and to live long healthfully and happily, there is the economic and the industrial angle. We have established on the basis of surveys by various specialized investigators that this nation spends annually for drugs, doctors' services and hospital maintenance a sum very close to a billion dollars. Think, my friends, of the endless number of other uses to which, let us say, half of this fortune could be put if it were saved as it can, without question, be saved, if we all did no more than merely to follow the most simple and easily available rules and practices of health preservation!

This sum is staggering but small in comparison to the fact developed by that great statistician and investigator, Dr. Dublin. He states after a thorough study

of a great mass of material and after a clear explanation of how his figures were reached, "That sickness cost directly in lost wages, in reduced production, as well as in the necessary care, a total of two and one-quarter billion dollars a year" and then he adds, "Having due regard for the value of life at each age period I estimate that the total capital value of the lives *which can be saved* annually through the application of modern preventive medicine and public health measures is over six billion dollars."

With these facts before us we must hesitate, even for a moment, in our labors to change and to improve this picture. With all the health units thus far organized, and there are many, we have as yet barely scratched the surface. And yet great work has been done, but the greater need and the larger field is before us.

The possibility of health preservation is not a fad, it is not a fanciful hope or an altruistic dream. It is a definite, precise and proven reality, the general acceptance and practice of which will not only diminish tremendous economic waste but it will increase human happiness and the length of human life.

In conclusion, may I ask you to pardon the injection of my purely personal opinion when I state that I have had the privilege of contact with a very great number of individuals of all classes through my life insurance work. I have in addition, the opportunity of daily bedside experience and I have been intensely interested and fascinated by this subject of preventive medicine. As a result of this experience I am convinced I am as certain as I could be of any truth, that if men and women will take the trouble to live according to the rules of hygiene, sanitation and preventive medicine already firmly established, the Biblical fallacy of three score and ten years of life as the satisfactory span for the chosen few could easily be relegated to past experience and that a new standard would easily be established which would grant those three score and ten years to the great majority and to a large proportion of the remainder a life of 80 years or even longer.

CHAIRMAN COTT: Mr. Walsh, will you please voice our appreciation of the Doctor's paper?

J. L. WALSH (Supt. of Safety, Missouri, Kansas and Texas R. R. Co., Dallas, Texas): I am sure we have all been glad to hear and greatly benefited by Dr. Geiringer's talk. It is a subject that has had too little discussion in our meetings. The safety work on the railroad was organized for the purpose of conserving life. You hear from the Doctor this morning what the economic loss is to our country from preventive diseases. I think it is up to the safety men of the country to take hold again and give to the members of your committees and employees of your railroads, the benefits which you got from Dr. Geiringer's talk this morning.

Most of our railroads have a hospital department wherein employees can get this physical examination without cost and I think it is clearly the duty of every safety man in the country to call attention of the employees of the railroad to the great importance of physical examinations. We may kill on our railroads 1,500 or 2,000 employees in the course of a year and at the same time during that year we lose 10,000 or 15,000 employees by a preventable disease. I am asking you if that is not a bad situation, when it is possible for us to get in on the situation and try to get our men to take this physical examination that means so much to us?

I think we have neglected this far too much. It is within our power and it is plainly our duty to get these facts before all the men on our railroad. As Dr. Geiringer said, it is pretty hard to get an old time railroad man to go to a Doctor when he is eating three meals a day and sleeping eight hours a day and feels in perfect health; yet from your own experience you know how rapidly those men between 55 and 60 years of age drop off, from diseases that could have been prevented. Their lives could have been prolonged by just a little time on their

part, either to the company doctor or any physician, to get this physical examination and find out what their condition is.

I am asking you men to give that matter serious consideration and let us endeavor to prolong the lives of our men by urging them to take this physical examination at least twice a year when they are above forty years of age. It is a matter that takes but little of time and a little effort on your part to get these men to do it. You all know how a railroad man hesitates to do those things and it will take persistent effort on the part of the safety men to bring about this result and I hope we will be able to do a great deal more in the future than we have in the past.

CHARLES E. HILL (Pennsylvania R. R., New York City): I think it might be interesting to the audience to know something about the character of the talk tomorrow.

CHAIRMAN COTT: We are without a report from the Committee on Present and Future Activities of the Section. Mr. Brennan, who passed away two weeks ago last Friday, only had his report drafted planning to complete that report later. Certain work has been done, certain files are available which are in the hands of Mr. Charles B. Hill, General Safety Agent of the New York Central lines, and the chairman who succeeds me, and he will probably find those files of use in planning the future work of this Section.

I am going to ask at this time if Mr. Bentley will please come forward and present the report of the Poster Committee.

Report of Poster Committee

By L. G. BENTLEY
Chairman

596,000 posters and 542,000 booklets were distributed by A. R. A. for 1928 campaign.

National Safety Council issued publicity material on Careful Crossing Campaign to more than 1,600 periodicals, and broadcasted messages over 100 radio stations.

10,000 copies of safety poster issued by A. R. A. were distributed to local councils throughout the country.

One article and one editorial were written on this subject in the May issue of *National Safety News*, and were reprinted in the *Lehi Valley Motor Club Bulletin* and many other publications of similar character.

I. C. C. records indicate the following for the first six months of 1927, as compared with same period for 1928:

	Accidents	Persons Killed	Persons Injured
1927 _____	2,561	1,062	2,901
1928 _____	2,634	1,097	2,934
	73 increase	35 increase	33 increase

During the year 1926, with over 22 million registered automobiles in operation, there were 2,492 persons killed and 6,991 injured in highway crossing accidents.

In 1927 with over 23 million automobiles registered, there were 2,371 persons killed and 6,613 injured in similar accidents. A decrease for 1927 over 1926 of 121 persons killed and 373 persons injured in highway crossing accidents.

The present chairman of the Poster Committee assumed the Chairmanship last April upon the urge of the Chairman of this Section because as I recollect the situation at that time there was no one willing to take up the burden and carry it on; and such indifferent success as has been attained in presenting bulletins

for the Steam Railroad Section of the National Safety Council has been hampered by the fact that the chairman of the Committee has been extremely busy. Not only in the preparation of bulletins for the Safety Section of the American Railway Association but the important work upon his own road.

I want to deal just briefly, and I think the subject merits some comment at this time, with the present situation as regards the production and distribution of posters in the Steam Railroad Section of the National Safety Council, and in order to give emphasis to what I want to say it is necessary I should refer to some comparable figures.

The committee on posters has endeavored to produce the same class of poster exactly as are being produced in the Safety Section of the American Railway Association. The only difference being that because of an agreement entered into between the Committee of Direction and the Executive Committee of the Steam Railroad Section,—one Section was to produce bulletins for railroad employees, dealing with methods of employee work and the other was to produce bulletins dealing with the public. That is the only difference in the class of bulletin. It is necessary to state at this time, that due to the fine spirit of cooperation that has existed and is now existing between the Safety Section of the American Railway Association and the National Safety Council executives, a plan has been worked out whereby the posters in both sections are sold at the same price, depending upon the distribution. Not only that, but sample copies of the posters of this section are sent to the Secretary of the American Railway Association and distributed to the members of the Section in order that they may see what they are asked to buy.

Gentlemen, I am firmly convinced that to expect Railway operating officers, even busy Railway Safety men, to look through a catalog of one colored posters and select therefrom and place a dignified order for their posters, simply because you are presented with about a one and one-half by two inch miniature, is expecting the impossible and I am strongly convinced by my experience that we should furnish to our prospective customers, a sample copy of what we are asking men to buy.

That has been worked out so that this distribution as you know is now being made. I want to say in connection with this distribution that before the present arrangement was worked out and the present chairman assumed the work, there were during the past year, produced 10 posters, the average sale of those posters being 2,500 copies. We have produced since that time, five posters and the sales have increased 100 per cent. The sales being 5,000 copies approximately instead of 2,500 copies and I attribute that to the fact that the customer sees that which he is being asked to purchase.

I would like to have some suggestions. I am sure the incoming chairman of the Poster Committee would like to have some reaction from the members as to whether or not they approve receiving all large posters. Previously we were allowed to distribute one large poster and three small ones, periodically. I have forgotten just how often but under the new arrangement we are only getting out one poster a month through the Steam Railroad Section of the National Safety Council. I would like to know, and you can give me some idea of your wishes now, by the uplifted hand. Those who are in favor of the small poster, nine by twelve inches, just that, exclusively, please raise your hands. Those who are in favor of the large poster, seventeen by twenty-three, please raise your hands. Thank you very much. I get my reaction by your uplifted hands. The Seventeen by Twenty-two is most popular and will be produced in the future.

During the past few months, Mr. Hale and Mr. Warfel have criticized the posters gotten out, not only in this Section but in the Safety Section of the American Railway Association. Their criticisms were constructive. They were the kind of criticism that a man who is striving to please the multitude needs. I want more of them. I want them in the Safety Section of the American Railway

Association. I want something that can be developed and please the people using these posters because, Heaven knows, my ideas in this respect are just about exhausted. I wish when you get the circular from Mr. Cobb about the public posters that you would place your orders promptly and as liberally as you feel like doing. Ordinarily a poster appealing to the public should produce a bigger sale than to the employees because you are appealing to the public on a subject that should influence millions of people. I do not know that I have anything further to say in regard to these posters we have gotten out.

I don't know what plan will be advised by the incoming Executive Committee but, my friends, I do want to take this opportunity of saying just one word about the Poster Committee of the Safety Section of the American Railway Association of which I am also chairman and speak of one poster particularly.

Last year we produced a Christmas poster and circular. Of that poster we sold 40,000 copies, and of the circular a quarter of a million copies. We are going to do the same thing again, I have given to the Secretary a copy of the poster that will be produced this year.

It represents a snow storm, a Christmas tree, the brakeman engaged in rushing between oncoming cars to adjust a knuckle and just at the point where he is about to be caught, the thought comes into his mind of his wife and children preparing for the Christmas tree at home; and we ask him at that time, and we would like to ask the question of every railroad man in the country, when he has an opportunity to promote safety and does not do it: "Will you make them happy or sad?" Gentlemen, that is the thought I leave with you.

CHAIRMAN COTT: We expect to adjourn at twelve so Mr. Bentley's paper will be carried over to tomorrow. We have time for two matters to come up. The report of Mr. Carrow which will be a treat, I am sure, because it will not only be a report but a travelogue.

I am going to ask at this time if Mr. Lewis R. Palmer will come forward and not take over ten minutes in presenting some facts and figures.

It would be very foolish for me to introduce "Green Book Palmer." You all know him.

The "Green Book" Report

By LEW R. PALMER

Equitable Life Assurance Society, New York City

I did not know just when this was going to be on the program and I did not exactly catch the time limit. The green book referred to went out in May and carried in it an outline of the safety contest developed by the National Safety Council, the railway employees National Safety Contest. The response that came in to headquarters in Chicago was most gratifying. The railway presidents, to whom those green books were sent, were most enthusiastic in their acknowledgment. I am sorry it will be impossible to give you extracts from those letters. It shows, however, that we have a right to be proud of the support that is given to our work by our railway executives.

The next distribution as most of you safety men know, was a photostat of the results of your work for the first quarter, 1928. I sent those out myself and the response that came back from the Presidents was most gratifying. From one railway system I received and have filed in one file, seventeen letters from the highest executive, the president. Also on down through the operating vice-president, district vice-president to the general superintendent.

I recall one letter that came in from the operating vice-president of one of the smaller groups. (By the way that railroad was in last place. I think it had a

batting average of 43.) The letter came in acknowledging it and said "you will be glad to note that we shoot a .15 now." That sounds pretty good for a bunch of farmers who never had a cue in their hands until recently. They have gone out to get to the top and are pretty well up the ladder.

One of the most gratifying accomplishments in railroad safety (and we are not mentioning any names) is, one of the largest railway organization in 1926 stood in 23rd place with .42. They did not like that so well and I think the next year they moved up to seventh place with .17. The first quarter of 1928 they cut that down to about .12 and one of the regions of that road now is shooting a .7. That shows what, regardless of where you were or what you are doing, where you can go and what you can do and of course being a large road I want to give those figures just to stimulate you, especially some of these groups and I am looking at one now. They had better get busy or some of these dark horses will run circles around them in the third and fourth quarters, which is the important thing.

In May, the president of the National Safety Council presented bronze plaques to the seven group winners. The Gorham people very kindly developed a plaster cast of this trophy; seven of them, duplicates, go to the winners of the seven groups. All that have seen it and had a chance to look at it close up agree it is worth while fighting for and that is what it takes to win in this day and age of Railway Safety.

The design is particularly interesting. The Spirit of Safety stands with a shield on her arm, the White Cross of the National Safety Council; and next to her, the executive and standing modestly behind is the Safety Representative. Then come the flag-man with the lantern and flag, the conductor with his watch, and the engineer with the oil can and goggles above his visor. (Of course he is in conference and it is all right for him to have them on his visor.) The shop man with the machinist's hammer and chisel. We discovered in the model it was a mushroom head on the chisel and we had to take it off. Then come the switchman and the track walker. In the corner beyond is the engineer with his rod and in the background is either a dispatcher or draftsman, whichever you want to play up to. The block signal is there also, then the rear markers on the side and the railway truck. It says, "Railway Employees National Safety Contest, 1927. Group Winner with the lowest total casualty rate," and the name of the road below—"awarded by the National Safety Council."

It has been most gratifying that what we set out to do is apparently going to become a fact, that is, that the contest for the reduction in total casualties is carrying with it a reduction in fatalities. That has been the thing that we have not been satisfied with. Although we have made a marked reduction in injuries, that fatal curve has not come down correspondingly. Any safety man that has had painful years of experience in safety work knows it is a darned hard curve to get down. It is a fluctuating curve, it does not always stay down but fortunately it does not very often go above what it was at the start.

The general trend is that if you keep hammering at it through your safety work, through your contest in injuries, you will get it down. Roads that have been working on the contest for years, the work they have done and accomplished in the saving of life proves that.

Sunday I went through the records in the accident bulletins as far back as 1923, which is the base line on which we compare the subsequent years' records. Nineteen twenty-three, you remember, was the year of the flood. Totaling those figures, men killed, injured, total injuries, total fatal injuries we find a reduction of 30.88 per cent, for five consecutive years, and the chickens for 1928 have been hatched and we knock wood on that basis. Estimating double what you had for six months of 1928, you will have 1,202 fatalities as against 1,866 for 1923. If you keep going as you went the first six months there will be saved on your railroads 664 lives in one year, 1928 as against 1923.

Now, I don't know of anything that should stimulate your increased effort more. I think it justifies you in going back and working even harder to make that thing a fact. Accumulative saving of total casualty amounts in five years to 215,426. Plotting the reduction, the casualty rate has been brought down in 1924 as against 1923, 11.46 per cent; 1925 as against 1924, 15.41 per cent; 1926 as against 1925, 22.70 per cent; 1927 as against 1926, 37.31 per cent, and 1928 as against 1927 47.41 per cent.

You are away ahead of your 35 per cent schedule at the end of 1930. That is about all that time permits. I only wish you could hear those splendid letters that come in from these railway executives. There will be distributed to the safety representatives listed in the membership of the National Safety Council, photostats of the work sheets kindly given to me by the Interstate Commerce Commission, showing for each region the second quarter figures, table 99.

CHAIRMAN COTT: Mr. Palmer, we thank you.

The next item on our program will be divided into two parts. You can tell when part two starts because of the fact that between part one and two Mr. Carrow will take a drink of water and take you over the water also. Mr. Carrow, will you please come forward and present part one?

Needless Waste of Human Life

By T. H. CARROW

Superintendent of Safety, Pennsylvania Railroad, Philadelphia

During the last thirty-eight years, 156,000 people have been killed and 169,000 have been injured in the United States of America, due to being struck or run over by trains while trespassing or walking on railroad tracks and bridges and unlawfully riding on freight and passenger trains. These figures make the staggering total of *352,000 needless deaths and injuries, or an average of 8,500 per year.*

Thirty-five thousand (35,000) of this great army of killed and injured were children under 14 years of age; 46,000 were between 14 and 21 years; 35,000 were hoboes and tramps and the remaining 209,000 were useful members of society, including clerks, industrial workers and professional people, the majority of whom lived in the communities in which they met death or injury.

Some people think that train wrecks cause most of the casualties on railroads, but this is far from being the case. As a matter of fact, fatalities to trespassers, that is, persons who have no business on the railroads, amount to eight times the number of all classes of persons killed in train accidents. It is even more impressive to notice that notwithstanding the inherent hazards of railroad operation, *one-third of all the fatal injuries that occur on the railroads are chargeable to trespassing on the tracks.*

This needless waste of human life is a sad reflection upon the intelligence of the American people and it will be stopped when the public spirited citizens in every town, city and community of the entire country become awakened to the full significance of this unnecessary killing and maiming of human beings.

Indeed, great improvement has already been made. Beginning in 1903 and up to 1915 the number of trespassers killed and injured on the railroads of the United States was about 10,000 per year, but the yearly average is now about 5,000 a year, notwithstanding a large increase in population and a corresponding increase in railroad business.

This magnificent result in saving human life and preventing untold pain and suffering is directly due to Safety Education in the home, the schools, the mines, the steel and iron industries and other manufacturing enterprises and to the general influence of the Safety First Movement which has been carried on throughout

the United States for more than fifteen years and particularly to the untiring efforts put forth by the railroads through their Police Departments to keep all persons off the tracks who have no business to be there. In this connection, the National Safety Council has given its unstinted cooperation to all the agencies mentioned.

To further prevent death and injury from trespassing, teachers, preachers, business men and women and all public spirited citizens are urged to use their influence in having these simple precautions followed:

1. Do not walk on railroad tracks or bridges.
2. Do not allow children to play around railroad tracks or stations.
3. Do not crawl under or between cars.
4. Before crossing tracks at crossings, Stop, Look and Listen to see if a train is coming, and after a train has passed make sure no other trains are approaching in either direction.
5. Do not crawl under crossing gates when they are down. Stop until train passes.
6. Do not allow children to play around turntables, cranes, cars or other railroad property.
7. Use the streets and highways instead of the railroad tracks in going to and from work.

As an indication of the possibilities of state, county and town authorities helping to lower the number of deaths and injuries from trespassing by the enactment and enforcement of appropriate laws, the accompanying table of figures are quoted from the records of the Interstate Commerce Commission for the year 1927.

ADJOURNMENT

October 3, 1928**E. R. COTT, Chairman****Supervisor of Safety, The Hocking Valley Railway Company
Columbus, O.**

The second session was called to order at nine fifteen o'clock by the chairman, E. R. Cott.

CHAIRMAN COTT: We are going to start our program this morning with an address by a chap who represents some 12,000 employees, an auxiliary of our railroad service. For a number of years the Pullman Company has had rather large delegations at our Sectional meetings. We have been favored by their quartette. These fellows from all over the country who have had the privilege of coming, sat here intensive listeners and I have had occasion to see some of the reports they have sent back to district headquarters following the meetings and I know they have been taking in every word of what was said.

The Pullman Company is doing about as good a job, if not better, than anybody else in the individual safety instruction of their employees and the Pullman Porter is in a measure the guardian of your passengers who occupy Pullman cars. I never in my life have found one in recent years, that did not tell me to "Watch your step"; who was not looking after my luggage, if I myself was careless about it; who was not on the job in the interest of safety all the time. So we have an opportunity this morning to listen to one of these boys and I am going to ask Mr. J. Wiley, Porter of the New Jersey District, to address the association this morning.

The Porter's Place in Safety

By J. WILEY

The Pullman Company, New Jersey District

The Pullman porter occupies a place in the Safety Movement of much greater importance than may be apparent to the casual observer. His attitude toward safety is somewhat different because he realizes only too keenly that an injury sustained by any one under his care means that a lot of his time would be taken up writing statements; and furthermore, that he may be censured for some act of commission or omission that he in some measure might be responsible for.

Safety has a triple meaning to the porter, because others are involved as well as himself: namely, his patrons and his employer. While the instinct of self-preservation is just as strong in him as in others, and while there may be hazards incidental to his occupation, these are not altogether his chief concern because "Safety First" has a different significance to him than to the average individual. To him it means safety for others—first and last—and an appropriate motto for the porter would be "Others Safety First," or "The Safety First of Others."

If, by his care and watchfulness, passengers are immune from accidents, then by the same token the porter is free from trouble. As he becomes more experienced in his work and observes and studies the various types and temperaments of his passengers, he becomes more receptive to ideas brought out at Safety Meetings, and out of his own experience he readily absorbs the doctrine and becomes a warm advocate of it.

Any accident, either serious or trivial, means trouble for him, and only by everlasting vigilance on his part can the majority of them be prevented. Very often the so-called "trivial" accidents are magnified into serious ones by unscrupulous

people, and the porter is never sure to what extent he may have to share the blame in spite of all his efforts and precautions.

The tenets and principles of safety are thoroughly drilled into each and every porter on the first day he becomes affiliated with the Pullman Company. Each applicant undergoes a thorough physical examination in order to make sure that he is in possession of all his faculties, and he is impressed with the fact that accident prevention is one of his most important duties. This is one of the reasons why porters, after a few months' experience, acquire traits which tend to make them one hundred per cent safety men. Furthermore, each one of his manifold duties, when properly performed and carried out in accordance with instructions, is primarily a matter of "Safety First."

It is his duty to make sure that all windows and door-catches are in proper working condition, that vestibule and trap doors and tailgates are in good working order. He must be absolutely certain that all equipment, such as stepping boxes, step ladders, mops, brooms, electric connectors, ice buckets, and the innumerable accessories used on his car are kept in the places designated, so that they will be out of the way of passengers getting on and off and passing through his car. In other words, the motto of the real porter is "A Place for Everything, and Everything in Its Place."

Sometimes, in spite of all his efforts, passengers will leave baggage in the aisle, thereby forming a tripping hazard. However, a tremendous improvement has taken place in this respect due to better supervision on the part of Pullman men, with the cooperation of the traveling public.

In addition to the initial instructions given the porter in the matters pertaining to Safety, he also attends the semi-monthly safety meetings at which he has the privilege of expressing himself freely on all matters concerning the safety of his passengers.

To the majority of people the definition of Safety is accident prevention. To the porter, however, it has the added significance of safeguarding the passengers' health, as it is the duty of the porter to see that the car is properly supplied with the necessary deodorizers and disinfectants which are used in any space that has been occupied by a sick passenger. He is governed by rules adopted from the most modern sanitary and health authorities. He must understand the proper ventilation and regulation of temperature in his car and must adhere strictly to the rigid instructions relative to the handling and disposing of soiled berth linen, towels, etc., to prevent the possibility of spreading disease germs.

Realizing as he does, that it is the little things that count, he is ready to drop everything to stop a passenger from opening or closing a car window, because he visualizes mashed fingers. The sight of baggage projecting from an overhead rack gives him a jolt because he knows that the lurching of the train might cause it to fall on the passenger. He must keep a sharp lookout for the children whose thoughtless mothers permit them to run around and stand on the seats where the movement of the train might throw them to the floor. The alert porter is always ready to assist passengers off and on the train with the verbal caution, "Watch Your Step," for in spite of the fact that this caution appears on the steps and vestibules of all Pullman cars, the traveling public is prone to ignore them.

Pullman Porters came into contact with thirty-six million passengers last year. The average porter believes that there is a divine spark in every man, so naturally he concludes that the majority of men are honest. The other type is best recognized by the following story, which although somewhat exaggerated, is more or less typical of some of the claims handled by public service corporations. The story runs like this:

A man and his wife were in a railroad accident. The husband was not injured, but the railroad settled with the wife for \$200 for injuries sustained. The husband

requested her to give him half of the money, but the wife stated that in view of the fact that she was the one that had been injured, she was entitled to the entire amount. The husband agreed, but reminded her that he was the one who had the presence of mind to give her a kick in the face at the time the collision took place.

CHAIRMAN COTT: I want to thank you, Mr. Wiley, for your contribution to this occasion. Mr. Gilbert tells me your paper will be published and placed in the hands of every Pullman Porter in the Pullman organization and I am sure it will be helpful to them.

We have a topic for item two of our morning program that should be of interest to every railway safety officer. Now, I think it is the wish of practically every Safety officer to have an opportunity to support the local Council and they do support it. There are a great many ways we can cooperate and spend money and like the travelling salesman's overcoat—it does not show up in the expense account.

There is no man better qualified to talk on the subject of cooperation between Steam Railroads and Local Safety Councils—can give us some new ideas whereby the Council itself may be of further aid to us and we ourselves further aid to it. I take great pleasure in introducing to you Mr. Girard C. Varnum, Secretary Manager, St. Louis Safety Council, St. Louis.

Cooperation Between Steam Railroads and Local Safety Councils

By **GIRARD C. VARNUM**

Secretary-Manager, St. Louis Safety Council, St. Louis, Mo.

The other day I was walking down the street in St. Louis and met a friend who told me of an experience he had with a friend of his. As he walked up the street his friend grabbed him by the hand and said, "Congratulations, John." "Thanks, but what for?" "I understand you made \$40,000 in the iron mines in Minnesota last week." "That is approximately correct. It wasn't Minnesota, it was Missouri. It wasn't iron, it was lead. It wasn't \$40,000, it was \$4,000. I didn't make it, I lost it."

Approximately correct. So is my introduction.

I want to say on behalf of the Local Safety Councils, we appreciate very much the opportunity of having a very brief place on this program and being permitted to talk to this most important Section of the National Safety Council. At the outset, besides acknowledging this courtesy that has been extended to me, I can't refrain from reminding you that we realize that in this group, represented in this Steam Railroad Section, we have perhaps the greatest group of safety advocates there are in this nation.

We realize this Steam Railroad Section has been for many years composed of men on the firing line, in the railroads of our country. We know that there is not a greater group of men and women in this entire United States concerned in this safety problem. The millions upon millions of dollars that have been expended by railroad officials for accident prevention in the cause of saving human life undoubtedly shows where the hearts of the railroad man are in this great safety question.

In the few minutes I am going to speak to you this morning I am going to try to touch on four or five fundamental things in connection with this matter of Cooperation between Local Safety Councils and Steam Railroads. At the outset

it seems to me, for the benefit of some who may not be as thoroughly familiar as others with the Local Safety Council activities, it might be well to state as briefly as possible what a Safety Council, a local Safety Council, is and why it is.

I hope you will pardon my referring to St. Louis occasionally, because that is where my experience lies, and that is where my contact with railroad men and others is.

Back in 1918, ten years ago, the St. Louis Safety Council was formed. Prior to that time a lot of agencies in St. Louis concerned with transportation, concerned with the management of industries, concerned with other means of moving traffic over the streets of St. Louis, had been attempting to carry on an accident prevention program. We had the public utilities, the street car companies, the taxi-cab interests and others—I might go on indefinitely naming the various types of organizations, many of whom had interested themselves in safety work. But I will confine myself mainly to the discussion of the street car company because that is the thing as like to the Steam Railroad as any of the others.

The street car company was trying to carry on an accident prevention program along the public streets and among its own employees; and it found, especially among the public, on every hand, its work was handicapped because the public said that it was just another scheme of the company to save money to reduce claims. Their efforts were handicapped because they said it was a selfish proposition on the part of the street car company. Finally, a group of business men got together and said, "Let us form a clearing house to handle this question of safety as concerned with the city of St. Louis. Let us pool our interests on this thing and let us form an organization and call it The St. Louis Safety Council," and they did.

Immediately they began to work out through this local Safety Council a plan of Industrial Safety work and a plan of Public, Home and School Safety work; and the great value that this local Council has had and that every local Council will have if properly organized, is that it was non-political, non-commercial, non-profit making and non-sectarian. A local Council is just like the safety movement itself. It is a leveller of humanity. In it you will find every class of people represented. You will find the Catholic, the Protestant, the Jew, the Democrat and the Republican. The safety movement knows no race, creed or color.

That is the great fact at the outset in this Safety Council work, because when a group of men who make up the Executive Committee, representing the various interests, meet around a table and consider a problem, whether it pertains to the street railway company as related to the public, or some other branch, the ideas of all are considered. It is never a proposition solely selfish in its nature. It must be something to benefit the public, this measure being considered, and it must have the approval of all these people who make up the various interests in the Safety Council before the Safety Council as a whole will endorse it. That is the real value of a local Safety Council.

Now, on our work in St. Louis we have gone first into industry. And it seems to me a Steam Railroad—of course it is a transportation industry—but it may be likened very much to many of our manufacturing industries in St. Louis. We went to the heads of these industries and said, "Some of you have organized accident prevention work and some of you haven't"—but confine it to those who have. Here is the situation we found, and it is bound to develop on every railroad in this country. I know all of you have the greatest respect in the world for Isaiah Hale and I am going to use his name. For Hale is a fine speaker on the subject of safety, as fine as there is in the United States. There isn't any question about it.

He is a wonderful speaker and he goes up and down the properties of the Santa Fe Railroad and talks safety to those men. Regardless of how much they

like him, the time is going to come when perhaps his talks are not going to appeal as much to those men as they did in the beginning. That doesn't pertain as much to a railroad as a manufacturing plant where all the employees are inside of a fence and the boss talks day after day, and they know him well; and after a certain while, it goes over their heads, in one ear and out the other.

Now, then, the local Safety Council comes into the picture, in this way. When they are having meetings at different times throughout the year, semi-monthly, monthly or whatever, the Council can work in cooperation with that railroad just as it does with industry, furnishing new blood in the way of speakers, furnishing safety films of the National Safety Council. There are others, too, the injection of new ideas to these people concerned in railroad work in our particular local communities. I think it is a very important service that the National Safety Council can render to the employees of any local railroad. For instance, we have taken the Judges of our City Court Bench to the various organizations and they have very gladly given their help that way.

When those men appear, representing, as they do, the Government of a city and a people engaged in this safety work, when they come before these group meetings of employees, regardless of who they are, whether in a manufacturing plant or employees of a Motor Bus Company or railroad, it makes no difference, here is the thought sold to these employees: This is a wonderful movement in which we are all engaged in saving life! And as a man sits in the audience and sees one of the judges of our courts standing before him, taking his time to make this safety problem impressive, telling of the people that are coming up before him and the reasons he is dealing out a certain type of punishment, he is impressed. Perhaps at the next meeting we have the Director of Streets and Sewers who tells of the work of the National Council on streets and highways. All of those things are appealing to those men in the ranks; it shows them the enormous scope of the safety movement, and impresses them. They are one small cog in the wheel; everybody must put their shoulders to it. And as a result we believe that service is very valuable to our local people regardless of whether they are railroad or manufacturing industries.

I only mention that one thing, as an instance of cooperation between the Council and the members in an industrial way, because I realize the largest percentage of the difficulty in safety work in the railroads is among their own employees, and that is a cooperation we want to build up in St. Louis further than we have. The cooperation directly between our employees and the organizations.

Who makes the work of a Safety Council possible? We have various types of membership. Industrial membership, Public Safety membership and under Public Safety we have Class A, B, and C. Class A is a concern like the Street Railroad who pays a percentage of the claims paid the previous year as an investment in the Safety Council work. Class B is a \$10.00 a year personal membership and then we have a two dollar a year membership where the people are members of the Safety Highway Club. In St. Louis at the present time we have practically every group supporting us actively and financially.

In our work with the Steam Railroads, there was a time not so long ago, perhaps a year or a year and a half ago, when we felt just a little bit bitter about it. To think that the Steam Railroads were the only large transportation group doing the safety job throughout the country that had not come in and supported us along with the bus companies, the street car companies, cleaners and dyers, and all the other groups I could go on mentioning—coming in and paying their proportionate sum and giving moral support in addition to the work we are doing.

Gentlemen, we have just about come to this conclusion, that perhaps it is not the fault of the Steam Railroad companies that they are not supporting us and other local councils. Perhaps it is our own fault and the fact that we have not

been able to sell them this idea. Many times a business man needs a certain commodity but if the salesman selling that commodity hasn't salesmanship ability enough he does not buy it. That may be true in the Steam Railroads. But we are looking forward to the time when we can get on an even basis of understanding with our friends among the Steam Railroads, and here is a definite recommendation that I would like to make: To the Steam Railroad Section of the National Safety Council I would like to recommend that a Local Steam Railroad Section be formed in the local council cities and that this Steam Railroad Section be composed of representatives to be selected by the president or the safety supervisor or whoever should do it, of each of these local roads running into the particular city, who would sit on this local session and determine what its activities should be, and the chairman of that Section be accorded a place as a member of the Executive Committee of the Safety Council.

There are many things I haven't time to touch on this morning that a Safety Council with such a Steam Railroad Section could do. With an arrangement of this sort the things that were actually done by this Steam Railroad Section would be entirely in their own hands and the hands of the Executive Committee. The chairman could very easily work out the plans and supervise them and approve them so that the local Steam Railroad section would have the push and backing of the entire Safety Council in the community.

It seems to me that would be an admirable arrangement. In that manner, any matter of expense concerned would be minimized just as far as possible because the program at the beginning of the year would be worked out and a budget arrived at as to the amount of money needed to support this Steam Railroad Section and then the method of securing it could be very easily worked out.

There is one thought I want to emphasize before I stop this morning and that is this: In any well organized local Safety Council we are not just coming to the railroad and asking them for their moral and financial support. I know how it is in many of these smaller cities, many of them do not have local Safety Councils. They want to start some sort of a movement to support, for instance, the National Council on Streets and Highways, and the first fellow they think of is the railroad. Without going anywhere else they run up to the railroad and present their desires. It is not fair. I agree to asking the railroads to come in and support something, but not unless the others are doing their part. But it does seem to me, especially in every large city where we have a local Safety Council and where we have the support on every hand by the transportation interests, by the industrial people, by the business and commercial people of our city—then it does seem to me that some sort of cooperative plan should be worked out between that Safety Council and the largest transportation group running into the city.

One thing more: Some time ago I was discussing this matter with the divisional superintendent of one of our big railroads, and he said to me: "Well, we don't have any tracks in St. Louis." "Well, what has that to do with it?" "Well," he said, "it has a lot to do with it." I said, "Supposing you had an accident on those tracks?" and I walked to the window and pointed to the tracks. "Does't your train pass over those tracks? Supposing you have an accident, who pays for it?" "The Terminal Railroad Section pays for it." "Who pays them?" "Well," he said, "we do."

Even though your tracks don't run into the city, if your trains run over those tracks, you certainly have a definite responsibility at every grade crossing where your trains run; you are going to have to pay the bill the same as if your tracks ran through. It is true. No question about it. If you can only prevent one small accident in a city, it is going to far more than pay for any contribution or membership that any Safety Council might be asking you to pay in any Local Council community.

I think that about covers the thing I have in mind and I want to thank you for the opportunity of being here and I hope we will have a chance to work out a real constructive agreement between the Safety Councils and the Steam Railroads.

CHAIRMAN COTT: I am sure we appreciated Mr. Varnum's outline of the subject of cooperation. He has given us a new thought that may be helpful and may be worked out. I am going to ask if Mr. W. H. Jones, Assistant Director of Safety and First Aid, Canadian National Railways, Montreal, Canada, will respond to Mr. Varnum.

MR. JONES: I certainly appreciate the opportunity of representing a young country like Canada in this wonderful country of yours. Especially in view of the fact that you people just 100 years ago were where we are today in Canada, from the standpoint of (what shall I say) enjoyment of Liberty, progress and development. But yet, with a young country like Canada, our railway situation in Canada is not (what shall I say) 100 years back of you. We are just as modern in railwayism as you are in the United States, due to the fact, as you suggested, that the Steam Railroad Sections in different localities should be represented on the local Safety Councils in the different communities. May I assure you, Mr. Chairman, that in Canada with all our beautiful cities, there isn't a city in Canada that our railway members are not members of the local Safety Council. That is something for you when I again repeat we are not so backward with our modernist railways in Canada.

Personally I have a very happy recollection of hearing Mr. Varnum a few years ago in St. Louis, and we shall always remember that very effective address he gave us at that time. You know two cities today that are so similar in my estimation are St. Louis and the humble city of Montreal, from which I came this morning. I will tell you why. They are notable today because everybody knows one is the city where the Spirit of St. Louis is famous and Montreal is the city of spirits.

That reminds me of a little Church in London, England. I understand some of you don't respect the railways so much over there. But they have a little church in London and it happened to be necessary from an economical standpoint to rent the space above for commercial purposes and the space below for religious work. It so happened the above was rented for a saloon and this is what they said of it. "The Spirits above are spirits of wine, the Spirits below are Spirits Divine," and those are the two spirits so popular between Montreal and St. Louis.

But, getting away from any attempt of looking at things in a frivolous manner this morning, I may say that this Convention is at this time a very sad one to me personally. I noticed in the original program outlined for this Convention that the man who was to respond was a man of eloquence, who could have done the work 100 per cent efficiently. And I am looking into the past of a few weeks ago of our popular friend, Mr. Brennan, who has passed away. I think, gentlemen, we are human enough to look into the past association with a real staunch, loyal friend as we had in Mr. Brennan, and at this hour, if you will permit me, couldn't we be human enough this morning as a little memorial to stand in silence for a second? Let us all rise. Shall we bow our heads?

Almighty and Infinite God, we come to Thee with a Spirit of humility and gratitude, realizing Thou art the Creator and Sustainer of all good things, that we are but little. In our smallness we approach unto Thy Presence at this time with gratitude in our hearts that Thou hast made it possible for human fellowship and associations, and we realize that Thou hast created in us that spark of fellowship. We Thank Thee that Thou art a God that makes manifest unto us, Thy Self.

Oh! God, we look up and revere the adornment in Thy Majesty and Glory but we thank Thee for the gift of Fatherhood—that relationship that makes each and everyone of us to regard ourselves as brothers and sisters. And as we come to Thee with our hearts full of grief that one of the links of our association has been

broken, grant that the Gift of immortality may be placed on these humble and human associations, and that looking up unto Thee, we may sometimes declare our best friends are up There.

O! God, grant that these human associations shall not be broken but continue to all Eternity when we shall be called, all of us, to Thee. Hear us in our humble pleading and bless those who are mourning; give them the gift of strength; succor to sustain the losses of human life. These prayers we ask in simplicity, with the forgiveness of our many sins. We ask it in the Name of Jesus. Amen.

CHAIRMAN COTT: While Mr. Varnum was talking I was reminded of the method of the local Safety Council in Toledo to secure the cooperation of the Steam Railroads in this particular instance in cooperating with them. The local Safety Council there, three winters ago, introduced a series of Railway Safety rallies. Several of the gentlemen in this audience have addressed them, Mr. Bentley, I see here; Mr. Hill also. He addressed them two or three times. Mr. Carrow has been there, Mr. Shedd was to be there, I don't know whether he got there or not. But some of you, at least, have had the opportunity of attending these rallies. They sell tickets to the railway company, which tickets in turn are given free to the employees.

These rallies have been highly successful. They have had from 900 to 1,600 railway employees and members of their families to these winter rallies. In that manner, the railways have helped to support the work of the Local Council because they have been profitable. The railway safety officer running into Toledo, and I think Mr. Hill, and every one having a line running in that town (and there are about thirteen of them) will agree that the work has been helpful in every respect. It has created a new interest and enthusiasm.

That is a thought I would like to leave with you; some of you who have local Councils in your City or along your line, that such a similar plan might be worked out along your railroad. You will find it both helpful to your Council and to your Railway employees.

The next item on our program is item five of yesterday's session, by L. G. Bentley. I don't need to introduce "Safety First Contest" Bentley, everybody knows him that has ever attended a Railway Safety meeting.

Safety Contests

By L. G. BENTLEY

General Safety Agent, Chesapeake & Ohio Railway Company, Richmond, Va.

I have within the past seventeen years enjoyed many privileges within the gift of this Section, but never have I enjoyed any privilege which carried a more vital spark of good for the Association than the privilege that confronts me today, of talking to you about Safety Contests which in the very expression itself, signifies the bringing out of the best there is in mankind.

It is in my mind to talk to you about Safety Contests today, somewhat on the basis of my own experience, the manner in which we have organized Safety Contests, the method of conducting them and the degree of success that has attended our efforts. There are many others present who have gone farther than we have and I have it in my mind that an opportunity should be given to such men as Tom Carrow, George Warfel, Art Rohweder and all of these other live fellows, that they may tell you what they have done in their safety contests.

It is my other thought that we should enter this discussion with this thought in mind. Safety contests are righteous. They are right, not only because they have saved lives and limbs and suffering and the loss of money, but because they

link more vitally those interests of foremen and men, those interests of management and employees, with the result that not only is there greater safety but there is a more harmonious contact between management and men. There is a cleaner organization from top to bottom and there is a more efficient organization. There is a speedier service and a smoother service. Whether we would acknowledge it or not, those of us who are actively prosecuting safety contests, those of us who are not, are in the midst of a National Safety Contest calling for a 35 per cent reduction of accidents, or greater. If we can organize local activities on our own line that will bring us even beyond that goal and those of us who have not yet reached that goal, so much the better; and it is my hope that this part of the program may influence some railroad safety man who has not a safety contest on his line, to return to his property and start one forthwith.

In the days gone by we have had "Safety Weeks," safety months, spirited safety contests that were effective for the time being but not permanently. A definite thought that I would leave with you, every representative here today, is this: That if you contemplate a safety contest it must be an institution and not an incident. There is a difference. An incident is something that comes and goes, its influence is but transitory. It is with us today and forgotten tomorrow; but an institution is something that is founded on a solid basis, it is progressive, it remains permanently with its everlasting influence. Therefore, let us make our safety contests, not flashes, but a strong, illuminating light that will be perpetuated in our organizations as long as they are organizations.

Safety contests must be fair. And there are various ways in which advantages may be taken by local organizations. I want to touch upon them. In the first place they must be departmentalized so that the spot-light of approval may rest upon successful organizations and a helping hand extended to those that are not so successful. Then, by organizing our safety contests by departments, let us put them on a fair basis.

May I refer to the manner in which our safety contests are organized? We have five groups; briefly they are: the transportation groups, the several divisions on our railroad and embraces the trainmen, the station employees of those divisions. Our main shops are grouped under the master mechanics. We had a second group which comprised outlying shops under the general foreman. We have a maintenance of way group, which includes all the track and bridge men within the supervision of each divisional engineer. On some railroads they are called assistant superintendents. Then we have a supply department group.

The bulletins I am going to mention just at this time, that we get out monthly showing the standing of these groups, have some significance. The white bulletin covers the supply department, because on our railroad the supply department is noted for its cleanliness, for the shining spotlessness of the supply department premises. The blue bulletin has reference to the large shops—dark blue because of the blue flag that protects the men working under or about cars. The yellow bulletin has reference to the track men because we use a yellow flag on our pump cars to protect our men. The green bulletin refers to the transportation department because green means "Safe"; and for each one of these bulletins the color of the bulletin is selected, as I mention merely as information.

We use the man-hour as a basis of determining the exposition to hazard. We believe that the cause of an accident which renders a man unfit for duty for twenty-four hours may be in itself as serious as the cause which renders a man dead. At the same time we believe that there should be a penalty attached to a death. Hence, we have weighted our accidents in this way. A fatal injury is penalized at five debits, and a reportable injury at two debits, and a loss of time injury at one debit. Therefore, we have all of these classes charged against the several units and several groups by debits. Our reason for penalizing for a death only five debits, whereas it is customary to penalize fifty, is that in some units,

as I mentioned a few moments ago, when a man is killed the cause of that accident may not have been any more serious than the one that took him out of the service for twenty-four hours; and if we penalize that at fifty debits and that unit had had but very few injuries, they would be discouraged for the balance of the year. There would be no opportunity to recover ground, and we have found that to penalize five debits for a death, two debits for a reportable injury and one debit for a loss of time is fair and gives every one a chance.

Reporting accidents. It has been my experience that if there is the right kind of an interest in a safety contest, you cannot hide your injuries. I have heard some comment and criticism on my own property, that I have heard nationally. Gentlemen, please remember that in criticism and suspicion, success is a shining mark, and if in directing your safety contests you have one unit that is disposed to say Bill Jones is ahead because he is covering up his accidents, the best way in my opinion to determine the fallacy or the truth of that allegation is to get that complaining unit to send a committee over and investigate the records of the other fellow. We have done that and we found he had a clean bill of health.

Nothing could inspire that complaining unit more to do good work in his safety contest than to go over there and find the other fellow is actually doing the work he says he is doing. If I should find within our organization a unit that was willfully covering up and not reporting accidents I would bar him from the contest for the balance of the term, and this is known.

There is another feature that enters into safety contests, that is extremely valuable if properly conducted and it may be the reverse if it is not, and that is in getting the injured man back to work. The time has been on my railroad and on yours when we knew (but we could not confirm) that men were remaining away from work when injured, for their own purposes. There was no check on their disabilities or on the time when they might be returned to duty without detrimental effects to themselves or the work which they were engaged in and the consequence was we were charged with hundreds of injuries that were not, as Mr. Cott says, injuries at all.

The safety contest inspires the foreman, the supervisor; it establishes a policy in regard to these matters, to the end that men are returned to duty as soon as they are physically able to do that work efficiently. On the contrary, fellows, I can think of nothing more discouraging to an organization, and nothing which would more quickly point the finger of suspicion at any organization contesting, than to go into that organization and find men working with their arms in slings or hobbling around on crutches. We will not have that in a 100 per cent safety contest.

Once more, what does the safety contest produce in a safety organization? It produces a fact-finding commission. If your safety contests are what they should be and what they can be made to be, those responsible for the standing of those several units are going to find the facts in regard to accidents where that responsibility belongs. I have been before committees investigating accidents when the words were put into the mouth of the witness by the examiner. You will never find the actual cause of an accident or trouble if your investigations are conducted in that way. I believe any accident that occurs on any railroad or in any industry is sufficient cause for an investigation because although that accident may have caused the loss of but nine hours' time, it might have resulted in death.

Statistics in regard to safety contests. I have a word to say on that. I do not believe a mimeographed sheet tacked on the wall is sufficient evidence by the management of an official interest in that contest to justify the units in contending with their whole hearts and souls.

I do not believe, that if it is worth while to engage in a safety contest to save lives and limbs, that contest justifies the getting out of a bona fide, dignified, impressive

and printed report so that every unit that is contesting may know at a glance where he stands and what difficulties he has got to climb over to get to the top. And let these details of statistics be so simple that even the most ignorant man can read and understand them. I believe that an occasional telegram from the president is worth while. "The love of praise how e'er concealed by art, reigns more or less and grows in every heart." If you have the contact with your general managers which will justify him in signing the telegram, even if you write it, complimenting the organization on its showing, you are not only going to encourage that unit to do better but you are going to put before the eyes of that general manager, so that he will understand and therefore be interested in the telegram he has sent. Many an officer has been influenced to give cognizance of such things as that by having to sign a letter he did not know anything about.

Another effect that safety contests have on the physical property and therefore on the personnel of an organization, is the fact that it induces cleanliness. The efficiency of your organization is advertised by the degree of cleanliness there is in this organization and the men take their cue from the physical cleanliness of the premises wherein they work.

Safety Boards for the Posting of Bulletins. As I intimated a moment ago I do not believe in tacking bulletins of this kind up on the wall. I believe in providing a regular and dignified and attractive place where those men may see where they stand. I believe a large bulletin board showing the standing of the intimate units of that unit as you might say—take a large shop wherein there are ten departments—make that board progressive. Have a vertical column for every day in the month and have a horizontal column for each department in that shop and let there be recorded on that board every morning, before the night shift comes off and the day shift goes on, what has happened in that shop the day before, so that these men as they come to work and go from work may know that that shop is interested and is recording promptly and in a dignified manner exactly where that organization stands. The boards should be lighted and then the night men can see what is going on. They should be absolutely kept up to date. Nothing in my mind could be more discouraging than to go down through their plant and see where their records had not been posted in four days and I have found such conditions on occasions. Then, I would say a word about trophies.

Thomas Carrow has some very beautiful trophies displayed in this auditorium. George Warfel has some beautiful silk flags and banners on his railway. My friends, they are necessary. They ought to be displayed, but they are not the whole story in a successful safety contest. Happy is that man who when there is a question of success, looks into his work for the reply. Not into the market for his services, not into the praise of friends but into his own consciousness of a job well done.

There must be love of achievement if we would make our safety work successful. It was the love of achievement that inspired Alexander to conquer the World. It was the love of achievement that induced these great engineers to build the Castleton Cutoff and to bore the Hudson tubes. It was the love of achievement that sent Byrd and Lindbergh to France, and Byrd to the North Pole. Others have flown, they have flown for gold, they have flown for fame and the plaudits of the Nation; but these two men flew for the love of achievement and nothing else.

Let us take a page out of the book of these boys when we would go back and start our safety contests and let us plant in the minds of our officers and the minds of our men, the love of achievement; that regardless of trophies or any other visible evidences of efficiency, will spur them on to the saving of human life. Friends, we do not need these trophies if our organizations are right. We cannot see God but we believe in the righteousness of His campaign of salvation.

We do not need these trophies if we can get our organizations so closely knit, so interestedly working for the mutual good, that they will work really for the love of the work.

CHAIRMAN COTT: Gentlemen, before we have the next paper we have approximately fifteen minutes which might be devoted to a discussion of safety contests. Mr. Hill and Mr. Carrow and Mr. Warfel and Mr. Bailey have been doing this work for a number of years. We have all had Safety Contests of one kind or another and I think we are deeply indebted to Mr. Bentley for his splendid presentation of this subject and we suggest now, that we do devote, not to exceed say fifteen minutes, at this time, to the discussion of safety contests. To get it started I am going to ask Mr. Thomas Carrow to say a word or two on the safety contest.

THOMAS CARROW (Pennsylvania Railroad, Philadelphia): Just to disabuse your mind that there is nothing cooked up between Mr. Cott and myself, this is the first time I knew we were going to talk about this. Bentley's talk crystalized the thought in my mind that I am going to give you for what it is worth.

The reason we have had to have contests, I think, to a very large extent, is because we had no data suitable for executive action. Here is what has transpired in our management. The contests are now a part and parcel of the means that our management used to drive home accident prevention and as soon as these figures are regularly systematic, as Mr. Bentley says, and intelligently prepared, particularly in a manner becoming to an organization such as we represent, then the people become cognizant.

Our contest, very briefly, consists of a comparison of the performance of the respective departments of our four regions in the Altoona Works. Those several departments are listed separately and stacked up one against the other. The original conception contemplated the division would carry on a similar contest, but I am ashamed to say our divisions have not as yet been sufficiently advanced to do something that would add to the management's contest. But it is my intention in the coming year to have every division of our railroad pitted against the several departments of the region.

In addition to that, the general manager gives a gold banner to the region having the best record and a silver banner to the one having the best reduction. Now, here is what happens with systematic, excellently prepared records. They go to the highest officers and the highest officers themselves have a part in the performance and they cannot witness the stellar champion all the time without recognition.

One more second and I will tell you how it is ramified. I had occasion to go into a bank president's office about a matter involving safety and I referred to these plaques over here and he said, "Yes, I saw them at the Board of Directors Meeting." The vice-president was a member of the Board of Directors and every month we put up the standing of the several regions of the Pennsylvania Railroad in the Board Room of the Board of Directors of our railroad. And so far as I am concerned, if the Pennsylvania Railroad doesn't make a good record it is nobody's fault under God's Heaven but that of T. Holmes Carrow, formerly of North Carolina.

CHARLES E. HILL (New York Central, New York): The New York Central lines were among the pioneers in the handling of safety contests. We started contests about five years ago and I shall state briefly how they are conducted.

We have twelve railroads that make up the New York Central lines and we divided them into two groups—A and B—based upon mileage, and we conduct an annual contest allocated to these two groups. The trophy you see here, next to those displayed by T. Holmes Carrow, is one awarded by our president, Mr. Crowley, to the road that makes the lowest employee casualty ratio for the year. We have two such trophies. The roads in group A are competing with each other and the roads in group B are competing with each other. While we have been

conducting contests for many years, during the past three years they have been on a more systematic basis.

We also have evidence in the board room of our Directors. On the 28th of February of this year we had a meeting in the board room of the New York Central in New York City at which time our president, Mr. Crowley, in person in the presence of every general manager and operating vice-president and practically every general officer of the entire railroad and a good many of the members of our Board of Directors, made this award to the two general managers on whose roads the trophies had been won for the year of 1927. In addition to the contest by roads, we also have departmental contests on a quarterly basis. We have our department of contests somewhat similar to that mentioned by Mr. Bentley. We have five major departments, transportation, motor car, rolling stock, maintenance of way, and stores.

These departments are competing with the same departments of their respective units. That means that each of these five departments has an opportunity to win a safety pennant four times each year. We publish monthly bulletins showing the standing of the respective roads, cumulatively and also the standing for the current month. In addition, we publish quarterly the standing of the respective roads and the different departments in their contests; and I want to tell you that there is no pamphlet that is looked for more eagerly, not only by the employees on the firing line but by the president of our railroad, than those bulletins and pamphlets.

They are considered almost sacred, by reason of the important part they bear in the operation of the railroad. I deem it unwise to take much more of your time, but I should like to go into just one other feature in connection with these contests.

We have, as I stated, many roads that make up our system and in addition to the other activities, quarterly we have staff meetings of the respective heads of departments of these different roads, at which time we display photographic charts showing the standing of the roads and respective departments. We assume the role of a physician and become a little more analytical and we go down and point out the weak spots, and those who may not know just how bad they are, begin to squirm, when they see those long lines.

I sat in a luncheon meeting in Cleveland last Friday at which time we had such a display of charts. The head of one of the departments referred to a similar meeting just one year previous at which time there was hardly room on that chart to give the length of line showing his standing; but he was happy to say at this particular meeting last week, the line had been materially shortened. In fact, it had gotten back to almost the edge of the figures, and he told some other men why it occurred. I rather suspect that the other officer whose standing is not so good will be in good standing next year.

It has awakened the safety consciousness of the men more than any other agency that we could employ. We could speak all day on this subject because I feel it is so important in the conduct of our Safety work that I should never think of stopping that particular part of our efforts.

MR. HARTENSTEIN (Lehigh Valley Railroad): In listening to the other speakers I don't see but very little difference in the conduct of their contests than on my road. We have conducted several safety contests on the Lehigh Valley Railroad. We started off on thirty days' duration. The results were fine. It resulted in substantial reduction in accidents but the last one we had was for a period of ninety days and it became stale. I would like to hear from some of the other members as to what they think the duration of a safety contest should be.

CHAIRMAN COTT: Mr. Hartenstein puts the question: They have run a series of contests for thirty days and they have had excellent results and they attempted

to carry it over a ninety day period and it became stale. That is contrary to Mr. Bentley's theory of an annual contest. It brings in a new viewpoint.

MR. HARTENSTEIN: Before an answer comes—when we had the ninety day contest we kept behind it with all the force there was in us but it grew stale just the same.

D. G. PHILLIPS (Wabash Railway, St. Louis, Mo.): When you get on this contest question you are getting on to something that means a lot to me. I want to say frankly that the splendid safety record we have on our road today, which is the Wabash, is largely due to the safety contests that we carry on. I don't want to steal any of George Warfel's thunder but you all know that the Union Pacific Railroad (at least you suspicion it) has a good safety record.

Last May at Chicago, prizes were presented, one for good safety records; one of these was presented to Mr. Calvin, operating vice-president of the Union Pacific system, and here is what Mr. Calvin said when he accepted that tablet. He said, "I attribute a large measure of the success of the safety movement on the Union Pacific Railroad to safety contests."

Now, if the Union Pacific made their good record based on contests, the rest of us can. I want to refer to what Mr. Hartenstein said. I don't believe that a thirty day contest is long enough, even in spite of his experience. Our experience has been not only to make the contest for a year, but to make the prize or trophy that is awarded by the president to the various departments, only a temporary property of that division or the department winning the prize. That is, we have five trophies offered by the president to about the same departments as Mr. Hill and Mr. Bentley spoke of. At the end of the year that trophy goes to the department or division making the best record for that year, but only to be held by them during the next year. Our president, in order to avoid some one saying that it is a scheme to make money, with the presentation of each of the five trophies, provides a substantial sum of money so that the winner can have an entertainment and dance, the value of which is much more than the trophies presented and the trophies themselves are to be at least \$150 each.

Here is the reason we have done that. It is a whole lot more pleasure. It gives you a lot more satisfaction to take something from the other fellow than to get the original in the first instance. I know as a boy it gave you a lot of pleasure to take that apple away from your brother, more pleasure than if your father had given it to you in the first place. And we have found out on our railroad, we have more enthusiasm when one division or department wins the prize; it becomes a slogan. All the other departments want to take that prize away from that division.

"Boys! Let's show them how we can do it," and we have never had the least bit of difficulty in keeping up interest throughout the entire year.

Just one more comment. I don't care how bad a record any railroad has if they will establish an honest to goodness contest system their records are going to be good. I don't care how good your record is, if you establish such a contest system it is going to make it better.

ROBERT SCOTT (Atlantic Coast Line Railroad, Wilmington, Delaware): It has been with the greatest difficulty that I have sat in my chair since the convention opened yesterday morning, because there have been so many interesting things under discussion. When you come to the subject of contests that is something I am very much interested in and I am sure all of you are. I think we should have contests. It was back in 1923, at Salt Lake City, that Mr. Carrow shook the whole United States with his proposition that we conduct a seven-year contest on all of our railroads. I ask Mr. Hartenstein, has interest waned in the slightest in that contest? Backed up by wonderful statistics Mr. Carrow has given us from time to time, hasn't our contest become a heated one?

I just want to cite you one instance of a contest on our system. We have a contest between our big shops. It has been run now for almost three years. It took us one year to get started, and last year was the best of all except this one; and I believe, gentlemen, if you want to do as Mr. Phillips says, make a bad record better and a good record still better, adopt the contest method and you will put it over. One of the shops I mentioned in 1923 had 249 personal injuries and in the first eight months of this year they have only had eleven personal injuries. That shows you what can be done by contests.

CHAIRMAN COTT: Mr. S. H. Osborne, Engineer, Maintenance of Way, Union Pacific, R. R., Omaha, Nebraska, will speak to us on "Motor Cars—Their Use, Care and Operation."

Track Motor Cars—Their Use, Care and Operation

By S. H. OSBORNE

Engineer, Maintenance of Way, Union Pacific Railroad, Omaha, Neb.

The maintenance of railroads presents two distinct branches, namely: the construction, inspection, and repairs to power, rolling stock and machinery, centralized at terminal points where concentrated supervision can be continuously applied; as compared with the construction and maintenance of track, bridges, and other structures, presenting a more difficult problem due to distances and necessity of transporting men and materials to and from the work.

A retrospection of the movement of men in the earlier days of the railroads brings to the memory of many here assembled the laborious hand car with its varying speeds of from two to six miles per hour, the operation of which with adverse grades and prevalent head winds encountered, resulted in the gang expending a considerable portion of the available man power in simply arriving at the point where the daily operations were to begin. In addition, there was more or less resentment filtering through the minds of the workmen a long time after this strenuous effort to arrive at the real work of the day.

In the early 90's experiments were made and some progress experienced in the development of gasoline engine propelled track cars. These, however, were makeshifts as compared with present types of cars, and it was more than fifteen years later before any really satisfactory improved type had actually come into general use. Today there are more than 55,000 track motor cars in service on American railroads representing an investment in excess of \$12,000,000.

It is obvious that such a large expenditure must have been justified beyond any question of doubt by fundamental economies and increased efficiency of forces having been obtained by the use of track motor cars.

The primary function of a track motor car is the transportation of men and tools to and from the work. In the bridge and building and water service departments, considerable quantities of materials used are also handled by track motor cars. Quick movement by track motor cars results in direct savings, in that the full efficiency of the gang is reserved for the day's work, but little effort being expended in arriving at the job. While there are no supporting figures to substantiate the savings made, it is evident that a considerable loss is prevented in the labor turn-over being minimized by the use of track motor cars.

Another feature in which the motor car has proven its efficiency is the quick mobilization of forces in emergencies to either reduce or prevent entirely traffic interruptions.

The additional uses made of motor cars are many. Various railroads have reduced hand work to a marked degree by the use of mechanically operated labor saving devices, propelled by the motor car or its motor. The use of track mowers, gravel dressers, weed burners, discing machines, etc., is made possible by the track motor car. Many railroads are using tie tampers, grinders, rail saws, drills and other devices driven direct from the motor of the track car.

Under systematic supervision the motor car has been responsible for reduction of work train service. Unless heavy materials in large quantities are to be distributed or picked up the use of work trains cannot be justified. A work train costs from \$75 to \$100 per day and much of its time must of necessity be used up in clearing other trains with resultant loss of working time of the gangs, while track motor car expense accrues only while cars are being used and the full time of the men is had where supervisory forces program their work ahead.

A comprehensive study of motor car operations by supervisory men with the proper allocation of gangs, results in definite, direct savings. An intensive time study of bridge and building gang operations and resultant programing of work with the elimination of haphazard gang movements has reduced the moving time between jobs and to and from work about 50 per cent on the Union Pacific.

The extent of diversified uses of track motor cars depends entirely on gang to which assigned, as also does the abuses so frequently encountered. Constant follow up by road-masters, supervisors and master carpenters is mandatory in order that full efficiency is derived and abuses and misuses minimized.

Of necessity, track motor cars and also trailers, must be light enough to be easily removed from the rails at points adjacent to the work yet amply heavy to withstand ordinary usage.

Such is the track motor car of today; a highly developed, simplified power plant, which any man of average intelligence can operate.

The average life of a track motor car is estimated to be ten years, and considering the comparatively few hours per week that a motor car is actually in operation, with the proper care and maintenance, this estimated life of ten years seems low enough. The track motor car in itself is an inert machine requiring the human element to convert it into a power plant in placing it in service. Its life and the service rendered depends entirely on the personal interest its operator uses in the operation and care given it. Heavy repairs should be made at shops equipped and manned for such work. Gas engine repairing is in itself a specialized branch of mechanics and most roads have sufficient work of this nature to employ competent mechanics constantly on this class of work. Replacement of minor parts and general adjustments are performed by field repairmen, leaving for the foremen and other operators the making of slight adjustments, also the keeping of all nuts tight, making minor repairs, applying proper lubrication and keeping the car in a clean and tidy condition.

Show me a dirty car with mechanisms covered with oil, grease and dirt and my reaction immediately is a careless operator with like habits extending into every portion of his daily work. A clean car denotes pride and renders every portion of that car open for minute inspection. A clean car is also subjected to less wear account of sand or abrasive substances entering movable parts. All cars should be inspected daily for loose nuts, improper adjustments, and both expected and unexpected defects. A more thorough inspection should be made weekly of every portion of the car in detail, including the motor transmission or friction disc, brakes, frame, bearings and flanges.

Proper alignment and gauge of wheels is paramount at all times. Correct lubrication insures against wear and gives car more power. Ignition will not follow paths broken by dirt contacts or gaps, hence the necessity for clean spark plugs and tight connections. Magnetos and coils are delicate and should not be tinkered with. Such parts are vital to a car and only experienced men should make repairs. A detailed cost of shop expense and repairs by the field repairman will readily develop the cars that are not being given proper care, and this matter can be adjusted along educational lines, or in case of a failure of this method, by suitable disciplinary action.

An alert operator can easily detect any unusual sound in his motor and in case of such sound developing, immediate attention should be given to insure against possible further damage, as motors have been completely wrecked and employees injured by connecting rods becoming loose or bearings burning out.

Cars should have only specified standard equipment. The use of special seats, boxes, trays or other contrivances makes extra weight which might overload that portion of the car on which placed, cause a stumbling hazard, or in some other way jeopardizing the safety of the employees required to ride the car.

The engine of a motor car must not be running when car is placed on or taken off the track, as employees have sustained serious injuries to their feet when standing on the front end with motor running while car is being turned. The engines must not be raced at any time, as this causes extreme vibration to all parts of the motor and car generally, resulting in unnecessary wear.

The safe carrying capacity of all track cars should be stenciled on each car and this specified capacity not exceeded, as the operation of an overloaded car is extremely hazardous.

Track motor cars should have the front wheels lifted out of flangeways where crossings are planked, before rear end of car is swung around to avoid bent axles and twisted flanges. More damage is done in one bouncing of the wheels over the rails where the ground is below top of rail than a month's ordinary wear on the car, as this strains rivets, loosens bolts, distorts the frame, may damage bearings or their pedestals and crack flanges. A summary of the accidents with resultant injuries and fatalities caused by cracked flanges, worn axles and thin treads on wheels coupled with high speed, reveals astounding figures and places a sad commentary on maintenance men.

Before any track motor car is put in service it should be fully equipped with safety rails which extend across both front and rear ends, with a hand rail extending over the full length of the deck between them to prevent men from falling in case of sudden stop or derailment.

Brakes, unless in proper adjustment, are a potential cause of many accidents. They must be maintained in such a manner as to assure a quick and positive stop. Soft iron facing on brake shoes has been found preferable to leather, rubber or wood. Brake levers must be readily accessible to the operator and care used in loading so that tools or materials placed on the car can in no manner foul the brake action. Foremen or operators of track cars will be in charge of brakes at all times and must give proper warning when brakes are to be applied.

Only after it is known by inspection that the track motor car is in good operating condition, should the car be placed on the track.

No one should be permitted to operate a track motor car until he has passed an examination on the rules, sight and hearing, which insures against possible ignorance of the rules and personal physical defects.

Every operator must carry a standard watch inspected at frequent intervals and must have a copy of the current time table in his possession, and also then make frequent comparisons with standard clocks or employees who have the correct standard time.

As much as practicable, each track motor car should be operated by one person who should be thoroughly familiar with the car.

Before starting a track motor car there should be a definite understanding as to what part each employee in the gang is to take in the handling of the car should an emergency arise. Three or four men who have been drilled in the details of handling can remove car more quickly and safely than eight men in confusion.

Necessary flagging equipment, as prescribed by the rules, should always be in readiness on the track motor car so that proper flag protection may be provided the instant it is necessary.

None but employees in discharge of duty should be permitted to ride upon track motor cars, except on authority of the Superintendent. All employees required to ride on motor cars must be seated and the capacity of any car is limited to the number of available seats. Men to be seated so that operator's vision is unobstructed. Men should be seated to face both front and rear to serve as lookouts. Where more men are to be handled than the seating capacity of a track motor car will accommodate, a trailer with seats and safety rails should be attached to rear of track motor car. Employees should not be permitted to ride on flat top of push cars or with feet between the cars.

No car should be pushed ahead of a track motor car. Any car attached to a motor car must be pulled. Such cars should be coupled with a rigid coupler having a minimum of slack and be so fastened that there is no possibility of cars becoming separated.

The placing of tools or material on motor cars or trailers must be carefully done, so that there will be no chance of same dropping off or sliding out to derail following cars or trains. Ends of tool trays should be high enough to prevent lining or bridge bars from slipping out. Such tools or material must in no way foul any of the working parts of the track motor car.

Everything about the operation of a motor car should be done in a cool, methodical manner, each man knowing what to do and no scuffling, horseplay, joking or unnecessary talking should be permitted. It is as essential that men be quiet and watchful while riding, as while at work on a busy track.

All employees riding upon track motor cars should be taught and impressed with their own individual responsibility so as to be alert at all times and not be permitted to depend on the operator or foreman for their personal safety.

Speed restrictions should be definitely fixed and religiously adhered to. If the operation of inspection cars is permitted at faster speeds than ordinary track motor cars, such cars should be specially designed and built for such service and especially excepted from established speed restriction, as it is a perverted reasoning that permits an officer (general or subordinate) to break himself, the very rules that it is his duty to enforce.

Cars must be operated at all times with caution, this is particularly necessary at night and during foggy or stormy weather. When necessary to use track cars at night or during storms or fogs, a white light must be displayed to the front and a red light to the rear, and when such movements are made extra precautions must be taken to ascertain exact whereabouts of other track motor cars and scheduled or extra trains. If communication cannot be established with the dispatcher, all such movements shall be made under full flag protection.

The operation of track motor cars while passing trains on adjacent tracks, has caused many accidents. On lines of more than one track, cars must be

stopped and all employees required to dismount and stand outside and clear of both tracks during passing of a train on adjacent track. Track cars must not pass between a standing passenger train and a station unless there is a fence between the tracks. When passing standing trains or cars set out on adjacent tracks, care should be exercised to avoid possible collision with any person coming around or from between the cars.

When operating motor cars on lines of more than one main track, the current of traffic must be followed unless deviations are permitted by special instructions due to grades, curves, or other conditions involving restricted vision or special operating conditions.

Track motor cars must not be attached to trains, and a distance of 500 feet must be maintained between track motor cars and the rear of trains on the same track, and 200 feet between all track motor cars.

Heavily loaded track cars which cannot be removed from the track promptly must be protected in both directions by stop signals. Heavy material must not be carried on track motor cars except in emergencies.

Employees must not get on moving track cars, except when necessary to start the car, in which case the pushing must be done from the rear end only. When a direct connected track car is coupled on front of a push or any other track car not equipped with safety hand rails, it may be started by not more than one man on each side pushing on the safety hand rail at front end of the motor car. Employees must not get off moving track cars, except in an emergency.

Only motor cars with free running engines should be used as gang cars, as there is always a hazard of accident in pushing direct connected cars to start them, with men compelled to board the cars when moving. Here enters also another evil with direct connected cars—that of the tendency to race cars for grades, it being impossible to shift speeds on such cars. Such cars also invite the practice of running across obscured highway crossings, when it is known that reducing to a really safe speed will necessitate dismounting and pushing the car to start.

Foremen and others in charge of track motor cars should be required at all times to keep themselves informed as to train movements in the vicinity of their operations, to avoid unnecessary hazards from running on short time ahead of trains, or in the face of traffic in single track territory. Foremen and operators of track motor cars must watch closely for signals carried by trains so as to know if there are more sections following. Dispatchers should give line ups to foremen of gangs and other employees operating motor cars when requested to do so and employees receiving this information must understand that they are given such line ups as a matter of information only and it does not relieve them of the responsibility of protecting themselves wherever and whenever necessary, for operating conditions may require running additional trains or light engines at any moment after a line up has been given.

Suitable setoffs should be maintained so that cars may be readily removed from the track. These should be in the vicinity of cuts, fills and ends of bridges and so provided at such other locations as operating conditions necessitate.

In dense traffic territory the operation of motor cars may demand special rules to govern their movements.

Gasoline being an explosive, requires careful handling at all times and must not come in contact with an open flame or spark. Carbon monoxide is fatal—never run a motor in a closed building.

Clothing is also a safety factor in motor car operation. Excessive or bulky clothing, such as to impair vision, hearing or prompt action, should not be

worn when riding track motor cars. Turned up overalls, ragged or torn over clothes can easily contribute to an injury when riding on track motor cars.

When rails are slippery due to wet weather or frost, additional care must be taken to insure the proper stopping of motor car. This must be taken into account by foremen and other operators when approaching switches, derails and highway crossings. Track motor cars should be pushed through spring rail frogs and over point derails and run at slow speed through interlocked switches.

A vehicle has the right to cross ahead of track motor cars at public highway crossings where flagmen or gates are not maintained, and track cars should stop and motion to vehicles to cross ahead of them, if both arrive at a crossing about the same time.

For years we considered it sufficiently safe to permit track motor cars to approach crossings of city streets or other public highways under control, and to cross without stopping if there was an unobstructed view of two hundred feet each way; and while collisions with automobiles and auto trucks were substantially reduced by intensive supervision, they continued to such an extent that just recently it has been considered necessary to require all track cars to come to a full stop before proceeding over crossings, and where the view is at all obscured, dismount and flag over the crossing.

Since the advent of the track motor car its operation has been a prolific source of accidents, perhaps contributing to more accidents in proportion than any other factor. Much of this is due to the natural obstacles of a railroad with its curves and grades, the ever increasing complexity of train movements and the continued extensive growth of the automobile traffic.

The first duty of railroad officers in furnishing track motor cars is to procure simply operated track motor cars, maintain them with every possible safety device, and supplement their operation with every known self-operating feature and condition.

It has been said that some profit more by intuition than others by a lifetime of experience. This is borne out forcibly in the operation of track motor cars. In dealing with accident prevention the human element is the colossal obstacle to surmount. Rome was not built in a day, nor is the selling of the safety idea to the rank and file accomplished easily or quickly, but rather by constant schooling by precept and example in a friendly democratic spirit.

A safety organization is not purely a departmental feature, but must be a well defined, deep-rooted movement, receiving its inception and sustenance from the head of the official family, thence filtering down through all the channels to the most remote employee in the service in such a manner that he is cognizant of unsafe practices, and has a definite course to pursue.

Detailing a safety agent to correct all the unsafe conditions and practices is comparable to a missionary in a heathen land,—it is a slow uphill problem of uplift. It requires the unqualified support and concerted action of every officer and employee of the property to put over a really effective campaign which will show a substantial reduction of personal injuries each year.

Were it possible to weed out at the source the misfits and derelicts, the problem of safety would be less difficult. Much has been done by physical examination when accepting skilled labor for service, but this still leaves the induction of the common laborers, who generally are not required to pass a physical examination, entirely up to labor agents and foremen. It is, therefore, imperative that the best material possible be trained for foremen, as the foreman is the one man standing between the treasury and the work at hand. It is he who is in direct contact with the rank and file, and it is very essential that he have the qualifications that his position demands. A maintenance foreman, due to his isolated position does not receive constant personal

supervision of general or subordinate officers, and it is mandatory that he be of the progressive clear-thinking, positive and courageous type. It is he who directly conveys to both the new and the older men of the gang the rudiments of "Safety First," and not only is he expected to instruct men in safe methods of conduct and proper manner of performing work, but also explain why such conditions are absolutely necessary.

It has been found highly beneficial to get all maintenance foremen together at stated intervals for round table discussions and general dissemination of instructions and interchange of ideas. At such meetings short talks are made by general and subordinate officers, stressing the feeling of kindred interests and democratic spirit. Every man is urged to handle his work in a cool, methodical and careful manner, with a feeling of pride in a job well and *safely* done. The details of practice are worked out at such meetings from the experience of the whole personnel.

As railroad officers, we are guardians of a trust jointly to the corporations we serve and the commonwealth from which we derive our revenue. Upon us rests the direct responsibility of the promulgation of rules and instructions pertinent to the safe-guarding of both the employees and the traveling public.

To the individual the prevention of accidents looms as a stupendous task, but with the coordination and lively interest of every officer, general and subordinate, the problem is simplified to the point where the individual employee can be reached and his conversion to safe methods obtained either by moral suasion, or if not amenable to that, by disciplinary action, even to the extreme measure of dismissal.

Loyalty cannot be purchased nor fixed, but is the spontaneous outgrowth of contact where the officers meet the rank and file of employees with a fair and friendly interest. It is then only that men can be taught to respect the rights of others, to reason methodically, act with inherent selfrestraint and control, and to hold the rules inviolate.

"Safety is fundamentally a habit of mind which may be acquired by all through the exercise of ordinary caution and forethought in the small details of each day's duties."

CHAIRMAN COTT: I want to thank you, Mr. Osborne, for that splendid paper. We are deeply appreciative of it. Mr. Rohweder, will you please report for the Committee on Nominations?

Report of the Nominating Committee

A. V. ROHWEDER (D. & R. D. M. & N. Railway, Duluth, Minn.): The Committee on Nominations, Mr. Walsh, Mr. Phillips and myself, beg to report as follows:

Chairman, Mr. John E. Long, Superintendent of Safety, the Delaware & Hudson, Albany.

Vice-Chairman, Mr. C. F. Larson, Superintendent of Safety, the Missouri Pacific Railroad Co., St. Louis, Mo.

Secretary, Mr. A. W. Smullen, Superintendent of Safety of the Chicago, Milwaukee Railroad.

CHAIRMAN COTT: You have heard the report, gentlemen. Under the By-Laws and Constitution you are entitled to make nominations from the floor.

(The report was accepted and motion made and carried, electing the officers named.)

ADJOURNMENT

October 3, 1928

Luncheon Session

E. R. COTT, Chairman

**Supervisor of Safety, The Hocking Valley Railway Company
Columbus, O.**

J. E. LONG, Toastmaster

**Superintendent of Safety, The Delaware & Hudson Company
Albany, N. Y.**

The luncheon session was called to order at one o'clock by the chairman, Mr. E. R. Cott.

CHAIRMAN COTT: The Toastmaster I personally selected, because I believe that toastmasters, contrary to the usual practice, should be seen and not heard, and I think you will hear very little of the present Toastmaster; so I take pleasure in introducing to you, to those who may not know him, Mr. J. E. Long, Superintendent of Safety of the Delaware & Hudson Railway, Albany, New York, recently nominated and elected to be my successor the following year.

MR. LONG: I deem it a pleasure and a privilege to act as Toastmaster for this Luncheon today. May I at this time extend to you a welcome. I am glad to see you here. I am especially glad to see so many ladies present and just before the luncheon started I remarked to my good friend, Tom Carrow, that you ladies look good enough to eat. I am glad to report from this vantage point that you did.

When my good friend, the capable chairman of this Section, requested me to act as Toastmaster, I told him it was a mistake, because in my opinion a Toastmaster should be able to tell funny stories. His reply was "Don't worry. You don't have to tell funny stories. They will laugh when they look at you." Ever since then I have been trying to figure out whether that was a knock or a boost and I am wondering, when you did laugh, if you laughed with me or at me.

Incidentally, speaking of the ladies here, a prominent man who frequently acts as Toastmaster said recently that when the ladies were present it cramped his style. He said that the ladies had cleaner minds. And a voice from the gallery said, "They should have, they change them more often."

I presume, as Toastmaster, I should exercise my prerogative and make a speech, but I am sure you did not come here today to listen to me, but to listen to the gentleman whom I am to introduce to you. However, I do want to say that accidents are not prevented by just hoping you won't have them. Successful accident prevention requires a carefully conceived plan, thoughtfully carried out. Everything worth while needs effort. Safety requires work and work is good for us. Practically everyone works. We worked yesterday, last week and last year. Did you ever hear of Adam walking around in the garden of Eden with his hands in his pockets? You will get that in one minute.

Incidentally I know some people say that the trouble in the garden was caused by an apple. Personally, I think it was caused by a "green pair."

In the past we have been favored at these luncheons with distinguished speakers, but I am sure we have never had a more distinguished speaker, nor one who is better or more favorably known in the city of New York, than our guest and speaker of today. Ladies and gentlemen, I take great pleasure in presenting to you Dr. Thomas G. Darlington, formerly Commissioner of Health and President of the Board of Health of the City of New York.

Address

By THOMAS DARLINGTON, M. D.
New York City

Mr. Toastmaster, Ladies and Gentlemen: It is a great pleasure for me to be here. I too would like to tell you some stories but there is not time and we will pass them over for I have so much else to tell you.

Sometime ago I was one of the Commissioners of Compensation of the State of New York and at that time made many investigations of the cause of accidents. My experience is that most accidents are due to carelessness; to lack of thought, a person's mind on something else. As for instance on Monday morning they are thinking of the Sunday before or something of that kind. There are many causes of accidents, but that seemed to me at the time when I was investigating the matter to be the greatest cause, and next to that and a very large factor was fatigue. Accidents frequently occur when people are tired, and it is to that cause which I wish to devote these few minutes.

The question of getting tired and how we many avoid it. I wrote a pamphlet on this once for the American Iron & Steel Institute and it was published. It was entitled "What Causes Fatigue? An address by Dr. Darlington." My daughter said that was a question and an answer.

To know something about the body getting tired we must know of the human body itself. You know it is made of bones, muscles, skin and nerves and various organs and glands. The principal thing we have to deal with, or one of the main things we have to deal with, is the muscles.

Getting tired or fatigued is the opposite of energy. How do we have energy in the body? I take my arm and move it up this way (raises his arm) what happens? This muscle the biceps pulled along the front of the arm and pulled the arm up, through the will. What happened? That muscle had energy in it, something to use up, it had fuel. What is that fuel, ordinarily? (I am trying to make this very simple.) The muscle contains sugar and we will put it in a chemical constituency. C-6, H-12, O-6. When I pulled up this arm what happened? That split into two parts. It becomes C-3, H-6, O-3. If you know anything about chemistry you see you have a different product, it is Lactic acid the acid of sour milk. We keep doing that and the muscle is getting sour. The strange thing that some of the lactic acid in the muscle goes back to sugar. That is what you cannot do outside of the human body; and it sends it back into sugar and it does it over and over again and finally the Lactic acid splits up and becomes CO-2, Carbon Dioxide which passes out through the lungs and H-2-O, water, which passes out through the kidneys.

We must compare the body in energy to the simplest thing, water in a boiler with fuel under it. Suppose we put coal under a boiler and we want energy. You light the coal. But doesn't it depend a great deal on the quality of the coal? There is a wonderful difference between some of the slaty coal I have seen and Pocahontas coal. Again, it depends on whether you get a draft under that boiler, whether you give it draft. Supposing you shut it up and don't have any oxygen, you do not get energy or steam. It depends also on the third thing, on getting rid of the ashes or waste.

The human body is like that. Our energy depends on the fuel, the food we eat, upon the oxygen we breathe in whether we burn the food in the muscles or not, and whether we get rid of the ashes or waste.

The first thing then is a question of food. Don't you see that if we have no fuel we have no energy, and fatigue is the opposite of energy. In other words if we lack food and lack fuel we get tired. I remember examining 150 lunch buckets in one day and after going through them, in the Carnegie Steel Company—I thought it was no wonder they got tired because of the character of the food. Some of

it was sour not worth while eating. There is a great deal in regard to this food business. Whether you digest it or not. Can you store it in the muscles and put this sugar away, for the sugar is not only stored in the muscles but in the liver which is the coal bin of the body. It is stored by food. It is a great thing to know what kind of food to eat and the right quantity to eat and the right time to eat. There is also a good many other things dependent upon the digestion of that food. In the first place, have you good teeth? Has the workman good teeth? Has he abscessed teeth containing bacteria that spoils the food after it gets into the body? And after he has swallowed the food does he digest it? That depends a great deal on whether he has gastric juices or not, a contented mind or not, upon anger, worry, etc. People who are in a stew all the time do not have gastric juice and do not digest their food.

On the shores of Lake Champlain some years ago there was an old Doctor lived there named Alexander Beaumont and he had a patient named St. Martin. St. Martin had been shot across the front with buck shot and there was a hole in his stomach. You could watch the food digest. Dr. Beaumont made a great many experiments. One day he said "I made St. Martin angry and all secretion of the gastric juice ceased." The mind has to do with it. It is like men who transact business over the luncheon table. They do not get the taste or flavor of food which is shown to be absolutely necessary for the secretion of gastric juice, and then wonder why they have high blood pressure.

Now, it is not only a question of digestion. Is the liver in a good condition to store away the food? There is a good deal in the food itself. I do not want to talk too long for I remember once I talked on Temperance and it is one of the first speeches I ever made. The people kept getting up and going out and coming in again, they each went out for a drink and by the time I got through with my lengthy speech on Temperance they were nearly all drunk. However I do not think you can do that here. Now, we come to the second proposition and that is the question of oxygen. It is the same as getting the oxygen to the coal under the boiler. The oxygen is carried around in the body by the red corpuscles in the blood known as Hemoglobin. Very few people have the full complement of blood, sufficient red blood to carry the oxygen properly. Most people are down to 80 per cent or less and if they have had any disease it is much less than that, especially some form of infectious disease. Unless one has a sufficient amount of red material in the blood, the oxygen is not carried to the tissues and a person gets tired because they do not have sufficient oxygen to burn the food to give them the energy, and therefore have accidents.

Under what conditions do we have anemia? I am thinking of a case of pernicious anemia. A person who came into my office and had just stepped out of an automobile yet she couldn't stand a minute, tired. Because the blood stream did not contain sufficient Hemoglobin, red material in the blood.

If the person's bowels have not moved, if they have not slept nights, if they do not eat the correct food; if they have abscesses in the sinuses or teeth, any form of local infection or typhoid infection, then the Hemoglobin is found to be down and a person gets tired and accidents occur very often because they are not in a condition to return to work.

In that connection there is something else with the blood. The blood must remain alkaline. Now, the human body is like this: We will draw a circle (draws on blackboard). This is the alkali and this is acid. Over there we have a slight range. The alkali in our blood is about the same as tap water that you drink and we put it in here. That is our range. If you lose your alkali over to this point you go to sleep and you never wake up. You get that in diabetes. Too much the other way you get convulsions and die. It is a very slight range you have. If the blood changes in its alkaline content they call it acidosis. It is a wrong name, for nobody ever has acid blood. If your blood is acid you die

immediately. The slight change of the soda in the blood and all the carbon dioxide, which is a product of the body, is not carried out through the lungs and it accumulates in the system and makes us tired.

Acidosis comes from a great many things—eating too much fried food and persons who are fat and try to diet too much have Acidosis. Then you are tired.

Finally the great thing about it is, the thing that makes people more tired than anything else is not getting the products of waste out of the body. You know very well that if under a boiler you allow ashes to accumulate and put on coal, and don't get rid of the ashes, it will not work, and it is so of the human body. I will show you just how it works. Let us say, that too much meat has been eaten, too many bacteria, and they have gone down through the intestinal tract so the movements become more or less putrid in character, there is then Indol Skatol and Mercaptan, but the most common one is known as Indol. When you go to a Doctor and have your urine examined you find in the report, so much Indican, that means the Indol absorbed has combined with sulphur and potash. But when it is in the form of Indol it is poisonous. Absorption of putrid materials from the intestinal tract lessens muscular efficiency. How do we know it?

This is an iron stand (draws on blackboard). This arm is movable. This is a muscle from the frog's leg. We get two of them. You take it very carefully with a razor. Apparently it does not hurt the frog much for he does not jump if the razor is sharpened. You get this muscle of the leg, put it in this machine. Here is a cylinder. That muscle still contains energy and will move under electrical stimulus. We, therefore, put a current through here, that pulls up the arm and we get a record of this cylinder. We can tell what it is worth in value. Now, we will take one of these; the two muscles from a frog's leg and we will put a small hypodermic of salt and water in so as to have the prick and disturbance to the muscle itself and then take a record of it and then take a small amount of Indol and put it in the hypodermic and put it in the second muscle, the muscles being alike and see what is the difference in the record of those muscles. From the normal muscle we will get a record like this. That is the record of the normal muscle with just a little salt water in it. Now, we take the second muscle which has a small amount of Indol in it and what does it do to it? It cuts off the energy. It does not work. What does that mean? A man who has a proper toilet and proper movement from his bowels is worth let us say \$6.00 to his employer, but that man who did not and who has absorbed the putrid materials is worth just \$2.30. That is putting the movement of the bowels into dollars and cents and you can put everything in welfare work in many.

What then does fatigue depend on? On these several things. There are numerous others—There was a boy visiting me in the country this summer and I wanted some pine limbs sawed off from the lower part of the trees. He started in and he went this way (indicating a fast movement of the arm) and of course he went so fast he couldn't get the oxygen into the tissues. Too rapid a movement will produce fatigue. It soon remedies itself though for you cannot keep it up. In general, most of these things depend upon everything pertaining to the man himself and to her—his home, his living and his home life.

During the war I was asked to do a great many things. Among others was to look after the welfare work of Hog Island, and one of the first things we did was put in twenty-two large places where the 22,000 men could be fed because we wanted them to have the right kind of energy and food. Upon that very question, to show you what that means (I am going to keep you only a few moments longer) there was a large factory up in New England that turned out an enormous amount of ammunition, but they were not turning out sufficient amounts. Why? Because they got tired.

We took the hourly output. The workers came in at seven o'clock (indicated on blackboard). They came from all over, some had to come from distant towns

and all they would have for breakfast would be a cold biscuit and a cup of coffee or something like that. Here is the output from seven to eight o'clock. It goes up from eight to nine and from nine to ten and then from ten it goes down and out. That is very simple. All we did was blow the whistle at ten o'clock and pass food, hot chocolate, ice-cream, molasses cake, anything they wanted and what happened? The output went up there instead of going down. Simply a question of feeding and proper care of the human body.

If you will think this matter over you will find the question of fatigue depends a great deal upon food and anemia and that the condition of a man's health and his general well-being often prevent accidents.

I know that you want to go to a meeting so I will close by saying this work you are doing and all the others are doing—(we are just now putting over a great fight against diphtheria) is a fight against ignorance, poverty, negligence and all the diseases that spring out of these things—I have unlimited hope in the future and abiding faith in the people for I know that

In the long days of God, In the wide paths untrod
The World will be led, Its Heart be Comforted.

Others may sing the Song, Others may right the wrong
Finish what we Begin and all we fail of, Win.

Not looking for the Millenium but for a brighter, happier, nobler civilization.
I feel like one who

Pulling hard against the Stream
Sees the Gates of Eden Gleam
And does not dream at all, a Dream.

CHAIRMAN LONG: On behalf of those assembled here today I wish to thank you for your able and interesting address. I hope we may have the pleasure of seeing you and hearing you again at some future time.

We are also honored today in having two other distinguished gentlemen on this platform. I am going to introduce them with the hope that they will stand up and say a word or two to you. Mr. Walber, the vice-president in charge of personnel of the New York Central Lines, who is with us as the personal representative of President Crowley.

MR. WALBER: You need not worry. I am not going to make a speech, but I am here to represent President Crowley and to convey to you his regrets at not being able to be here personally. I am sure he would have enjoyed this wonderful address by Dr. Darlington which brings out so clearly and simply a phase of the situation in which we are all interested.

I only want to make one remark and that is, no matter how many phases are involved in this wonderful work you men are all engaged in, the outstanding phase of it that appeals to our president is the humanitarian aspect of what you are doing. There are economies in it, there are monetary advantages in it, but above all, the human side of it, the prevention of injury, the prolongation of the life of the employee, more than compensates for all the time and energy and money an employer can expend in this kind of work.

You men, in addition to doing a real practical work for the railroads, are engaged in one of the most Christianlike works imaginable, and from that standpoint alone it should be in the heart of every employee to have a real enthusiasm in this branch of the very necessary work you are engaged in.

With these few remarks I want to leave with you the regards of our presi-

Seventeenth Safety Congress

dent, Mr. Crowley, and convey to you the deep interest and personal concern he has in this subject, wishing you unbounded success in the work in which you are engaged.

CHAIRMAN LONG: Thank you, Mr. Walber. We are very glad to have you with us. The other gentleman is Mr. Bagwall, general manager of the Seaboard Air Line.

MR. BAGWALL: I came to this meeting for selfish interests. I came to further the safety work of the Seaboard Air Line. I had no idea of talking to you, much less being up here in this elevated position with these illustrious gentlemen. I told a man this morning that I attended one safety meeting and that was in Salt Lake City, and I obtained an idea that I went back home and put into effect. I was divisional superintendent at the time and I said today that I wanted to get one thought to take back home that I could put across that would do good to the men on the railroad and the railroad as a whole.

I have heard Dr. Darlington's speech with a great deal of interest. I have just been wondering how to put that thought over on the Seaboard. I don't know yet whether that is the thought I am going to take home, but I am going to take one thought home and I have that thought of Dr. Darlington's very well registered in my mind.

I am very happy to be here and I hope to get a good deal out of this convention and I know I will.

CHAIRMAN LONG: Thank you, Mr. Bagwall. We are happy to have you with us.

ADJOURNMENT

October 3, 1928

J. E. LONG, Chairman

**Superintendent of Safety, The Delaware & Hudson Company
Albany, N. Y.**

The third session was called to order at two o'clock by the chairman, J. E. Long.

CHAIRMAN LONG: As I promised you at the luncheon just closed, the first numbers on our program this afternoon are some selections by the Keystone Quartette of the Pennsylvania Railroad, which has come here through the courtesy of Mr. Carrow. The members of the quartette are W. G. Harshaw, J. C. Mainwaring, E. A. Rodig, G. C. Hartel and C. C. Hallman, Pianist.

(Selections were rendered by quartette.)

CHAIRMAN LONG: Thank you, gentlemen. I think the applause shows that those of us who are here appreciated that Keystone Quartette. Personally, I would very much prefer to sit here and listen to that for the balance of the afternoon but time flies and we have work to do. My sole remaining duty is to turn this meeting over to Mr. Carl T. Bailey of the Oregon Short Line, Salt Lake City, who is to conduct the Round Table Discussion this afternoon.

CHAIRMAN BAILEY: This is going to be a job of work. I was watching you as the quartette was singing and I thought, what a peaceful crowd! Now, this is one of those meetings where we call a spade a spade and we expect everybody to participate in this Round Table Discussion. It is one of the outstanding features of our session.

I am going to ask Mr. J. A. Carney, superintendent of safety, Chicago, Burlington & Quincy R. R. Co., Chicago, to start us off on Item (a) "The Whistle and the Highway Crossing." I think it is a subject of considerable importance to the American Railroads and I think we should get a good discussion.

The Whistle and the Highway Crossing

By J. A. CARNEY

Superintendent of Safety, Chicago, Burlington & Quincy R. R. Co., Chicago

In the horse and buggy days, the whistling sign for road crossings was located from 990 to 1,320 feet from the highway grade crossing and the whistle signal was two long and two short blasts sounded near the whistle sign. The movement of the vehicle was seldom over eight miles an hour and usually much less. The vehicle was usually open and the whistle could be easily heard. The temperament of the horse was in many cases a factor in preventing a crossing accident.

With the introduction of the automobile, the speed of the vehicle approaching the grade crossing was increased to twenty-five miles or more per hour. The vehicle was closed and the whistle could not be heard easily. The result was that when the whistle sounded, the engine was nine hundred or more feet from the crossing and the automobile approximately six hundred feet away. The automobile driver did not hear the whistle for the crossing.

To overcome this condition, we tried sounding the standard crossing signal a second time. This made extra work for the engineer, annoyed the passengers and the first sounding signal was superfluous.

It, however, seemed to solve the problem by keeping the whistle blowing until the crossing was reached. With these facts before us, we decided to adopt the highway crossing signal of two long, one short and one long blast of the engine whistle, holding the last blast of the whistle up to the crossing. The following bulletin was issued:

"Enginemen and Trainmen. Effective 12:01 p. m., Saturday, August 7, 1926, joint bulletin dated December 1, 1925, joint important bulletin issued during October, 1925, and Special Time Table Instructions with reference to the sounding of highway crossing whistle signal 14-L, are cancelled.

"Rules 14-L and D-14-L are modified as follows:

"Two long, one short and one long.

"Approaching public crossing at grade. The last blast of whistle to continue until engine reaches highway crossing.

"Enginemen will give consideration to speed train is moving in gauging the distance from the crossing that whistle signal 14-L or D-14-L, will be started.

"The warning signal approaching public crossing at grade is for the protection of pedestrians, drivers, and occupants of vehicles. Their safety and safe operation of trains depends on the vigilance and judgment of enginemen in approaching the crossing and sounding the whistle signal as provided by rule."

This bulletin was issued by the general managers and approved by the operating vice-president.

We are fully convinced that this system of whistling is good. We have had favorable comment from automobile drivers and have personally observed cars that made short stops at grade crossings. We have had a few cases of automobiles struck at the grade crossing while the last blast of the whistle was in progress. We sound the whistle in accord with the rule but we cannot guarantee that the people who ought to heed it even hear it.

One great menace is the driver who runs into the side of trains. This varies from 25 to 45 per cent of our crossing accidents. Taking this fact into consideration and the cases where the whistle would be useless; a back-up switch movement for instance, we are satisfied that two long, one short and one long blast of the whistle, the last blast continued up to the crossing, is making a reduction in the number of crossing accidents where the locomotive hits the automobile.

It is our practice to make checks at grade crossings to know that the crossing whistle rule is being lived up to.

We know that some automobile drivers are thoughtless and unobservant and often fail to note they are approaching a railroad crossing.

To such drivers, the whistle continued to the crossing, should prove a life saving influence. The sound of the whistle should awaken them to the danger confronting them.

Some railroads continue two long and two short blasts of the whistle, but specify in their rules that the sound of the whistle must be continued until the crossing is reached, the engineer to use his judgment as to when the crossing whistle shall commence.

An analysis of highway grade crossing accidents as published by the Interstate Commerce Commission shows that the Burlington Railroad in its efforts to reduce grade crossing accidents is well toward the head of the list of the larger railroads.

We believe our rule for whistling for railway-highway grade crossings to be a good one but whatever system of whistling may be adopted by any railroad, the real protection to the public is to keep the whistle blowing until the engine is on the crossing.

CHAIRMAN BAILEY: Mr. Carney, that was a very nice leadoff. I think this is a subject that interests every railroad man in the country, particularly a safety officer. Is there anyone who wishes to discuss the paper just presented?

J. L. WALSH (Missouri Pacific R. R. Co., St. Louis): I would like to ask Mr. Carney what his experience has been in the tests he has made as to where they stop blowing the whistle? As to the point with reference to the crossing?

MR. CARNEY: Personally, my observations have been this: when the engineer

can see that the road is clear he usually stops the whistle shortly before the crossing is reached but where there is any evidence of the approach of an automobile, he holds the blast of the whistle until the engine is on the crossing. I will say this: the employees of the Burlington R. R. are just as reliable as any other railroad but unfortunately old fellows have gotten into the habit of giving a "Toot, Toot, Toot," and it is pretty hard to get them gaged in some places.

We have had to use a little discipline to wake them up to the fact that there was a rule that had to be followed.

MR. WALSH: Our rule is similar to the rule of the C. B. & Q. It requires the last blast of the whistle to be sounded until the engineer has passed over the crossing. In addition, our rule requires a second sounding of the whistle when the crossing is obstructed or where an automobile is approaching. I think those two things in our rule are a little better than the C. B. & Q., perhaps, and on numerous checks, we found that our men were stopping the last blast of the whistle anywhere from 100 to 200 or 300 feet from the crossing. I have contended all along and believe firmly that the last few seconds elapsing when the automobile gets on the crossing and the engine gets on the crossing has averted a good many crossing collisions. I believe from our experience that the automobile driver has an opportunity of turning parallel with the track and I am sure in many cases avoided contact with our engines, where, if the whistle was not sounded clear over the crossing, he would have been hit.

Our rule is based on giving the engine man a very definite place in which to stop blowing his whistle, that is when the engine is over the crossing. In other words, when the cab of the engine is in the centre of the crossing, we consider our rule fulfilled. We have many failures, of course, but checking of the time of the whistle in accordance with the rule is being made all the time and our checks in that regard have proven it. I think it a very important rule to all of our railroads.

CHAIRMAN BAILEY: Is there any other railroad that has has similar experiences as Mr. Walsh has stated?

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): This subject can only be of interest—it seems to me—to those railroads that have not adopted this new crossing signal whistle. I can only reiterate what I said last year, that there is no officer, no engineer on our railroad that would care to go back to the old original signal. To those of you who have not given consideration to this phase of the question, I would urge and recommend that you get hold of your management and undertake to educate them and impress upon them the importance of changing to this approved whistle signal arrangement.

J. J. HEALEY (Erie R. R., Huntington, Indiana): With such an appeal as we had for a change of the standard rule I recommended for consideration to our management, the changing of that rule, but they did not feel disposed to do so at that time. They did issue, in bulletin form on the West End of our territory, specific instructions to our engineers to carry on the last sound of the whistle up to the crossing. Not in accordance with Mr. Walsh's reference, over the crossing, but up to the crossing; and from a careful check-up almost daily, that is literally carried out on our fast trains. Some of you may not think the Erie has any fast trains but we have. But our tonnage trains is the problem that I think ought to be regulated through this association or through the American Railway Association.

Now, this thing of one railroad doing this and another doing that is not getting anywhere. I have heard lots of flowery speeches on the floors of these conventions, but we go back home and forget about them. I would like to recommend to the Committee of Direction that we go into the proposition by reaching the proper channels and have that standard rule changed in all our operating rules on our American railroads. I am fully convinced that Mr. Walsh's reference to the last

half second of the sound of the whistle is the solution of the prevention of many crossing accidents.

CHAIRMAN BAILEY: This matter was discussed by the Executive Committee and also the Committee of Direction and I believe submitted to the Rules Committee of the American Railway Association for their consideration, I think it is still being given consideration by that committee. Before any standards are changed it has to have their approval.

T. H. CARROW (Pennsylvania R. R., Philadelphia): I think with Mr. Healey's eloquence he might be more successful with the American Railway Association than I am and I suggest he try to do so. I would like to ask Mr. Walsh, if when a train is not going so fast, whether his engineers make a comparatively long interval between the third and fourth blast or sound. In other words you can comply with the rule by blowing "Toot, Toot—Toot—Toot." I would like to know if you have an interval between the third and fourth blast?

MR. WALSH: On our slower trains we begin within the 200 feet from the crossing and just give an ordinary Highway Grade Crossing signal. Of course, we have made changes and found that some of our men would strike that whistle too far from the crossing and it would make it long. It is discouraging to the people and we have had a good many complaints; but an engineer with judgment, if he is running 15, 18 or 20 miles an hour, will regulate his whistle so he can comply with the rule and not disturb the people along the way.

MR. CARROW: I take it the laws of your State do not require it to start at the post.

MR. WALSH: Yes.

MR. CARROW: You ignore the law then?

MR. WALSH: No. By law they sound the whistle 120 feet from the crossing and if not obstructed in the vicinity of the crossing, it is not necessary to sound that whistle again. If it is clear so you can see half a mile up the highway it is not necessary to blow that whistle at all but when it is obstructed in any way, by trees, houses or cars, then that whistle must be sounded in accordance with the rule.

CHAIRMAN BAILEY: Some rules have been so constituted they may omit it. That has been adopted by many Western lines.

D. G. PHILLIPS (Wabash Railway, St. Louis, Mo.): One of the things I am crazy about is this matter of the crossing whistle, because I have become firmly convinced that by the right kind of whistling, lives are saved. Here is a rule we have on the Wabash. No whistling is good no matter where it is, where it commences, or how loud it is—unless it extends clear up to the crossing.

Now, fortunately in some States through which the Wabash passes, we don't have to begin the whistling at the whistling post. Take the State of Missouri, for instance. The law there states that the whistle must be started or the bell, at the whistling post, so we start the bell at the whistling post and then start the whistle at least nine seconds from the crossing. Now, there is no point at which whistling can be located that will indicate the proper place to start all trains. It is easy enough to see that if a train going 70 miles per hour, like they go on the Erie, should start at the whistling post—where should a train start if going 12 miles per hour? It is ridiculous to insist that those two trains start whistling at the same point, so we have got to locate a starting point of the whistle by something else other than space, and why is it not reasonable to make that a period of time from the crossing rather than an appointed space?

MR. CARROW: What do you do on places where the law requires the whistle?

MR. PHILLIPS: Just what you do. We violate the law. I know nobody will take offense at this but I am going to say there isn't a railroad running through the State of Illinois that observes the law at all times. The State of Illinois says that the whistle must be sounded from the whistling post, one quarter of a mile

from the crossing. Now, there isn't a railroad that is going to require an engine moving 15 or 20 miles an hour to whistle all that distance. I don't care whether it is the law or not. They are not going to do it. Now, if I tell our engineers this, I say: I can't tell you fellows to violate the law but I can tell you this much, if you are determined to violate the law as you do when you don't whistle all the way, I suggest that you do your whistling up next to the crossing where you save lives, and quit whistling and violate the law back at the whistling post. We have never yet had an engineer arrested or a law-suit based on our failure to whistle at the whistling post. We have a great deal of complaint on account of the noise from the whistling though.

The other day, near St. Louis (I won't mention the road) an automobile was struck and five people instantly killed; sixteen people had to be taken to the hospital and a number more were slightly injured. It was a bus load of people. All the evidence pointed to the fact that the engineer on that train had whistled at the whistling post. That seemed to be understood. He gave a signal back at the whistling post, but here is what a further investigation developed. It was a heavy freight drag running 12 miles per hour. The automobile was travelling 35 miles per hour. Now, where was that automobile when the whistle was blown? No matter, it did not hear it. Where was that crowd of people at the time that whistle was sounded? It was three times as far away as the freight train was. No chance to hear it. A lot of women and children on it; of course they were all talking at once and the driver could not possibly hear the signal.

A few mornings after, I happened to have the privilege of riding on a special train on which were a number of high Wabash officials. One of them had ridden on a special train over the road the night before (and on these special trains they do not have a lot of baggage cars and express cars between the engine and the place where these men are sleeping). He said to me "I pretty nearly went back on your whistling rule last night. The Engineer never missed a crossing all night long, they never failed at the whistling post and my sleep was disturbed." I called him by name and I had the newspaper in my hand that told of that accident near St. Louis and I said, "Which would you rather do? Get up as you did this morning with the knowledge that you had lost a few minutes' sleep or have a message like this handed to you—five people killed and sixteen injured?"

Then there were the damage suits, the lawyers were going to sue the company because they had not done a good job of whistling. I think that is true of everyone. Down deep in your heart you would rather be annoyed a little by it than to hear that somebody had been killed, and that is what whistling is for... To keep people from getting killed.

It is not that the engineer likes the music of the whistle; they are trying to save human lives, and when you get complaints for whistling from people along the road, explain to them why it is; that it is to save lives; their lives and their neighbors'; not to make a noise.

MR. HEALEY: A point of information. How does the Wabash establish that nine seconds period?

MR. PHILLIPS: Our engineers have pretty good judgment and we feel they guess it when we tell them to start whistling nine seconds from the crossing. Our engineers are intelligent. They don't always get it just right but they do come pretty near it.

L. H. COLLETT (Santa Fe R. R., Topeka, Kansas): We have a couple of engineers here and I would rather hear them than to get into it myself.

J. A. KOWALSKI (Santa Fe R. R., Emporia, Kansas): We haven't the Wabash rule in effect, that is in so far as the nine seconds rule is concerned. We haven't anything like that.

CHAIRMAN BAILEY: That does not clarify the situation as to the terminating of the whistle at the crossing with reference to the speed of trains.

L. T. SHEDD (Rock Island R. R., Chicago): Some six months ago the train rule committee of the American Railway Association presented for consideration and hopeful adoption, the new standard code. The committee did that after a long and tedious labor. It was adopted practically unanimously by a committee who met before the rule was presented. That committee saw fit to preserve two long and two short whistles, but appended a note to it, that the whistle should be sounded up to and (I think it said) over the crossing, either by continued blowing or by repetition as the case required; and I think you gentlemen assembled, if you will refer to it, it would be enlightening. My own opinion is that the rule thus adopted covers the situation in every particular and would meet all requirements.

CHAIRMAN BAILEY: I think an attempt on the part of this organization to make any effort to change that rule would be rather futile in view of the action taken by the committee of the American Railway Association and I believe the recommendations from the American Railway Association to the respective lines may be adopted.

MR. HARTENSTEIN (Lehigh Valley Railroad): I was present when the Rules Committee of the American Railway Association made their report to the Executives and, briefly speaking, they left it to the discretion of the railroads as to whether they would adopt a new rule or carry on the old rule which has been effective for so many years. We, on the Lehigh Valley, practically cancelled rule 14-L and adopted the same rule Mr. Carney speaks of here. We are going along, we think, very successfully with it. From checks made from time to time we are well satisfied that our engineers are trying to comply with it.

CHAIRMAN BAILEY: I might say, representing a railroad, that we thought we had that old rule effective. I had occasion to go out and make some tests and I found every engineer was hanging on to the last blast of the whistle up to the crossing.

J. H. WRIGHT (Union Pacific, Omaha, Neb.): I am a locomotive engineer on the Union Pacific and, naturally interested in this talk. I thought this thing over quite a little. I don't see where you could improve on the crossing question. The signal is all right if properly handled and in my experience I have been able to call the attention of parties at the crossing to it by the short blast where the long blast was confusing. It depends largely on the way the signal is given. I start at the whistling post with my first long blast of the whistle. Sometimes, if I am going to make a stop, I may make an application of the air before I reach for the whistle, but I always thought the short blast of the whistle immediately before reaching the crossing best, and I think that is the way, the proper way, it should be handled.

MR. CARROW: Did I understand you to say you strung the long one out?

MR. WRIGHT: Yes, sir. I wait a little space between according to my speed, then the next long one and then a space and then a short and then a space and the last one immediately before I come to the crossing. It is very effective. The last one is short. Two longs and two shorts.

MR. CARROW: In actual practice doesn't it come out a little longer?

MR. WRIGHT: It depends on the situation. I believe I have said all that is necessary. That is my view of the matter and I don't think any change in the rule is necessary.

I would like to call your attention to another point in considering the public. The engine man ought to have a little consideration too. Remember we have to sit behind that long whistle all day and it affects the cars. That is why I object to those long whistles. You don't get any more out of them than the short.

MR. KELLY (Baltimore & Ohio R. R., Baltimore): I have made a number of tests in so far as the blowing of the crossing whistle signal is concerned and I

want to say that it is not a question of whether the train is running 12 miles or 70 miles an hour. We, of course, have a standard rule in effect, of two long and two short, and in order to overcome anything that might happen because the driver of an automobile did not hear the first whistle, we have a rule in effect, which says to our engineers—if necessary blow it the second time, or the third time if necessary, if your judgment so indicates. I believe when the whistle is sounded the second or third time it is a great deal better than to have two long and two short and waken the neighborhood.

CHAIRMAN BAILEY: I think you are right. The Chairman will have to rule this discussion suspended. There is one matter I would like to speak of which we are all interested in. You know for many years we had the extreme pleasure of having with us, one of the pioneers of safety on the American Railroads, Mr. John T. Broderick, and I think it is fitting on the part of this assembly that some time during our session we forward him a message expressing our hope that he is progressing in life and the Secretary has a message I would like to have read to the assemblage.

John T. Broderick:

Baltimore, Md.

Your friends of the Steam Railroad Section assembled at the Seventeenth Annual Congress National Safety Council miss you and sincerely regret your absence. We enjoyed your counsel and feel that your thoughts are with us. We wish to assure you of our prayers for your happiness.

E. R. COTT.

CHAIRMAN BAILEY: The chairman, Pro Tem, will order the message sent. The next subject is of vital interest, and was to have been handled by Mr. H. M. Mayo but he is unable to be here with us but he has very kindly forwarded his paper and I am going to ask our Secretary to read the paper as a start off on this suggestion.

The Front Foot Board

By H. H. MAYO

Superintendent of Safety, Southern Pacific Lines, Texas and Louisiana,
Houston, Texas

At the suggestion of D. G. Phillips, president of the Safety Section, A. R. A., and a gentleman who has been persistently and successfully forcing safety to the front ranks in the world of railroad effort, in common with a host of enterprising and ingenious co-laborers, I have set forth here a brief thesis upon the "front foot board."

Every railroad man having active knowledge of yard service and a definite sympathy with safety as applied to the human units who function in this department of rail operation, has long realized the menace of the front foot board. That it represents a constant threat to life and limb and has been the cause of tragedies, both numerous and harrowing, is a fact universally recognized, yet not sufficiently acute in the minds of the old-timers to justify a change in methods of long standing.

I mean by this that it is somewhat difficult to cause the antiquated canine to sidestep carefully acquired habits of thought and action in order to try out something that does not conform to standards often born of reckless hardihood and a haste that was seldom ever justified.

On the Southern Pacific lines of Texas and Louisiana, there is no "front" foot board on a switch engine, at least so far as its occupancy is concerned. With our lines, the front foot board is that board which leads in the direction

moving, and employees are prohibited from riding this board under penalty of severe discipline. The rule has been in effect since January 18, 1920, and in spite of early criticism and objection, has overcome practically all opposition.

A recent questionnaire sent to all division and terminal superintendents on the Southern Pacific Texas and Louisiana lines, dealing with the foot board rule and as to its modification, elicited a unanimous objection to any change in its present provisions and reaffirmed the efficacy of our positive regulation prohibiting use of the front foot board in the direction moving. It was also the consensus of opinion that the rule did not slow down yard traffic or movement and, as one of the officials suggested—even, if it did, the added safety to employees would fully justify the delay.

That the adoption of the positive rule was somewhat revolutionary may not be denied. However, we cannot be expected to proceed along lines fashioned when the railroads were yet young and be governed by conditions that were created when the industry was in the process of early development. Not to digress into avenues opened by advanced thought and methods or take advantage of experience, would be to deny to operation the benefits of modern achievement, and we all know that the railways of today in the character of their organization, equipment, facilities and service, and the personnel of their employes, represent a distinct advance upon the same factors a quarter century since. However, as revolutionary as it may have been, the rule was based upon a generous desire of the management to save life and limb by decreasing the opportunity for its loss. It followed close upon the heels of two or three fatal accidents due to derailments of switch engines and the instant demolition of front foot boards upon which our illfated employes were riding. What counted the delay to car movement even if, as one yardmaster estimated, it would add one full engine shift to the yard; why figure on the expense if life was to be conserved or suffering decreased? This was the attitude of our management and the years which have followed unto the date of this writing have demonstrated the wisdom and humanity of the decision and the profit which counteth more than dollars to the yard employees whose duty is on or about cars.

The history of all switching yards contains one or more chapters which chronicle the front foot board accident or injury. Either it was a derailment, spring hanger breaking, obstacle between the rails, low joints, failure of drawbar or coupling while shoving, as applied to the physical equipment, or foot slipping while mounting, falling while running ahead of engine, caught while making coupling, adjusting coupling apparatus from board, or similar failure as applied to the human factor. No matter the cause, the front foot board furnished the opportunity and with the inhibition of the front foot board, the cause and opportunity departs.

During the nearly nine years the prohibition of the front foot board has been in force, there have been two accidents due to the front foot board. Yardman ran engine over a derail causing board to be demolished and employee to lose both feet above the ankles. Another yardman fell from front footboard while mounting and was so badly injured that he died a few days later. In both unfortunate cases employes violated the rule and in both cases paid the penalty of the disobedience. These two injuries represent the physical cost of the rule and practice, but numerous instances of switch engine derailments in our several terminal yards in which destruction of front foot boards was recorded during the period, suggest pertinently and significantly what might have been and what probably would have been had the old rule of operation governed.

Owing to the physical construction of several of our larger passenger stations, it was thought wise to modify the prohibition in order to additionally

safeguard the interests of our patrons. Thus at Houston, San Antonio and El Paso, switch engines passing through the station and on tracks adjoining and paralleling tracks on which trains are coming or leaving, and over which passengers are required to pass, are permitted if not required to carry one switchman on leading foot board during the passage of engine. This to better control movement of locomotive at a time when passengers were liable to become confused and inadvertently place themselves in a dangerous position by attempting to cross tracks immediately ahead of engine.

I am not prepared to state that the revolution was accomplished pronto, or without a constant and consistent policy of friendly education and support. Men who had been accustomed to use the lead foot board in their early training and through the years which had elapsed since their novitiate, found it difficult to coordinate their thoughts in harmony with a rule that switched them, *nolens volens*, from one end of the machine to the other and which added a mile or two to the usual footwork of the shift. Many of the boys "fell down" time and again, but only through habit. The older boys were at times rather cynical in their comments but few there were who did not recognize the added element of safety. While occasional infractions of the rule crept into the records of our operation, these were treated as the occasion demanded. In several instances employes were dismissed from the service after being repeatedly cautioned. Others were charged with demerits, but the "hard boiled" violations were infrequent, and I believe I can safely assert that the yardmen, including the yardmasters charged with the duty of proper and expeditious terminal operation, are solidly behind the practice and would object strenuously to its elimination or change.

Very competent and capable yardmasters the country over are ready to assert and do assert that with the leading foot board "verboten," transportation in terminals will be seriously hindered. Our records and experience fail to manifest this condition. We believe we have moved a step forward in the direction of safety and efficiency, for real efficiency can not nestle under the wings of possible disaster. One life is worth what it is worth. Who can estimate its value?

CHAIRMAN BAILEY: The subject is one of considerable importance to yard operation and I believe it is a problem that you are all confronted with and if there is anyone wants to bring up the question the opportunity is now afforded.

MR. HARTENSTEIN (Lehigh Valley Railroad): Mr. Mayo's paper takes me back a good many years when I was switching in a yard. I stood just a short distance from the yard engine which I had charge of that time, and at a frog the engine left the train. It was coming head on toward me and as she left the track the front footboard caught the rails, bent it right around the wheels of the engine and I immediately said, "I can see where I would have been if I had been on that footboard." From that day to this I have never attempted to climb on the footboard of an engine when it was moving toward me. I have discontinued entirely the practice of getting on the footboard. We have a rule on the Lehigh Valley, and while it may not be strictly adhered to, we are trying to enforce it.

CHAIRMAN BAILEY: It is a matter of supervision that the rules be adhered to.

MR. PARVIN (Ann Arbor Railway): I believe the matter deserves further discussion or more enlightenment. In the first place the gentleman's paper does not confine itself to the question under discussion. Mr. Hartenstein's statement just made was not confined to the question under discussion. As I understand it the question is, "in operation, how many men are you going to permit on the front footboard?" Mr. Mayo's paper speaks of various things that happen that were in no way connected with the man who was simply riding the front footboard. Mr. Hartenstein speaks of getting on the front footboard, I presume, when the engine

is approaching him. We all have that rule and it is a good rule. It seems to me when you say to your switchmen that they cannot ride on the front footboard you are going just a little too far in the interest of safety. Anyone who subscribes to that plan will next introduce a plan to put folding steps in the gangway of an engine, the engineer will let them down after the engine is stopped and he will raise them when the engine is started. Every moving engine or car has a hazard. I believe you can make a step forward in the riding of the footboard. How many accidents spoken of here would have happened if you adopted the simple rule of the man riding the footboard placing himself outside of the rail and only permit two men—not three or four—a maximum of two men on your footboard? If each man were riding outside of the rail how many accidents would happen that today are contributed to the front footboard?

J. W. HOPKINS (Pennsylvania R. R., Pittsburgh): We prohibit the riding of front footboards except at the passenger stations at Pittsburgh and that is under special rules of the general superintendent. It does not slow up the movement, it saves lives. It can be done. We don't allow any to ride it.

CHAIRMAN BAILEY: Under the present safety devices we have cars and switch engines equipped with, we do not permit switchmen to ride the front footboard. I would like to ask Mr. Warfel, of the Union Pacific, what his experience has been with that rule? They have a rule permitting one man to ride under certain conditions.

Various Ideas About the Front Footboard

GEORGE H. WARFEL (Union Pacific, Omaha): Mr. Chairman: It has been our experience and it is our belief that it is advisable to have a man on the footboard of a switch engine in the direction that engine is moving when it is moving in territory where there is likely to be any damage done by that moving engine to persons or cars. We therefore have a rule requiring one man only—forbidding more—to ride the leading footboard of the engine, except when the engine is making long moves from one yard to another over territory where there is likelihood of encountering trouble. That man rides on the engineer's side of the draw-bar, on the outside corner of the footboard in a position to see around corners as you come to the corners of elevators, buildings or other quarters and around curves when the fireman may be engaged or the engineer can't see, to immediately pass signals to the engineer should any condition arise requiring the stopping of the engine.

We permit only one man, and we would like very much to take that one man off, but we believe the interests of safety are better served under those conditions by requiring one man and one man only to do the most good with the least danger to himself.

J. A. CARNEY (Chicago, Burlington & Quincy R. R., Chicago): We permit men on the front footboard, one on the right side and one on the left side, and specify they shall ride on the end of the board outside of the rail. We do not permit anybody else.

MR. HARTENSTEIN (Lehigh Valley Railroad): This question of having a man ride on the outside of the board outside of the rail is interesting to me. I would like to know in what respect these gentlemen claim it removes the danger. Take, for instance, clearance. We all know men have been injured. We all know in the winter time in deep snow it is dangerous to ride there. My contention is it would be safer in the winter time in the middle of the board.

C. W. HAMMOND (New York Central, New York): We have special instructions that only one man shall ride at any time when he is not switching or yard lead. We find that one man on in switching or yard lead is perfectly safe riding

on the leading footboard. We may have a switching lead of 20 or 30 cars, which is common on the New York Central; perhaps five or ten switches long, fifteen switches against you. We feel that the man on the leading end, to go up and throw that switch, is perfectly safe and that is the only time we allow him there. If he is going from yard to yard he is absolutely prohibited from riding the engine, on the footboard. He must not ride there except when absolutely necessary, and it is very seldom necessary to ride on the road engine. Take local men doing local work in the summer time. They found it was a nice place to ride to cool off. We fought that and today our accidents are practically nil with reference to men riding the footboard and it is because we have enforced the rule.

E. J. COTTER (New York City): We don't permit anybody riding on the front footboard of engine in terminals and have not for some years. We have not experienced any slowing up on that account. The last accident we had, a man lost his life riding the front footboard of an engine going about four miles an hour. He attempted to get off and the cut-off lever was in his pocket. After that no more men were allowed to ride on the engine and we have all kinds of corners and things right in New York City. Nobody on the footboards.

The Strict Footboard Rule a Safety Matter

CHAIRMAN BAILEY: I think the consensus of opinion is that the strict footboard rule is a real safety matter.

MR. KELLY (Baltimore & Ohio, Baltimore): I am very familiar with that rule. We have a president that always stands for one thing and that is safety first, Mr. Willard. I want to say that our rule prohibits riding on the leading footboard in the performance of duty unless absolutely necessary to be there to do it and then his position shall be on the outside of the running rail; making switching movements from one side to the other we don't permit. We don't have any trouble and do our work safely.

MR. WARFEL: To answer a question that was raised with me I would like to say further, the man whom we require to ride the footboard is not permitted to remain on the footboard when the engine comes in contact with the cars. He is not permitted to mount the footboard when the engine is moving. It stops for him to get on and stops if he is throwing a switch.

W. R. SPETTIGUE (Los Angeles & Salt Lake R. R., Salt Lake City): About three weeks ago we had a switch engine making up a train, in a backward movement, and they knocked down and crushed the legs of one of our workers. The men were discharged for the responsibility. Our rule requires that one man must at all times be riding the leading footboard in the direction the engine is moving under such circumstances. They did not do it. Our rule also requires that only one man will at any time ride the footboard in the direction it is moving the same as the Union Pacific Railroad.

MR. COTTER: I can't agree that a man should be on the footboard at any time, neither can I agree that they should be protected. My thought is when the blue flag is lifted from the shuttle, keep all employees outside of danger, before the flag is lifted. Footboard riding is a dangerous practice and I can't see where it is any benefit to anyone.

CHAIRMAN BAILEY: We will have to terminate this discussion on account of lack of time. I am going to introduce Mr. J. E. Long, who needs no introduction, to start the argument on "Freight House Accidents and Remedies." We will ask him to step up front.

Freight House Accidents and Remedies

By J. E. LONG

Superintendent of Safety, the Delaware and Hudson Company, Albany, N. Y.

There appears to be a slight difference of opinion between the representatives and my safety colleagues in the Wabash and Hocking Valley Railroad. Perhaps you will recall that my good friend from the Hocking Valley, in introducing me, stated that I was selected as Toastmaster because I was a man of few words. Apparently my good friend from the Wabash doesn't believe him because when he asked me to lead the discussion he told me he wasn't expecting me to occupy the floor for more than three minutes. With the understanding that my talk was not to exceed three minutes I have not attempted to prepare a paper but have made a note or two on the subject I am hoping to help you with.

Instead of discussing details, such as handling freight, gang-plank slipping, falls of men and material, I prefer to touch on what I consider to be the basic cause of freight house injuries. My study of the situation has led me to believe that those injuries caused by faulty supervision are most frequent. By this I mean the failure to properly educate freight handlers in what I choose to call "safety sense." If this education in safety sense were started by the supervisor, regardless of what that supervisor's title is, at the time the employee entered the service and continued during the time the man remained in the service, we would have mighty few freight house injuries.

That is all I have to say, excepting that at freight stations where we have been able to convince the supervision—the supervisors, if you please—that this is the right method of preventing freight house injuries, we have had very few of those injuries. Unfortunately I have not been able to sell my idea to all of our supervisors.

CHAIRMAN BAILEY: I would like to afford the opportunity at this time to discuss this important subject. I think our freight house accidents are at a very low minimum. I know I saw a graphic chart of those accidents chargeable to station forces on our own line and it was very small compared to some of the others but I presume from the fact that the program committee had it placed on the program, a number of persons had requested it to be discussed.

A. B. HOFF (Erie Railroad, New York): We have, like every other railroad that has business in a large terminal like New York, this problem but far from having the experience that the Union Pacific has, we have quite the opposite. We have in the Erie, just begun to tackle this subject because a short time ago all our freight house handling was done by contract labor, so we are attacking it from sound fundamentals such as we are all agreed upon. We are putting into effect now what we hope will be a real standardized system. We have about 1,200 to 1,500, sometimes going as high as 1,800, freight handlers in the vicinity of New York. They come and go. The average freight handler stays about five to six days on the job. If he stays two weeks we consider him almost due for a pension. So you see, this is quite a difficult and quite a separate problem from our standpoint with freight handlers on our line from here to Chicago. Where we have comparatively few accidents most of them are local boys who know their supervisors, know their agents, amenable to reason, don't want to get hurt, and so on.

I am not going to take up much time except to show you that there is for some of us a very real problem. I know from talking in previous years with Mr. Carrow and Mr. Hill, they have had this problem presented to them. We have found that supervision of course is the answer where you have casual labor—just as this morning you heard of the casual labor in the gangs where they have Mexicans and so on. Supervision is the whole thing. It is difficult to instill the ideas of interest and competition although we are starting that system which I

believe they have on the Baltimore & Ohio, New York Central and Pennsylvania. We are also introducing the same methods of local safety committees among the oilers, flag-men, etc.—people more or less permanent. It must be a matter of supervision to keep men from overloading the trucks, to get some kind of ideas in their head which will improve the situation.

CHARLES E. HILL (New York Central, New York): I am not going to tell you how to avoid station accidents but I hope to get some information of value to our lines in the Metropolitan District. There is a great need of safety in the stations. In our own organization we have taken the position that there is no reason why we can't have so good a safety record in our stations in New York as we can in Chicago or any other large terminal. But we are not undertaking to be too specific. The ratios vary all the way from practically nothing. In fact we have several large stations that go months and months without an accident, with the ratio for the full year of only one casualty for a million man-hours. We take the position that it matters not what conditions are, we have to meet them. Those of us in the safety work day in and day out, know what the fundamentals are that produce real results. One of the difficulties we have here in the Metropolitan district—this is not an alibi, but is one given to us—is men mostly are floaters. They may not be working under their right name or the proper address. They disappear from the face of the earth. You are unable to locate them. I would like to hear from those who have this problem, particularly in the Metropolitan district of New York. If they can give us any solution you don't know how happy we will be for we are in a real dilemma, so far as station accidents are concerned.

MR. HARTENSTEIN (Lehigh Valley R. R.): I will only talk concerning the Metropolitan district here because in our other large freight terminals we have very few terminal injuries. The forces are regular and old experienced men. For illustration at Piers 8, 34 and 166 in New York City: We have regular forces to some extent at all three of those piers, but there is a certain turnover every day and that turnover consists of new men, and it is among those men that personal injuries occur. We very seldom hear of an injury to any of our old employees. Our agent or freight manager on these piers will get a report in the morning as to the amount of incoming freight and of course you can't tell about the amount of outgoing freight; but he places the number of men required upon the report of incoming freight received in the morning. He may need several more gangs than his regular force and as I said before, it is among those fellows we usually have personal injuries. We have no difficulty with our foremen. They are all sold on the safety movement and do all they can to keep men from getting injured.

CHAIRMAN BAILEY: The labor turnover is the main factor. I believe it is a matter that representatives should get together on and work out. It is a matter of supervision.

JAMES PRATT (Reading Company, Reading, Pa.): We have made greater reduction but I believe that the two committees working together, the freight claim and the accident prevention committees are making that reduction. I would say that we have more than twice the reduction with the freight handling than we have with any of the other occupations but we do have trouble where we have contract labor, by tonnage. That is under our men too. They watch but they do destroy freight and injure each other. We have more trouble with that class.

MR. HARTENSTEIN: I want to say we have contract labor too in Jersey City but those forces are pretty regular too and we have very few injuries among them. Once in a while we have one. The handling of freight there is on a tonnage basis and the contracting, too, the railroad company is held responsible for it.

CHAIRMAN BAILEY: The next subject is a subject interesting to railroads centering here, "Marine Accidents" and I presume they have a relationship to your accidents occurring in freight houses. I am going to ask Mr. A. B. Hoff of the Erie Railroad Company, New York City, to come forward.

Marine Accidents

By A. B. HOFF

Manager of Safety and Employment, Erie Railroad Company, New York City

Are there any marine superintendents or gentleman of a slightly different title here? If so I would like them to come to the front. There were nine marine superintendents, head of marine departments asked to be here today. I don't know whether any of them are here or not.

The question of Marine accidents is also covered by the Marine Section which is meeting simultaneously with our own. There are two classes of Marine accidents, one of which might interest railroad men such as we are, and the other which interests solely, marine people; that is the accidents that occur solely from the operation of the ships, tugs, lighters, etc., in their capacity as floating equipment; ferry boats and others which interest us in the handling of freight and their contact with floats, bridges, docks and other places where they meet the railroad.

Now, there is to some extent very little to start this off on. Examination of our marine accidents, both those reportable and those of which no time is lost, show the largest number come from very much the same causes that we have on the docks among our stevedores and freight handlers—slipping, falling, stumbling and so on. That is magnified when you get in contact with floating equipment. You then have the added hazard of water—I mean water on the deck, not water in the river. On a dry day on shore it is often wet on the ships, especially low ships where lines and so on are being slapped over the decks. I might say, I was a sailor by trade before I became a railroad man, and that is one of the reasons they pinned this to me. However, I find we have such accidents in our marine equipment as being hit with lines, hooks; falling into frog plates on the decks, bumper plates; getting caught between the float and the car; rails breaking on a tug or lighter; a man falls from the next deck below and catches his hand between the line and the bit making it fast; closing a door on thumbs, which might happen in any place.

Then we have planks breaking between the ship and the shore. In those cases we don't have these plates. We had one man washing windows on a ferry boat in mid-stream. I question the advisability of that, while moving; I don't think it will occur again. The variation in those accidents could be carried on and on in detail for a considerable time, but in the main and essentially they are the same. They come mostly from the slipping, handling of lines, falling down between the floating equipment and the dock or between two lighters; and the answer to that is clearly, get better supervision.

To get better supervision is a favorite alibi where you are handling a lot of men but it is the only thing you can do. In other words where we are handling casual labor, such as we do on the docks and such as we have among the stevedores, not among the crews of these vessels but among the stevedores. It has got to be supervision and the supervisors are the ones that have to learn to do it right. They can't use the same kind of supervision or the same degree of supervision or the same amount of effort that they do where they have men that are with them day in and day out, know their ways and carry out their routine performance of duties. They must use more and greater effort and that is the message I am personally going to bring to my marine department. I have already brought it as far as that. I am speaking of accidents connected with the operation of the marine department. That is of course, not marine employees in all cases.

We have our dock stevedores, passengers, etc., and dock stevedores come under Class 5 the same, as marine employees do, but the answer is, as far as I can see, greater effort and a more intelligent and intensive performance on the part of the supervisors.

The physical characteristics are generally good on all floating equipment. Men

had been going to sea hundreds of years before they ever went on railroads; and people in the seafaring end of life had been handling the safety question and putting it forward in prominence long before we ever heard of a railroad. So that end is not a menace as a rule. It is what people do around docks, the way they behave and in handling freight, etc., on or off floating equipment.

MR COTTER (Erie Railroad, New Haven): In talking about marine accidents I have noticed around New York Harbor a tug boat captain has the habit of trying to get a boat into a narrow space where there may be 75 or 100 men working. They have no knowledge of the tugs coming in and the tugs hit the dock whereby the laborers are injured. Furthermore, there have been accidents due to unloading and loading cars from floats when tide is too high or too low. Cars become uncoupled, and that is a case where I believe people should eliminate the handling of floating equipment during such tidal conditions. I think that has something to do with our friend from the New York Central. We have about 300 men on our piers in New York and we don't have many accidents. We aim to notify them before the arrival of a tug boat coming in to pick up a float or lighter to move away from that point.

C. W. HAMMOND (New York Central, New York): I would like to ask Mr. Hoff how many men he has in the marine department and if he is showing a reduction of accidents in the marine department?

MR. HOFF: We have about 800 men in the marine department, and I can't say we are showing a reduction, because we don't have many accidents among the marine employees, that is reportable accidents. They run all the way from none in a month, or a bad month, five. But, we have a number of accidents that don't lose time. One or two cases affected passengers, such as slipping while getting on or off a ferry boat. That is what makes it difficult to check up on this subject because the accidents we have are hardly marine accidents. They occur to people in the marine department.

REGINALD FEY (New York Central, New York): As the marine superintendent of the New York Central and having at one time served my apprenticeship on a tug boat, I am quite familiar with those conditions. The only thing about the accidents in handling a tug, is that on railroads you do not have that tidal condition and there is a little bit more motion on tugs in the river than a freight train in the yard. But the handling of lines in bad weather, I mean snowy, wet weather, when you can take five or six turns on a nigger-head and they won't hold; slipping on the decks, breaking of lines and getting caught between the barge or float or whatever it might be—these weather conditions make it rather perilous and in some instances we might have more accidents due to those causes than otherwise. But in the handling of heavy equipment such as the railroads are building today; for instance, a float 366 feet overall; and the wind blowing hard, say 47 miles per hour, we don't operate much after that period; it is rather perilous and you have got a good deal to think of both from a personal standpoint and accidents that might happen to other equipment. So I think the conditions on the river in New York Harbor are at times rather strenuous.

MR. HARTENSTEIN: We also have several men in our marine department and our friend from the New York Central and Erie has described the marine hazards which occur and there is very little difference. However, we do maintain a marine department safety committee consisting of the assistant superintendent of the marine department who is chairman, the captain, engineer and deck hands, and we cover pretty close to every department on that committee and they are working very conscientiously in keeping down accidents.

CHAIRMAN BAILEY: I think some committee should make a study of this subject edifying to the Steam Railroad Section and also to the marine section.

W. W. FULLER (Seaboard Air Line, Savannah): I only want a minute. I would like to ask Mr. Hoff as to the clothing worn by the men in their work.

We operate tug boats and frequently have accidents on the Seaboard due to improper clothing and I would like to know something as to what requirements they have in safe clothing, shoes especially.

MR. HOFF: I am not the marine superintendent, I am manager of safety. I don't know except that I see the men and I don't notice the clothing being any different from anybody's else around the docks. In looking over the accidents of the past year I found no injuries or accidents that had any reference to the clothing worn. These sailor men know pretty well what to wear. They know they must be warm in cold weather.

CHAIRMAN BAILEY: We will have to terminate this discussion. The next subject will be by Mr. Z. B. Claypool, St. Louis, San Francisco Ry. Co., Springfield, Mo. We will ask Mr. Claypool to start off this discussion.

Falls in the Mechanical Department

By Z. B. CLAYPOOL

**Assistant Director, Accident Prevention, St. Louis—San Francisco
Railway Company**

The Interstate Commerce Commission's "Accident Bulletin, No. 96," for the calendar year of 1927, shows that on roads of all classes, 51 deaths and 6,693 reportable injuries occurred from falls of employees in non-train casualties.

Just what percentage of this number of casualties is chargeable to falls from elevations, we do not know, but believe the majority are from that source, with the temporary scaffold one of the chief causes.

A great many of these falls could be eliminated by adopting the policy of moving the job to a permanent scaffold instead of taking a temporary scaffold to the job. For example, the car department repair track, where rebuilding is done, the work can be specialized and handled on the progression system in much the same manner as an automobile is built. Start at the head end of the track with the truck rebuilding gang. The trucks when rebuilt are moved on down the track to the workers who apply the car sills, from there to the carmen, who do the framing, with their permanent scaffolds necessary for such an operation, and so on down the line until the car is rebuilt by the time it reaches the opposite end of the track from where the first operations began. The workers have remained in fixed locations and performed their work in less time and with greater safety as the job and material was moved to them. We have adjustable permanent scaffolds in our coach repair shops and coach paint shops. Why not on our freight repair tracks?

We can never entirely eliminate the use of, or the necessity for, the temporary scaffold, but any temporary scaffold can be made safe. The average employee, however, seldom uses the time it takes to make a temporary scaffold absolutely safe, and that is where the supervision must step in with education and discipline, if necessary.

Falls from stepping into depressions, such as cinder pits, engine house pits, or air and steam line hose connection pits in train and repair yards, are all too frequently a cause of personal injury.

Some pits may be amply protected with iron fences or railings while with others it may be necessary to cover them entirely. Pits which are covered should have the covers as light in weight and as small in sections as possible to equal strength requirements. This will insure better and quicker replacement when job is complete for which pit covers were removed.

Pits in train yards with removable covers are not sufficient protection, since the cover lids may be left open or thrown to one side. The standard on our lines is to have such lids flush with the ground, hinged on one side with a

short chain underneath the side opposite the hinges. This chain to be connected short enough that lid can be opened less than half way which will make the lid self closing when pit is not in use. All lids of these pits to be painted white so they may be more readily seen at night.

Falls over obstructions such as scraps or misplaced material as results from bad housekeeping in or around shops is a direct reflection on the supervision even though the injured person may have appeared to have been careless. The foreman who keeps a clean shop and has for his motto: "A place for everything and everything in its place" will not have injuries of this type charged against him.

In conclusion, how are we, as organized Accident Prevention workers, going to reduce this number of 51 killed and 6,693 injured last year due to falls of employees on American railroads? Briefly: first—by sufficient and efficient scaffolds, second—by safeguarding openings, and third—by clean housekeeping.

CHAIRMAN BAILEY: That is a very good presentation of the subject for discussion. Is there anyone wishing to discuss this matter?

MR. CLAYPOOL: I would rather you would waive the discussion of this and take up the time left for Safety Contests. I would be perfectly agreeable.

CHAIRMAN BAILEY: Does anyone wish to discuss the subject on the program? If not, we will give the time to the discussion of Safety Contests. This is a very important subject, a matter of vital interest to many of the railroads and I am going to afford you this time to ask questions.

H. W. HUDGEN (St. Louis, San Francisco Ry., Springfield, Mo.): The gentleman raised the question about his contest giving out. I just want to tell you briefly about our experience. In 1926 our president put out two plaques. One for the mechanical department and the other for the maintenance department, won each quarter by the superintendent or division having the least number of accidents and the same as to the mechanical job. We have been running that contest almost two years and we have just as much enthusiasm at this time as we had when it started. That is all.

MR. LAUTEN (Gulf, Mobile & Northern Ry.): We have, from time to time conducted these thirty and ninety day contests but we found that after they closed, the interest began to lag and eventually we go back to the same old rut; so on June the first of this year we inaugurated an all year round campaign. Now, on our road a safety contest begins at the top. The president, general manager or vice-president is the leader but while the foreman is the key to the situation, we have established a fair rating for the ranking of each foreman or supervisor. Every injury is reported regardless of whether time is lost or not. For every hour or fraction of lost time, one point is charged against that foreman, supervisor or trainmaster and against their records. Two hundred points is the maximum to be charged against any injury; of course that includes a fatal injury. The standing is published monthly and includes cumulative figures as well as those for the current month. This provides a means whereby the trailers can eventually come back as leaders.

Since May 19th of this year we have not had a single reportable accident or injury to an employee on duty. I will qualify that. From May 19th to September 28th, we did not have a reportable injury. That one September 28th was due to pure carelessness. A colored section laborer started to get on a motor car from the side, violated instructions and broke his leg. That supervisor had come to our assistant manager just a few weeks before and said, "Mr. Brock, I wish something would happen on our division. I am getting nervous. We haven't had any injuries since the campaign began. I would like to see somebody get a finger mashed or something, it might relieve the tension."

When that was broadcast through official notices you can imagine the effect it

had on the railroad. It meant instead of a perfect record for the third quarter our casualty ratio was reduced to six tenths.

C. F. LARSON (Missouri Pacific Ry., St. Louis): In the month of July the Wichita Division of which he is master mechanic had three lost-time accidents aggregating twenty-four hours lost time for the whole division. That division has made month after month a clear record, but I think that is about the best that has been done on our railroad; the Missouri Pacific going for a whole division, thirty-one days with three accidents that aggregated only twenty-four hours lost time.

CHAIRMAN BAILEY: I would like to ask if you attribute that to the fact that you are carrying on contests?

MR. LARSON: Absolutely; and I would assure you our contest was started in the early days of 1925 and is just as acute today as it was then and I would feel a severe reflection on myself if it slipped.

CHAIRMAN BAILEY: I think the consensus of opinion is that this discussion has proved conclusively to the minds of some of the brothers that have doubted the wisdom of instituting contests on their lines, that contests really bring about results.

L. G. BENTLEY (Chesapeake & Ohio R. R., Richmond, Va.): As I started this thing, I thought I would just have a word to say in closing it, and that is, that while I would not detract from the value of a short safety contest, the whole value of it may be summed up in the perpetuity. Carry it on year after year and the longer you carry it on the more lively it will become if you inject the proper spirit in it. I appreciate most sincerely the discussion of this subject which, as I said this morning, is paramount in so far as carrying on safety work is concerned. Your discussion has stimulated me and I have enjoyed it all.

JAMES PRATT (Reading Co., Reading, Pa.): We are sending circulars to the section men twice a month giving them the standing of all the divisions.

MR. HARTENSTEIN: I started this discussion on the length of time the contests should be conducted. I don't want the men to understand that I don't favor these contests, for I do. I think they are a mighty fine thing but the length of time was a large question in my mind and I am glad to have the information I have obtained.

CHAIRMAN BAILEY: The time has now come when we must adjourn and I will turn the meeting back to Mr. Long, the Chairman.

CHAIRMAN LONG: I am going to use my prerogative as Acting Chairman this afternoon to give a thought to our friend from Frisco which may help him. We have monthly meetings of our supervisors in the maintenance of way department; monthly meetings of safety. What I mean by the supervisors, are the divisional engineers who are chairmen; our bridge and building men, road masters, our railroad and track supervisors and the general foremen on that division having the larger gangs. To those meetings we invite four or five track foremen. Different foremen every month. Now, the way our message is carried out to the foreman on the job in the outlying points is through the track supervisor, the road master, the bridge and building master and his assistants. In addition to that, these foremen who are brought into the meetings, for instance, this month are at the meeting for a sufficient time until they give their ideas of what the track foremen should do to promote safety, and their ideas are embodied in a letter addressed to all foremen, after it has been dressed up a bit by the division engineer's chief clerk. If those letters would be of interest to any of you I would be glad if you would write me at Albany and I will send any of you copies of those letters as they have been coming out for the past two or three months. I hope you won't ask me to go back but I will send the current ones as they come out.

I think our track foremen today know just as much about the mechanics of safety, despite the fact that some of them are a good many miles from headquarters, as our shop foremen do.

ADJOURNMENT

October 4, 1928

E. R. COTT, Chairman

Supervisor of Safety, The Hocking Valley Railway Company
Columbus, O.

The fourth session was called to order at nine o'clock by the chairman, E. R. Cott.

CHAIRMAN COTT: We have an item on our program this morning which is not on the printed program. The speaker is here at the request of a number of railway engineers interested in the safety men learning something of a problem they have. The man who is to address you is engaged in a work that is non-commercial; in other words, he has undertaken a study for the American Railway Association and the American Engineering Association in connection with train accidents due to transverse fissures in rails. The chief engineer feels that he needs some support in the campaign which will probably be undertaken before long, following a series of acceptances of a device that has been perfected by Mr. Sperry. As I say, it is non-commercial, it is something that should be of interest and which will enable you, knowing of the device, to be of some assistance to your chief engineers of maintenance of way in handling this problem on your road.

I take pleasure in introducing Mr. Sperry, who will talk to you on "Transverse Fissures in Rails."

MR. SPERRY (Sperry Gyroscope Company): I hope you will come up forward for we haven't any slides and I want to show you some pictures of queer kinds of cancer that grows inside of a steel rail. There is no outside indication of where it is; no indication of the tragic thing at all. The late Mr. Felt (I am sorry to say "late"), then president of the American Railway Engineering Association and chief engineer of the Santa Fe Railway, wished the job on me and I said, "How can I look inside of a steel rail any farther than anybody else?". He simply said, "You have got to do it."

There was a challenge and we went to it. After working some four years we found a way to look inside of a rail and when you look inside of some rails you are rather surprised at what you find. I have some pictures here. I told them if they would send me some rails that had broken in service and were therefore under suspicion I would see what I could do. I don't suppose you can see that picture. Those are fissures; we have located many. Here is the head of a rail with one of them, you can imagine the rest of the rail down here. That is *some* break. I think you can see it very well.

These things grow inside, starting from a very small thing and finally they are so nearly cut in two that the locomotive does the rest and sometimes starts out through it for a ten-acre lot. It is a mighty good thing if there is a ten-acre lot to receive it. Sometimes there is not. Here is a case (exhibiting picture) where the ten-acre lot failed to appear and there was a pile-up. Three of those have occurred this year.

These fissures have grown until they have cut the rail in two to the tune of about 5,000 of them the last year, so it is serious. The process is sort of a wireless process, we don't necessarily touch the rail, simply look at it. The committee sent me some eighty-five rails supposed to have fissures in them. One rail had no less than eleven fissures in it, and when I notified the Rail Committee they didn't believe it. I don't blame them much, because as a result of other investigations, they had seen hundreds of rails broken up and never found a fissure.

"When you come down here we will break this rail and I will show you what is in there," I wrote them. So they started from their headquarters in Chicago and gathered railway men as they came until about twenty walked into my office and wanted to know what I meant by finding fissures. "Come down to the laboratory

and I will show you. I will break a rail up and see what is in there." Before we did that we had this blue print of the rail made, showing exactly the location of each fissure and exactly the size of it. So I said, "Here is a case where you can hang me if I don't find fissures."

Well, we broke the rail up and found eleven fissures exactly as we stated we would and here are the photos of the eleven fissures on the two sheets. So we strike twelve once. Now, the funny part of it is (I ought to knock on wood) we have never located a fissure, determined its size and broken the rail but what we have found two things. First, the fissures were where we said they were, sometimes within a thirty-second of an inch and, secondly, they were about the size we said they were.

The roads have had some rather severe experiences in that line. This pile-up is a report of the I. C. C. and that is the fissure that did the trick. This poor road for that one accident was sued, I believe, for two and one-half millions of dollars. That would pay for looking into the rails pretty carefully, but there was then no way of doing it.

Now, there is a sunny side to this thing. The New York Central sent a lot of fifteen rails which had broken in service and another lot of eleven. Now, do you know that only three rails of all those pieces that came to us had fissures? These fissures, by the way, have been known to grow over night in a brand new rail, and have cut the rail in two. Then some of them take fourteen years to grow, so you can't most always sometimes tell what you least expect most in this job. Mr. Bronson of the New York Central felt that in the first lot of fifteen rails that he sent us there must be a number of other fissures. We examined them and found it was the finest steel you ever saw and there was not a single fissure. They would not believe it, so in reviewing the matter with some officials it was decided to pick out three rails of the fifteen. We re-examined them, refined the process, and absolutely found nothing there, not one-half of one per cent. Nothing in them at all. Still they wouldn't believe it.

A friend of mine has a great big steam hammer and we loaded the rails on our truck and had them broken up into chestnuts, four or five bushels of chestnuts. You bet if any fissure had been in those rails, under the method of breaking, not shearing at all, but breaking, they would have broken exactly where the fissure was. But there were none. We took photos of the pieces of rail so as to have a permanent record. So, that is the bright side of the story. There aren't as many fissures sometimes as we expect there are.

The best part of it is that we have been able not only to tell where they are but to make a record of them, making each fissure sign its own death warrant, as it were, in red ink, and the apparatus is all contained in a car which is rather a practical sort of apparatus. It is enabled to go up the track, pulled by a good, strong power hand car, about ten miles per hour. In this car there is a recording apparatus that is shown here. There is a table with a paper tape coming along that has seven lines on it, three for one rail and three lines for the other, and the middle one showing where the rail joints are; we number the rails as we go along and also squirt white paint on the side of the rail when we find a fissure. That is all done automatically, so we have a permanent record of what is inside of each rail, and the ones that have any trouble down to one per cent are marked. We can tell the size; if it is a small fissure, one pen operates; if it is a middle-sized fissure, the first two pens work and if it is a big one, then the three pens work and that rail ought to be taken out of service.

The car was accepted, as your Chairman stated, the day before yesterday by the American Railway Association and is now operating on the tracks of the New York Central. That car is to be taken and loaned six days to each of the roads in the United States so they will all get a taste of it. Of course that can't remove all the fissures, but it will show the practical operation of the apparatus that we

have devised. It so happens I am chairman of the National Research Council, Engineering Division, and it was along the line of research, as your chairman stated, non-commercial, that the work was undertaken.

I have some fissures here. I don't know that you can see them from that distance, but when they get about that size they are very dangerous. That is a smaller one and these others show them with the growing pains when they are smaller. I think you can see that fissure plainly for it is darkened. Now, then, I think that presents the matter. If there are any questions you practical people have, I should be very glad to struggle with them and see if I can enlighten you on any point I have not made clear.

CHAIRMAN COTT: There are several chief engineers of the railroads here.

W. L. ROLLER (Hocking Valley R. R., Columbus, O.): I would like a more detailed explanation of the method of detecting the fissure, if Mr. Sperry cares to give it.

MR. SPERRY: Now, your Bureau of Standards tried some eleven years, using magnetic methods, putting magnetism into the rail and expecting the deflections to tell what was in it. Such of you as are engineers know every generator and motor in the world has such a thing as an air gap: Here is a stationary field and here is a revolving armature and an air gap through which the magnetism has to pass. So, in the normal operation of a motor or generator an air gap is its middle name and these air gaps may be a large fraction of an inch. These fissures constitute a very minute air gap. Science has never known how small the air gap was until some months ago when we tried an experiment on one. Knowing exactly where the transverse fissure was within a thirty-second of an inch, we put a drill hole in so the point of the drill went right down into the hidden fissure, as you can see there. Then we put iodine in and each morning for a couple of weeks, adding a drop at a time, knowing that the tincture of iodine would go in and discolor it. Then when the Rail Committee came down we broke the rail, expecting to find the dark color, but when we broke it it was silvery like the things we have before us there, showing not one particle of the tincture of iodine could get in. Why not?

If you went into a pattern shop, took a back-saw and made a slit down in a plank and took buck shot and tried to see if the shot would drop down into the narrow slit, you would find they wouldn't. They are so large they can't commence to look at the slit even. This molecule of the halogen group, though the smallest molecule we have, was so big it couldn't squeeze itself into that little crevice. So, when you use the magnetic method, the gap is so minute that magnetism passes through as if nothing were there. That is why they never found any fissures. We use the electrical method. By that I mean we use electricity, making it pass through the rail. The contact points consist of thirty-two heavy copper brushes that pass along the rail with the car. Two thousand amperes pass through the interior of the rail. When it comes to this little air gap, even if it is only half a molecule thick as we know it is, electricity is different from magnetism which passes with perfect ease. Electricity says, "Here is an awful chasm; I can't cross it, I will have to go round," and we just catch him in the act of going around.

D. G. PHILLIPS (Wabash Railway, St. Louis): Do those transverse fissures exist in rails as they come out of the mill?

MR. SPERRY: They do not. We have just taken the system down to the Illinois Steel Company and put through 1,000 thirty-nine foot rails. We could find but little in them except shatter zones in the "A" rail of the heat. These, it is barely possible might develop into fissures later, but "A" rails having such zones, if known, need not be used at critical places on the road. Never any fissures in new rails, but possibly nuclei. You know Mr. Moore down at the Illinois State University has been conducting tests for about twelve years. It so happens that I was vice-chairman of a committee here that furnished about \$40,000 to conduct

those experiments and he has tried out many thousands of test pieces of steel. There is one peculiarity in the breaking of steel from fatigue. You understand every wheel that goes over the rail, produces a visible deflection, not only under drive wheels but every wheel, and our wheel loadings are constantly growing higher and higher. This deflection causes the fatigue. But Mr. Moore has found in his thousands of tests that many breaks occur where the flexure is not the greatest. It breaks somewhere else. Why? It is because there is some little thing in there that starts it, so we have an idea there may be some small thing in the rail that allocates where this fissure is going to be. The rail mills are giving us very good product, especially considering the fact that the roads are demanding steel that is excessively hard. If you want to know how hard a piece of rail is, give it to your foreman and tell him to put it on the planer and take a cut off it. He will come back for some very peculiar hard tools, for it is so extremely hard it is almost impossible to tool it.

They are doing their best. They are giving us superfine steel. What causes the fissures to develop? I should say fully 95 to 98 per cent fatigue after they are laid and 2 per cent allocating fault or inclusion in the rail. In rails with shatter zones this percentage may almost, on occasions, be reversed. Constant bending creates and brings about new molecular conditions of stress.

Method of Locating the Fissures

MR. HARTENSTEIN (Lehigh Valley R. R.): I would like to ask Mr. Sperry what his method will be of informing the railroads just how he detects each fissure in the rail. I may have misunderstood him, and what his method will be of displaying them to the railway.

MR. SPERRY: That car is owned and operated by the American Railway Association, involving all of the railroads of the country, and they have started out on a regular program.

MR. HARTENSTEIN: Then the car is under their supervision?

MR. SPERRY: To help you along I might tell you on this particular point that a company has been formed on advice of the roads to make some of these cars available to them for quick service, using our trained men, because we have about five thousand of these fissures occurring per year. It is a serious thing and it was thought wise to have a number of cars out on the various roads apprehending these fissures, pointing them out, as to size and exactly where they are, so that those rails having large fissures may be lifted and our railroads swept clear of these awful menaces.

CHAIRMAN COTT: I want to thank you, Mr. Sperry, in behalf of the Steam Railroad Section of the National Safety Council for coming here on our request and giving us some enlightenment on this subject. Science has here come to the aid of safety as it has in other cases and there is a possibility that the menace which is terrible so far as the railroads are concerned, is about to be brought from darkness to light.

My attention was called to this; I knew nothing about it before, by our chief engineer, Mr. Michael, who knew of the fact that the first car owned and operated by the American Railway Association was now on the New York Central lines. Mr. Phillips, chief engineer, also made a request that we hear Mr. Sperry. I am glad we had the opportunity and I wish to thank you for the Association.

We will get immediately into our program now. We will ask Mr. W. P. Mountford to come forward and present his paper.

Mr. Mountford is just recovering from an illness, Mr. Neff tells me, so Mr. P. T. Neff will present Mr. Mountford's paper for him.

Safety in the Shop

By W. P. MOUNTFORD

Safety Inspector, Pennsylvania Railroad, Philadelphia

"Safety in the Shop" may now be looked upon as an actuality whereas a few years ago this was viewed as a gigantic task. During the year 1925 the casualty rate per million manhours of injuries reportable to the Interstate Commerce Commission for employees in the maintenance of equipment department of all roads was 35.45 as compared with a rate of 19.62 for 1927.

It should be remembered that year after year the casualty rate for injuries to employees reportable to the Interstate Commerce Commission for all railroads was worse in the maintenance of equipment department than among any other group of employees. But it is pleasing to note that the latest figures show a material reduction in the rate for this group of employees, which is now among the best.

In view of this performance it is fair to state that accidents can be reduced and thus produce safe working conditions in the shop.

Reasons for Improvement in Rate

To effect such an improvement there must be some underlying conditions responsible so that it is necessary to set forth briefly some of the reasons, a few being as follows:

1. Increased interest and added stimulus given to safety among the officers and supervision.
2. Cooperation of the employees.
3. Definite appreciation among the immediate supervision of their responsibility for injuries.
4. Stable forces.
5. Thorough investigation of all injuries to definitely establish and place responsibility.
6. Recording injuries to employees to avoid "repeaters."
7. Appropriate action with respect to observations before an injury occurs.

We strive to instill in the minds of the supervision and employees the thought that "a report of a preventable accident is a record of failure in the performance of duty, either on the part of the employee involved, his supervisory officer, or both."

It should be borne in mind that, to a very large extent, most of the employees in the maintenance of equipment department are assigned to definite locations, making it easier for the supervision to properly control the situation, which does not obtain in most other groups of employees. Under the circumstances it is not unreasonable to expect that at each shop they should have a rate equal to or better than the average for the system.

Supervision's Responsibility

You can make all kinds of overtures to the employees for an improvement in the accident record, and you may get temporary results, but a continued and sustained performance will only obtain when the supervision fully appreciates that it is their responsibility when an injury occurs to an employee. They must further make it their duty to analyze and know their job; understand and appreciate all the conditions in their immediate department or unit that are likely to result in injury to employees.

After they have mastered this information they must not be hesitant in im-

parting it to the employees. When an employee is observed performing a duty in an unsafe manner it is their duty to promptly take corrective action to prevent an injury, but infrequently we find that corrective action is not taken until an injury has been sustained.

An illustration of this recently occurred at one of our shops. An employee in removing a peep hole plug from a cylinder, the threads of which were badly corroded, placed a grate shaking bar on the end of the wrench, the shaking bar slipped off the wrench and caused injury to the employee's foot. It is needless to state that after the injury instructions were issued stating this to be an improper manner of performing the work. In this particular instance no action was taken until an injury was sustained, which is to say, that if the injury had not occurred they would still be performing work in this haphazard manner.

We are all familiar with the usual practice of corrective action when an employee, especially machine operators, spoil material, but how lax we have been with respect to holding the supervision responsible when it comes to human wastage.

Employee's Responsibility

It should be distinctly understood that the employee has a responsibility in the prevention of accidents. When this has been fully established we should not hesitate to take the proper action.

It is the duty of the employee to accept the advice of those who have made a study of safety. When his attention is called to an unsafe practice or careless manner of performing the work he must appreciate that it is for his good and that he is the one to derive the most benefit. He should, therefore, whole heartedly assist those who are endeavoring to improve his working conditions and methods of work.

Causes of Injuries

Most of us are familiar with the general causes of injuries due to removal of guards, inadequate inspection of tools, failure to wear goggles, failure to display blue flags and many other causes which occur from day to day, but the supervision and employees need to have pointed out to them unusual conditions, many of which result in serious injury, a few being listed as follows:

- A. An employee removing brass screws from a cylinder jacket, screws badly corroded, top screw had been removed and was turning next screw, which broke off at the head the tension in the sheet causing the screw head to fly out with terrific force, striking the eye. An unusual condition not generally covered in the goggle rules but which resulted in the loss of an eye.
- B. Tool rests on emery wheels allowed to be more than a permissive distance from the stone resulting in tools jamming causing them to fly or weaken the stone. Faulty maintenance. Rests should follow the wear of the stone.
- C. Failure to properly maintain limit switches on overhead cranes, or to test them daily, resulting in the block falling on employees working on the floor, invariably resulting in a fatality. Also, accumulation of tools, grease cans, buckets, etc., on the runways. The supervision seldom go on the cranes.
- D. Overhead crane cables secured to loads or loads suspended at lunch time, cranes not equipped with rope ladders making it necessary for operator to get to stationary ladder by walking along the runway, straddling the rail.

- E. Men working under cars with truck removed, car suspended on jacks, failure to use trestles.
- F. Use of high ladders to build platforms alongside of locomotives, planks placed on top cross piece which are not provided with end stops permitting planks to slip off ladder.
- G. Working in stationary boilers without having crown valve or blow-off valves closed and locked.
- H. Stationary firemen firing boilers with roll flue curtain immediately above their heads left in an open position.

These are but a few illustrations which could be considerably increased but are given as an indication of what the supervision should look for and guard against. It is easy to determine the possibility of injury when operating a machine, but there are many other operations about a shop which does not readily indicate the danger connected with them, making it necessarily a part of the supervisor's duty to be able to visualize the possibility of danger and subsequent injury and to instruct his employees accordingly.

It is a sad commentary on shop management when serious injuries and fatalities occur before the danger of an operation is developed and instructions issued to avoid a recurrence.

Observation of Improper Practices

How many of us are aware of the repeated observations of safety inspectors and safety committees? What is the significance and what is done about it? Are we performing our duty in permitting an employee to continually work in an unsafe manner without taking action? An employee may indulge in 50 cases of carelessness before an accident occurs but when that accident does happen it definitely places the responsibility on the supervision for not taking corrective action when the observations were made.

All observations of violations of rules, improper practices and carelessness must receive the same attention and cause the same action to be taken as when an injury occurs, otherwise we defeat the very purpose for which safety inspectors, safety committees and the safety organization were appointed.

There must be some arrangement provided whereby an employee observed working in a careless manner and whose attention has been directed thereto will know that such information will not be treated lightly but that persistent violations will be charged against him and should an injury result from failure to correct a practice he must necessarily stand the consequences.

That these dangerous practices are not regarded the same as when an accident does occur is probably one of the reasons for poor records at some shops.

Minor Injuries

In the past too little attention has been paid to the large number of so-called minor or first aid cases, many supervisors directing their attention to reportable injuries. A reduction in reportable injuries is heralded as a great achievement, but it is only part of the work.

As an illustration of this an employee may have a foreign particle lodged in his eye, go to the first-aid room, have it removed and return to work. The seriousness of the situation is not considered, notwithstanding the foreign particle lodged in the eye as a result of failure to comply with the goggle rules.

This provides a vehicle for minimizing the value of goggle rules, also a disregard for safety rules in general, and lays the foundation for a more serious accident which might result in the loss of an eye.

It is not unreasonable to insist and expect that each injury, regardless of disability, shall be treated in the same manner as serious injuries are treated.

Have we been lax in our safety endeavors or have we permitted ourselves to think that scratches, bruises and laceration on a large scale are inevitable in shop operation? Where a reduction in reportable injuries has been effected it should be expected that the same appreciable percentage of reduction will obtain among the no lost time injuries.

When we fail to find such a condition the efforts along safety lines are obvious. Efforts are concentrated on the reduction of disability rather than the reduction of accidents.

Record of Injuries

Most of our master mechanics keep a daily "blotter" or running record of all injuries occurring to employees under his jurisdiction. This blotter shows the name of the supervisor responsible for the safety of the employee, name of employee, cause of injury, disability, responsibility and action taken and other pertinent information.

This information is posted daily and indicates the trend of his performance from day to day. It enables him to determine in what departments or units injuries are occurring. Should one department have too many accidents or accidents occur through faulty maintenance he is then in a position to take such action as may be deemed necessary to bring about increased activity among the supervision.

We have found this to be an excellent arrangement which has helped materially in the reduction of injuries in that it provided for immediate action rather than waiting until the end of the month for a tabulation of the injuries. Waiting thirty days to make comparisons with the previous month is too long and does not enable the master mechanic to take action to bring about an improvement in the record.

Recording Injuries

On most of our divisions a record is maintained of each injury, being posted on a separate index card. Careful investigation of injuries at points having poor records indicate that a few employees are usually responsible for a large number of the injuries.

As a result of the adoption of this method the divisional or shop people have been able to take prompt action against those employees who have proved themselves to be habitually careless or unfit for the work. These employees are referred to as "repeaters."

You can readily appreciate that an improvement will be effected when the master mechanic writes to a department head citing the poor record of an individual employee. By this method we have made safe workers out of habitually careless men and in many instances have removed men from their regular position or out of the service as being a "misfit" in the position they were holding.

Does it not seem inconsistent that we provide machinery for recording all employee derelictions with respect to poor workmanship, absence from duty without permission and many other causes, but fail to record personal injuries sustained by the employee or injury to others for which he is responsible?

As a matter of good management this information should all be recorded so that when the master mechanic reviews the employee's record he has before him the complete performance of the employee and can readily determine his natural tendencies.

Investigation and Follow-up

One of the features we stress in our safety activities is that a prompt and thorough investigation and follow-up be made of each personal injury accident regardless of nature of injury or extent of disability, to determine:

- (a) Cause.
- (b) Responsibility of employee or supervisor.
- (c) Whether absence from duty is warranted.
- (d) Whether injured person has been previously injured within, say, two years.
- (e) Whether injury was the fault of injured person or due to conditions over which he had no control.
- (f) Where consistent, supervisory officer, his assistant or someone delegated for the purpose, will accompany injured person to first aid room, hospital or home, or call upon injured person, if necessary to ascertain facts.

In conducting investigations they should be inaugurated with the sole view to definitely establishing the cause and responsibility without regard to whom it may affect. The management should be willing to accept their responsibility just as readily as they are to carelessly charge them to the employees.

I say "carelessly" advisedly. Statistics have been presented showing that approximately 85 per cent of all injuries are due to carelessness, indifference, thoughtlessness, ignorance and many other causes and supervisors, safety agents and others have grasped at these causes in fixing the responsibility. Many illustrations could be cited where the responsibility was placed upon the employee under the above causes when as a matter of fact the supervisor failed to visualize the danger connected with the operation or through failure to properly instruct the employee. The following illustrations will emphasize the point:

An electrician was working on the junction box of a multiple unit car, with trolley removed from wire. A helper came along and replaced the trolley pole resulting in the electrician being shocked and burned, sustaining approximately 60 days' disability. Since the accident positive correcting action has been taken which I am sure will remove any possibility of a similar accident. In this instance responsibility was placed on the helper. But the basic cause was due to failure to visualize the possibility of injury by the supervision through lack of coordination long before the injury occurred.

A gang foreman and a number of employees were riding on a motor car, the gang foreman leaning on the front guard rail. When they reached the point of work an unauthorized employee reached over and applied the brake, throwing the gang foreman forward with the car passing over parts of his body. Several fractures resulted, the employee losing approximately 90 days. In this case the responsibility was shown as that of the gang foreman's, due to weakness of the guard rail, but nothing was done with the employee who applied the brake which induced the accident. If the brake had been applied by the operator gradually as he was accustomed to rather than suddenly as by the unauthorized employee, it is doubtful if the rail would have given away.

The desired result will not obtain if the investigations are held in a perfunctory manner and responsibility placed without regard to basic causes.

At many shops, it is the practice for the department head or his assistant to accompany the injured employee to the dispensary. This gives him the advantage of first hand knowledge as to the seriousness of the injury and also information as to whether loss of time will result.

One advantage to be derived from such an arrangement is the effect of responsibility placed upon the supervision. It also arouses his interest in safety and causes him to take prompt action on observations of unsafe practices, thus

reducing the number of trips to the dispensary. This has been found to be very successful and is now employed at other shops on the system.

Conclusion

We have found nothing cumbersome in any of these methods, all of which have been tried and proved practical and the adoption of these methods will tend to greatly reduce the number of accidents and gradually reduce the amount of time now employed in the preparation of reports, investigations, etc.

We should not direct our efforts solely along the lines of reduction of disability but concentrate on the reduction of injuries which, when accomplished, will bring about the former. Thus when accidents are reduced to a minimum it will not be necessary to reassign forces, conduct investigations and other actions which will then permit the supervision to apply more time to productive efforts.

In presenting this paper I have done so with a view to avoiding generalities and theories, actual conditions and experience being more productive and convincing and the results indicate that we are arriving at the solution of the problem.

We do not feel that we have any secret formula or control the panacea for this trouble, realizing that many other shops on other railroads have equally as good a record, but I have simply talked about methods which we know have produced results.

Something About Repeaters

CHAIRMAN COTT: Thank you.

MR. WALSH (Missouri Pacific R. R., St. Louis): May I have just a moment? I would like to stress what the gentleman brought out about repeaters. We are keeping a card index of our trainmen and engineers, our shop men, and our section foremen and we have found it to be very beneficial. For instance, after we started this card index system, going into the records of engineers who had had accidents on crossings, we found one man would have six or eight accidents in five years, while the man running opposite on the same run didn't have any. We get from the claim department a statement of every settlement made with an injured employee or others and we keep that and add the cost on this card to this engineer, charge him up with \$1,200, \$1,500 or whatever the claim amounts to. When he has another accident we furnish that record, giving the amount of money the company paid out by reason of this particular man and add it all up for the benefit of the Superintendent and General Manager. When they see the amount of money paid on account of this one man and we call their attention to the other men on the same run not having trouble, they go after this particular engineer pretty strongly.

There is something wrong where one man is doing all the damage and we have found one particular man who had killed eight or ten people in five years and cost the company something like \$35,000. That was several years ago when we developed that and in his case it has resulted in his not having any accidents in the last two or three years. It is not hard to keep this index record. One foreman will have six, eight or ten laborers injured in the course of two or three years. We give that to the District Engineer, to the Superintendent or the Roadmaster. In other words every accident that comes to our office—we go to the card index and keep the Superintendent advised on what is going on. You might say the Master Mechanic should do it himself. They don't do it. They lose track, in the course of their work, of the offender. A brakeman may be injured once a year and the total claim payments made to that particular brakeman amount to nearly

as much as his salary. That is valuable information for the superintendent and it points out very clearly that that particular man is an offender.

Something ought to be done about it and they do it in that way. They keep close tab on those men that are getting injured so a repeater is called to the attention of his Superintendent in such a way that we have found it to be very beneficial and the work is not particularly hard at all. It is easier to keep that up than you might imagine and it is very, very good.

CHAIRMAN COTT: Thank you, Mr. Walsh. We also keep such a card index system for the purpose of locating repeaters on our road but I would be rather inclined to doubt the advisability of keeping such a record. I wouldn't feel the responsibility entirely theirs, I am quite sure.

The Power of Imagination and Vision

I want to go back just a moment to Mr. Mountford's paper. Mr. Neff, as a pinch hitter made a home run. I was thinking, as he read the paper, of the need, so far as all of us are concerned—and it implies just as much to myself as the rest of us—for the visualization of things that may occur. In other words, for the power of imagination and vision. You know, a child imagines things and one of the most terrible tragedies is to have a parent who feels whenever his child has had some kind of a dream and imaginary vision that he ought to put his foot on it. It is only by imagination that children learn and grow, and if we stifle that power in a child we stunt the growth of a man.

I recall an accident a number of years ago in which we followed the usual procedure by learning all about it after it occurred; when, if someone had taken a few minutes to study this one particular man's tour of duty and had some power of vision and imagination, they might have foreseen what eventually happened and therefore prevented it.

We had in the yard certain inspectors and oilers on one side and an oil house on the other, and there was a certain gentleman's agreement among ourselves, that when the trick went on duty they would furnish oil through the next trick; and it so happened that the first trick got the day, the second trick secured the next day and so on. They all had their turn. It so happened that the third trick, of course in the middle of the night, had to cross through a repair yard at about an hour when the blue flags in the locks were removed and the engine crew was taking the repair cars, coupling them up and putting cripples in the repair shop. A man was coupled up between two or three of these cars, the father of something like eleven children—I have forgotten just how many. But after that accident occurred we saw the picture very clearly so arrangements were made by the master mechanic to send this oil across to the other side of the yard in the day time when the movement could be done with safety.

Now, if someone among that particular force had sat down and reviewed the tour of duty of that one particular man, had had a little power of vision, a little foresight with a long view, that man might still be in our employ.

There is need of foresight on the part of supervision, and on the part of the safety men. Sometimes we are accused of looking ahead at things that never happen, of harping on a thing until it does happen; but I don't think the power of suggestion is going to cause very many accidents while the lack of foresight and vision, imagination, or whatever you want to call it, is the cause of a great many accidents.

I think that was an excellent paper of Mr. Mountford's. I recommend it to you for study.

The next subject will be handled by Mr. W. L. Butler, chairman of the Engineering Committee of the Hocking Valley Railway, Columbus, Ohio.

Safety in the Maintenance of Way and Structures Department

By W. L. ROLLER

Chairman, Engineering Committee, The Hocking Valley Railroad Company, Columbus, O.

In a very true sense, the safety work in the maintenance of way departments of American railways ante-dates the present safety movement a great many years. In fact the element of safety of operation of freight and passenger trains entered as a primary consideration into the construction and maintenance of bridges, roadbed and track from the very beginning. It has been the continuing and ever absorbing aim of the maintenance man to provide a good "factor of safety" in structures, equipment and roadbed over which his jurisdiction reaches.

This aim has involved no little effort on the part of the maintenance engineer. With the rapid growth of population, the constantly increasing demand for transport of freight and passenger, has come a phenomenal and almost incredible increase in size and weight of locomotives and cars, while at the same time greater speed in the movement of trains was demanded that the railroads might cope with their growing business. This constant change has required the development of a technique in an engineering way which, in its growth and its effectiveness, is as unique as the growth of the railroads themselves. It has involved study and research into the bearing power of soils, the ultimate strength of materials such as wood, stone and steel. It has led to the development and further refinement of concrete. This demand carried the engineer far afield in the realm of metallurgy in order to discover suitable alloys for specific uses where strength, lightness and durability might be combined; the proper ingredients in steel rails producing the requisite hardness without being brittle, the necessary ductility without being too easily deformed.

The question has always been an economic as well as a safety problem, requiring the engineer to produce a safe result within certain economic limits. This has been productive of a highly technical, but very reliable fund of information bearing upon all sorts of materials and properties of materials, the use of which is so productive of good results in the widely heralded safe operation of railroads. We have come a long way in the matter of material safety in the operation of railroads and nothing should be allowed to interfere with the continued use of the knowledge gained over the past or the continued research to insure even greater safety to life and limb of railroad employees and the traveling public as well.

It should be at once the privilege as well as the duty of the engineer through the knowledge he has acquired and will acquire to provide better materials for railroad use; improved appliances for the execution of work and perfect methods of operation; design and construct better roadbeds, etc.

The results of the experience developed and the value of the research in matters of material safety is best attested to in the marvelous record which is now being made in the operation of passenger trains on the railroads of America today—a record which shows that it is safer to travel by rail than to pursue many of the so called safe occupations.

There is a tendency oftentimes to cheapen the quality of materials which enter into the construction of railways, to compromise in the purchase of equipment and tools with which the work of the railroad is done and with which the worker has to work. Cheap or shoddy tools have been responsible for a great proportion of injuries to the maintenance of way worker. It should therefore be the aim of those responsible for the maintenance of railroads to use every effort to find the tools best fitted for safely doing the work and then insist that they be purchased or other-

wise provided. This is done usually by proper specification. The wholesome cooperation and coordination of the purchasing and using departments will go far to reduce the number of personal injuries among railway workers.

We have been emphasizing the material phase of safety work on the railway, the material safeguards which the company and its responsible officers throw around the worker, the traveler and even the trespasser, but there is another phase of safety work which, to my mind, far transcends the material phase. It is that phase which finds lodgment in the mind, yes, in the very soul of the worker himself. This phase of safety work depends upon the mental and moral fitness of the maintenance of way worker as well as his physical fitness. The continued success and progress in safety work and the reduction in personal injuries will depend very largely on the mental and moral attitude toward the idea assumed by the railroad employee, whether he be in the shop, on the road or elsewhere. Progress will be commensurate with the degree of enlightenment brought by the various agencies to the mind of the average worker as to the true aims and significance of the safety movement. The frame of mind of the worker brought to bear upon his work, his enthusiasm for his work, his loyalty to his employer, his confidence in his superior officers, all have a direct and potent bearing upon the future safety record of his department and the railway as a whole. While we are not ready to assert that right living always goes hand in hand with safety, yet we have learned that right mental and moral attitudes in the worker are the best known preventives of personal injury. The man who is mentally alert, wide awake, interested and enthusiastic, rarely contributes to the personal injury record but on the other hand is one of the greatest assets in the matter of accident prevention. He is the nucleus about which the safety movement is to grow and wax strong. He has been set right on the very fundamentals of safety. He has achieved the true safety view-point and one may be well assured that the other essentials will follow.

Stress the Education Idea

A great deal has been said about the progress of safety work in the future depending upon education in safe methods and practices, and rightly so. Too much cannot be said about the cultivation of habits of safety but it seems to me that the first essential is the development of an incentive to "safety first," the desire, if you please, to live and to live greatly, even nobly. With this incentive developed among your workers, it will only be a mere matter of form or routine to teach them safe methods and practices, in fact, these things then come as a matter of course.

How is this to be done? How are we to create this moral and mental attitude? How are we to enlist the loyalty and enthusiasm of our employees? How are we to arouse their undivided interest in the safety idea?

I find the answer to this question in many of the activities which have already gained great headway on many of our railroad systems, namely, the organization of health and recreation departments through which employees and their families are encouraged to participate in wholesome social and recreational activities. One is the publication of an employees' magazine for distribution throughout the whole railroad organization. These magazines are messengers of good cheer to every railroad employee and his family. They convey the message that the railroad company is not a heartless corporation but an organization built up for the prime purpose of giving service to the public; that the door of opportunity is not shut to those who aspire to rise but in reality opens into a broad avenue for those who aspire to positions of greater responsibility and greater opportunity for service. Through this magazine the most lowly railroad employee learns of the importance of the part he himself plays in the organization, of the sacredness of his task and the importance of doing it well.

Other activities such as the younger men's movements having to do with the education of the younger men in the railroad organization, in the solutions of problems relating to railroad operation and maintenance, are productive of a better degree of understanding and will go a long way toward creating and fostering the proper mental attitude toward safety.

As regards the more specific means of creating the proper mental attitudes in the maintenance of way department, there are many ways of encouraging a more active interest and enthusiasm in the safety work as well as other laudable ventures; means by which the maintenance worker will know that the company is interested in his comfort, physical and financial welfare.

Better housing conditions, more comfortable quarters and more cheerful surroundings for maintenance of way workers temporarily denied the comforts of home will be helpful in creating a spirit of cordiality and awaken the interest of the more aloof.

Another means, the solution of which will make for a better mental attitude, is the elimination of seasonal employment as near as may be in the maintenance of way department. The work of maintenance on railways especially in this latitude may be so planned as to maintain a greater continuity of employment thus insuring to the steady reliable railway worker employment and an independent income throughout the year.

Get-Together Meetings

Great good may be accomplished in the interest of better understanding and greater cooperation by holding frequent get-together meetings of foremen for the discussion of mutual problems and to promote a closer contact between officers and men. These meetings are mutually helpful to officers and men in eradicating false impressions and creating a better *esprit-de-corps*.

There are two schools of thought in relation to the safety movement: one in which violation of safety rules is deemed justifiable cause for discipline. In this plan safety becomes a matter of coercion, the violator is penalized for his infraction of the rules. The other school depends upon the power of moral suasion to engender obedience to the safety rules by awakening in the employee an active interest in the movement itself as well as a more intelligent participation in the affairs of his organization. I think no one can deny the right of an organization to penalize any of its employees for damaging or otherwise putting in jeopardy the most valuable of their assets, namely their man power. But it seems to me that more will be attained and the movement will go farther and do more for the eternal good of man when pursued on the principle of voluntary cooperation, rather than on the principle of compulsory participation. By the one you achieve your material ends but neglect the spirit; and the Good Book says:

"Man does not live by bread alone but by every word that proceedeth from the mouth of God."

CHAIRMAN COTT: It wouldn't be polite of me, I don't believe, to express how good a paper I think that was. I think it is, so I won't say anything more about it.

The next number on our program is to be given by a man from a busy, busy terminal, from a city in the State of Ohio, where there are twelve or fourteen railroads: It is a busy town and he represents one of the busiest railroads going through that town—Mr. J. H. Spooner, Terminal Trainmaster, New York Central R. R., Toledo, Ohio.

Safety in the Yard

By J. H. SPOONER

Terminal Trainmaster, New York Central Railroad, Ohio Central Lines,
Toledo, Ohio

Let me say at the start that it strikes me as being rather out of place for a transportation officer to attempt to tell a group of men, many of whom have made accident prevention on railroads a life study, how to prevent personal injuries, and from the subject assigned me do not believe I should do that, I will endeavor, therefore, to confine myself to the experience gained in furthering the safety movement on that part of the New York Central terminals at Toledo, which I have the pleasure of representing.

To give you some idea of the scope of our operation I might say that during the year 1926 we handled a total of 1,497,554 cars; in 1927, 1,514,380 cars; and in 1928, to October 1st, we have handled 1,032,000 cars. During the lake shipping season about 25 per cent of the total cars handled consist of lake coal, each of which is handled from two to four times. The daily car handling runs from 4,000 to 6,000 cars; including crews engaged in transfer service we work from 50 to 60 eight-hour trick engines daily; the total capacity of the several yards is approximately 7,000 cars; an average of approximately 22 trains are made up and moved out onto the road daily and about the same number are received from the road and classified either for connections, or in the case of lake coal it is grouped according to lake consignee, of which we have about 75 at the present time, and held for arrival of a boat to handle a particular grade; the above in addition to approximately 14 transfer runs handling interchange business from and to the yards of our connections. We also operate a coal machine dumping approximately 600 cars daily into boats for movement to the upper lake ports. Aside from the above, of course, we have an engine house, car repair branches, and the various other auxiliaries which go to make up a terminal of this size.

We in railroad service, and especially the transportation officers, usually refer to the Book of Rules as our Bible. The first rule in that book says "Safety is of the first importance in the discharge of duty;" Rule 107 says "In case of doubt or uncertainty the safe course must be taken;" those two rules if followed literally will accomplish the results which this body is striving for, although it has been truthfully said that every rule in the Book of Rules is a safety rule.

Safety Committees

In my judgment every terminal of any consequence should have a safety committee; the local heads of the different departments should hold membership on this committee, and, of course, the rank and file from the different departments should be represented. At Toledo we have a live, wide-awake committee, of which I have the pleasure of being chairman, and feel this committee has been largely responsible for any small measure of success which we may have accomplished. There are approximately 750 employees under the jurisdiction of this committee. To secure success from a safety committee it is of the utmost importance that the chairman should have the confidence of its membership; you men who have advanced from the rank and file are familiar with the feeling that exists toward an employee who reports another for an infraction of rules. In an effort to overcome this feeling I have promised the membership of our committee that discipline will not

result from any reports of unsafe practices made by them and this has brought good results, although there is still hard work to be done in this direction.

It is almost unbelievable, to one not familiar with the facts, to understand to what extent railroad employees are criticised by their fellow-employees for reporting infractions of safety rules; however, I am glad to say the officers of the Brotherhoods are helping me in every possible way to break up this feeling. Too many men when appointed a member of the safety committee get the idea that their job is to find all the unsafe conditions that exist without giving much thought to the unsafe practices indulged in by their fellow-employees; and yet safety statistics tell us approximately 85 per cent of accidents are due to unsafe practices.

Another thing to be guarded against in handling unsafe items reported at meetings is the disposition on the part of some employees to use the safety committee for selfish purposes and to avoid doing some disagreeable job, although there may be nothing particularly unsafe about it. Have tried to impress upon the membership of my committee that where they observe an unsafe practice they should endeavor to correct it at once with the employee involved and if they are unable to accomplish results, to refer it to me and I have a talk with the offending employee.

Written Instructions

We all appreciate the necessity of written instructions on safety but unless these instructions are followed up and enforced on the ground nothing is accomplished. It is natural for some men to follow the course of least resistance and as some safety rules require additional steps they will not be observed regardless of all the written instructions unless we can make the men understand such rules are for their benefit. Take for example our present footboard rule which requires that the lead footboard must not be boarded while the engine is in motion, and that only one man can be on the footboard at a time, and then only on a switching lead. Many of the old timers in the past have expressed the opinion to me there is nothing unsafe about getting on the footboard as an engine approaches, and as riding some other part of the engine means additional steps when coupling onto cars or handling a switch, it was hard to enforce this rule when first established. Our answer to their argument, of course, was that while we do not have many footboard accidents—those we had usually resulted fatally. It is just as natural for a switchman, especially an old timer, to step on the lead footboard as to perform any other part of his work and after this rule was established I have actually seen men get on the footboard before thinking and then immediately get off; it did not occur to them until after they had gotten on that they had violated the rule.

This is our big problem, gentlemen, to teach the men to think before rather than after they do something unsafe. Too frequently one lapse is sufficient to remove an employee permanently from railroad service. At the present time the big majority of our men are making an honest effort to observe this footboard rule.

Along this same line take Rule 104a, which prevents fouling a switch before it is lined; we are all familiar with the practice in years past of seeing engines drive up into the switch points and in some cases spring them to avoid extra steps for the switchman. To enforce this rule we had to get the cooperation of the engineers, and while at first there was considerable grumbling on the part of the switchmen, with few exceptions the rule is being observed.

There is still some disagreement among railroad officers as to the advisability of applying discipline to enforce safety. Personally I feel after a man

has been cautioned about a particular violation by his superior officer and fails to heed the warning, he should be impressed in some forcible way that he must not repeat that violation, and if that fails to bring results he should be dismissed, because the fellow who disapproves of safety is a menace not only to himself but to the other employees with whom he comes in contact.

Handling the New Man

The problem of getting the new man started off on the right foot from a safety standpoint is a big one. Under our practice before a man is permitted to go to work he is made to understand the most important part of his duty is to keep from getting hurt. Frequently the new man tries to copy everything he sees the old timer do and in some cases tries to go him one better, and too frequently the old timer sets him a bad example. We also give the new man a letter to the conductor with whom he makes his trial trips, requesting the latter to take a personal interest in him and to show him the safe method of performing his different tasks.

A big help in accident prevention is a clean yard; draw bars, brake rigging, coal, etc., present an invitation to stumble, and to get results in this direction requires a mutual understanding on the part of all departments. To illustrate my point; while the maintenance of way department ordinarily gets no direct benefit from the elimination of stumbling hazards, unless they are willing to act promptly on the request of yard supervision to remove such hazards the accidents from this cause will be high; however, the transportation department can help itself a great deal in this direction by teaching the switchmen that the removal of such hazards reacts to their benefit. They should keep their switching leads clean by picking up small articles such as coal and tossing them to one side out of the way; also where an engine is down in a yard track and discovers a brake rigging or draw bar, it should be loaded onto a footboard by the switchman and brought out to the lead. If they wait until the section forces can get down into that track someone may stumble over it. This is especially true at night.

A prolific source of accidents in yards, especially yards where engines are working at both ends, is the practice of shoving tracks without sending a member of the crew to the opposite end of the cut to determine the amount of room. This particular form of violation reminds me of smallpox or measles, it seems to run in epidemics. About two years ago we had one of these epidemics and it was necessary to apply severe discipline to break it up; in several of the cases, however, the crew working at the opposite end of the yard laid a trap by leaving cars just in to clear. We now have a local rule which requires that in yards where engines are working at both ends cars will be left in to clear two car lengths.

Cooperation is a word which has been very much over-worked, and I might say abused, but it can be very well applied to the situation which should exist as between the operating and the medical and claim departments. It gives me a lot of pleasure to be able to say that the attitude manifested by the claim and medical departments at Toledo has been one of mutual helpfulness and they have both assisted me in every possible way in trying to improve our safety record.

The Real Loser in Personal Injuries

There are still some employees who feel the officers of a railroad are only interested in the safety movement from a selfish standpoint fortunately those who feel that way are becoming fewer every day. We agree, the railroad

loses when an employee is injured, not so much from the standpoint of claim payment but from the fact we are obliged to start a new man in to replace the injured employee, but neither of these losses compare, to the officer directly in charge of men, to the loss of a good friend and a valued helper; the real losers, however, are the folks at home.

I dislike to mention the question of hazard because every large terminal has them, and we have our quota, and off-setting the effect of these hazards is simply a question of familiarizing your men with them; however, to give you some idea of our situation in this respect I might say we have all of the ordinary switching conditions and some unusual ones. Our transfer crews make use of approximately 12 miles of a terminal switching line to enter the yards of six connecting lines and terminal men can appreciate the effort involved in educating train and engine crews to be on the lookout for all of the hazards in those different yards.

Right in our own terminal in some of the older yards we have tracks with close clearance, and that is especially true of our dock yard; but for various reasons it is not practicable to increase this clearance, and it resolves itself into a question of making the men understand the hazard is there and to be on the lookout for it. In this same dock yard we have what is locally known as our "High Buck" crews which handle coal from the supporting yard to the coal machine; these crews are working under high pressure all of the time to avoid delay to boats and on numerous occasions I have seen these boys go without their lunch to avoid such delay, and yet we have not had a reportable injury in that yard during the present lake season.

Regardless of the feeling which exists in some quarters, in my opinion safety and efficiency are synonymous. If you terminal men will check up your situation in yards where equipment damage is heavy, I believe you will also find that personal injuries in that particular yard are heavy. At times in the past I have been amused to hear some of the older men say as to a particular safety rule, that its strict enforcement would slow up the work, and then a few months later have these same men tell me their experience had shown them they were mistaken.

A good illustration of how efficiency and safety go together is represented by the situation in our dock yard. This yard has a total capacity of approximately 1,400 cars and is used as a supporting yard for feeding our lake coal machine. The lake season usually starts about the first of March and continues until the middle of December. During the year 1926 we dumped over this coal machine 4,126,673 tons, or approximately 75,000 cars, and had in that yard seven reportable personal injuries. During the year 1927 we dumped 4,616,143 tons, or approximately 84,000 cars, and had eight reportable personal injuries. During the present season we have handled up to October 1st 3,850,000 tons, or approximately 70,000 cars, and, as mentioned previously, have not had a reportable personal injury in that yard.

Selling Yourself on Safety

Looking at the safety situation from the standpoint of the supervising officer, to my mind the most important thing that officer can do is to search his own conscience and determine whether he has sold himself on safety. I am frank to say that it was not a great while ago that I really began to sell myself. I felt safety was a good thing and that we should make every reasonable effort to keep men from getting hurt, but the real problem of talking to the men at every opportunity and calling their attention each time some unsafe practice was observed escaped me, because I felt with the multitude of other duties I had not the time to do this.

This sort of attitude will not bring results and the only way we can get them is to make the safety subject one of our paramount duties and keep continually and everlastingly drilling the men on the things they must not do. Until the supervising officer can get himself into that frame of mind he is not going to produce the result which all of us hope to accomplish.

Too many of us in the past have talked safety and acted something else. It is difficult to appreciate the effect on a group of men of seeing one of their supervising officers, who is supposed to be an advocate of safety, direct, or at least permit, the performance of a particular piece of work in an obviously unsafe way with the mistaken object of speeding up operation. Safety must start at the top and come down and just the minute your men get the impression you are not sincere in carrying out the safety work, right then they lose interest; and it not only affects the men immediately involved but quickly reaches all the men in the terminal because they talk such things over among themselves, and many of you are familiar with "switch shanty talk."

Without any thought of boasting, some one has said that blowing is a function of the wind and I don't care to steal any of its force, but merely as a matter of information I might mention that at Toledo in the transportation department, with approximately 450 employees, we have not had a reportable personal injury since February 8 this year. Personally I take no credit for this showing; it has been entirely due to the efforts of the safety committee and to the efforts of the men themselves, who have become sold on the safety subject; and selling them has been pretty largely a question of convincing them by our acts, rather than by talk, that we are sincere in trying to keep them from getting hurt.

Commendation of a Trainmaster

CHAIRMAN COTT: There is a talk that I enjoyed listening to and I think every man in this audience did so. I think you will recall, some of you who saw my playlet—and I am willing to come any reasonable distance to give it—that there were two terminal trainmasters in that play. At the time I was both of them, but they were entirely different characters and I certainly have Mr. Spooner catalogued right now as to which of those trainmasters he was; and if the New York Central ever gets so unappreciative of your services, send in your application to the then chairman of this Section, Mr. Spooner, and I assure you you won't be without a job long.

We are getting along splendidly on our time but there are a few things to do following our regular program so I am going to proceed.

"Safety on the Road," by a gentleman from the M. K. & T. Lines, and I am going to let you in on a secret. He may object to it but I am going to tell it. This particular gentleman after being selected by his boss, my good friend, Mr. Walsh, proceeded to write me a letter asking me for certain information to talk about at this meeting. In it he remarked that it was all right, he could talk to the bunch of boys at the M. K. & T., but getting up here in New York was a grey horse of another color and so he wanted some kind of high minded stuff from the chairman who, he presumed, had some particularly extensive knowledge and ability, so he could talk about what the chairman had put in his mouth. So I wrote him a letter and told him what I had thought of was to comply with his wishes; but as I read his letter I saw in that letter there was a man down there of ability, and that this group up here in New York was just the same kind of a bunch of boys as he had down on the M. K. & T. and they did not want to have this man talk Cott, but talk Cole—Hugh C. Cole—to this bunch and I bet a dollar he will do it.

Safety on the Road

By HUGH C. COLE

Brakeman, M. K. & T. Lines, Smithville, Texas

To be accorded the privilege of addressing you is indeed a great honor and one that I had never hoped to obtain for I am not an orator in any degree, but an ordinary railroad trainman whose whole time and energy for the past eighteen years has been spent in the business of transporting cars, both loaded and empty, over the line of railroad by which I am employed.

Now speaking of hauling loaded and empty cars reminds me of a young fellow back home who had only been married a short while when he got into a little poker game with some of the boys on pay-day, and lost about half his pay-check. He sought to square himself with his better half by telling her that he had been handling nothing but empty cars that month, and that they were paid only half-time for handling empties, hence the small amount of money that he brought home. He would probably have gotten by with his story but his wife happened to remark to one of her neighbors that she hoped "George" would catch something besides empty car trains during the next period—and then the truth came out. The moral to this story is:—Don't play poker! But if you do, and lose, don't tell your wife that you have been hauling empties, not if you have been married as long as I have.

The subject "Safety on the Road," is such a broad one that I will not be able to cover it properly in the limited time that I have to talk, so I will endeavor to give you some ideas in a general way that will enable you to elaborate upon them in your own manner.

The first thought that I wish to give to you, and to my mind the most important one, is to read your Rule Book on Train Operation. You will note that the first rule in the book means just what it says: "Safety is of the first importance in the discharge of duty," and the next one is also true: "Obedience to the rules is essential to safety."

Our present operating rule book is the result of nearly 100 years of railroad experience. Each rule that has been added from time to time has an interesting history of its own, and if you care to go into its history and inquire how that particular rule came to be written, and adopted, you will find that it had its birth in an accident or the hazard of one, and when any rule is violated or allowed to lapse into disuse, the type of accident that caused the birth of that particular rule is liable to re-occur. Let us therefore keep this fact in mind; Resolve that every rule must be lived up to and preach this doctrine to others, every day and every hour.

Perhaps the excuse most often given for the violation of a rule is that of avoiding a delay. It is a fact that time is an important element in railroad work, and we know that delays are vexatious and costly, but we must never admit that the avoiding of delay is more important than safety.

If every supervising officer was as energetic in discovering and correcting the causes for injuries among his men as he is in investigating the causes for delays or lack of production, it would result in a certain amount of permanent good. What we need most is local officials that will comply with the rules and suggestions of their safety departments, and in turn, train, encourage and insist that their men adopt safe methods in performance of their duties.

There is an old adage which says: "As the twig is bent, the tree is inclined," and we know that if a child is trained in a certain way, that this impression will remain with him throughout life. By the same token, a new employee will retain the instructions and impressions that are given him when he comes into the service. He comes in with no habits along the line of work that he is going to do, but he is going to form them right away, and those habits will be good or bad, safe or

unsafe, just in proportion to the impressions that are put upon him at the time he enters the service. The old method of handing a man a lantern and switch key, and putting him to work, should be abolished, and instead, the trainmaster or other official employing the man should scrutinize his record closely and avoid the undesirables.

The applicant should be questioned as to his attitude on safety and willingness to obey rules. He should then be given detailed instructions and made to understand that personal responsibility should be uppermost in his mind. This will take a little time but the effect is worth it.

The student should make sufficient trips with various conductors, or engineers, as the case may be, to qualify and he must be O.K'd. in writing by these various men, who are made to feel a personal responsibility in approving him for further service.

We have a fertile field to work in when we consider the type of men who are now engaged in road or yard service. In the old days, there was little thought of safety and the fellow who got on a fast moving car or engine, regardless of the hazard or chance he was taking, was considered the best railroader. Their occupation did not appeal to the ordinary run of young men, but more to the adventurous, hardy type. Today, it is not possible to distinguish the ordinary railroad man from any other high class citizen. Many are high school graduates. Many are home owners and men of affairs in the community. What has brought about this change? Safety in railroad operation. Safety must be sold just like any merchandise. In selling goods, we educate the public to its advantages. Likewise with safety, we must educate the employees to its advantages.

Now in order that you may profit by the experience of others, I will give you a few examples of causes of injuries to men on the road, and means by which these accidents or injuries, and deaths may be avoided. Taking the figures for the year 1927, we find the cause for train accidents in this order: 1st, Derailments; 2nd, Collisions.

Causes of derailments are shown under four headings:

1. Negligence of employees—12 per cent of the accidents.
2. Defects in or failure of equipment—45 per cent.
3. Defects or improper maintenance of way and structures—24 per cent.
4. Miscellaneous causes—19 per cent.

The most frequent causes of derailments under negligence of employees were on account of switches being set in wrong position, switches run through, running off derail, and failure to latch or secure switch lever. This should impress us with the importance of watching switches more closely, to see that they are properly set at all times, switch levers in proper position, and main line switches locked. I wish to mention also under this heading, the accidents due to disregard of fixed signals. While these accidents are not so numerous as the ones previously mentioned, they are of a more serious nature.

The two outstanding causes of derailments, due to defect in, or failure of equipment, are, arch bars, bolts, etc., bent, broken or other failures, and cast iron wheels broken, overheating, or other causes, many of which could be eliminated by more frequent or more efficient inspection, thereby correcting the condition before it becomes dangerous.

The most prevalent cause of derailments due to improper maintenance of way and structures, are first, insufficient, excessive, or uneven elevation of track and improper alignment and surface of track, which accounts for nearly 10 per cent of the derailments. This condition is brought about by failure of the men assigned to this work to see that it is properly taken care of.

Broken rails is second in importance. Maintenance of way employees can, by careful inspection, detect and remove many defective rails before they break. Third

in importance is rails spreading because of joints loosely or improperly bolted, another condition brought about by improper supervision and maintenance.

The miscellaneous causes comprise 73 different headings under which the accidents are quite evenly divided.

The causes of collisions are shown under four headings, the same as derailments. The first, negligence of employees caused 88 per cent of the total collisions. This is a serious indictment of our train and enginemen on observance of rules. 67 per cent of the total number of collisions are due to switching accidents, the principal causes being failure to properly control cars or secure them with hand brakes, switches set in wrong position, improper handling of cars, or locomotives in switching or coupling, failure to keep proper lookout, absence of man on front of leading car and failure of parties supervising work to see that it is properly done.

Train service accidents: The causes of train service accidents are grouped under ten headings. The most frequent cause of fatal accidents to employees is due to being struck or run over by cars or engines, other than at highway grade crossings. This alone resulted in over 41 per cent of the total employees killed in train service accidents.

The most frequent causes of injuries to employees, and second in importance so far as fatal accidents are concerned, are due to getting on or off cars and engines. We know there is an element of danger in getting on or off cars and engines, especially while moving, and I realize that many of the accidents of this nature occurred when every reasonable care was taken by the employees. We also know that a large percentage of them could have been avoided by doing what common sense and good judgment would have suggested.

Third in importance are accidents due to coupling or uncoupling locomotives or cars. There has been so much said and written about accidents due to this cause that it would appear to be only a repetition to say more on the subject but I know from my own personal experience in train service that there is absolutely no justification for this large toll in death and injury and the large percentage of them is due to violation of rules and is the result of reckless and careless practices which the men have acquired and to which they have become so accustomed that they do their work in this manner without realizing the dangerous chances they are taking.

Next in importance is operating locomotives, and great care should be taken in getting on or off engines either standing or moving, as failure to secure a safe foot-hold or hand-hold caused 13 per cent of these injuries and almost half the fatal accidents.

Failure of mechanical devices either through defect or faulty operation, while shaking grates, dumping ash pans, operating reverse levers, etc., caused 545 injuries and the failure to give proper warning or use proper care before moving locomotives caused injury to 257 employees.

Many accidents were formerly due to coming in contact with fixed structures and while many close clearances were corrected, results were not obtained until trainmen were instructed by bulletin, time-table, and word-of-mouth, where these structures were, and a strict rule was put in force that employees must *face in the direction the train is moving* and must be alert to their surroundings at all times to avoid striking bridges, signal masts, switch stands, water cranes, platforms, etc., when riding on tops or sides of cars.

Accidents caused by coupling or uncoupling air or steam hose are eliminated by having the angle-cocks or valves closed before parting the hose with the train standing still while this is done. Care should be used in opening angle cocks to set air brakes to avoid force of air causing hose to whip and strike the man. Hand brakes and brake clubs have caused many accidents and study was made to ascertain the proper manner of handling brake clubs. I am of the opinion that the safest way is for a man to push and not pull on a club and when using the club to

place himself in a position so that if anything gives way he will fall against the car instead of away from it. In tightening up the chain he must feel it out before putting full power on the brake as it is liable to slip due to chain being knotted.

Trainmen and others should not ride between engine and cars when cars are being pushed or pulled except when necessary to make cut between engine and first car and should not ride on pilot or footboard when coupling engine to cars.

Falling off or being thrown from tops of cars has been a major cause of injury to trainmen from the beginning of railroad history. The safest place when on top of a car is to stand or sit on the running board in the middle of the car and then be on the lookout for sudden stops.

While riding in the cupalo of the caboose a constant lookout must be maintained to observe running condition of train and when waiting for other trains all cars should be inspected for defects that need attention promptly.

One of the best methods to use for this purpose is for some member of crew to stand on ground and let train be moved forward at a speed of six or eight miles per hour until entire train has been inspected. This can be done when entering or leaving sidings or when making stops to take water.

Another thing that trainmen and others riding in the caboose should be on the lookout for, is the slack running in or out, especially on trains that are moving at a low rate of speed.

The disregard of blue signals by train and yardmen has resulted in many accidents. Men must be trained to be on the lookout for these signals at all times and not obstruct the view of them. A blue signal should be regarded as though it was poison, by a trainman and should not be touched by anyone except the man who uses it for his protection.

And last but not least is the matter of employees maintaining their physical condition and in trying to keep home life pleasant, as many accidents in the past have resulted from impaired health, loss of sleep, or worry caused by unfavorable conditions. Each of us should submit to an examination at least once a year by a competent physician so that we may know our true condition and then take the measures necessary to remedy same, if found deficient in any respect. By all means get your rest while off duty so that you will be in a position to do your work in a safe and efficient manner and not be handicapped by a brain that is slow to act and a body that is sluggish in its movements.

Some of you may ask "What can I do individually to prevent accidents"? I'll tell you some of the things you can do: First and most important, you can get in the habit of thinking about your own safety and the safety of the other fellow. You men in train service can stop kicking over drawbars when the cars are about to come together; stop opening knuckles with the hand just about the time a coupling is being made; stop going between cars when they are moving or just about to move; stop mounting the front footboards of engines approaching you.

Always read the orders as required by the rules and make a proper check of meeting points with some member of the crew. When necessary to cut train at a highway crossing, a member of the crew will remain at the crossing to protect highway traffic until cars are again coupled.

When a train or engine is approaching a crossing that is obscure, the engineman will sound the regulation crossing whistle at the whistling post and then when at a distance of 600 feet from the crossing he will repeat the crossing whistle and prolong the last blast until the engine has passed over crossing.

You enginemen can get in the habit of trying the gauge cocks and not depend upon the water glass entirely. While at your work you can remember your family at home and that you have no right to do things which may cause you to be brought home to them mangled and bloody or possibly dead. They need your support and protection, but when you have been crippled for life by some careless act you will be a burden instead of a protection. We have all heard the statement so often

made by railroad men. "Oh! I'm in no danger. I have been on the job for a good many years and I have never even been scratched." Remember, that is absolutely no argument. I venture to say that out of nearly thirteen hundred railroad employees killed every year in this country, the majority have at some time or other made just that same remark, in spite of which they are today lying in their graves and their families are making a living as best they can. The fact that you have never been injured is no proof that you may not leave this meeting and go back to your work and be killed during the first hour.

Remember that it is the little careless acts which cause the greatest number of injuries. I venture to say that less than 10 per cent of the injuries on our railroads are caused by dangerous conditions, or by failure of machinery, or equipment, while the other 90 per cent are caused by little thoughtless acts on the part of the man himself, or someone who is working with him.

Every wage earner should personally and conscientiously interest himself in the matter of accident prevention, because the wage earners in this country have suffered frightfully from accidents during past years. I wonder how many of you know that each year in this country there has been an average of about two million and a half wage earners injured, more than 250,000 of whom are crippled for life, and between thirty and forty thousand killed.

It is appalling to think that in addition to this great mass of temporary injuries, each year adds more than 250,000 new cripples to this country and more than 30,000 new graves and that in all these cases the men injured and killed were among our best citizens—wage earners—valuable to themselves, valuable to their families, valuable to their employers and valuable to the country at large.

Of course, not all of these injuries occur on railroads, but the railroads contribute their share. Statistics indicate that on an average of every 19 minutes somewhere in this country a railroad man is injured and on an average of every 7 hours one railroad man is killed. Such a situation ought to be enough to arouse every sensible railroad man to his full sense of duty to help earnestly with this work of accident prevention.

I have used considerable time, perhaps too much, in my attempt to convey to you a clear conception of safety on the road as seen through the eyes of a railroad trainman, when no doubt a more experienced speaker could have told you all that I have with less words and in a manner that would be easier understood.

It may be that I have failed completely to give you an idea that will promote safety in any degree, if so I am exceedingly sorry, but you must remember that I told you at the beginning that I was only an ordinary railroad brakeman and not an orator in any sense of the word, therefore, if I have failed in my endeavor to make you understand, I can only say that I did my best, in the crude manner and with the poor language which I have at my command.

If, on the other hand, it is possible that I have succeeded in making an impression upon the mind of even one of you, by the mention of some thought, idea or suggestion during my discourse, which will enable you upon your return to your field of labor, to do your work in a manner that will be safer than formerly, and perhaps—who knows?—eventually be the means of saving someone's life or limb, then—O Glorious thought!—my efforts here today, feeble as they are, *will not have been in vain.*

CHAIRMAN COTT: If that man is just an ordinary brakeman I don't know what one is. I was down in Texas during the old war they had down there but, Mr. Cole, we do appreciate your coming here and we are sure your contribution has been appreciated.

We haven't a great deal of time and we want to adjourn on time. I asked Mr. Long, Chairman of the Resolutions Committee, if he would please come forward and present the report of that committee.

Report of the Resolutions Committee

J. E. LONG (Delaware & Hudson Ry., Albany): Mr. Chairman, because of a cold which I contracted I asked Mr. Bailey, a member of the committee, to present the resolutions and I think Mr. Bailey has them.

C. T. BAILEY (Oregon Short Line, Salt Lake City): Mr. Chairman and members of the Section: The Resolutions Committee wishes to present to you for your approval the following resolutions:

WHEREAS, Almighty Providence has seen fit to remove from our midst Thomas P. Brennan, one of the staunchest supporters of Safety on American railways, and thereby a beautiful and human character has been lost to the work in which we are engaged; therefore,

BE IT RESOLVED, that in bowing humbly to Divine Will, we recognize the departure of one of our sincere and faithful laborers whose work will unquestionably live in our hearts as well as in the annals of the Steam Railroad Section of the National Safety Council, and we express to his beloved family our heartfelt sympathy; therefore,

BE IT FURTHER RESOLVED, that this resolution be placed on the minutes and a copy be sent to his family.

WHEREAS, these sessions of the Steam Railroad Section of the National Safety Council have afforded much pleasure and provided material and inspiration which will prove of lasting benefit to those in the attendance,

BE IT RESOLVED, that we hereby express our sincere appreciation to those speakers who sacrificed their time to bring to us their valuable messages.

BE IT FURTHER RESOLVED, that our thanks be extended to the Keystone Quartette for their splendid entertainment; and,

BE IT FURTHER RESOLVED, that the thanks and appreciation of the members of this Section be extended to the officers and committees for their efforts in making this meeting so successful.

(Signed) J. E. LONG,
J. L. WALSH,
C. T. BAILEY.

(The motion on adoption of resolutions carried.)

CHAIRMAN COTT: Gentlemen, I want to acknowledge, before I call our Grandmaster up on the platform to install the officers, the services of some people who took chances, of course, when they came to my aid after I was appointed chairman. And, then to some whose services have been extremely valuable during this session. I want to tell you that Mr. McLaughlin and two or three assistants, Mr. McLaughlin and Mr. Rohweder, have taken over a rather thankless task in this registration and the sale of luncheon tickets.

Mr. Long, the vice-chairman, I might speak of him as one of the few living vice-chairmen that worked while he was vice-chairman. He has certainly been of extreme help to your chairman and I want to acknowledge his services.

Mr. Larson, here, you all know him, has been most helpful. He has worked lately under extreme difficulties due to illness, which I am glad to report is better, and I intended with his hay-fever, to have a bouquet of goldenrod on his table but I overlooked that slight feature.

The Executive Committee has been one with whom it was a pleasure to work. Some of the men were good enough to come to me following the convention a year ago and offer their services. Men that did not desire or ask for limelight but just simply had the love of work down in their hearts and who have worked during the year. Not just men who wanted to show up in front here at the session but men who were willing to travel hundreds of miles, sometimes thousands of miles, to get together and talk over some of the few problems that come to

this Chair during the session. Those men risked their reputations perhaps in associating themselves with me or perhaps, knowing my weakness and loving the Section, did not want to take any chances on the falling down of it, and naturally came to my rescue. Regardless of whichever motive it was, I am deeply appreciative, and I want to speak for the new chairman, too.

Those of you willing to work and having an interest in the work of the Section, would you be good enough to come to your new chairman and tell him you will be glad to be of service throughout this year? I speak of that because he perhaps would not care to, would not wish to, but I, singing my swan song, can do it. I hope a great number of you will give him the support you have given me.

Duff Phillips, the other day, said the chairmanship of this organization had sobered me, and now I am going to have the opportunity, very shortly, of getting down back among you and I want you to know I have never felt above you at all, but going back to my own character, I am satisfied with it, whether you are or not. But, laying all jokes aside, it has been a happy sort of year. Perhaps I have not done as well as I could or as much as I should, but nevertheless, doing what I have done has been a task of love and interest. And, so, I am going to ask now if our good friend Robert Scott, who put me in office last year, will come up this year and take the gavel of so-called authority and present it to the officers you have elected for the ensuing year. And if I, in going back down among the chairs can be of any help, I am at your service. Mr. Scott, please come forward.

ROBERT SCOTT (Atlantic Coast Line R. R., Wilmington, N. C.): I am not altogether sure whether I am to officiate as the manager of an undertaking establishment at this moment or whether I am superintendent of the Maternity Hospital. It seems that I am to assist Mr. Cott in leaving the platform and assist the new officers in coming into their new existence. I feel that I should say a few words about Mr. Cott's administration as chairman of this Section. I feel that I am qualified to sympathize with him in some of the difficulties under which he has labored, having occupied this position some years ago, and I think I express the views and the feeling of every member of this Section, Mr. Cott, when I say to you that your administration has been a success from every point of view.

Mr. Cott has handled this job as chairman, not only intelligently and efficiently, but he has handled it most courteously. In fact, Mr. Cott could not perform any sort of job in any other way.

In speaking about our meeting generally, I would like to touch upon just a few of the high spots. We sometimes ask ourselves, What do we get out of these annual sessions of the Steam Railroad Section?

For my part I am willing to take one week out of every fifty-two and spend it at these sessions because I always feel when I go back on the job I am better able to make a success of the thing that I am undertaking. I not only receive new ideas but I receive much needed inspiration. I am sure that all of us do need inspiration in our task.

One of the high spots of this meeting, to my mind, and something that has been entirely different from anything we have ever had, was the instructive lecture of Dr. Darlington at our luncheon the other day. That thing must have impressed many of us, especially those of us who have reached the age of forty and perhaps a little over; because the good Doctor told us that we had better watch our step. We can all profit by his advice and his admonitions.

Another phase of this meeting was the lecture we had from Mr. Sperry this morning about rail fissures. How many times have you ever had that explained to you as intelligently and as thoroughly as it was done here this morning?

Another thing, have you ever seen a trainmaster on this platform or any other platform at any of our meetings that went so fully and so thoroughly into accident prevention at a terminal as did our friend from the New York Central at

Toledo, this morning? I wish that we might have more terminal trainmasters like that in the part of the country where I come from.

If I might be permitted to offer one bit of criticism about the meeting, I hope it will be accepted as constructive and with the idea that we might profit by these things at future sessions. It seems to me that with so many other sessions going on, and I refer particularly to the Public Speaking Lectures of Professor Hardy, it is thoroughly impracticable to expect our members to attend a meeting at 8:30 which lasts an hour, to be here at the opening of our sessions at nine o'clock. I, therefore, recommend to the incoming administration that our program in the future be so arranged that all of us, so much in need of instruction in public speaking, may have an opportunity of attending those lectures and at the same time have an opportunity for absorbing all that is good in our own session.

We all are not Isaiah Hales, or Tom Carrows or Duff Phillips, who were born orators. Most of us have to make orators out of ourselves if we ever hope to become one. I don't mean to contend oratory is so essential in connection with safety work, but I do say that the man who is properly trained in presenting the subject of safety to the employees on our railroads has a much better chance of success, and why not take advantage of this opportunity of becoming more proficient?

One other thing that has impressed me at this meeting has been the absence of prepared papers and copies available for us to take home with us. I know from experiences, after ten years of connection with this Section, that there are many people who come to these meetings, oftentimes for their first visit and all of them like to take something back home in their pockets because our minds are not big enough to hold it all. And I recommend to the incoming administrations that they undertake to instruct those who are to present papers at future meetings, have copies for everyone in attendance. I am sure that will meet with the popular approval of everyone.

Now, we come to that part of our program where our good friend, Mr. Cott, steps down in the ranks and I know he is going to enjoy a rest from his labors. I am sure all of you will be glad to give a vote of thanks to Mr. Cott for his wonderful services and to the other officers. That has been done by resolutions but I want to see a little more demonstration of just how we feel about the services they have rendered and I would entertain a motion for a rising vote of thanks to Mr. Cott, Mr. Long and Mr. Larson, for their services during the past year.

(Motion made and carried.)

Mr. Cott, you have been duly thanked. I am now going to ask our new secretary if he will come to the platform and take his seat—Mr. Smullen. It seems our new secretary is among those absent. I will now present to you our incoming vice-chairman. The vice-chairman has been elevated to this position from the secretaryship. I think this gentleman is thoroughly entitled to his promotion because of his ability and because of service rendered to the Section, and I now have great pleasure in presenting to you Mr. C. F. Larson of the Missouri Pacific Railroad, St. Louis.

MR. LARSON: Thank you.

MR. SCOTT: I will now ask our new chairman if he will be good enough to come to the platform.

It is my great pleasure, Mr. Long, to present you with this gavel, and with this gavel the responsibility of looking after the welfare of this Section during the coming year; and I am sure that I express the thought and feeling of every member of this Section that that duty will be well performed.

MR. LONG: My friends, I don't know just what Mr. Cott meant by this sobering process and I am wondering if that is one of the reasons why you conferred this honor upon me yesterday. I have never felt I needed it but perhaps I do.

I want to say to you that I deeply appreciate the honor which you have conferred

upon me and I fully realize its responsibilities, and, realizing them, am a bit fearful. But, I will promise you that I will do the best I can to carry on during the coming year and in that carrying on I need the help of every one of you and I hope you will give it to me as freely and in as large a measure as you have given it to the previous officers of this Section.

MR. SCOTT: I think the members would like to hear from our new vice-chairman.

C. F. LARSON (Missouri Pacific R. R., St. Louis, Mo.): Gentlemen of the Steam Railroad Section: As the new chairman has said, I very deeply appreciate the honor that has been conferred upon me from the time that I came into the Section until this time. This is only the third Session of the Congress that I have attended.

At the second Congress, or meeting of this Section, I was chairman of the Program Committee and last year I was made the secretary of your Section. I do not know and will never know why these honors have been heaped upon me, on almost an infant among the men with whom I have so gladly associated.

I shall do everything I can to further the interest and to help the chairman. It was said of him that he is the only living chairman who has worked during the entire year of his office. I hope to follow that example and if the incoming secretary was here, and I don't know why he is not here to be installed with us—I want to offer him my deepest sympathy for the job he has gotten into. In my last *News Letter* which some of you did not get before you came here, I suggested that an associate editor of the *News Letter* be appointed to lift the burden from the secretary's shoulders in trying to prepare, without much assistance from the body of the Section, a letter that would be of interest. I then suggested that I would want the appointment of the associate editor to help him carry that burden. So, Mr. Chairman, I want to be of the greatest assistance to you in anything that I can, to lift the burden from you; and on the other hand, standing between the chairman and the secretary, it is my great desire to be of the greatest assistance possible to the secretary during the year that I am in between the two.

I thank you one and all for the honors you have given me. I don't know why they were but may God help me and give me the strength to carry on the greater work that I know we can be engaged in.

CHAIRMAN LONG: I thank you for the offer of assistance, Mr. Larson, and if what Mr. Cott said was true of the working vice-chairman—and I have never doubted his veracity—I assure you there will be another working vice-chairman for the coming year.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Taxicab and Fleet Owners Section

New Section Officers

- General Chairman*—H. L. CUMMINGS, Yellow Cab Company of Va., Richmond, Va.
Vice-Chairman (Bus Fleets)—RICHARD W. MEADE, The People's Motorbus Company of St. Louis, St. Louis, Mo.
Vice-Chairman (Delivery Fleets)—J. E. DOBBS, Detroit City Service Company, Detroit, Mich.
Vice-Chairman (Taxicab Fleets)—J. G. WILLIAMS, National Association of Taxicab Owners, Chicago, Ill.
Secretary and News Letter Editor—A. J. RUSSELL, JR., *The Taxi Weekly*, New York City.
Membership Committee Chairman—DALE HARMAN, Yellow Cab Company, Kansas City, Mo.
Poster and Slide Committee Chairman—CARL C. CLEMENTS, Sheffield Farms Company, Inc., New York City.
Program and Statistics Committee Chairman—W. O. HINCKLEY, The Peoples Gas Light & Coke Company, Chicago, Ill.
Publicity Committee Chairman—A. E. LUNDSTEADT, Bowman Dairy Company, Chicago, Ill.
Engineering Committee Chairman—S. J. STEINMANN, Indemnity Insurance Company of North America, Philadelphia, Pa.
Executive Committee: THE OFFICERS AND
ROBERT CLAIR, Liberty Mutual Insurance Co., Boston, Mass.
W. W. CLOUD, Yellow Cab Company, Baltimore, Md.
MARCUS A. DOW, Vander Poel, Pausner and Jefferson, Inc., New York City.
T. A. HORROCKS, Minnesota Truck Owners Association, St. Paul, Minn.
HENRY J. MINEUR, J. M. Horton Ice Cream Company, Inc., New York City.
A. F. WAITE, The Green Cab Company, Cleveland, Ohio.
RICHARD J. WALL, Yellow Cab Company, Toledo, Ohio.

Retiring Officers

- Chairman*, J. ROBERT CLAIR, Liberty Mutual Insurance Company, Boston, Mass.;
Vice-Chairman, HARVEY D. WOOD, Yellow Cab Company, Chicago, Ill.; *Secretary*, J. E. DOBBS, Detroit City Service Company, Detroit, Mich.; *Membership Committee Chairman*, J. G. WILLIAMS, National Association of Taxicab Owners, Chicago, Ill.; *Publicity Committee Chairman*, S. J. PLIMPTON, Bus Transportation, Chicago, Ill. *Executive Committee*: THE OFFICERS AND MARCUS A. DOW, Vander Poel, Pausner and Jefferson, Inc., New York City; DALE HARMAN, Yellow Cab Company, Kansas City, Mo.

October 2, 1928

ROBERT CLAIR, Chairman

Safety Engineer, Liberty Mutual Insurance Company, Boston

The first session of the Taxicab and Fleet Owners Section at the Seventeenth Annual Safety Congress was called to order at 10:30 o'clock by the chairman, Robert Clair, Highway Safety Engineer, Liberty Mutual Insurance Company, Boston, Mass.

CHAIRMAN CLAIR: It is with a great deal of pleasure that I welcome you to the first meeting of this section and to the Seventeenth Annual Safety Congress of the National Safety Council. I want to say a few words of thanks, first to the members of the staff of the National Safety Council for the wonderful help and cooperation they have given us during the past year and for assisting us in taking care of the many details in connection with the work of the section. I also want to thank those members of the section who, when they have been called upon for various assignments or ideas, have responded so generously. I want to welcome here especially the representatives of those fleets of commercial vehicles who are our guests this morning and who have participated in the great New York safety driving contest.

Our nominating committee for next year's officers will report at tomorrow's session.

We are indeed fortunate this morning to have with us our opening speaker, who has done some remarkable work during the past months in supervising the tremendous amount of detail involved in operating this Interfleet Contest, Mr. W. J. L. Banham, Traffic Manager of the Otis Elevator Company, has been acting as chairman of the Commercial Vehicle Committee of the New York Safety Committee.

The Inter-Fleet Contest as an Aid to Safety

By W. J. L. BANHAM

Chairman, Commercial Vehicle Committee of the New York Safety Committee, and President of the New York Board of Trade and Transportation

We who have been responsible for the conduct of the first Commercial Vehicle Safety Contest in what is known as the New York Metropolitan area feel very much elated with the impressive results.

Not only was the contest successful in achieving what the committee hoped for—greater skill in driving and greater safety on the highways—but in the number of contestants. We understand there were 10 times as many in this as in any vehicle safety contest ever staged.

With the great number of vehicle accidents that occur on the congested streets of this area we know we had an opportunity to improve conditions, and we have done this. We have every reason to believe that the good work we have begun will be continued by the participating companies and their employees even if there

is a contest—for it is to their own benefit to decrease the accident total. We started out knowing that 10,823 accidents occurred on New York City streets in 1927, in which motor trucks figured and from these accidents 376 persons came to a premature death. The figures for the first six months of 1928 showed that motor trucks figured in 4,876 New York street accidents and these brought death to 165 persons and sadness to many homes. There was plenty of room for improvement and anything accomplished would be helpful to the community.

So we began a campaign of education backed up by a good organization. This organization plus the education, turned the tide and the results of this three months contest will, we are sure have a decided effect on the 1928 motor vehicle accident statistics of New York City and vicinity.

Through speakers at meetings of the drivers of fleets, and conferences with owners of these fleets of vehicles we got our message over, we stimulated a desire in the drivers to drive with greater care, to give thoughts to the rights of others, to observe the laws and to prevent accidents. There was no let up in the campaign for improvement and our records show that the further the contest went, the fewer were the accidents. The standing of the concerns caused each to try and improve their standing—just as the clubs do in a baseball league race. Any one can be at the bottom. It takes ambition and will power to get to the top.

We sold the idea of safety in vehicle operation to more than 22,000 drivers and fleet operators and we believe they will remain sold—for they are aware now of the benefits that accrue to them through being more careful. If the contest could be continued for an indefinite period or another contest begun, it is our opinion that the accident and death total would be decreased perceptibly in the Metropolitan area. These figures prove this contention—that we are on the right road in accident prevention work on the streets.

The contest began on July 9th and the first report was compiled for the month of July. 450 concerns entered vehicles to the number of 18,565. Of this number 9,947 were motor trucks. These vehicles covered 21,240,000 miles in 3,340,862 working hours and the number of accidents was 1,738. Boiled down this means one accident to every 2,036 working hours or one accident to every 12,220 miles of operation.

The figures for August show that only 13 concerns failed to make report, but the number of contesting vehicles was but little changed, there being 18,561.

These vehicles covered during July and August an estimated mileage of 50,018,466 in 8,336,411 working hours and in that time the number of accidents totaled 3,456. This is an average of one accident for each 2,412 hours of operation or one accident for each 14,470 miles of operation.

The results for August alone show 2,566 hours operated per accident—a 20 per cent improvement over July. The August mileage figure, shows 28,662,082 miles of operation with an average of one accident for each 15,401 miles of operation and improvement over the July figures of 20 per cent.

The figures that I have been able to get for September, however, are a little disturbing. The mileage increased to 14,315 miles per accident, but there was an increase during that time over the month of August of 8½ per cent. That is really the sad part of my report, showing that the job is not done. I want to leave the thought with you that we must continue what we have been doing for the last three months and just because we have had a bad month we cannot quit and go home. One of our very good members told me that his accident record was nearly perfect for the last six months and then he joined the Safety Driving Contest and everything went blooey. It does not mean that he had not been careful, but things went wrong. On the other hand, one of our members ran into good luck and improved his service 55 per cent during the three months of the safety contest. Let us not get discouraged for, like poor relatives, these accidents seem to come along in bunches sometimes.

It was a contest that will go down in history with this Congress—but it is no different than other vehicle contests. Wherever they have been applied, they have been successful, they have reduced the number of accidents, in some cities as much as 50 per cent. There isn't any question as to the value of the vehicle contest as an aid to safety in any city or to the nation. This has been definitely proven. Perfect an organization as we did, and develop simple and understandable rules and you will be successful.

We classified the entrants in 22 groups, according to the lines of business and the character of vehicles operated. Firms reported monthly on forms we furnished them, all accidents that involved their own vehicles. While they were in motion or temporarily stopped in traffic, including all cases of personal injury or property damage, regardless of the amount, or which driver was at fault, or which vehicle was damaged, reports in code showing the standing of the contestants were mailed monthly. These bulletins were posted where the drivers could digest them. The standing of the firms was determined on a basis of the percentage of accidents per vehicle hour. On the report cards the contestants stated the number of vehicles operated, the average number of hours daily these vehicles operated, the number of days operated, the number of hours operated and the number of accidents.

The winner in each group receives a prize of a handsome clock while others with exceptional records receive certificates.

We might add that the Commercial Vehicle Contest also proved a good advertising medium for the Safety Congress as all of the vehicles carried posters and wind shield stickers announcing the competition and the Congress and we were able also to secure some good newspaper notices each time the statistics were tabulated.

Too much time has been spent in talking about accident causes. Also, as to who is responsible for the accident. It does not require any imagination, however, to locate the guilty party. It is always the other fellow.

The prevention of accidents is one that we are all interested in and it was with this in mind your committee labored early and late to prevent accidents rather than to develop their cause. It is very difficult to figure the expense of accidents. Only a small part of it will be found in the premium paid to insurance companies. How about the expense of the truck out of commission? Is the driver an asset when he spends his time in the Courts? How about the boss? His time means money, too. How about your customers? Is it an asset to your company to have it be known that you are continually having accidents and that your customers' goods are damaged from time to time? Is it a good advertisement for your company to have your trucks dash madly down the streets without regard to public safety? I see these trucks personally myself from day to day and the effect it makes upon me is the truck that is so recklessly operated would of necessity be backed up by an unreliable company.

All of these truckmen are salesmen for the Fleet Operators. They are your contact with the public. They reflect on the company whether it be good or bad.

Your committee have officially concluded their task. The job, however, is far from complete. The committee have shown the fleet operators and drivers a way to avoid accidents. In the continuance of this, the problem remains yours. We have blazed the trail for you. It is up to you to carry on.

CHAIRMAN CLAIR: We trust that representatives are here from those fleets which have been successful in winning prizes and trophies in this great Inter Fleet Contest. Mr. Banham has kindly consented to award these prizes. I wish that as he reads each name, the representative here from that organization would come forward and receive the trophy.

MR. BANHAM: I sometimes tell a little inside stuff. First when we decided we

could have prizes the great problem was what should be the prize. We had many suggestions, but sometimes the least part of the problem is the most difficult. I would like to tell a little story about a little place upstate where they wanted to build a church. They devised ways and means and talked it over, and after much trouble they got the money and in time the church was built. Then came the great question as to what color they would paint the church. They had more meetings and more trouble about painting the church than about the whole question of raising the money and getting it built. Finally one man who had sat through all the meetings without saying a word was called on for a suggestion about the color. He said he was neutral on the subject and did not care what color they painted it as long as it was green. Well, our committee decided that they did not care what kind of prizes they had as long as they were clocks, and so we have clocks. Here are the winners:

General Baking Company, Manhattan Plant.

General Baking Company, Jersey City Plant, horse-drawn vehicles.

Sheldon, Foster Company, Laundry Division, horse-drawn vehicles.

O. K. Dairy Company, Milk Division.

Schwartz & Son, Wholesale Jobbers.

National Oil & Supply Company, Gas and Oil Division, trucks.

Harkavy Beverages, Bottlers' Division, trucks.

Imperial Laundry Company.

Long Beach Bus Company, Bus Division.

I understand that the Long Beach Bus Company has made an exceptional record. Let's give them another round of applause.

Stephens Fuel Company, Inc. Coal and Ice Division, trucks.

Sheffield Farms Company, Milk Division, trucks.

Durkee Company, Department Store and Furniture Business.

Public Service Gas and Electric Company, Public Utilities, trucks—electric and gas.

Hyman Express Company, General Trucking Companies.

Knickerbocker Ice Company.

Devere, Harris Company.

Thomas Henry, Inc.

Bayonne News Company.

Nassau County Mosquito Extermination Division.

C. J. Mallett, Inc.

Pioneer Ice Company.

Hygeia Ice Company.

Gordon Farms Company.

In conclusion I wish to express the gratitude of my committee to you fleet operators and to your drivers for the wonderful job you put across. I feel this way about it, however, that what we have done the last three months is not so much, but what we have built into it is our reward. If after we close this session everybody goes home and forgets about safety, that is not a very great reward. I want you gentlemen to feel that your committee has gone about this work in a way we felt would bring results. It has done so. We have shown what can be done if you try. We are all for safety; there is no question about that. It is the eternal keeping at it on the safety measures and trying to prevent accidents that will bring the reward to this committee and to the National Safety Council, the reward they richly deserve. Your job starts where ours leaves off.

GEO. J. HARDY (The Nassau County Mosquito Extermination Commission, Freeport, N. Y.): We have done all we could to brace our men up and I would recommend that we, at least at some future time if not now, have something in the way of a button or a badge that we may bring back to our men rewarding their individual efforts. Without their efforts we could not do anything. We

have 50 or 60 men in our organization and only about 25 cars, two shifts a day and the cars driven by two sets of men, and we sometimes have to shift them about so that another man drives in one man's place. We have begged our men for the sake of the commission and for the sake of themselves to keep this record clean. We have had only two claims against us since 1915, so safety is nothing new to us. I believe if there could be something for these men in the way of just a button or something they would appreciate it. I know the commission would stand for their share of it, pay for the work if necessary. I have a feeling that my men would get so much out of something like that that we would be willing to pay our share.

CHAIRMAN CLAIR: We had a regular speaker to appear this morning, Mr. Richard J. Wall, vice-president Yellow Cab Company of Toledo, Ohio. We have received a telegram saying that he will probably not be able to get here, due to some important organization matters.

We have a wonderful opportunity right at hand this morning because we have men here who have supervised successful safe driving campaigns. I think it would be almost a tragedy were we to let these gentlemen go out of this room without telling us very briefly some of the stunts they have used in putting their successful campaigns across. I have made notes here of the winners of the clocks and I am going to ask each representative of those companies to tell us briefly just one or two thoughts in which we will get a quick picture of the principal stunt or the thing that they have done to make their campaign successful. Now usually our meetings are much smaller than this and the chairman does not need a gavel. I have one but I do not want to use it. I am going to run through this list and I would appreciate it if the various people would give us in a few words the various stunts they have used.

We have the manager of the Manhattan plant, General Baking Company, which won the motor vehicle prize. Mr. Fried.

C. F. FRIED (Manager, General Baking Company, Manhattan Plant, New York): Safety with the General Baking Company is not a spasmodic thing. We have been working on it for years. I do not think we did anything of a particular nature to win this contest, that is, anything more than we are doing right along. One thing we did do. We found that a large number of our accidents occurred on the 59th street bridge. We did make a drive at this point and talked to all our men, asking them to try to eliminate accidents on that bridge. I believe that 20 per cent of our accidents for the last year or two occurred on this bridge.

SAMUEL HYMAN (Hyman's Express Company, New York and Jamaica): We find that by keeping the same men working on the same cars at all times, without changing them from one to the other, we get the least accidents.

J. E. OHLMAN (Imperial Laundry Company, New York): I have to say about the same as Mr. Hyman. It is important to keep the drivers on their regular cars and to urge them to "stop, look and listen."

THOMAS O'CONNOR (Bayonne News Company, Jersey City, N. J.): The Bayonne News Company had so many accidents that the insurance companies refused to handle them. One New York company finally took a chance but doubled our rate. We offered the men a bonus of \$50 a year, gave each man a suit of clothes if he would keep his truck in good condition, and tried in every way to interest the men in safety. We have not had an accident since February.

Public Service Gas and Electric Company, New York: In connection with this contest we made no special effort to make a record. We carried on our regular routine and put in our regular record report. I would say that in connection with the safety end we have a regular safety department that makes periodic visits to the various plants and gives talks to the men. In connection with

automobile equipment we make monthly inspections and keep them in good mechanical condition, so there are no accidents from that source.

HAROLD JACOBSON (General Manager, Long Beach Bus Company, Long Beach, N. Y.): Our campaign was brought about when we had one of our busses crash into a train and fourteen people were severely injured. From that day we put on a vigorous campaign. Rigid maintenance of busses from the mechanical standpoint was insisted on. We have a blackboard at the door of the garage on which we describe any accident occurring to our busses or to any vehicles in our locality. These accidents are carefully dissected, how they happened and how they might have been prevented. We have regular meetings every Saturday morning of all the men we can take off and go over every detail of operation and try to encourage the boys in every way. We have a slogan, "On time, all the time," and also another, "When in doubt, stop."

A. E. VINCENT (Devere, Harris Company, Patterson, N. J.): We have meetings every two weeks. We have a blackboard and we write the names of those having an accident. We rarely have a bad accident.

JAMES J. GANNON (Manager, General Baking Company, Jersey City Plant, horse drawn vehicles, Jersey City, N. J.): We have not made a stunt of safety but have incorporated it in our every day work. We have worked on the idea that the man is the head of the family and as such should be concerned about safety, the safety of his wife and children and of himself. We have worked to make the men feel that it was entirely up to them and that an accident would bring disaster on him and to those near and dear to him. We have tried to make safety synonymous with "Bond Bread," and tell him that if he drives carelessly and in a reckless manner he causes the public to be afraid, and this reflects upon the General Baking Company and will bring the name of Bond Bread into disrepute. I think it was on the basis of an average every day proposition that we were successful; no stunts, nothing out of the ordinary. We do it just as we make our product which is just as well as we can possibly do.

W. M. OLLER (Knickerbocker Ice Company, New York): Safety with the Knickerbocker Ice Company has now become a regular part of our routine. One of our officers devotes about 75 per cent of his time to safety work. We appealed to our men that safety was a by-product of interest in the job and efficiency. We have tried to appeal to them from the humane side by making them realize that the children are in the streets through no fault of the children but because most of them have no other place to go. We owe a duty to these children. We made no special drive in this respect but we tried to make them realize that this was an ordinary part of the job and that we were one hundred per cent for safety.

C. C. CLEMENTS (Sheffield Farms Company, Inc., New York): The only stunt that I can suggest is a continuation of the safety work that has been carried on since a year ago this July. No special stunt was inaugurated for this contest but we do hold safety meetings at least once a month in one of the branches and we have about 30 branches in the metropolitan area. We appeal to the men in the same ways that the other speakers have described this morning, through their families. We do not ask them to save the property of the company but to save their own lives and look out for themselves and their children. We ran two inter-division contests and awarded loving cups to the division which came through with the best percentage. We ran it practically the same as the National Safety Council contest. We had some small stickers made, about 2x1 inches and these were placed on the route book of each man. The sticker says, "Remember, three people were killed in New York each day in 1927. Drive carefully. Sheffield Farms Company Safety First Campaign." We used the letters S. F. C. to bring out the point, Safety First Campaign. I suppose many of you saw last month's

National Safety News in which was a picture of the wagon which we had painted for our work. We took the idea from the Fifth Avenue Bus Company. We painted the wagon white with green lettering using the safety green. The front of the wagon says, "To promote safety." Underneath is the symbol of safety, the spread wings, and the wording, "Always be careful." One side says, "Safety first for health and happiness." We have the slogan of the National Safety Council, "Accidents do not happen without cause." On the back we have, "Help us make New York safe for you and yours." On the top we had a panel reading, "Sheffield Farms Company Safety First Campaign."

C. H. ROLKA (Sheldon, Foster Company, Brooklyn, N. Y.): We have a meeting every Wednesday morning and tell our drivers what we expect of them.

HOWARD JAFFE (Hygeia Ice Company, New York): It has been stated that we did not make any drive at this time but always followed our quest for safety.

CHAIRMAN CLAIR: I have been asked to request that the various members write letters to the National Safety Council stating what you think about a continuation of this Interfleet contest. I want to say, with apologies to our good friends the taxi operators here, that this program has perhaps been a little over-balanced on the commercial vehicle side. I know we have had a number of interesting thoughts brought out and I hope these have given us a number of ideas to take home with us. There are two or three gentlemen I wish to introduce to you who will say a few words. The first is Mr. W. W. Cloud, who is President of the National Association of Taxicab Owners:

W. W. CLOUD (President, Yellow Cab Company, Baltimore, Md.): It is a pleasure to be here this morning in the interest of this industry which I represent. We took the precaution of bringing our publicity representative with us. We are interested in the movement for safety that has developed so rapidly and effectively throughout the country in the last few years. In the cab industry, those of us who have seen the light and try to operate our business as the passenger transportation companies, give a great deal of time and attention to safety. The various methods differ and time does not permit us to go into that, but I can say that marked improvement has been made and that we are heart and soul in everything that goes toward the betterment of safety conditions on the streets and highways. I am very glad to see this relatively large gathering. It is quite an increase over last year and I am sure we all unite in congratulating you on the able administration which you have given us during the past year.

CHAIRMAN CLAIR: Thank you, Mr. Cloud. The work has been a pleasure.

We have with us another man who has done a whole lot of pioneering work in safe vehicle operation, not only with motor trucks but also with teams and wagons, which to some of us presents a very difficult problem. I am going to ask Mr. A. A. Clarke, secretary and treasurer of the General Baking Company, to say a few words. You may have known or heard of Mr. Clarke before from his movement in encouraging driving from the left hand side of the seat in horse drawn vehicles and also for the developing of a new safety wagon.

A. A. CLARKE (Secretary and Treasurer, General Baking Company, New York): Bringing in our field men this morning to take home the prizes to their organizations, I felt I could sit on the side lines. I notice that the chairman asked for but a few remarks so I will just say a few words as to just what we do for safety.

You have heard the gentlemen from two of our plants say that we work on the personal contact basis. We place personal contact first, last and all the time. We have our slogan; we do not say "safety first," we say "safety always." Safety first, last and all the time. The chairman said something about the safety wagon. With our numerous horse drawn vehicles and the rapid turnover of operators of these vehicles, it is necessary for us to use extreme care. We engage a man not only for his ability but for his experience with safety previously. We not only check a man up for his safe driving but for his ability and on top of that we check up

the whole character of his experience and the state records against him. When we have done that, we have started right with the employee. Then we start with the vehicle. We make sure our vehicles are right, that the tools are right. The horses are trained for this particular work and the man is trained for his work. When we send him on the street, he knows all the ordinances and the rules and he has perfect tools to work with. He knows what he should do and what he shouldn't do.

Now for our safety wagons. We have been working on these for a long time. We have blocked off the left hand side of our cab which means that no operator can get off on the highway side of the vehicle. We have a foot brake on every vehicle, a brake with a ratchet on it. We have installed also on these wagons, as you see them around the streets, two uprights. We have found from experience that when horse drawn vehicles are hit in the rear that nine times out of ten the operator is thrown out. With these two uprights, if he can grab them, he will be saved from falling under the horse's hoofs or under the wheels. We have changed the step and placed it so that the man's foot cannot slip between it and the wheel. We have made the step larger. We have put on a storm curtain. We want open vision in every type of weather. We have incorporated all these features on our wagons and all the other safe features we can think of. We require every operator to turn in every night a report of the condition of his wagon that night. That prevents an alibi of any description on the part of the operator.

I want to stress again the personal contact work. To my mind personal contact work is safety work in its most effective form. We stress on the home. We tell those in the home how to live safely. We tell them of the summer perils of swimming, and of other hazards in their living conditions. We tell them about their children, to keep them off the streets. We go into every phase of their personal life. We believe that all the so-called stunts, bulletin boards, contests, etc., are supplementary to personal contact. Once you have gotten the main idea of safety these others are only supplementary details.

CHAIRMAN CLAIR: Thank you, Mr. Clarke. There is one more gentleman here sitting modestly in the corner whom I am sure you will not only like to see but to hear. He is on the program for Thursday morning and I hope everyone can hear his address as he is always very inspiring and always has something worthwhile to say. He has just written a book, which many of us believe is the finest that has been turned out in recent years for furthering the safe driving movement not only among commercial drivers but among the general driving public as well. I want to introduce Mr. Marcus Dow. I would like to tell you all the positions Mr. Dow has held in the past but I will just say that he is a pioneer in this work and a past president of the National Safety Council.

MARCUS DOW (Vander Poel, Pausner and Jefferson, New York): I really did not expect to have to talk twice to this distinguished gathering, as I am on the program Thursday. I am glad to have the opportunity here first of all to thank those who participated in the contest that has been carried on here in the city of New York for the past several years. In my capacity as an officer of the National Safety Council I have been close to a number of these contests. Here in New York we had about ten times as many vehicles as have ever been entered before. I do not know that that is anything particular to brag about, considering the size of the city, and the opportunities for enlistment yet the spirit has really been quite wonderful and the cooperation received from the motor vehicle committee of which Mr. Banham was chairman has been truly excellent.

In listening to the discussion of the various ways to keep up the publicity I was impressed with what Mr. Clarke said about personal contact. I agree with Mr. Clarke that it is one of the most important things that you have to do to keep up the proper amount of interest in safety. If you do not keep the men inspired by personal contact a great deal of your effort is lost. We get out certain safety

posters and bulletins to put over the safety methods. To make them doubly effective we have a plan which calls for the cooperation of the foremen in charge of the drivers, in order to find out whether the drivers read the posters that have been posted a few days before. He would inquire, "What lesson did you get out of it?" If they did not reply properly the foreman would know that they were handing out a lot of bunk and did not see the poster at all. You must keep after these men all the time.

What are the basic predominating causes of these accidents? That is the question I am going to take up Thursday morning and I hope that everybody is here, particularly those interested in this contest in New York. Mr. Banham has asked you to keep up the good work. You have only started this campaign and must carry through by continuous efforts. Safety is a day by day proposition, hour by hour.

You men that have been taking part in this contest and others here from out of town places who are interested in this problem of street safety, I would liken you to a great safety army. I recall that during the recent great war I had the privilege of going out on a special train in the interest of one of the Liberty Loan campaigns. We had with us a young soldier who had just come back from the front. He told the story of their captain who had been shot down by a machine gun at Chateau Thierry. He was mortally wounded, two of his lieutenants bending over him tried to hear his dying words. Lifting his head painfully he said, "Lieutenant, the command is 'Forward,'" and with that he sank back upon the ground and died. Men, you who are a part of this campaign, of this great safety army in peaceful America today, your command is "Forward." Let us all who are privileged to be a part of this magnificent army for greater safety today remember that the command is "Forward." Thank you.

CHAIRMAN CLAIR: To me this meeting has been a very inspiring one. When we come to such gatherings as these we come, not as insurance representatives, not as commercial fleet representatives, not as taxicab company representatives, but as practical men who have a common interest. That one interest, regardless of the specific problems which keep us busy, is the prevention of highway accidents. We are not theorists but we come into these meetings to discuss methods that we have used in our various lines. Our associates, even though they are working in different fields, may carry something away with them—something to assist them in their particular problems. That is the spirit of these meetings. We all have something to give and we all have something to learn.

This first meeting has been, as I said, very inspiring to me and I trust that all of you are going to take away some new inspirations and ideas. I know I could keep you here for the next hour listening to worth-while remarks from a number of other gentlemen here this morning. I am not going to call on anybody else but I do not want anyone to feel that he has been deliberately overlooked. It is now quarter of twelve and we can well afford to spend ten or fifteen minutes in further discussion. We would be glad to hear from anyone else present who has anything in the way of a new wrinkle that has helped him in putting this message across to the men behind the wheel who are the direct subjects of all our efforts.

GEO. J. HARDY (Secretary, Nassau County Mosquito Extermination Commission, Freeport, N. Y.): The thing that has appealed to me is the movement of the taxicab people. Let us take off our hats to their wonderful control and great amount of courtesy that the taxicab drivers show to us who are pedestrians.

A. E. LEVINE (President, Yellow Cab Company, Cleveland, Ohio): We operators in Cleveland are very fortunate to have as Commissioner of Licenses a man who is greatly interested in safety and the prevention of accidents. We have a plan down there which has been very successful and in my own operations we have cut our personal injury accidents 51½ per cent in the last six months, compared to the same period last year.

MR. ZUKOR (Commissioner of Licenses, Cleveland, Ohio): I did not come here for the purpose of talking, I came to learn. But if I can be helpful because of my public service over a number of years I will give you a brief outline of what I have attempted to do. As Mr. Levine said, our experience on the streets of Cleveland was terrible. When I first came into office they were insured for \$120 a year covering five, ten and one. Prior to March first we had the good news that our insurance rates would be \$750. Something had to be done. We all had the same problems, competitors who were bitter, and I took it upon myself to get these gentlemen to agree on some sort of campaign.

I tried to put the fear of God into the driver and I think I have done that. The police department cooperates with our department. We do the licensing and the checking up of the drivers. Each driver has a card. The employer must make out a card and send it to the police department for each driver. Every accident must be reported to the police department, and by the operator. As soon as a man has two or more accidents his card is forwarded to my office with a report. The man is notified and there is an attempt to suspend or revoke his license. The hearings are open to representatives of the police department and to the interested companies. The man is given an opportunity to make a defense or explain his actions. His employer is there to hear what is said. He is given an opportunity to say anything he wants to before his employees. If the man is found negligent and careless or of anything improper in the way of lack of courtesy or in his method of driving, we suspend his license for a period of one to thirty days or revoke his license. I can say from experience that this method has met with a lot of success. I thank you.

DALE HARMAN (Vice-President and Manager, Yellow Cab Company, Kansas City, Mo.): I am booked for a talk a little farther along on the program but in view of the fact that these gentlemen have given up their time to come and listen I would like to tell you of a little thing brought about in our organization. I do not want to take credit for the idea because it was second hand. We inaugurated the "Milk Bottle Safety Club." I don't know why they call it that but that was the name given to me and we used it. I was going away on a little trip at the time that I started this. We had already done everything we could think of and had tried everything we had heard of. We do everything in our city to help our local safety council that we can possibly do. The president of our company is one of the head officers of the safety council. I am on the fleet owners' section. We have our own safety man that takes our drivers to all the safety meetings where we can get in and get recognition. This milk bottle safety club was started April 1, 1927. I got every man to stand up and pledge that we would go through with the proposition. I said, "Now, there will be some trouble with this and a lot of little things the boys will not like but I want you to promise that you will start it and carry it on while I am away." I had the one sole thought that it would reduce our liabilities during my absence for that is a matter I personally have to watch.

When I got back after about three months I found that they had been able to stick it out. Every man was required to put five cents in a milk bottle for each call. For every nickel the men put in the company put in a nickel. It made a fund of about \$750 a month, and it was divided among the men according to teams, with a captain for each team. I picked the captains and each captain could pick his men by lot. One team was winning all the time. There was strife in there and the men fought to win their nickels and fifteen cents more with each one. I am going to tell you honestly and conscientiously that it reduced our accidents almost to none in traveling six million miles a year in an area that is comparatively just as congested as your city. Our district is not as large but in the downtown district it is just as congested and we have not as many automatic signals and other helps to control traffic.

I have been asked to give a little history of this milk bottle safety club. One firm calls it the ice box safety club and another calls it the refrigerator. If you can get strife between the men, get them watching the talley bulletin for how many accidents and how much money is in the fund, you can get the men to prevent accidents. We have been able to get our men to report the smallest kind of accidents to their own cars or somebody else's. He does it because some of the captains of the other teams will report it if he does not. This was originated in Richmond, Virginia. If you can get something with that sort of strife and something where they win a little money you will be surprised how they will want to get on a team that wins, especially if there is a bad boy on their own team.

In reply to a question about labor: We advertise for men and they respond very readily and all of them have to go through our schooling. There is one man in my organization who is very rigid. He takes them through hazardous points of the city and shows them what he wants done at that point, how to slow up and not try to hurry. We have a thorough training school. The men are very much surprised when they realize that they must spend at least five days and some of them seven or eight days in school. They cannot pass until this man O.K's. them. We give them a very rigid talk and show them what the safety idea and the prevention of accidents means to the company and to them and their families.

CHAIRMAN CLAIR: The meeting seems to be getting more interesting all the time but it is now twelve o'clock. Mr. Dobbs of the Detroit Cities Service Company could tell you that all Mr. Harman has said about the milk bottle club is true. He tells me that this has practically done away with his accident problem.

MR. HARMAN: I would like to introduce the man who inaugurated this milk bottle safety campaign, Mr. Cummings.

H. L. CUMMINGS (Yellow Cab Co., Richmond, Virginia): Mr. Harman very graciously gave me the credit for this, but it was not myself but one of our drivers. About two years ago Mr. Cummings, our manager, started a campaign on suggestions for a safety campaign. He wanted all the boys to write a short article on what they thought would be interesting in the way of a safety campaign. One of our boys suggested that we start a "safety jit contest." We held a little meeting and asked him to tell us what he meant. He suggested that every man should put up a nickel when he got his manifest (job sheet). It really amounts now to every man buying his manifest for a nickel. In Richmond nickels do not come quite as easy as they do up here in New York and the man is going to think a little about how to get his nickel back.

For awhile the contest ran along in an ordinary sort of way with no special work behind it. We had a milk bottle sitting on the counter and the men would drop in a nickel and go to work. It was my duty to take out the nickels at the end of the month and to divide them between the various teams. After awhile we began to notice that accidents were decreasing. For awhile we thought it was the articles we were writing and the talks we were making but we found out that it was really the "safety jit contest" that was causing the decrease. We set aside a certain fund each month to pay for the petty accidents, the kind that will eat you up in time. Out of this fund we pay for the petty accidents. If drivers are caught speeding on the streets they are fined two dollars which goes into the safety jit. It has to be split to a hair's breadth to satisfy those boys and if it is one nickel out of the way I am going to catch it.

CHAIRMAN CLAIR: Are there any other remarks?

J. P. MALLOY (General Accident Insurance Company, New York): I want to say a word in connection with the selection of drivers. We went over about 2,500 claims to find out that the driver did not thoroughly understand the essentials of accident prevention. That is, he was lacking in experience. If he is young we must expect him to learn from his accidents. But in every case it shows his experience was insufficient. He was not educated enough as to what to do. We

formed a questionnaire which we distributed. We confined the questions to what we thought were very essential for us to know. We gave this questionnaire to our assured asking them to give it to the drivers, and then return it to us.

When we checked up we found that the driver never worked for companies he claimed to have worked for. Where he worked for two months he claimed it was longer. We sometimes found that they were fired for reckless driving. Very few put down any accidents. We asked for two personal references. We have run across lots of drivers that have improper vision and even had one man with a glass eye. Some of them have bad feet; some of them cannot think properly, are very dull witted; their intelligence is limited. If the people knew how dull and ignorant some of them were they would take steps to prevent such careless selection of drivers. In the department stores some of them break in helpers and promote them. The promotion system is much the best. It is most important to look up a man's record before you put him on the list.

CHAIRMAN CLAIR: I wish to repeat the invitation to everybody here to attend the meetings on Wednesday and Thursday. We have good reason to be pleased with the success of this meeting and I want to promise you that we have a fine array of talent during the next two days.

ADJOURNMENT

October 3, 1928

ROBERT CLAIR, Chairman
Safety Engineer, Liberty Mutual Insurance Company, Boston

The second session was called to order at ten o'clock by Chairman Clair.

CHAIRMAN CLAIR: We have as our first speaker this morning a man who is president of the National Association of Taxicab Owners, Mr. W. W. Cloud. It is a great pleasure for us to have Mr. Cloud with us. He is a man with many varied interests, a man whose interest in safety is keen and he is going to talk to us this morning on "Standardized Cab Companies' Relation to Public Safety."

W. W. CLOUD (Yellow Cab Company, Baltimore, Md.): Ladies and Gentlemen, the subject which has been assigned to me is one in which I am deeply interested. It is a very important subject and it is more or less of a serious nature. Personally I would like to talk to you about cab companies, about the cab industry, about the romances, and I might say, here and there—the tragedies of the cab industry. There is no industry that has grown as rapidly, particularly one that is so close to the public, or in the public eye as much, as the cab industry. Any industry that has grown as rapidly as that industry in the past fifteen or twenty years naturally excites interest and when we excite interest we invite observation; and when we invite observation we open ourselves to criticism; and when we are subject to criticism we begin to appreciate how much there is to be done that has been left undone.

I mention this simply incidentally because from my contact with this industry, which now measures about twenty years—twenty years the third of next March—I realize and appreciate both the personal and the official contact with the men identified with this industry and that they have really sincerely and honestly striven to build this industry along sound, substantial and permanent lines. I know that they feel their own obligations and responsibilities. I know that they are striving sincerely to live up to the obligations that have been imposed upon them.

Now we recognize the two great schools of transportation and in mentioning only two I classify the street railways and the steam roads on the one side and the motor passenger transportation industry on the other. The development or the permanency of the motor passenger transportation industry is inevitable. We cannot regulate or legislate it out of existence. It is here to stay and I am glad to state, and I say this from official contact with several organizations that have been very close to both of these major industries in the past few years, that a much better spirit of understanding, a much better spirit of cooperation, and a great part of what I might say was friction—not friction exactly but feeling adverse to harmony which developed and was developing in a way that would not be helpful to the public safety—has been smoothed out. We now kiss each other on both cheeks and we can lay our problems before each other and at least we have the respect and feel the confidence of one another, and more harmonious conduct of the industries.

I simply touch on this because it is vital to the public safety. These major forces (and that is a better word than industries probably) are the two great forces that come into immediate contact with the public and they are largely responsible for the safety of the public. They have no right, nor can they on the basis of fair play or sportsmanship, pass the buck or try to smoke screen or to do otherwise than assume their full responsibility in the premises. I have viewed with some degree of apprehension and purposely have avoided controversial debates which could only result in misunderstanding or lack of cooperative feeling. Safety, in the last analysis, is primarily and fundamentally the development of safety work, which has for its great objective the safeguarding of life and limb. As I said

before I view with some degree of apprehension, considerable at times, the growing tendency to commercialize safety. Now time does not permit me to go into detail and probably this is not the place, but I have sounded this note, or have tried to sound it, that in our National Safety Council meetings and in our local Safety Council meetings that is one thing we must guard against. We must remember that the main purpose and the fundamental interest is the safeguarding of life and limb and that is the serious and important responsibility which we must assume. I did not mean, Mr. Chairman, to get into a prologue but I had it in my system and I thought best to get it out.

Standardized Cab Companies' Relation to Public Safety

By W. W. CLOUD

President, National Association of Taxicab Owners, and President Yellow Cab Company of Baltimore

The relation of the standardized cab companies to public safety is very close. In many ways they are closer to the problem than any other class of people. This is due to the fact that they have to see both sides of the question. First of all, they see it from the standpoint of the general public because their cabs are going day and night into the thickest of the traffic in the city streets; therefore they know the dangers from reckless drivers, and from improper attention to the traffic rules. Then, as passenger carriers, they have the responsibility to taking care of their passengers, and this makes them more interested in the question of public safety than is usual in a company doing business in the ordinary city.

The National Association of Taxicab Owners has membership representation in many of our cities, and is an association of standardized service. There is no financial connection between the companies but the standards of service as maintained in the association gives the public a fair opinion of just what they may expect from these companies all over the United States.

This association, in its relations to the question of public safety, has realized that to a great extent the question of public safety insofar as automotive vehicles are concerned is tied up with the question of the men who operate the machines, and for this reason we have standardized the drivers so that the public safety is protected in this way:—

A man to secure employment with a standardized cab company must first of all produce proof of a good character. This is to prevent the employment of the careless, and those who have no ideals as to honor, or right and wrong. By securing a proof of the good character of a man who is to drive a cab, the company then is as sure as is humanly possible that the man will take his work seriously; that he will deal fairly with the public, and with his company; that he will feel that he has an obligation to the public and refuse to take chances which might endanger the lives of the public.

A man who is careful, diligent, honest, and sober will naturally be safer to trust with a car in the public streets than one who does not come up to these qualifications, and then in addition to this the very fact that a man has these qualities will make him careful of any accident due to carelessness or through his own fault which would mar his record.

Therefore I consider the fact that the standardized cab companies do require character reference as a step in the direction of public safety which in the aggregate means much to the public. The standardized cab companies have a force of morally clean men, men who are careful of the public safety, and careful of their own records, and this combination makes them safe men to trust on the streets of the city with cabs.

Then too, there are some people who are physically unable to drive a car safely. Either through nerves, or some organic trouble they are unable to keep cool, well balanced, and able to reason in case of an emergency. Such men as these should not be permitted to endanger themselves, and the public by driving cabs or automobiles through the busy traffic of a city street.

There are others who due to their mental qualifications are unable to judge wisely in an emergency, to keep their head when a decision which involves lives must be made on the spur of the moment, and who are not capable of making the best choice under given conditions where that choice involves safety of the public. They would be a menace to those who came in contact with them.

These two classes of men are not permitted to drive the cars in standardized cab companies' service.

Through rigorous physical and mental examinations the ones who are unfit are weeded out, and only those who are able to meet the exacting requirements are allowed to drive the cabs of these cab companies.

By doing this the public safety is protected, and there is no danger of cars being driven over the city streets by mental or physical weaklings who would be unable to make the necessary decisions, or who lack strength to carry them out when a question of safety is involved.

There is one other class that the standardized cab companies are always careful to keep out from behind the wheel of their cabs in the interest of public safety, and that is the person with defective vision.

A person may have a small defect of vision, but with the speed which carries a person along with the steam of traffic a very slight defect in vision may in the end involve a very serious accident, and for this reason the person with a defective vision should never be trusted at the wheel of a cab.

I am firmly of the opinion that in the interest of public safety each city should have a school for those who desire to drive cabs, that they should not only be thoroughly trained in the traffic rules of that particular city, but that they should also be compelled to work under traffic conditions and those who did not show ability to harmonize their driving with the traffic rules which governs the traffic in which they move should be released. This would be a rather strict test, but after all when you come to check up the value of safety, unselfishly from the public standpoint, and selfishly from the standpoint of the cab companies it is none too strict.

The relations of the standardized cab companies with public safety in a general way in my opinion reflects good credit on the men who in connection with their business are endeavoring in every way possible to make the streets of our cities safer for all who have occasion to use them.

This relation is reflected by the membership which various members of our organization hold in Chambers of Commerce, Traffic Clubs, and other moves of a civic nature. In this relation with the public they are well qualified, and have done a great service, in furthering the usefulness of the local branches of the National Safety Council.

They have carried on local campaigns which has emphasized safety, and made the word safety stand out in each section of the country. This place of leadership should be held by the standardized cab companies, and they should continue this activity in every place in which they are located to the end that they make public safety on the streets and roads a slogan which everyone will heed, and help to carry out. By doing this they will be helping the public, helping themselves, and fulfilling a public duty which they are best qualified of all organizations to fill.

The fact that the standardized cabs are found all over the country, and operated under standardized service rules makes our relations with the question of public safety general and applicable to every section of the country. This places upon us a trust which we must if we are to live up to the standards of our code of

ethics keep a trust of emphasizing safety at every opportunity, and of practicing it in season and out of season.

In our relations with the public as carriers of passengers, we voluntarily assume an obligation for the safety of the life and limbs of such passengers, and in taking up this obligation we can in justice to ourselves and the public do nothing less than make every effort that lies within our power to carry out the obligation and deliver each and every passenger at their destination promptly, without injury to themselves, and without injury to anyone else. Safety of our passengers is an obligation which we assume, and which gives us a relation with public safety which keeps it constantly in our minds.

This particular phase of our relation with public safety makes us much more mindful of the matter than even the public carriers, because the railroads in their operation run over rails, they do not have to look out for the other fellow because whoever gets on their tracks does so at their own peril. More mindful than the interurban bus service which for long stretches will run over roads that are not crowded, while all of our business is transacted in the city streets, where the traffic is heavy, and where we have no right of way which will give us an excuse for overlooking the other fellows' failure to live up to the rules of traffic, or will excuse us from complying with the rules of safety for the public to the fullest extent.

A Sincere Interest in Public Safety

Complying with the necessary safeguards for the public ourselves, we also are interested in public safety on account of our desire for the public to accord us the same protection which we accord to them. There is no place in the streets of a city for the careless, the reckless, or the drunken driver. The standardized cab companies do not have such drivers, and they are interested to the fullest extent in seeing that such drivers are not allowed on the streets, to hazard the lives of the general public, the cab companies employees, and the passengers who expect to be carried promptly, and safely from point to point.

For this reason we believe that in the interest of the public safety that the rules of the road should be made applicable to all. That they should be so arranged as to facilitate traffic so far as is consistent with safety, and that all concerned should be required to live up to them strictly.

In the interest of public safety we provide only the most skillful drivers. The beginner, the careless, the reckless and the road hog have no place in the driving staff of a standardized cab service. These drivers are not protected by us if they do not comply with the necessary traffic and safety rules, we not only refuse to protect them, but actually penalize them ourselves. This makes every driver feel that we must use his best efforts to comply with all traffic laws, and regulations; that he must comply with the rules for safety. And in addition to penalizing them when we find them violating traffic and safety rules, we reward them for good work. Therefore there is no encouragement for the driver who does not feel that his driving is a trust, and those who take their work in the spirit in which they should are rewarded in proportion to the safety involved in their driving.

We are constantly at work inventing methods of interesting our drivers in safety work. Safety work has a recognized part in the training of all of our drivers, and in our whole scheme of operations. We are in season and out of season seeking new and effective safety ideas, and when we find one we use it. Therefore there is a consistent improvement in the standards which we set up for our operation. New ideas and plans which are of proven merit are used in the place of those that are no longer effective, and the whole organization is keyed up to the standard of better and more effective work along lines which makes the safety of the public of paramount importance to the operators, and the drivers of standardized cab service.

When our National Conventions are held the question of safety always has an important part in our program. In this way the plans which have been proven effective are discussed, studied, and where they are found practicable and more useful than those which have been used they are applied.

In this way up to the minute plans of the men who are making a study of the question of safety on the ground are applied by the others who have the same problems, and who work to the same end, doing immeasurable benefit to the standardized cab companies, their employees, and the general public along safety lines.

The question of safe driving is a subject of constant study. With the present traffic situation it is necessary that every man who drives a cab be up to the highest point of efficiency, and for this reason there is a steady and a consistent study of the problem of safe driving. These results are available to anyone who wishes to have them, and the investigation in this field is thorough, effective and conclusive. This field alone is a unique contribution to the problem of public safety, and one that should be utilized more and more as the years go by.

In the heart of the city traffic, on the streets where speed is permitted, and through the by-ways of the city, moves the standardized cab companies' drivers. In daylight, in darkness, in the fair warm days of summer, and in the sleet and snow of a winter day, our drivers carry the greatest number of motor riding passengers. They are the safest drivers that are found on the streets and highways. They have fewer accidents than any other class of drivers. These facts prove conclusively that Standardized Cab Companies relation to public safety is something that is real. An obligation which is sincerely recognized, and an obligation which is assumed to the fullest extent by the responsible companies in this group.

The Highest Obligation

The safe guarding of the lives and limbs of the passengers, and the public is the highest obligation which rests upon them. The slogan is appearing all over the country now, and will through the school year of "play safe with the children." Which means in its final analysis to play safe with the public. To properly safeguard them and to see that they are not injured by careless or reckless driving. The total of lives lost through this class of driving is more and more bringing the question of who should be permitted to drive an automobile into the minds of the public.

To turn loose an immature person, one that is not qualified, and who has no thought for the safety of others, with a high powered automobile on the streets of the city, is to virtually give them the power of life and death over those on the streets. The Standardized Cab Companies realize this and for this reason their drivers are people who are qualified, who take their obligations seriously, and who feel that to fail to live up to the obligation entailed would be unworthy of a public carrier, regardless of its character.

The Standardized Cab Companies in their National Association in their code of ethics in dealing with the questions which involve public safety have two sections which are well worth the attention of any or all people who are responsible for the sending out of drivers of cabs or other motor vehicles through the streets of the cities.

The first of these sections deals with the duty of the owners to the employees:—

"We will consistently endeavor to elevate the moral character and the financial condition of the men employed by us. We will interest ourselves in their welfare and elect their earnest cooperation in our common endeavors, knowing that misunderstandings between employer and employee too often provoke those disagreements disastrous to both."

As contented and satisfied employees may be expected to render the best service, this is a step that is well worth while in the direction of public safety. No man harassed by troubles of any kind can give his best to his work. Therefore anything which will make for contentment will make for safety.

The other section in the code of ethics which is well worthy of emulation deals with the duty to the public. There are three sections under this particular heading, but the section which I wish especially to mention is the one dealing with safety:

"We will see to it that our driver is courteous to everyone, to the passenger in the vehicle, to the pedestrian on the streets and to the other driver. We will see to it, above all things that he drives his own vehicle safely."

If a driver drives his own car safely he cuts the danger of accident in half, and the insistence of the standardized cab companies that their drivers drive their own cabs, safely will, as is proven by accident reports, cut down the accidents to a great extent.

The work which has been done in the past is a great work, and shall continue to grow and spread. Today we have the same problems of public safety, which can only be met by constant attention, by diligent training, and by keeping up the standards and the morale of the drivers.

Companies Are Leaders in Safety Effort

In the forefront of the battle for safety the standardized cab companies have always been found. The leadership which has fallen on them by virtue of their position has been assumed and is being carried on. The standards required for drivers is higher today than it was five years ago, it will continue to grow higher and higher until the misfit will be weeded out of the field entirely, and the men who drive cabs not only for the standardized cab companies but also for other organizations will be found to measure up to the standards which the standardized cab companies as pioneers in the field have set up for themselves, and through pressure of demands for public safety, others will adopt as the standards which should be followed.

Leadership involves obligation. We have achieved leadership in this particular field by force of our work which we have done and are still doing. This lays on us the obligation of continuing to point the way to public safety measures and means, which others will be glad to follow on account of their sheer merit.

And while the obligation may be heavy, I am sure that the reward for the work done in training, research, investigation, and precept and example, will be commensurate with the duty which is involved and the responsibility which is laid upon us.

Let us therefore carry with us at all times the feeling that public carriers have a public trust, and that public safety is as much a part of our work, and our responsibility, as is the carrying of passengers. As we do this our field of activity will constantly broaden, and our rewards will be greater in proportion to the way we work, and keep up the work which we are doing so well now along the lines of public safety.

CHAIRMAN CLAIR: I am glad that Mr. Cloud, in his opening remarks, referred to that very unhappy fact of the commercialization of safety. I think his remarks were well chosen and I am sure we all know of instances where the safety movement, generally and specifically, has been substantially hurt by selfish commercialization. I think the key note he struck there was very much in order.

There is one particular item of business that should come up at this time. It is concerned with the nomination and election of officers for the coming year. Our nominating committee is composed of Mr. Dale Harman, Mr. J. G. Williams and Mr. J. E. Dobbs. They have completed a very carefully thought out slate. Mr. Harman has asked me to read this list for him.

Report of the Nominating Committee

Chairman, H. L. CUMMINGS, Manager, Yellow Cab Company, Richmond, Va.
Vice-Chairman for Delivery Fleets, J. E. DOBBS, Detroit City Service Company, Detroit, Mich.
Vice-Chairman for Bus Fleets, R. W. MEADE, President and General Manager, Peoples Motor Bus Company, St. Louis, Mo.
Vice-Chairman Delivery Fleets, J. E. DOBBS, Detroit City Service Co., Detroit, Mich.
Vice-Chairman for Taxicab Fleets, MR. J. G. WILLIAMS, Secretary National Association of Taxicab Owners, Chicago, Ill.
Secretary and News Letter Editor, MR. A. J. RUSSELL, JR., Managing Editor of "The Taxi Weekly," New York City.
Chairman Membership Committee, DALE HARMAN, Yellow Cab Company, Kansas City, Mo.
Chairman Poster and Slide Committee, C. C. CLEMENTS, Safety Division, Sheffield Farms Co., Inc., New York City.
Chairman Publicity, A. E. LUNDSTEADT, Bowman Dairy Company, Chicago, Ill.
Chairman Program and Statistics Committee, MR. W. O. HINCKLEY, The Peoples Gas Light and Coke Company, Chicago, Ill.
Chairman Engineering Committee, MR. S. J. STEINMANN, Indemnity Insurance Company of North America, Philadelphia, Pa.

Executive Committee,

ROBERT CLAIR, Liberty Mutual Insurance Co., Boston, Mass.
 W. W. CLOUD, President, Yellow Cab Co., Baltimore, Md.
 MARCUS A. DOW, Vander Poel, Pausner & Jefferson, Inc., New York City.
 T. A. HORRÖCKS, Minnesota Truck Owners Ass'n, St. Paul, Minn.
 H. J. MINEUR, J. M. Horton Ice Cream Co., New York City.
 R. J. WALL, Vice-Pres., Yellow Cab Co., Toledo, Ohio.
 A. F. WAITE, Green Cab Co., Cleveland, Ohio.

MR. WAITE (Green Cab Company, Toledo, Ohio): I move that the nominations be closed and that the secretary cast a unanimous ballot for these officers.

(The motion was seconded and carried.)

CHAIRMAN CLAIR: I just want a few more minutes to make a little explanation and apology. It may be that in the next half hour I shall have to leave for the reason that I agreed to read a paper before the Food Section at the Pennsylvania. I am going to ask Mr. J. G. Williams if he will take the chair and finish the meeting.

We will now proceed with the next speaker on the program, Mr. H. A. Inness-Brown, editor of the *Taxi Weekly*, New York.

How the Press Can Help to Prevent Street Traffic Accidents

By H. A. INNESS-BROWN
 Editor, Taxi Weekly, Inc., New York City

I do not think it is necessary for me to sell you on the subject of street traffic accident prevention. Any of you who have consulted your books within the last year will admit that it is costing you enough money for you to be interested without my trying to interest you further. I take it that you men, in coming to this meeting today, are looking for a practical means of street accident prevention. The most direct means which have been pointed out by anybody who has ever had anything to do with safety work is education. I am to do my little bit here this morning by telling you something of what I think the press might do to help in this education.

Certainly the press is the best arm that education has. We learn to read and write in school, we go to college and learn higher mathematics (which we afterward forget) but our everyday lives are more or less governed by what we read in the newspaper. If we can enlist the daily press in our fight, that will insure us victory.

The daily press is a rather human institution. Most of you have probably come in contact with it. I have never yet gone to the daily newspapers and asked for a legitimate favor that I have not been able to walk out with it tucked under my arm. It is a human institution and it is ready to aid in the saving of life. I think this organization should go home with the idea of making friends with your newspapers.

Taxicab men know particularly that it is necessary for the newspapers to understand the point of view of the operators. Commercial fleet operators should know the same thing. They know that many erroneous reports of accidents or fights on the street are printed merely because they represent news. It is also necessary that they represent true news. I think that unless the managing editor of a daily newspaper has that called to his attention he is likely to slight the taxicab operators. Certainly that has been true in our City of New York, and during the last three years we have succeeded in bringing about a different viewpoint. They look upon us now as being reasonably decent, not crooks and gun men. That has been the work of my little paper and has been more or less successful.

I made a survey in preparation for this little talk of the daily newspapers throughout the country. I wrote to over 150 and received replies from approximately 100 of them. I was surprised to find that this matter of street accident prevention was not as well received throughout the country as we thought. I was surprised to find that only eight papers out of 100 had a definite policy in reference to street traffic accident prevention. In other words, 92 per cent entirely ignored street traffic accident prevention.

I do not want you to think that I mean that newspapers are ignoring safety measures. They are cooperating with safety things but not cooperating to help prevent street accidents, which we are interested in because they cost us money as well as trouble. They all print news of accidents, but they do not print educational news which is necessary to reduce street traffic accidents.

About the only way that I can approach this problem is to outline what I would do if I were the editor of a daily newspaper. I can speak with some experience, both as to national papers and local papers. I would never let the paper go to press without some safety story tucked away in it and that story would always try to teach a lesson. We have tried to cooperate with the National Safety Council and have received their literature. You can always find a safety story, so in recommending a program I would recommend that. I am speaking from my heart telling the things I would be willing to do if I had a paper under my control.

I would print all the news truthfully. Probably you have at times asked a newspaper to keep out the report of a certain accident. I think that policy is unwise because generally when that happens you get a garbled report and it is better to have the true report even if you think it is going to hurt you somewhat. I do not believe that the commercial fleets are bothered as much with this sort of thing as the taxicab men, but taxicab men are rather proud of their accident records and they do not want to have a story of an accident on the front page blaming the company.

I believe, in view of the fact that we are fighting accidents, that it is better to allow the newspapers to print a true statement of what has occurred. I would see that every accident that occurred in my city was printed in my newspaper and I would try to give at the end in bold faced type the reason for that accident. I do not believe that would bother your liability very much. I do not think you

would have any difficulty about that and I think you should go ahead and tell the truth about your accidents.

I would print each month a map of my city with the accidents which occurred during the month clearly outlined on the map. Not only would I have the map in my paper but have a large blackboard outside of the newspaper office and when accidents occur they should be shown on the proper streets. I believe I could justify the use of the space because it would meet with the good will of my readers and increase my circulation. That map should be printed large enough so everybody could read it and have an analysis of all accidents. I believe that would pay in dollars and cents to a newspaper publisher.

As a third thing I would see that the traffic laws are obeyed. Unfortunately in many of our cities the newspapers are in politics and sometimes ignore the traffic laws. If you wish to prevent street traffic accidents you must see that the traffic laws are obeyed because it is generally in violation of those laws that the accidents occur. Every year, especially just before the opening of school I should cooperate with the taxicab companies and commercial fleet owners and the automobile associations in running a campaign of education for school children. The Automobile Association of New York ran a campaign and cut the accidents from something like 103 down to 45.

The next thing that I would do would be to mark with a blood red cross all the streets and every place where a fatal accident occurred. I do not know whether you have had the experience that I had. When a boy I saw a great splotch where a man had been killed and I could not pass that place for years without remembering it. Whether it is uncomfortable or not we should have that mark always before us. I think I would encourage that in my paper. I believe that would be a policy that would pay, as far as saving life was concerned.

I would cooperate with the National Safety Council by printing the news about it and encouraging the people to belong. When you join an organization that is fighting against wrong you are going in the right direction.

I would print traffic laws on the first page of my paper. Do not think that this paper is going to be all devoted to safety work, but some of it is, and I believe it is important enough even for a metropolitan paper to have. The *New York Sun* ran a series of courtesy slogans that was extremely popular. It also ran a slogan about making bets on horses. I would say not to disobey traffic signals or something of that kind.

I would make a fight against the ambulance chaser. That is a thing that I really should talk about here today. I am a good soldier so I followed orders and talked about these other things. I am not so well qualified to speak what I would do as an editor of a daily paper as I am qualified to speak about the ambulance chaser. I believe the ambulance chaser is doing more to harm safety work than any other thing. They work in the dark. They encourage rules against safety and they are looking always for people who have been in accidents. They go to the trouble of making you pay money to protect yourself against them. If it were not for the ambulance chasers you would find that the safety work would go ahead a great deal faster. You would be able to have the publicity that you should have on all accidents. But now the company wants to keep it quiet because the company knows that the ambulance chaser will not be far away.

In New York we have made a fight against the ambulance chaser. The *New York World* and the *Brooklyn Eagle* led in that fight and we have succeeded in curbing to a great extent the work of the ambulance chaser so much so that your mutual insurance companies which were practically bankrupt a year ago are preparing to pay dividends and this has been done by not paying small claims to ambulance chasers. One man filed 250 cases in two and one half months. Another man 1,500 cases in something over a year. He must have been a pretty good

lawyer. I believe it is the duty of every paper throughout the country to try to fight the ambulance chaser and have active campaigns against them.

The last thing I would do if I published a paper would be to back up the code of the Hoover Committee. It has been carefully prepared and I believe it is ideal for taxicabs and fleet operators as well as the general motoring public. I would see that this code was advocated in my paper. I would have a study made to see where the local ordinances conflict with the Hoover code. I would bring the pressure of public opinion in order to have the local laws comply with the model traffic code suggested by the Hoover Committee.

Gentlemen, these are some of the things I would do if I were the editor of a big metropolitan newspaper. I am not the editor of that kind of a paper so it will mean little or nothing unless you carry back these ideas for your own local papers. I do not see any reason why you cannot suggest such a program to your local papers. I believe it would be well received and that you will find that they will be willing to cooperate with you in putting it over.

The last thing I should like to say is that if these meetings are going to amount to anything some good must go out of them. Therefore if you have come merely to listen without any idea of acting on the suggestions, my suggestion is not to come again. I believe you must work actually for safety to follow out the precepts of the meeting.

CHAIRMAN CLAIR: I hope that the editors of some of our local papers will have these matters brought to their attention. I was talking a few weeks ago with one of the boys in my organization who had just come from a visit to St. Louis. I said to him, "Never having been in that city before, what do you think of St. Louis?" He said, "I'll tell you how I feel about it, especially in relation to the traffic situation. St. Louis is a congested area situated between parking spaces." I think we are very fortunate this morning in having the next speaker with us. He is a man who has been actively engaged in the business of transportation. He has done much pioneer work, especially in matters pertaining to safe bus operation. It gives me great pleasure to introduce Mr. R. W. Meade.

Safe Bus Operation

By R. W. MEADE

President, The Peoples Motorbus Company, St. Louis, Mo.

When, a little more than twenty-one years ago, the gasoline motorbus was introduced in New York as a new medium of public transportation, there was very active discussion among street railway men (of whom I had been one until shortly before that time) as to whether the bad accident record accumulated at that period by the street car—both cable and electric—would not be greatly outdone by the motorbus.

Here was an independent, self-contained mechanically-propelled unit plying for gain through the city's most congested streets, not even confined to tracks and free to run amok if the driver so willed—potentially a powerful engine of destruction. The record in London during the pioneering period, during which three large companies were vying with each other in rapidity of expansion to serve the most profitable routes, had been so bad that the motorbus was regarded at that period as the most dangerous vehicle engaged in street traffic. With such a record in London where the regulation of traffic was considered well nigh perfect, what would it be in New York?

I am glad to say that the outcome was most gratifying. Far from piling up a record of costly collisions with vehicles or pedestrians, accidents of a serious character were comparatively rare, and the pedestrian accidents were almost com-

pletely confined to cases of drunkenness or gross heedlessness on the part of the victim, who usually walked into the side of the bus after the front of the vehicle had passed. Our few fatalities were nearly all of that character. In the first ten years of operation during which our buses ran more than 25 million miles and carried nearly 100 million passengers there was but one fatal accident to a passenger and three cases of serious injury, while accidents involving persons other than passengers totalled 16 fatalities and 24 cases of serious injury. This comparatively favorable record was reflected in a monetary way in the fact that the amount we set up on our books as a reserve against injury and damage claims amounted to more than three times the actual calls on us during the decade. At the end of that period we had a reserve of nearly a quarter of a million dollars unexpended.

These results proved that, given proper organization and supervision in a city with adequate police traffic regulation, the motorbus when compared with the street car makes a highly favorable showing from the point of view of safety, both of its passengers and of others.

Inasmuch as the experience gained and the methods pursued in New York have been largely followed in the organization and operation of bus service in other cities, an outline of some of the basic factors involved in the operation may be of interest.

1. *Standard Rules.* In the very beginning the standard rules of the American Electric Railway Association for city street car operation were taken as the basis for the rules for the operation of motorbuses. Thus the underlying principles that had been found valuable in street car operation were applied to the motorbus so far as practicable. One rule which has probably done as much as anything in saving life and property has been that which requires a full stop before crossing any street railway line. I have heard bus operators scoff at this rule as causing unnecessary waste of time but I am firmly convinced that the additional time involved (which is, of course, considerable) has been richly repaid in immunity from the most dangerous type of collisions to which the bus is subject.

2. *Tried System of Discipline Employed.* In the enforcement of the rules, the methods developed in the steam and electric railway fields, under which a cumulative record of every man is kept and can be reviewed, were employed and have proved their value.

3. *Training and Promotion.* The practice of employing every man first as a conductor, where we have a chance to observe his general habits and reactions before he is permitted to drive a bus, with all the responsibility this entails, has been of the highest importance. The street railways generally keep the two positions on a parity as to pay so that there is no advantage in transfer from one to the other. We have always maintained a differential pay rate in favor of the driver, and this has proved a strong incentive to the man working on the rear end to give meritorious service and win promotion to the position of greater responsibility and remuneration. We have also found that the man who has served on the rear end when promoted to driver shows a greater sympathy with his team mate, and this makes for greater safety. Nothing is more important to safety than the character and thoroughness of the training the prospective driver receives. Only the best men can be safely entrusted with that important duty, and on the principles and practices absorbed by the new driver during this process his success in safe and economical handling of his vehicle will largely depend. Moreover, the right kind of man in this position will discover and eliminate men with slow reactions or other dangerous tendencies that might be overlooked by the average driver detailed to such training.

One of the important details of the training process is a systematic follow-up during the first month of service to observe the progress of new men. This frequently uncovers lapses from accepted practice through the tendency of some

men when they get "on their own" to "express themselves" in ways that do not conduce to the safety or comfort of their passengers.

4. *Physical Examination of Crews.* The physical examination of men employed as drivers and conductors of motorbuses is of the highest importance. While the term "physical" is employed, our examinations have always gone beyond the literal interpretation of that word, our physicians being particularly alert to eliminate men with mental or psychopathic tendencies that would render them unfit for this exacting service.

5. *Incentive to Longevity in Service.* Our experience shows that, in general, the longer a man remains in our service, the better he is, and this applies in the matter of safety as well as other characteristics of his work. Therefore it is not only simple justice but good policy from the economic viewpoint to increase his pay according to his length of service, and this has always been a feature of our policy. It is the best substitute we have been able to devise for bonuses for meritorious service, the successful administration of which is almost always attended with drawbacks and complications.

6. *Mechanical Excellence of Equipment.* Nothing but the very best equipment obtainable, regardless of its cost, has ever been good enough for our use. In the beginning we were obliged to import all our bus chassis, paying 45 per cent duty, freight and packing, but until our American manufacturers were able to produce vehicles and their component parts of equal excellence, the heavier cost was well repaid in the freedom from failures to which the American product of those days was all too subject. Absolute safety can only be assured by using vehicles competently designed for the service they are intended to perform and built conscientiously of material capable of withstanding the arduous duty and heavy strains imposed in public service. In our infancy we were fortunate in having the experience of London to guide us, where, under the relentless eye and hand of Scotland Yard the character of motorbuses permitted to ply on the streets of London was never permitted to fall below the high standards prescribed by the Police Commissioner's engineering advisers. By adopting these standards as our own we avoided the pitfalls into which so many other enterprises of this type were falling in that day, living their short and hectic lives in happy disregard of the danger signals, and disappearing as suddenly as they arose.

7. *Mechanical Inspection and Repair.* Possessed of equipment capable of withstanding the arduous service to which it is subjected, the next requisite is to keep it continuously in the best of condition. Here again the experience of London was of the greatest value. The system employed by the London General Omnibus Company and adopted by us has been aptly termed "mechanical prophylaxis"—in other words, anticipation and prevention of trouble instead of waiting for it to occur. This consists of a periodical inspection and overhaul of every vehicle based on the performance of a certain mileage, varying from 2,000 miles up, and regardless of the vehicle's apparent condition at the time. During this process, which is performed on the scheduled day between 7 a. m. and 4:30 p. m., every part of the vehicle is subjected to a rigid inspection, all wear is taken up, and weak, worn, or defective parts replaced. On the completion of this overhaul the vehicle is ready for another tour of 2,000 or 2,500 miles with reasonable certainty of immunity from mechanical failure, while, from the standpoint of public service and economy of operation, the loss of service is reduced to a minimum, the vehicles undergoing this overhaul all being available for service during the evening peak load on the day of overhaul.

In addition to the foregoing, every vehicle is subjected to an annual overhaul, equivalent to a rebuilding, during which every element in it is brought up to the latest standard. Under the combined program accidents due to mechanical failures are reduced to a minimum. Brakes, steerings and elements in the transmission

line, failures in which are likely to cause accidents, are always given special attention.

8. *Means to Prevent Skidding.* Slippery pavements and skidding accidents are two of the worst dangers of bus operation, and this refers not only to the bus itself but to all other vehicles on the street. After providing vehicles that by excellence of design are reasonably free from skidding tendencies, careful training of drivers in methods of handling their vehicles on slippery pavements is the first requisite. The third line of defense is to so treat the pavement at critical points as to minimize the skidding of any vehicle no matter how driven.

Early in our New York experience we found the mechanical gravel-spreader an important adjunct to our service, because the City had not learned at that time the value of rendering such a service. The same device has proved valuable if not absolutely essential in other cities where extensive bus services are operated and has demonstrated its value to, and appreciation by all vehicular traffic in large numbers of motor vehicles, both passenger and trucks, that are attracted to the gravelled bus routes in slippery weather.

On one particularly dangerous stretch of pavement on an important route in St. Louis we prevailed on the City to permit us to give the descending grades an experimental permanent non-skid treatment, and this has demonstrated its value in the two years or more since it was laid. If our cities would treat all their pavements on descending grades in this or an equivalent manner it would eliminate many preventable accidents.

9. *Safety Organizations.* With equipment of the best design, material and construction, maintained in the best condition; with rules based on wide experience and with an expert organization and approved methods for enforcing them; with thoroughly trained and supervised drivers and conductors, it is further necessary to keep the idea of safety prominently and constantly before the entire organization and to secure the cooperation of the rank and file in maintaining it if accidents are to be kept down to a minimum. For this purpose a wide variety of expedients may be employed in the form of financial bonuses, prizes, contests, etc., but the basis for any of them and the most effective, year in and year out, is some form of safety organization. This can vary widely in its make up and functions so long as it provides for the free and active participation with the supervisory and executive forces of the rank and file, that being the essential characteristic without which it would not differ materially from or properly supplement the operating organization.

10. *Records and Statistics.* It is of course important to keep complete records of accidents and to classify them, the most important objective of such records and statistics being to diagnose the direct and underlying causes, and thereby be able to apply preventive remedies. I have often felt that the ability to make readily at any time such special classifications as are only possible by means of some selective mechanical system would be exceedingly helpful in this direction, and on a large system might easily repay the rather high expense involved.

The bus is inherently a safer medium of transportation than the street car. In the accident statistics of the electric railway there is one important item almost entirely omitted, but which from the public viewpoint is really chargeable to that system of transportation. I refer to the heavy toll of fatalities and injuries taken every year of electric railway passengers going to or from the place of boarding and alighting, sometimes while actually standing in so-called safety zones or crossing the lanes of rapidly moving traffic. All too frequently there are races between passengers running from the curb to the loading place of an approaching street car and a flock of automobiles striving to get by the loading zone before the street car comes to a stop and blocks them until it again gets under way. In my opinion, the provision requiring all vehicular traffic to come to a stop while a

street car is loading or unloading regardless of the width of the lane between the tracks and the curb is a most unwise and unnecessary one because of the strong tendency it has to cause just such wild races as mentioned above and others of equal danger in attempting to beat the car to its next stop. The alternative provision under which vehicular traffic is permitted to continue to move but at a moderate speed and at a distance of eight feet from the street car is in my opinion a far safer one. It is unfortunate that the full stop provision has been incorporated in the Hoover Model Code of Street and Highway Laws. Objection is sometimes made to the eight-foot rule on the ground that it is difficult of enforcement. There is no reason why it should be if an eight-foot zone were *painted* at every car stop, and this is the least that the railway could do for the safety of its passengers. A few arrests and convictions of the motorists that endanger human life by driving recklessly past loading zones would soon break up the practice.

All this emphasizes the great superiority of the bus from the standpoint of safety in its ability to take and leave its passengers at the curb—the only true safety zone—and also the fact that in this process it permits all other vehicular traffic to pass freely by, eliminating the wild driving so common along every street car line when motorists are contending with this prime obstruction of our thoroughfares.

No one can deprecate more than I the callous indifference of a motorist who will endanger the life or limb of a street railway passenger going to or from his car, and I feel that the penalty for such reckless disregard of safety should be severe, but that is no reason why a vehicle that is inherently super-obstructive should be artificially made more so to the serious detriment of all other vehicular traffic.

Recently I returned from the Annual Convention of the American Electric Railway Association where the principal subject under discussion was Modernization. Much was said of the importance of the street railways controlling and utilizing the motorbus, but not one speaker even suggested the possibility of the only step that would really modernize a system of city transportation, namely; the removal of all rails, poles, wires and other obstructions, the repaving of the roadways with a smooth, homogeneous pavement, and the substitution of motorbus for street cars.

Speaker after speaker reiterated the dogmatic statements that there is no substitute for the street car as the prime method of mass transportation and that the bus can not handle passengers as cheaply as the rail car. I strongly disagree with both those statements and my proof is readily available in the service of the London General Omnibus Company in London, which handles more passengers than any street railway system in the world, at fares approximately the same as those of the London County Council Tramways, and earns a handsome profit, while the tramways run at a considerable loss. The fact is that there is nothing done today by the street car that can not be better done by the double-decked motorbus.

The substitution of the bus for the rail car would give fluidity and expedition to *all* vehicular traffic instead of expediting the public transportation in street cars at the price of obstruction of all other vehicles. But beyond that—and this is the reason I mention the subject of modernization—it would be a great forward step in the direction of public safety, substituting for the archaic system under which passengers must twice in a journey risk the hazard of crossing streams of vehicular traffic for one in which they are taken and left at the curb. The city that first eliminates this serious hazard by substituting a modern bus system for its fixed rail system will not only make history in the solution of the troublesome traffic problem but will make an important contribution to humanitarian effort in the saving of human life and limb by lessening the great unnecessary toll of street railway passenger casualties that is the penalty of adhering to an outworn system.

J. G. WILLIAMS, Acting Chairman: Is there any street railway man present? If there is we would like to hear what he has to say in reply to Mr. Meade. We do not seem to have any. We are very grateful to Mr. Meade for this splendid paper on bus safety. Who has something to say about it? At a meeting of this sort when set papers are given it is very fine to listen to them but the things that get driven home in our minds are usually provoked by the discussion and we would like very much for you to take this meeting in hand and say what you have to say. A lot of you have come all the way to New York full of this safety idea and we would like to have your ideas, the more unconventional the better, and the newer and less talked about the better, because they develop into something really worth while.

L. E. MACBRAYNE (General Manager, Massachusetts Safety Council): I want to stress one point in selling your motor transportation to the public. About a year ago one of our busses had a rather nasty accident and this immediately created a sales resistance to the operation of our busses in the city traffic. It happened that on the same day the New England Transportation Company covered 25,000 miles in the operation of its busses without an accident—equivalent to running around the world. We staged a big dinner with the Chamber of Commerce and among the exhibits we had posters indicating that, "We drove around the world yesterday without injuring anybody." We really have a very low accident record from being organized much along the lines you have indicated. When you have made the reduction in your accidents you have a good field for publicity and it is sometimes most difficult to obtain the publicity needed for your operation.

E. W. MARSH (Traffic Engineer, City of Pittsburgh, Pa.): I would like to say a word, as one of the members of the Hoover Committee, about the model traffic ordinance. I feel that one phase should be amplified a little bit. That relates to the provision of the ordinance concerning stopping vehicles when the street car is loading or unloading. This subject was discussed and considered very thoroughly and carefully by the committee, of which the present chairman is a member. I believe that all points of views were carefully considered. It is true that the final result of prohibiting or recommending the prohibition of passing a street car when it is loading, regardless of the width of the highway at that point, provided, however, that if a safety zone has been created the vehicle may pass at a cautious speed, is a wise one. I believe that although the eight feet of clearance which has been used in Massachusetts and in other places has some merit that it also involves a decided hazard. What may be eight feet to you may be six feet to somebody else.

The point behind the solution as set up by the Committee is that we believe that through these means we will foster, where they can be well placed, a type of safety zone that will give safety. That, of course, is perhaps a little out of the line of thought of you gentlemen if you believe that the bus will immediately supersede the street car. Most of us working in traffic, but not in any one branch of it, cannot see that this is going to take place soon. We do have to face the problem of getting the people safely to and from the street car. Do you not believe that if the law adopts this recommendation it will bring about greater safety because when the roadway is wide enough it will cause them to make a really safe zone.

Your chairman said that if anyone had anything different to bring up that it would be welcome. I am not so sure that what I am going to say now will be. I would like to have your thoughts and constructive criticism on this subject. I belong to several committees in different parts of the country who are working on our traffic problems. We had a meeting in Chicago with the Engineering Committee of the National Safety Council and considered certain problems we should like to direct attention to. The membership of the committee is trying

to put engineering analysis on the traffic problem in the cities. One of the subjects which received the most attention was the subject of taxicabs and their regulation. I would like to bring to this group the question of what you people are doing to help the communities to take care of safety in the question of licensing operators, etc. I would also like to bring up the point which seems to me to be a great opportunity to the group you represent. I think it is generally true that there tends to be controversy between the people who are trying to take care of general traffic conditions and the taxicab people, possibly the bus people too. My thought is that if the people who represent the leading thought in the taxicab game could formulate principles for safety and regulation, they will forestall undesirable regulation which cities find they have to adopt.

Let me illustrate, taking the case in Pittsburgh, where at the present time, after attempting to secure some results by working with the taxicab companies unofficially, we have finally introduced an ordinance which comes up for a hearing today, which may be considered very drastic by the taxi people. If the taxicab people will study in a broad-minded way the problems which are bothering the city traffic officials and cooperate with those officials, it may in the end result in better conditions both to the city and the taxicab companies, as against a too hasty adoption of measures which may be considered by the cab companies very drastic and may lead to lots of unnecessary controversy. The licensing and regulation of taxicabs, proper insurance protection, etc., are some of the points that have to be considered. I would like to leave those subjects with you gentlemen and ask that through your organizations and your contacts you give some constructive consideration to these subjects in the coming year, to the end that we may cooperate and arrive at a reasonable solution of some of these problems.

ACTING CHAIRMAN WILLIAMS: In the City of Chicago, we have 300,000 registered private vehicles. The fleets of commercial vehicles are not the ones that are congesting the streets. We have about 3,000,000 people and that is one vehicle for ten people. Private vehicles that make the trip down town and back usually accommodate one patron or at most two. So then the 300,000 private vehicles might possibly accommodate 600,000 persons in their trips down town and back during the day. Then you have 2,400,000 people who have no vehicles at all and they pay for and ride in taxicabs and other public vehicles. Are you going to take the vehicles away from the 600,000 who ride in private motors or from the 2,400,000 who ride in public vehicles? Are you going to put them off the streets so that the other 300,000 can run their machines?

Of course you are not. You are going to regulate the streets so that the greatest number of people can have a vehicle to ride in. When you come to regulating vehicles you must regulate the private vehicles off the street, because they represent one-tenth of the population. Your vehicle that accommodates one or two persons occupies just as much space as a taxicab, or perhaps more space because they are longer. A taxicab during the day will accommodate 15 to 20 people and your private vehicle accommodates one or two. That will have to give place to the vehicle that carries most. Then when you come to regulate vehicles that 50 or 100 people can ride in you have still another problem. That is what Mr. McClintock has found in his survey in Chicago. He found out who rode in the private vehicles and who rode in the taxicabs and they restricted the private vehicles and allowed the taxicabs to go back and forth because they belong to whoever wants to buy a ride. That seems to be our angle of the problem.

MR. MARSH: That is not quite the angle I had in mind and indeed I agree with the remark made to a considerable extent. There are a number of problems of the taxicab driver licensing, protection to the public, regulation and insurance, which are questions that have not been met in a good many places though they have in some. There are also the principles which should govern the location of taxicab stands which, to my mind, would be exceedingly valuable. It is for

that sort of thing I am speaking rather than anything about allowing private vehicles to park in the streets and excluding the taxicabs, or anything of that sort. Anybody who has any sense will realize that the taxicab has a distinct function in public transportation and wants to take care of it. Some of these problems concerning the relation of the taxi to the city traffic to my mind have never been given that joint broad-minded, progressive, cooperative attention which would probably bring valuable results.

A. J. BAXTER (Minneapolis, Minn.): I am not connected with the taxicab companies. In a way I would like to cover the point the gentleman spoke about. I was chairman of the street traffic committee in Minneapolis for a number of years. We have attended several of these conferences and we are interested in public safety. For the past year our committee has taken up the matter of regulation of taxicabs. When we first called in the representatives of the various taxicab companies, there was a situation which was not at all satisfactory. There were no taxi stands designated although we had tried to designate them by giving the police department authority to designate cab stands but the police paid no attention to them. At the last session of the legislature we had an amendment giving the city the right to establish taxicab stands. That gave the City Council authority to establish them.

As soon as the law was passed, we went about establishing taxi stands. We have a few independent owners and drivers and about 500,000 population. There are 54 square miles of congested streets like many of the eastern cities. The taxicab owners thought, "Is that new City Hall gang going to raise hell with us now?" When we talked it over, they realized that we were hoping to bring order out of chaos that had been existing up to that time. We asked the taxi owners to suggest to us where they wanted the districts located and the number of cabs at the various stands. They suggested about 50 stands and how many do you think we cut out? Only three, and then we differed with them as to the number of cabs in some instances. Only in four or five instances we cut down the number from three cab stands to two cab stands and from five to four. We got along very well.

There was a bad situation right in the center of town where the hotels and theatres are. The business men continually complained about taxicabs, double parking, etc., and after we created the cab stands the business men in that highly congested district were much pleased. They worked with us on the proposition and we have had very little complaint about our taxicab situation there now as far as parking is concerned. I have talked with a number of drivers and independent owners and have asked them how it works out. One of them said, "Before, when we were busy, we were not interested in any cab stand but when we were not busy and looking for a place to light, we would have to run around for blocks. Now we always have a place to park the car."

Another thing we have been doing that is being tried in several cities, San Francisco, I think, is to allow taxicabs to stand at hydrants marked taxicab stands. Under no consideration can the driver leave his car when parking at a hydrant. If he is going to leave his cab he must drive away from the hydrant on account of the menace of fire breaking out in the region. So far, we have not had any trouble and have been working on that since last spring. They generally get into those stations when work is slack and generally have the very best taxi stands because they are used when business is very quiet. What is agitating us now is this. The newspapers have taken the matter up and I would like to get some opinion to bring back home. That is regarding insurance, whether the taxicab companies should have mutual insurance or be bonded with some insurance company, the rates paid, etc. . . .

ACTING CHAIRMAN WILLIAMS: We have not very much time and I think we had better stick to the subject in hand and you can bring up this insurance matter later.

MR. MARSH: I feel that my first remarks are perhaps too general. I would like to suggest subjects for consideration, to outline more specifically what I mean. Should there be special licensing of taxicab operators and what should the rules be? Should there be special taxicab insurance and what type of regulation?

Taxicab Stands: Under that subject is it better to have common stands where all cabs may come in or independent stands as a few cities have, used by one cab company. Where should stands best be located to meet the taxicab demands and still help the traffic officials. What regulations should govern the stands and what should be the maximum? If they should have stands, should they be permitted to stand elsewhere? Should taxicab stands be permitted on no-parking streets where you exclude other vehicles, and so use what may be considered a subsidy to the taxicab companies. Is the future going to bring off-street stands in the congested districts? Can taxicab companies better govern the number of cars which are out during a period as regulated to the demand at that time? This is related to the serious problem of cruising which is a difficulty to every taxicab operator and to those of us who are trying to handle traffic conditions. How can the problem of cruising be traced more specifically than at present?

DALE HARMAN (Vice Pres. and Mgr., Yellow Cab Company, Kansas City, Mo.): I feel as a worker in this association that your questions should be put to the National Association of Taxicab Owners, who have representatives in more than one hundred important cities in the United States and Canada. I can count a dozen or fifteen members here and I am trying to defend all of them. I know Mr. Cloud and Mr. Cummings are working in their respective cities and Mr. Walter Laird of the Yellow Cab Company of Pittsburgh is one of the greatest workers for safety. I feel that we should defend these people. We have ordinances in every city in the country. Some of them need revision and I do not know of any of us hindering efforts of the Safety Council or the police department in trying to regulate traffic.

MR. MARSH: Every city has traffic ordinances but in view of getting better traffic conditions, it has been deemed wise to get people together or their representatives to devise a standard code to improve conditions. My appeal is that your industry by getting the best thought in it together can cooperate with the committee, I believe more thoroughly than it has done in answer to some of these questions. Please do not get me wrong; I do not want to say that Walter Laird is not a good safety man for he is. The future is going to require some further steps along these lines and my thought is that here are problems that may be answered satisfactorily now which are going to come up in increased numbers in the future.

W. W. CLOUD (Pres. Yellow Cab Company, Baltimore, Md.): Does not what you have just said apply to every character of transportation, street cars, busses, railroads, etc.? Now, under the deliberations and conferences of the Hoover Committee, there has been a great effort to get these interests all working together in the interest of better traffic conditions in the cities. You have made some very important and enlightening suggestions there. I do not resent them at all. We always welcome anything that will better the conditions, but in the making of specific recommendations throughout the United States, the conditions are so very different that it has been hard to standardize or to formulate principles that we could recommend as representing a certain industry that would have been applicable to the entire country. Following what Mr. Harman has just said, I feel that in a matter as important as this that does not apply to a particular industry as well, we would probably make progress with that if it

was submitted to the authorized representatives of that industry who would have cooperation of the engineering experience and then see how close their findings would match those of the Hoover code. I think we could reach a point where we would agree and make progress in the end.

ACTING CHAIRMAN WILLIAMS: Along the line of regulation and safety endeavor, we have Mr. Zukor from Cleveland, and I want to ask him to say a few words about what he is doing for accident prevention there.

L. C. ZUKOR (License Commissioner, City of Cleveland, Ohio.): As I sat here it was rather amusing to note that we all seem to have the same problems. First, the question of licensing the driver: I do not claim to have the solution, but we have gone a long ways in acquiring some degree of success in selecting the type of man that will best serve the owners and the community as well.

I shall give you an outline of the method of procedure we use. Each man is obliged to fill out an application on which he answers questions pertaining to himself, his last employer, the period of time employed, etc., and for the past five years, his residence. On the inside there are two vouchers, who should have known the applicant for at least one year. These are sworn to before a notary public. He must submit to physical examination before a doctor. That is part of the application. He sends in four pictures of himself, front view. The applications are received by us. We are separate from the police department, but they make an investigation and one of my inspectors goes into the community and finds out where the fellow lives and what his habits are. Sometimes, we find that his address is fictitious or that he is a dead beat. His police record is verified. He is brought into the office and his finger prints taken.

I recall that when this was first inaugurated, it caused a lot of strife and objection. Men do not like to have an identification as rigid as the finger print, but you can take it from me that we have only a limited number of cases where we need to use the finger print and fortunately, it is just as needful for the protection of the innocent as to secure conviction of the guilty ones. I am going to try to make this brief and may leave out some points of interest to you. I know you are anxious to get away.

The question of compulsory insurance: Every cab in the City of Cleveland metered or non-metered, must carry insurance, five, ten and one. There is an alternative whereby a regularly constituted company may give bonds in sufficient amounts according to number of cars they operate. For those of you that might carry this idea home and try to promulgate that, bear in mind that the bonding features are not always what you expect them to be. It is not all gold that glitters. The operators put up the collateral and it is tied up for so long a period that you could grow old and die and your posterity would never collect. The laws of various states control that.

The subject of mutual companies: There may be insurance men here, and I am not going to mince words, but I will say that your mutual companies are no bigger than their power of collection. I will not except that. The ordinance is so constructed that the final say rests with me, subject to the law department. I would warn any insured to be mighty careful before they accept a mutual policy.

The next question that comes up is, "What can you do to maintain a sensible standard of rates when it comes to the charges for insurance?" That is a great bugaboo. Our experience has shown that about the first of January, our rate was \$575 per cab or approximately a little over two dollars a day. In order to offset this to some extent, we started a round table discussion and got all our competing operators to come, nothing official, but a sort of get-together meeting and we all agreed that there was some solution to be had. We inaugurated a system whereby each company assumes that the operator must make a return to the traffic division of his number and by whom he is employed. This is done for

every accident, no matter how trivial, it must be reported. This is in addition to reports made by the police department.

The record is kept and if a chauffeur is transferred, the new employer must report him. As soon as a man has two chargeable accidents,—I mean accidents that could be prevented—on the testimony of witnesses and your investigators (and the police department will assist you), the man is notified of a suspension of his license. This is sometimes put into immediate effect. He is given an opportunity to be heard before representatives of the traffic division, the police and each of the companies. They are permitted to hear the cases. If you have a lot of floaters in your city, there is where you will see them. The man is given an opportunity to make a defense. If he has a bad record (I saw one fellow the other day with seven accidents since the first of March), we take his license away and do away with him. Only four of these accidents were chargeable, but any time a man has a rear end collision, he is out of luck. If a man is a potential accident maker, careless, wilfully disobedient of orders, then he loses his license.

One company told me that in one month their experience was improved 55 per cent. It is worth trying.

Now as to a method of supervising your public stands: We have eliminated them on the highways during the rush hours, but you must serve the patrons of your hotels. You must accommodate the public whenever you can. We do not permit cruising and a special detail of motorcycle police enforce this regulation.

ADJOURNMENT

October 4, 1928

ROBERT CLAIR, Chairman**Safety Engineer, Liberty Mutual Insurance Company, Boston**

The Third session of the Taxicab and Fleet Owners Section was called to order at nine-thirty o'clock by the chairman, Robert Clair, Highway Safety Engineer, Liberty Mutual Insurance Company, Boston, Mass.

CHAIRMAN CLAIR: The meeting will please come to order, gentlemen.

The first speaker whom we have on our program this morning, is one from whom I am sure we will get a great deal of inspiration, as we always do.

It gives me great pleasure to introduce Mr. Marcus Dow, author of "Stay Alive," and an ex-president of the National Safety Council.

Little Things That Cause Big Accidents

By MARCUS A. DOW

Vander Poel, Pausner & Jefferson, Inc., New York City

Of course, I have been engaged in safety work for a great many years, and have had a long and quite varied experience in all phases of accident prevention work. And the more I see of accidents and their causes, the more I become convinced that it is the little things that go to make up the majority of accidents, big and little.

The great trouble with the average mind, that is, the mind of the average person who drives a truck or automobile, in regard to accidents is that they think only of the bigger things which cause accidents. For instance, if we pick up a newspaper and read about a train wreck where a score of lives have been lost, why, we are somewhat impressed. We read where the engineer was asleep on the job, that he ran by a red signal, that the safety of a hundred souls had been placed in his care. Black headlines stare us in the face! It is a terrible thing. Federal and state railroad investigations are immediately begun, and for a few moments, at least, the public mind is impressed with the single act of negligence that brought on death and disaster.

Or again, an automobile, perhaps in the dead of night, traveling at a high rate of speed, mounts the curb and plunges into a tree. The driver and the other occupants of the car are instantly killed. A bottle of gin in the wreckage tells the story: "The driver was drunk." It gets front page space in the newspapers, and the public mind sees the picture of an untold number of drunken drivers careening along the highways and we fix upon them the responsibility for a large proportion of the deaths and injuries occurring on the highways.

Or again, some traffic court magistrate adopts a laudable policy against speeders, and we get the impression from that publicity that the speed maniac is responsible for a great deal of the accidents we have today.

Now, I do not want you to get the wrong impression. I am not offering any excuse whatever for the drunken driver or the habitual speed maniac. I go on record to say that any automobile or other vehicle in the hands of a drunken driver is a potential death car, and any motor vehicle in the hands of a reckless speed maniac is a deadly weapon.

But what I would like to impress upon you and bring to your attention, is the fact that these major violations, serious as they are, cause only a small proportion of the total number of accidents occurring on our streets and highways today.

A man stepped out of his house in a small western town, on a dry, clear, sunshiny day. There was no rain or no wind, nothing whatever to interfere with his actions or to get his goat. This man had two good eyes. His hearing was O. K. He was not crazy or bughouse. As a matter of fact, his physical and mental construction, you might say, was Grade A. So he did not have an alibi to cover what he did, and I will leave it to you whether he did or not.

Well, he got up on the seat of his automobile parked in front of his house, started the engine, threw it into reverse, and backed up. Well, he slammed into another car parked three feet behind him with such force as to start it rolling downhill. Now this second car ran smack into a baby carriage being wheeled across the street by a 12 year old girl, and tipped it over. There was a six months old infant riding in the go-cart, and it landed on the pavement on the top of its head.

You all know that kids of that age have a soft spot on the top of the head, very tender, and the blow killed that little mite deadlier than a door nail.

Now, the man that backed up his car and slammed into the car behind him was not speeding. He was not even drunk, although you would think he must have been cockeyed the way he handled his car; but he backed up without looking behind him to see what the conditions were. He backed up quickly and suddenly with a jerk, stepping on the gas too hard, and he broke not a fender, but a mother's heart.

Remember the little things! Because some of the things that to you may seem of the least importance, are oftentimes the cause of serious injury or death.

I picked up a copy of the *New York Times* only a short time ago, and down in an obscure corner of the inside page, I read a paragraph that told about a fatal injury to a man who, while cranking his own car, was killed by a man backing into him without any warning, and without the driver looking where he was going. I can count on my fingers a half dozen injuries of that kind that have come to my attention, from carelessly backing up.

So I say to you it is the little things that really go to make up the great majority of these deaths and injuries that occur on the streets and highways today.

Another case that comes to my particular attention and recollection at this time is one that occurred out in Chicago not so very many months ago, where the driver of a huge truck was bowling along one of the streets of that city and in front of him was a small car of the type commonly known as a "Tin Lizzy." This car in front of him came to a standstill on account of another car cutting out in front of him, and the driver of this huge truck plowed into the rear end of this little automobile crushing it like an egg shell.

There were two women riding in the rear seat of that little car, and one of them gave out a piercing scream that indicated she was badly hurt. They took her to one of those places where they have white iron beds, and nurses with white uniforms pass quietly about, and there they performed a serious operation on this woman, and there she closed her eyes with a final spasm of pain and suffering, and died.

Now, the guy that ran into the rear end of that car thought he had a tough break, he thought he should have gotten off with just a dented bumper, as happens nine cases out of ten in an accident of that kind. But it only goes to show that you can never tell how serious any one of these little accidents may turn out to be. This guy thought there must have been a jinx or hoodoo following him about, some black cat that brought him bad luck, that a woman should have had to be killed in a little accident of that kind. Whereas, as a matter of fact, that black cat or jinx or hoodoo, or whatever you want to call it, was right underneath the little brown cap he was wearing. It was his own careless, indifferent method of following so closely behind the car in front of him that he did not have a

safe braking distance, so that he could come to a quick stop which caused that accident.

Remember the little things in the educational campaign among your drivers! Because it is the little things that go to make up in the long run the greatest proportion of deaths and injuries on the streets and highways.

I remember when I was a kid in school we used to hear the story told of a boy over in that little country known for its windmills and wooden shoes, Holland, where much of the land is below water level, and where we find miles and miles of dikes built to protect the countryside from flood and the ensuing disaster.

According to this story, this little boy one day was walking along the top of one of these dikes, and like all little boys he was very observant. He noticed that on the landward side of the dike there was a little, thin stream of water trickling down the side of the dike; and his interest being aroused he made a closer inspection and found that there was a small hole in the dike through which the water was seeping.

Well, the thought flashed through his mind that the little hole might enlarge, that the little stream of water might make the hole larger, and that, the dike being old, it might possibly give way and the surrounding country might be flooded and scores of homes wiped out and many persons lose their lives.

So, according to the story, he stuck his finger into the opening and stopped the flow of water; he held it there through the long and dreary hours of night, until finally the next day help came. He had saved the dike and the surrounding country from flood.

Now, that was only a little thing, that thin stream of water dripping down the side of the dike. But in the mind of this young boy it foretold the possibility of disaster. That lad, realizing as he did the important relationship between the little thing and possibility of serious accident and disaster, was a real, honest-to-God safety man. Now it is that spirit, that idea, the realization that the little things do cause big accidents, that needs to be instilled into the hearts and minds of the people who drive automobiles on the streets and highways of our country today.

In order to bring about anything near the possibility of solving this great problem of highway safety, we must always bear in mind that it is often the little things that lead up to the big accident and disaster.

Referring again to my experiences and some accident cases that have come to my attention, I recall the case where the driver of a small electric delivery vehicle was bowling along a certain highway in a certain town at the high and terrific speed of about eight miles an hour. His mind was not upon his job. As the teacher used to say in the old days, when I went to school and some kid was thinking about baseball or a dance that he was going to that night, "Johnny, you are wool-gathering." Well, this guy was wool-gathering, he was not thinking of what he was doing, and he didn't have his eyes on the road in front of him. And at the speed of eight miles an hour the front wheels of his little delivery truck hit a bump, and the steering wheel was jerked out of his hands, his truck careened over to one side and collided with a moving van alongside the curb, and the front end of his vehicle was crushed in like an egg shell and crushed his right leg with it.

They took this young chap to a hospital and to save his life they had to cut his leg off above the knee. Going at a speed of eight miles an hour! Only a little thing, not having his eyes upon the road in front of him and his mind upon the job of driving, but it cost this lad his leg.

Remember the little things! Because it is some of these things that to you may seem inconsequential and trivial that really go to make up the majority of

the accidents resulting in death and injury that occur upon the highways and streets each year.

Another case in point I recall very vividly: About last Christmas time, a few days before Christmas, a guy who drove a truck for a certain concern out in a large western town parked his vehicle out in front of the store and went in to make a delivery. He came out and got up on the seat, started his vehicle, and pulled out into the line of traffic. He was collided with by a six-ton truck going hell bent for election, coming behind him, demolishing the front end of his vehicle. When they took this guy out of the wreckage he was unconscious; and when they took him off the stretcher at the hospital a half hour later, he was dead. And, instead of the bunch of toys they expected for Christmas, his two little kids and his wife had a funeral on their hands. Instead of candles on their Christmas tree they had to put them around their daddy's coffin. And all for what reason? Because this guy didn't take the precaution of looking behind him to see what was coming, before pulling out into line of traffic. Why does Dame Nature give a guy a swivel neck so that he could turn his head on it, if he doesn't look behind him once in a while to protect himself from dangers from the rear in making a turn into traffic?

Only a little thing, but in conducting your safety campaigns endeavor to train the employees to think of the little things, the little acts of carelessness and neglect that in reality, in the long run, go to make up 90 per cent of the toll of death and injury that occurs on the streets and highways.

Remember the little things! Because it is in the long run that these inconsequential, small little things cause the majority of accidents in the operation of trucks and automobiles.

Take our collisions that occur at street intersections. One of the most prolific causes of serious accidents that occur upon the highways today. There is a simple little rule that is enforced in a railroad yard which tells a railroad engineer when operating a steam locomotive in the yard limits, where it is not controlled by block signals or any automatic devices for his control of that train, that he must be prepared to come to a stop within his range of vision. How many automobile drivers ever stop to think of a simple little rule of that kind in the operation of their automobile?

If one of the men employed by you is driving a truck along the street or highway and he approaches an intersection, where there is a building, let us say, on the right hand corner, on the near side of the street facing him, and it stands ten feet back from the curbstone, and his vehicle is four feet out in the highway: That gives that guy as he approaches that intersection a range of vision of only 14 feet. Therefore, to be upon the side of positive safety and protect himself from the possibility of death or injury, he will approach that intersection prepared to come to a stop within a distance of shortly more than, well, surely not much over 14 feet.

But how many automobile drivers ever take that precaution, that simple little precaution of safety!

Remember the little things in the training of your men! Bring out to them by forceful, constant lessons these little things, these little acts, of precautionary things that they should do to protect themselves and others from death or injury. "Stop, Look and Listen!" That is a simple rule. It is a little thing, a rule that is easy to learn, easy to master, its observance takes only a second's time. Yet failure to observe it becomes a colossal act of neglect—a tremendous chance—a dangerous sort of chance-taking.

And what is taking a chance? The answer is, it is a form of gambling. If a man who is a gambler goes to the racetrack and bets on a horse to win the race, all he does is to put up a few dollars as a stake. He takes the chance of some

horse that he picks out will win the race, and if he is a good guesser and is lucky enough, perhaps he will gain a few dollars. That is gambling.

On the other hand, if your drivers, any one of them, approach a grade crossing, and they fail to slow down and shift into low gear to prevent the possibility of stalling, and look both ways and listen carefully for the trains, if they fail to do that they put up their lives as the stake, and they take the chance that no train or engine will happen to come along and strike them. And if no train hits him the driver will win, and gain what? Nothing more than a few seconds of time. And in that gamble for time his life, human life, is the stake.

Remember the little things in the training of your men, because after all it is the little things that go to make up the great majority in this toll of death and injury upon our streets and highways each year.

The pity of it, when some careless driver dead from the ears up runs over an innocent child in the street! The pity of it!

The pity of what? That any one isolated case causes injury or death to a child? No, not entirely. But the pity of it that the concern who employed him had not taken the precaution to train that driver to bear the little things in mind that might result in death or injury, due to the careless operation of his truck or automobile.

Remember the little things! Remember the little things!!

Now, how can you help this situation, in developing your campaign along these lines? First, by keeping a very careful record and analysis of your accident experiences, classifying every single accident that occurs in the operation of your fleet of vehicles as to its specific cause, so that at the end of six months or a year you will be able to ascertain by perusal of your accident records how many back-up accidents there were, how many rear end collisions, how many collisions at street intersections, how many on account of hitting bad spots in the street and losing control of the car, how many of this and that and the other thing; and you have something to show and train the employees and educate them, to teach them how to avoid accidents by remembering the little things that went to make up this toll of accidents that are indicated in your tally sheets of your actual experiences.

Way back in my early days, I remember the little story that ran something like this: You will all remember it.

For want of a nail the shoe was lost,
For want of a shoe the horse was lost,
For want of a horse the rider was lost,
For want of a rider the kingdom was lost."

Because an important message was not delivered to those defending the kingdom.

And in these days of the operation of millions of automobiles upon the streets and highways, each year a great army of human beings are lost, destroyed, crushed, maimed, for want of a little care and education and training to impress upon their minds the necessity of remembering the little things that cause accidents.

So let us not neglect in our educational campaign this training of the mind of the motor truck driver to remember the little things. I think that is a duty that every operator of a commercial fleet has to perform, not only for the benefit of his own concern, not only from the economic standpoint of the operation of his own business, but in helping to solve the great national humanitarian problem.

I remember the story told of a young doughboy who lost his life on one of those bloody battlefields of France. After the smoke and din of the battle ceased, and the ambulance men were searching the field for the dead and wounded, they came across this young American boy, who lay there with his face upturned, still in death. And in the pocket of that boy's coat they found a little slip of paper upon which in his own handwriting was written this sublime pledge:

"I shall enter this fight cheerfully and will do my utmost, as if the entire success of this campaign rested upon myself alone."

That was the American spirit, every man desiring to do the best he could, without thought of greater compensation than the knowledge that he did the best he could.

In these days of peace, without the incentive of flag-waving, and the blowing of trumpets, brass bands, and the patriotic fervor, we ought to take stock of ourselves and determine whether or not we are still giving our utmost in whatever form of human service it falls within our opportunity to render. And aside from this economic aspect, which is so important to all of us, aside from the saving of a few dollars, aside from the creating of good will among the public which is so necessary in the operation of our business, we ought to take stock of ourselves and find out whether we are still giving our utmost in a great humanitarian life-saving effort.

By teaching our employees, the drivers of our trucks and vehicles, the ways of avoiding these accidents, and pointing out the many little things that go to create this great toll of death and injury, we will help to solve the national problem and promote the great humanitarian movement; and after all, that is a great and noble effort.

CHAIRMAN CLAIR: I wish to thank Mr. Dow on behalf of those present for the inspiring talk he has given us. I am sure his words will give us new courage and enthusiasm.

We have tried during the last year, in the various matters which we undertook to further the interests of this section, to really accomplish something. I feel that it is a real, sincere tribute this morning to have such a fine gathering here. And I am sure those of us who have worked for the building up of this program, and those many details leading up to it, can feel well repaid. Whatever we have accomplished this year must be carried on.

Yesterday this section elected a slate of officers to carry on the activities of this section during the coming year. The new chairman whom you elected yesterday is here this morning, and I think it is very appropriate at this time that I should introduce him to you and ask him to say a few words.

So it gives me great pleasure to introduce Mr. H. L. Cummings, manager of the Yellow Cab Company, Richmond, Virginia, who is to be your Chairman for next year. Mr. Cummings.

H. L. CUMMINGS (Manager, Yellow Cab Company, Richmond, Va.): Mr. Chairman and gentlemen, I have always felt that Dale Harman was one of the most enthusiastic of safety workers, and as much interested in safety work as any man that I know in the country. But from what he put over on you here, I am inclined to doubt it.

I received a letter from Dale last Friday telling me the Nominating Committee had nominated me as chairman of this section for the coming year. He didn't write to me until the last minute. I tried to get in touch with him, I tried to get him on the long-distance telephone, and I could not. I was very busy at home, it was impossible for me to get here Monday or Tuesday, and not being able to locate him I took the midnight train and decided to come here and get in touch with the Nominating Committee and try to get them to put some man in here capable of handling this job. I got here yesterday, and when I got here the dirty work had been done.

I appreciate very much the honor conferred upon me, but I do not feel I am as capable of doing the work as some of the others in this section. But I pledge you that I will carry on the work to the best of my ability. And in order that the section shall be carried on successfully, it can not be done by the newly elected officers alone, but each and every man in the section must take an interest in it

and help us carry on the work and enlarge our membership, and create more interest in safety work.

Your presence here is evidence that all of you are vitally interested in the question of prevention of accidents. If you were not, you would not be here. And it is up to you to sell the idea of safety to the other operators of your towns that are not at the present time doing anything to promote the safety and accident prevention work. Get busy with these men and try to get them interested in it and carry on this great work.

I see from the program this morning that Mr. Harman is going to give us a talk that to my mind is the greatest thing, the greatest of any accident prevention message that can be carried, "Respect for the Other Fellow." Teach the drivers courtesy and respect for the other man, and that is going to eliminate your accidents.

If the driver of the truck or taxicab remembers that, to extend courtesy to the pedestrian and to the driver of the other car, the courtesy that is due him, and to the fellow parked behind him, and possibly the jay-walker that steps out in front of his truck or vehicle, and remembers at all times to extend courtesy and have respect for those people, your accidents are going to decrease.

I appreciate very much the honor you have bestowed upon me and I am going to do all I possibly can to help promote the welfare of this section. As I said before, I can not do it alone. The other officers, I know, are all going to do all they can. But we can do very little unless we get the cooperation of you men here.

Now, as your new chairman, I want to see the hands of those who are going to support me and help increase the membership in this section--the ones that will endeavor to secure at least one member in this association.

(There was a showing of many hands.)

CHAIRMAN CLAIR: Mr. Cummings has told you the secret of what will be the future success of this section. Speaking from experience, I can tell you that we most sincerely appreciate the contacts, by correspondence and otherwise, that we have with all you gentlemen who have a common interest at heart.

I might tell those who perhaps have not been interested in this section before, that one of the attractive features of being associated with us is to receive every month what we call the *Section News Letter*. That *News Letter* is edited by our Secretary and News Letter Editor and it contains each month brief articles of interest. Through this letter we introduced to our members last year the now famous nickel a day, or milk bottle, safety club, which by the way Mr. Cummings started down in Richmond. If you have any particular problem in which you are interested, drop our secretary a line and he will place that question in the next *News Letter* and ask for solutions. Replies will be summarized and subsequently published.

This *News Letter* should be a valuable piece of safety literature. Those of you who would like to receive it may do so by requesting the National Safety Council headquarters to place your name on the mailing list. It is a fine thing to keep in touch with matters and you will find it very valuable.

I am glad Mr. Cummings has received such an indication of support. I want to ask you sincerely to help carry the work along and keep in touch with us and keep in touch with Mr. Cummings and the other officers, and the secretary. We must help one another. We must stick together, and by combined effort and exchange of ideas we may make ourselves more efficient in combatting the highway problem in its many forms.

The next speaker on this morning's program will talk on the subject of "The Commercial Truck Driver." This subject will be handled by Mr. Henry J. Mineur, safety director of the J. M. Horton Ice Cream Company, New York City.

HENRY J. MINEUR (Safety Director of the J. M. Horton Ice Cream Company, New York City): I think I should make a few preliminary remarks before reading my paper. To begin with, my name appears on the program as Safety Director of the J. M. Horton Ice Cream Company of New York City. I know that there are here this morning some men connected with the other companies for whom I am also Safety Director, and I want to tell you that I also direct safety work for the Reid Ice Cream Company, the Dairymaid Company and several others.

And my paper has been changed somewhat, that is, the contents of my paper, rather, has been materially changed from its original form. After I received the program I found myself flanked on one side by Mr. Dow and on the other by Mr. Harman, and knowing the inspirational character of Mr. Dow's talks, and knowing that Mr. Harman will present the hard, practical side of the subject on which he is to speak, I had to condense my paper to about one-half. That ought to be rather interesting to you.

The Commercial Truck Driver

By HENRY J. MINEUR

Safety Director, The J. M. Horton Ice Cream Company, Inc., New York City

"The Commercial Truck Driver" is a subject to which we could devote considerable time with little occasion for repetition.

At this time we are concerned with that phase of the subject which is related to the problem of accident prevention and more particularly the measures which are most likely to offer a solution. It is my aim to deal with the practical aspects of the matter and to do so as briefly as consistent.

It is important that we first consider some of the known conditions we are seeking to correct.

In reporting accidents, drivers are prone to make light of the matter and almost without exception they start off by saying they had a little accident. They are always little, but often you will find before their story is completed that someone has been sent to a hospital, some property has been badly damaged or both. They do not seem to view the matter in its broader aspect nor realize its importance.

In most cases the acts leading up to and causing accidents reveal all the earmarks of improper training and utter lack of understanding. For instance, we all know that the practice of what we choose to call road courtesy would eliminate a very large proportion of the vehicle accidents yet the commercial driver goes on without much thought of the other fellow on the road. The road hog is an excellent example of this type. Why he does not readily give way to a vehicle which is about to overtake him is hard to understand. He does not seem to realize that the faster car has a perfect right to pass. This type of driver will make left turns across traffic, pull away from the curb, turn between intersections and overtake other vehicles without giving an adequate signal. When he backs up he will do so as fast as possible. He travels along approaching and crossing intersections in such a manner that he is ill prepared for the unexpected. Notwithstanding all of this when he has an accident the other fellow is always at fault.

He attributes his predicament to bad luck but never bad judgment. He is very much concerned about what other people fail to do and overlooks entirely what he himself could do to prevent an accident.

What is the reason for this attitude? What can be done to correct it?

The fault in my opinion is divided between employer and drivers. The employer or operator may be indifferent to organized safety effort as we understand it but certainly he must have definite written or unwritten rules regarding the conduct of his business. He at least knows or should know his obligations to the com-

munities which he serves. He must know the cost of accidents even though he has no interest from the humane standpoint. He is in a position to set the driver straight on these points at the time of employment.

There is no good reason why the driver of a vehicle should not be held as strictly accountable for accidents as he is for the infraction of other rules and courtesy to the trade. The public have every right to expect that before a driver is permitted to operate a vehicle on the public highways he should be fully instructed as to the necessity and wisdom of safe driving. This should be a condition requisite to employment.

We come to a consideration of the means by which the existing conditions can be remedied.

There are certain phases of the subject which must be more or less apparent to everyone engaged directly or indirectly in working out a solution. We will all recall that in the matter of industrial accidents a vast number is reported each year by a large group of small operators employing variously from one to twenty-five men. We have a very similar condition in the field of commercial truck operators.

I think it is these small operators with whom we are chiefly concerned. Not infrequently we will find our vehicles involved in accidents the direct cause of which is some faulty condition of the vehicle usually owned and operated by an individual or corporation who having only a few trucks, limit the repairs to those essential features which will keep them on the road. They seem to have no thought of their obligations nor fear of the law. They invariably assume a narrow, selfish viewpoint. I think you will agree, however, that this procedure is costing such individuals or corporations many thousands of dollars every year. We are therefore anxious to know the agencies through which these operators can be dealt with effectively.

There is no doubt that the easiest and least harsh method would produce the most beneficial results. A limited form of membership in the National Safety Council through which they can obtain a continuous flow of safety literature and suggestions coupled with the work of a local council would be very helpful.

There is no sound reason why the smaller operator cannot adopt in a limited way the methods employed by the large operators. Their problems are identical and as a matter of fact the smaller operator is in the better position of the two to solve it. It means that operator himself, his assistant or other person in a similar position of authority will act in lieu of a safety agent.

Unlike the small operator we find the large operator as in the case of the large industries well organized with definite plans for solving their problem, primarily because they have seen the economic soundness of keeping their equipment in the best possible condition and insisting upon its careful operation. It is perhaps fitting at this time to state that these so called large operators were not entirely sold on the monetary considerations alone. In many cases they were convinced that the experiment was worth while, if for no other reason than for the humane considerations which must be the natural outgrowth of such an undertaking. Of course, we realize that there are some who have been forced into the safety field because of ever increasing insurance and truck maintenance costs. It is gratifying however that the number in this group is limited to a very small percentage of those who have organized permanently for safety. We will all agree that there are some operators of commercial truck vehicles who have been and always will be indifferent to the matter of organized accident prevention work.

It has always been the policy of some of the operators to maintain a large inspection and repair force with the view of keeping the equipment rolling. This inspection and repair force has now become recognized as the first essential part of every safety organization.

I have gone into this detail merely to point out that before any organized safety effort can be started amongst the commercial truck drivers the owners of such trucks should first get their own house in order by placing all of their mobile equipment in perfectly safe running order. He is then in a position to make demands upon the drivers which they can be reasonably expected to fulfill.

What then are the plans of the large operator who has been able to obtain satisfactory results. These are both numerous and varied. In this respect I will state as briefly as possible the plans and procedure of the companies with whom I am associated.

We start off on the theory that each vehicle is mechanically perfect before we ask a driver to operate it on the public highways. We then hand the driver a set of printed instructions relating to its safe operation and proper maintenance. These instructions are limited to a single page of printed matter clearly written so that every man can readily understand them. At the bottom of the page there is a perforated sheet upon which the driver signs his name as an acknowledgment when the instructions are given to him. In the instructions we find the following: "Should the brakes, steering or other equipment effecting the safe operation of your vehicle get out of order while you are driving, stop—and phone the garage for instructions."

With this set up the matter of placing responsibility for accidents becomes comparatively easy, because we have definite control over two important factors in practically all accidents, namely, mechanical defects and failure to observe instructions. A third factor to be controlled is the driver himself. This covers the many problems with which he is confronted in the course of the day, that are too numerous to mention. Were we to stop here there is little likelihood that we would get any permanently good results. We therefore have a committee appointed by the president of the company, the personnel of which consists of vice-president, general superintendent, superintendent of motor department and the safety director. The committee meets once each week and the accidents reported during the previous week are reviewed.

Whenever it is found the driver involved has failed to carry out instructions or in some other way contributed to the accident he is penalized. Penalties range from a one day suspension to actual discharge. The man's previous record is taken into account in all cases.

After each meeting a notice of the committee's findings in each case on a form provided for that purpose, is sent to each driver who has reported an accident. This is done whether a penalty is imposed or not and whenever the circumstances warrant the notice contains a detail of how the accident could have been prevented with specific reference to the actions of the driver which were not consistent with the safe operation of his vehicle. These notices sometime contain a warning that the report of a future accident will result in more drastic action.

Supplementary to the system of penalties we have adopted a plan of awards for safe driving and the proper care of the company's equipment. Under this plan each driver is entitled to a maximum of five dollars per month for an excellent accident and maintenance record. Awards are made every three months and the man's record during that time is considered. The plan is flexible to the degree that a driver may qualify for an award in any one of three classes, namely, A, B and C. Drivers who are rated A will receive the maximum for the quarter, B ten dollars for the quarter and C five dollars for the quarter. If any one is further interested in the other details of this plan they will be gladly submitted upon request.

The educational work carried on in our organization consists of regular meetings of the drivers at which the safety director discusses the causes of accidents within the industry. Specially prepared bulletins based upon our own experience

are used in connection with those furnished by the National Safety Council. Finally, safety messages are printed on the pay envelopes.

We have found that these methods have entirely changed the complexion of our accident situation. It is rarely that we have a report wherein excuses are given for causes or where the driver claims a mechanical defect was responsible. Our men know that we are only concerned with the answer to the question, "Could the accident be prevented by our own driver?" They know we do not care what the other fellow failed to do and their reports are made accordingly.

In other words there is no attempt to justify the occurrence of an avoidable accident by placing the responsibility on the other fellow. Moreover, misrepresentation is dealt with as severely as the case of an accident caused by gross carelessness.

We feel that we have the solution to our own problem and this is clearly indicated by the results of the last three years.

I have not gone into the matter of personal injuries to the drivers or certain phases of the safety problems which affects teams operation alone.

In conclusion I would state that standardized methods of accident prevention are just as important as the traffic rules and regulations published by the State and City authorities. In case the small operators cannot be reached through the usual channels then we must depend largely upon the City and State agencies to develop and carry out the plan. There should be State Police inspection of all motor vehicles and a check up on the drivers at intervals and without prior notice that such inspection is to take place. Whenever it is found that an automobile is not in condition to insure its safe operation on the highways a definite penalty should be imposed upon the owner of such vehicle. There should be continued efforts to standardize State and City traffic regulations and the traffic police should be augmented to the degree necessary to enforce them. Lack of enforcement is perhaps one of the greatest indirect causes of accidents because it fosters contempt for the laws and regulations of the road. The traffic laws are different from the others laws which are disregarded to the extent that they are popular with the large majority of vehicle drivers.

You will readily appreciate the contents of this paper is based upon my own experience, observations and opinions. I make this statement to emphasize the idea that the greatest good results from the discussion rather than the contents of the paper itself. I sincerely hope that there will be free discussion of the entire subject. I thank you.

CHAIRMAN CLAIR: I wish to thank Mr. Mineur for his very fine handling of the topic assigned him. About the matter of discussion—we seem to find it more advantageous, in conducting these programs, if we dispense with the discussion until after the final speaker has given his paper.

With such a fine gathering as this, I know a good many of you have questions which you want to ask, and I hope you will not hesitate to do so. The speakers are prepared to answer you on the subjects they have handled. And we would also like suggestions as to ways and means of carrying on next year so that you will help us to be of the most value. Following the next paper we will open the meeting for discussion of any of the subjects you want to bring up.

It is always a pleasure to introduce Dale Harman. He is a great friend of the section, always has been, and has given generously of his time and effort to the furtherance of our interests. Mr. Harman is an ex-chairman of this section and served last year as your chairman of the Nominating Committee.

DALE HARMAN (Vice-President and Manager, Yellow Cab Company, Kansas City, Mo.): I would like, first, to comment a little about our section, in view of the fact that our present chairman, Mr. Clair, mentioned the fact that I was an ex-officer.

I want to congratulate you and work up a little enthusiasm for my friend Cummings over here. I want to compliment you for the wonderful attendance you have here, and for the growth of this work. I believe it is something to be able to say that we do more work with respect to traffic safety than any other section. Of course, we should, because we are in the cab and fleet owners section.

Mr. Cummings (I will have to reply to him on the floor) wondered why we elected him as chairman for the next year, but he forgot to tell you that down in Richmond, Virginia, he and the cab owners have won a trophy just recently for operating more miles with less accidents than anybody in that community.

And I think, if he can bring that about in his home town, that he ought to steer you through the year to a howling success, and I know he will.

Now, I have been assigned to talk on "Respect for the Other Fellow"; I am not much of a writer or orator, but I will try to give you just a few of the things that come to my mind on the selfishness of the automobile driver. I feel that that ought to be the name of my little story, more than "Respect for the Other Fellow."

Respect for the Other Fellow

By **DALE HARMAN**

Vice-President and Manager, Yellow Cab Company, Kansas City, Mo.

When your worthy chairman, Mr. Clair, asked me to become chairman of the Nominating Committee, I naturally felt highly honored as most of you know I have endeavored to the best of my ability to render as much assistance and cooperation as was possible to the Taxicab and Fleet Owners Section of the National Safety Council. But with the aforesaid honor, Mr. Clair also asked if I would write an article for presentation to this convention using as a subject, the caption "Respect for the Other Fellow."

Having served the public for many years as an employee of one of our large railroad systems, I can well remember how the employees of that railroad treated the public—in a don't-give-a-damn manner. On leaving the service of the railroad and getting into public life, where patronage and continued patronage meant a volume of business, I was much surprised at the difference in my own attitude in "Respecting the Other Fellow" in my endeavor to secure his patronage, and he favored with his continued patronage as well as good will. I am free to confess that meeting the public with a smile and indulging in a little conversation pertaining to weather, business conditions, etc., or whatever else I thought the prospective patron might be interested in, other than the direct business contact, was one of the best assets or paying investments that could be indulged in. At the same time I learned many years ago that it was a pleasure and made the world seem brighter than the old atmosphere that others, with myself, had been living in and dealing out to the public.

On entering into the Taxicab industry, I became connected with the same at a time when that link in the transportation field was just changing from the old horse cab to the motor driven cab, and as you are all aware, the horse cars had been manned by good fellows, but usually lacking in education, etiquette and were oftentimes men who were crippled in some manner which incapacitated them for doing manual labor, and their education had been neglected to such an extent that they could do nothing else. As a result we had a hard time in those days finding men who understood the driving and care of an automobile, and the shop foreman or superintendent of drivers of our respective companies were called on to render assistance in educating the men to handle automobiles. We found in employing men that the young men were much more adept in learning and much more willing to accept the positions than men of some twenty-five to forty years of age. We soon also learned that the young men were more inclined to drive fast

which was detrimental to the best interests of the operator as well as dangerous and hazardous for the patron, all of which thoroughly convinced me and the various heads of the departments that we must lend our efforts toward hiring men who were a little more matured, and as a result, many years ago we made it a rule to employ no one but a married man, twenty-five years of age or more. In our effort to have them familiar with the streets of our city, only men that had been residing in our city for a period of two years or more were taken into the service.

Then the growth of the automobile commenced. You are all aware of the phenomenal growth it has made, as well as the growth of the taxicab industry and the number of cars used in delivery by our Fleet Owners. I know that each and everyone within my hearing will agree with me, that when there is an accident both of the drivers concerned are always right. Being in direct charge of the payment of claims for either property damage or personal injury, I have for many years made it a point to personally attend the scene of the accidents. When it was impossible for me to do so I had my employees secure all the information possible as well as take pictures when same could be secured before either of the vehicles were moved. In attending the scene of accidents I endeavored to the best of my ability to "Respect the Other Fellow" acting as a judge between the two interested drivers of automobiles at fault, in a fair and unbiased manner. If you will pardon me for quoting myself, after our industry began to grow and we had as many as seventy-five to one hundred cabs on the street, I was, on several occasions called into our local courts in the capacity of assisting our judges in determining which of the two drivers in any particular case was responsible for the accident. This demonstrated to me quite clearly that "Respect for the Other Fellow" was bearing fruit, and that if the policy that we were striving for among our own employees in the handling of claims, which you know is one of the most important duties of our National Safety Council today, was bearing fruit, it would bear equally as good results if the cab drivers in daily traffic would remember the subject of this article and have "Respect for the Other Fellow."

We have, in our city, inaugurated the automatic lights at many of the important street intersections and naturally they are bringing good results, but how often all of you have seen the man driving a car, and waiting for the light to change, who would be on the outside and make a left turn in front of all other traffic, without regard to the other drivers who were going straight forward. Whereas, if he had had any thought for his fellow man or the density of traffic and a tendency to lend a hand toward avoiding congestion, he would have pulled to the inside or near the direction in which he was going to turn, before arriving at the intersection where possibly one or two blocks away he knew that on reaching that intersection he would be stopped by the red light of the automatic signal.

Again, in traffic where there are two, three or four lines of traffic going in the same direction, how often all of us have seen a driver who, in order to gain one or two lengths of his car would turn over to the other line of traffic when there was an opening and by the time he was straightened out in that line of traffic, would see an opening back in the line of traffic he had just left, and would again cross traffic in order to again gain a car or two length without regard to how many drivers he was discommoding and causing to slow up or practically drive their cars and watch his. This is the element of driver who has no "Respect for the Other Fellow" and should receive some education or read some articles such as appear in numerous periodicals pertaining to safety.

Only recently we received a copy of a weekly newspaper printed in a small country town west of Kansas City wherein a resident of this small village had been in our city and in crossing a street intersection in our town business section which naturally is congested, a cab driver drove up to the path of pedestrians, stopped his cab, and motioned to the man from the small town to cross the street. Naturally the cab driver did not know the man and neither did the man know the

cab driver, but he did go home to the small town and tell his story to the editor of the weekly paper. The editor who wrote up the article gave it a place on the front page, and on receipt of a copy, we in our organization were able to locate the driver and appraise him of the fact that he had "Respect for the Other Fellow" in assisting a man to get across a crowded street, who was not familiar with the heavy traffic of the city. We make mention of this instance to again show the result and benefits derived from "Respect for the Other Fellow."

Ofttimes in driving down the street in an automobile, you have seen water standing on the pavement as a result of rain, low places in the pavement or having settled there after the streets were flooded and the drivers of automobiles could have driven slowly through the water or even to the side of it with only a slight turn of the wheel, but on the contrary no, they drive through the water pell-mell without any regard to the other fellow, and ofttimes throw water over a nice clean car or all over a pedestrian who has no opportunity to protect himself. This to me is one of the most careless and uncalled for habits that our automobilists indulge in.

In our School of Instruction for Drivers we use many ways and means of demonstrating most clearly and in a simple manner, what ideas and thoughts we have pertaining to safe, sane and courteous driving of automobiles. I can recall many instances where I have personally demonstrated to new men what we would like to have them do in a case where two cars are driving side by side and are reaching a safety zone, bridge, viaduct or some other narrow portion of the street where the cars will be required to go single file. We have asked our drivers to try and catch the eye of the other man driving the car beside him, motion him ahead with a smile, and at the same time to slacken the speed of his own car and let the other fellow go through the narrow portion of the street first. This has been done in many, many instances, and I can conscientiously advise all of you that we hear of instances of this kind in the daily operation of our cabs in our city, almost as frequently as we do the day or two following a good substantial newspaper advertisement, all of which is further demonstration that "Respect for the Other Fellow" when practiced is usually recognized.

I feel that in attempting to give any new ideas to you members of the Taxicab and Fleet Owners Section, I have a difficult problem, as the caption "Respect for the Other Fellow" is so closely allied with the word "Courtesy" which has been dwelt on so very often, especially in our previous annual meeting. And yet either of the subjects play a most important part in the ever increasing traffic problem. Under the head of "Courtesy" I can well recall a very dear friend of mine who used to be steward on a dining car leaving Kansas City for Chicago every evening at 6 p. m., who as soon as the train left the station, would come through the sleeping cars and address different passengers by name and ask them what time they would prefer to have their dinner, and he would arrange to have them cared for at a time that suited their pleasure most. In fact, this man practiced this method to such an extent that people wondered how he secured the names of the different passengers, when he was unknown to them and they unknown to him. One day I asked him how he secured the information that enabled him to call the passengers by name and he informed me he had made it a point to look over the sleeping car diagrams just before they were turned over to the conductor, and in fact went so far as to make a little diagram showing who had purchased each berth. His object in so doing was that people always felt better if addressed as Mr. Jones or Mrs. Smith as the case might be, and this instance is mentioned by me at this time to demonstrate how far this man went to show his "Respect to the Other Fellow." I am pleased to inform you that I later found this man's mother was the author of one of the best books that was ever written in this country, dealing with "Courtesy." He was courtesy and politeness personified in his every day dealings with the public. This is an experience that came to my attention

from actual life, and to me it is one of the best demonstrations of the result of "Respect for the Other Fellow," in every stage of life.

CHAIRMAN CLAIR: I am sure we are all very thankful to Mr. Harman for his very excellent handling of the important subject of his paper.

MR. CLOUD: Before we enter into a discussion which I am sure will be interesting and illuminating, I would like on behalf of all present to move for a resolution of thanks and appreciation to Mr. Robert Clair, chairman, who has so effectively and successfully conducted, not only the proceedings of this convention, but the work throughout the year, and I would therefore call now for a rising vote of thanks.

(The entire meeting rose in thanks to Mr. Robert Clair.)

CHAIRMAN CLAIR: I am sure I appreciate your kindness very deeply—both the kind words of Mr. Cloud and your vote of thanks. I wish to say that whatever I have done I have been repaid many times by the pleasure it has given me to be in contact with such a fine crowd of men. I am sure anything I have done has given me a whole lot of pleasure.

The meeting is now open for discussion of any of the papers that have been read or any matters you see fit to talk about.

MR. SONNTAG (Travellers' Insurance Company): Yesterday we listened to an address by Mr. Brown, editor of the *Taxi Weekly*. In a portion of that address he referred to a character well-known in New York, the ambulance chaser. I believe that every man in either organization of the fleet owners is familiar with the various practices of this type known as the ambulance chaser. Now, I feel that this is an excellent time for us to extend our thanks and appreciation by applause or by any other method the chair may suggest to the Appellate Division and the Bar Association for the able and efficient investigation recently conducted, which has succeeded in materially reducing the activities of the ambulance chasers in New York.

CHAIRMAN CLAIR: I suggest as a means of handling this matter that this meeting go on record by passing a motion to have such a vote of appreciation be sent to the proper authorities through official channels of the Council. Will somebody please make that motion?

(The motion was made and unanimously carried.)

CHAIRMAN CLAIR: Any further discussion, gentlemen?

D. A. DREW (R. H. Macy & Company, New York): I would like to ask Mr. Dale Harman if he would go a little more into detail with regard to the instruction, how he trains the driver, and so forth.

MR. HARMAN: I do not feel that this body of men at this time and place, Mr. Chairman, have got the time to go into it and do justice to it. This is a big matter, gentlemen. The employing and the training of men to take automobiles out on the streets and highways, it seems to me, is just as great a problem in Kansas City, say, as it is in New York. Our traffic distribution is over a radius of twenty blocks square, and yours in New York is perhaps miles square, and Chicago has many square miles of traffic, and so has Philadelphia, and so on.

But in training the drivers in our own school, I write what I want the driver trained in, and at the present time I have twenty-nine different questions, or things for them to be trained in. I take these rules myself and send them one at a time around to the superintendent and to the night superintendent and the safety director, and sometimes to the assistant manager—who fights the ambulance chaser and runs down accidents and claims—and so put it up to them. I ask for improvements on these rules, and in that way I get the ideas of five, six or seven, or even ten men; I get their opinions as to what sort of rules are proper, and do not need remodeling and revamping, and in that way we try to keep up to date.

And we give them the benefit of changes in the traffic rules on a blackboard. That also is an important feature. That is of great help.

I might say, in reference to safety work that we are a small company that holds a rather small membership in the National Safety Council, but I feel it has done a great deal toward the prevention of accidents.

We get five posters a month; and we have a large recreation room in our place, and we have taken these posters and framed them, and the walls are pretty high around the room, and when new men are taken in, our instructor takes a pointer and points out what each of these safety posters means; and we keep changing them over as new ones come in. I think that alone is worth many times what it costs any of us to get into the National Safety Council.

But when it comes to the training of a driver, I think there are so many angles to it, that it is impossible at this time to go into full details. It is constant handling, constant giving of instructions, and following up the instructions every day. Do it collectively if you can, in so far as you are able, and if that doesn't bring results, go into it individually with each individual man.

CHAIRMAN CLAIR: I would like to refer the last speaker, who made the inquiry about the selection and training of drivers, that the proceedings of each Congress are published annually by the National Safety Council. Every paper read here and at every other meeting during this Congress is published about January 1st by the National Safety Council.

Now, those volumes are all on file and may be obtained. You may buy a copy for a certain fee. You will find in it both the discussion and the papers read in the last two or three years, and some of them are very valuable papers. You will find much information in these Proceedings concerning the selection and training of drivers.

FRANK OPTENBROM (Inspector): Regarding the so-called road hog Mr. Mineur touched upon in his paper, don't you gentlemen generally find that in most of the cases of trucks, the larger trucks especially, that a number of drivers do not give you the right of way, due to the fact that the noise prevents them from hearing your signal; and I have also found that unless the law generally compels the vehicles to be so equipped, that the employers or the owners will not put on mirrors voluntarily.

Now I have more or less tested out this thought or theory, you might call it, from New Orleans to Providence, because I was making that territory for some insurance companies; and during that entire trip I made particular note to approach truck drivers who really would not give you a chance to get by them, and invariably (I have the percentages and the figures) the men were justified in a sense, because they really did not know you were back of them, and could not see you. Due to the construction of the vehicle, they could not see you because they did not have the proper mirror on the truck.

I would like to know what is the general opinion, from some of you here as to how it is in other parts of the country. I speak of the country east of the Mississippi. And furthermore, I would like to say that the only state where I have found general equipment used, in the way of mirrors, was in the State of Connecticut, where I found I had no trouble getting by any of the trucks, and conditions were very good in that respect. I would like to know if that is the general rule in other parts of the country.

CHAIRMAN CLAIR: Those questions are very pertinent. At the risk of imposing myself again upon you for a few minutes, you might be interested to know that the motor vehicle laws are available from every state that publishes such a pamphlet. We have collected thirty pamphlets from thirty different states. I remember checking them to see which states require adequate rear mirror vision equipment.

There are twenty-one out of thirty states that specifically demand that commercial vehicles be equipped with a mirror so constructed that the driver is given a clear view to the rear, whether such vehicle is loaded or empty.

The road hog, in the guise of the heavy truck driver, is of course a bad one. We conducted a little survey of that situation in and around Boston on the outlying roads, and this was done by stopping big trucks and talking to the drivers. We asked those fellows, "Why is it that you insist on driving in the middle of the road?" Well, there was a very interesting general reaction obtained. We stopped a big boy driving a six ton Mack. He, as did the majority of others, said, "Sure I stay in the middle of the road, and I'll tell you why. My truck weighs six tons, and if I carry five ton on her, that makes a heavy load. I'm on a delivery schedule. If I continually keep way over to my right of the road, I'm on pins and needles every minute for fear that my right rear wheel will slip off the shoulder of the road and sink into the soft dirt. I sure don't want to get stuck with this load."

I think, gentlemen, that that is a sensible reaction, and that it explains why the big trucks stay in the middle of the road. The only solution may come about by an improved road construction program giving broader highways.

Now, are there any other remarks, or any further discussion?

J. T. MALLOY (General Accident Insurance): We have had quite a few accidents on these large trucks, and particularly those with the tractor unit. The drivers of course were always in the center of the road. The drivers often work very long hours, and sometimes they are replacing another driver who has not shown up and they are getting overtime for it. The driver is probably driving a car that is making a terrible lot of noise, and he is well gassed up with conversation as well as fumes, etc., and he gradually falls asleep; and that is one of the reasons he does not like to stay on the edge of the road.

Only last March we had a horrible accident in New Jersey, when two trucks came together. One truck had a piece of machinery on it, and the impact caused the machinery to plunge forward and crush the driver of the truck. He was killed instantly. The Police out there were unfamiliar with accident investigation work and for a time nobody understood how the accident happened. Finally somebody got on the job that did know and the conclusions were that the driver of that truck was asleep, and the other fellow said to himself, "Well, he isn't going to get out of my way, here is where we meet." And they did.

Now any man interested in fleet operation knows that drivers of these trucks will not get off the road, but they will rather come together. Sometimes they meet a fellow asleep at the wheel, due to long hours, and sometimes perhaps he has had a little hooch, and if he is in an enclosed coop he is apt to get groggy, he goes over.

Then again, lots of drivers tell me that some driver will come along the road with a newspaper on the wheel, reading. The driver of a passenger car or other truck believes he will move over, and if he does not there is a collision.

Also some of the drivers of these trucks look to the side and pay attention to the girls going to work, always looking at something they should not look at. Sometimes they turn their heads right around.

These factors are never brought out in an investigation of an accident, unless witnesses are about that happen to see them.

MR. RUBIN (Constitutional Indemnity Company, Philadelphia, Pa.): I would like to ask Mr. Mineur a question, and before he answers it I will give my reason for asking it.

Mr. Mineur states that invariably if a man continues to have accidents they are finally discharged. A condition has come within my range of vision within the last six or seven months that may or may not help some of you fleet owners. The condition where two men were subject to frequent accidents. When the question

of the frequency of their accidents was taken up with the employer, the employer gave out the fact that these two men were wonderful workers and had been with the firm a long while, and he hated to see them discharged or dismissed from the service.

Now, it happened that one man was suffering from sinus trouble and the other man from something that affected his eyesight, and both of which tended to poison the condition of their bodies, and the faculties of those two men while driving their motor cars were not one hundred per cent.

In talking to these drivers I was informed by the one man that while he had these accidents he was absolutely powerless to in any way avoid them. He knew that he was going to have a crash, and his faculties would not work in such a manner as to enable him to do the necessary things to avoid the accident.

I think that is something that may interest all of you. It is a condition where you have a man that has been working for you for years and some trouble may creep in, and instead of discharging the man and probably getting someone worse, it might be well to make a physical examination. It may be some physical condition that could be overcome.

MR. MINEUR: That is true. And incidentally, I might say that all of our men are examined and we take into account not only their physical defects, but also their home conditions.

MR. RUBIN: The condition did not develop at the time of employment, but it developed after some years.

A VOICE: Mr. Chairman, I think the speaker might be interested to know that a psychological test might have brought that condition out.

CHAIRMAN CLAIR: With respect to this hazard of drivers falling asleep, that is not a problem for the driver, but rather for proper management. It is a crime to send a driver on a long, hard trip and make the working hours so difficult that it is impossible for him to keep awake. I think that is something the driver is powerless to fight against. We have got to have reasonable, sensible delivery schedules. If we are making a big haul it is better to send two drivers than one. In trying to save a day's pay, we are apt to find we have a wrecked truck and ruined cargo and lots of other trouble on our hands.

MR. MINEUR: What I would like to see is something spread upon our minutes to the effect that we are in favor of some active work on the part of the newspapers. They mold public opinion and conduct, and are a force of great good, if they would only interest themselves in it.

CHAIRMAN CLAIR: I know we all realize that, and I am sure the Council is following that carefully, but it is a big matter, and the progress must be made slowly. But I think it is advancing, because the newspapers have been taking more and more notice of that.

MR. BROWN (Atlantic Refining Company, Philadelphia, Pa.): We operate about 150 trucks. We are not compelled by law, but we find through practice that it is best to put two mirrors on the trucks, one on the right and one on the left. Furthermore, our men are instructed that when they are on a road where there is not much room, on the approach of another vehicle they must come to a stop. We feel that the other fellow will notice that, and we are not liable to do any damage.

I would like to ask now what is the best record established in the last two years, a comparative record as to road accidents. I am vitally interested in that, and I feel we have a good record.

CHAIRMAN CLAIR: I don't think we have time to give you any accurate records or statistics. From the library of the Council headquarters you can get some very comprehensive figures as to driving records, set up by inter-plant fleets.

I suggest that rather than ask this meeting that question, you communicate with headquarters. In the meantime I am sure we will all be interested in hearing of your records.

MR. BROWN: I just want to quote what we have done—and we operate about 250 to 300 motor, gasoline vehicles.

We started in with each man and followed very much along the lines of the Horton Ice Cream man, Mr. Mineur. We have critical examinations of all men for six months, say, for eyesight, heart and any other troubles, and in that way we weed out—we don't fire the men who don't come up to standard, and we don't wait until an accident,—but when we find a man is unfit for the work he is then given some other work that he can do without any harm being done to anyone.

In 1926 we had an average of 124 accidents a month and travelled 3,700 miles per accident. That was rotten. In 1928 we travelled 7,805 miles per accident; in other words, an increase of 107 per cent more miles in 1928 than in 1926. I do find that the penalizing of the men should be carried a little further than it is. We penalize some men by giving them a week or a day off. And then we demote them in rank and give them less pay for a period, and say "Well, when you can pull up to be a first rate man you can get that pay again."

And we keep that idea in their minds, if you don't keep up to first rate, we don't want you. And as a fellow said the other day, "You know, Mr. Brown, the men would rather have their arms cut off than to have an accident."

We had one man back into a bicycle that was standing at the curb, and he said that it didn't seem anything to him to penalize him for. We took off 3 cents an hour. We said that if the boy had been there it would possibly have been a death, and he would have been held for manslaughter.

I want to say that we are heart and soul with this accident prevention work on the highways.

CHAIRMAN CLAIR: Thank you very much. I am sure we all have driving records of which we are proud. I am sure we could ask many of these taximen, who would reply in terms of millions of miles. But I am sure these results are all matters of record, properly tabulated, and I think we can all tell of some instance in which our vehicles have operated for some unusual number of miles. I assure you that if you want any comparative figures that they can be obtained from headquarters or through our News Letter.

J. E. DOBBS (Safety Engineer, Detroit Service Company, Detroit, Mich.): Mr. Chairman, we had a serious accident the other day, and our driver says that a new set of hydraulic brakes failed him. I wonder if anyone can tell whether it is possible for them to fail, without the tubing breaking, or something of that kind.

MR. MACADAMS: Speaking of brakes—particularly hydraulic brakes—I am not an authority, but I had them in my own car, and they did fail, for various reasons. It cost me a lot of money for brakes, and when they are not working they are impractical, of course, both from the standpoint of service and that of monetary cost of repairing them.

You say they failed, and you want to know if they can fail without the tubing breaking. I don't know how they can. If they are in good mechanical condition they won't fail. But I have known them to fail due to neglect of the brake band, wherein so much of the brake band is worn that the whole limit of cylinder travel had been reached, so that the band had not taken up. That is one cause of failure to make allowance for vibration in connecting the pipe, and the pipe would loosen up; had they put a couple of loops in it, that would have never happened.

MR. FITZGERALD (Safety Engineer, Liberty Mutual Insurance Co.): Perhaps on the brake question I might be able to give a little information on the failure of hydraulic brakes to work. That is often caused by air in the lines. An air bubble is built up between the piston and the cylinder which prevents the fluid from getting down into the cylinder. But for some reason or other, by the constant working on the pedal and pumping on the dashboard, it is very possible for that pressure to be worked down. How that air gets in there without a weak

connection, is not known. But that is a possible source of failure of hydraulic brakes.

MR. McARTHUR: I may be speaking out of turn, when I go into this little brief of my own, but all along in this discussion of the accidents and the various causes, a great deal of stress was put on the fact that there is a mental condition immediately behind an accident.

Now, here of course we are discussing accidents with regard to taxicabs and trucks and so forth, and it has been my experience in two or three different cities to observe fleet operations, and I will tell you something about where a mental condition exists.

But that is a point that is very seldom touched upon, and gone into, usually with reluctance, because it deals with a sensitive question.

I have questioned a lot of these drivers working for fleet operators, and I just heard a remark a while ago wherein it was brought out that upon hiring the man you investigate his record and that investigation includes home conditions.

Now, when they take a man on, what sort of monetary consideration is he offered, is it such as to make him entirely satisfied with his position? For to say the least, the truck driver's job is not very attractive, after all, and if the monetary condition is there, the mental condition that would otherwise be there is usually erased, and in turn his home condition can be improved.

That man of course is only valuable as a truck driver. If his returns are rather ample for his particular job, I think the mental condition there would be greatly enhanced.

CHAIRMAN CLAIR: I think you have touched on a pretty fundamental problem of the relations between the employer and employee. If we get into this too deeply we will get far afield. Proper selection and proper remuneration are very important points. There is something in the last speaker's remarks. I do not think we can follow that up at this time, but it is a very important point.

In other words, the job must have attractive features to expect the right results from your labor.

E. J. McDERMOTT (Accident Guaranty Corporation): There has been a great deal said here about the taxicab driver and the commercial automobile driver, and I would like to know if any concerns are taking any action if they find a driver is prone to accidents, if they have taken any action toward seeing that he, when he is discharged from their employ, is not hired by another employer for the same type of work.

In accident prevention work I think it would be better that where a man is shown to be incapable of safe operation of a vehicle, that some measures should be taken to see that he is not put on the street with a vehicle where he is liable to cause an accident, death, or damage of some kind.

CHAIRMAN CLAIR: I think Mr. McDermott's idea is well taken. It seems to me Mr. Harman brought out the point, where he investigated the records of the State Highway Department. I think that is the office through which we should get such information. I know that the taxicab companies, and I am positive a great majority of the commercial fleet operators, investigate very thoroughly the past accident records of drivers, before they employ them. As to whether or not a man has been discharged, however, from some accident record while employed with some other operator or owner, it is very difficult to find out. The only solution I see is to make it a community problem in your district and try to build up among the employers some sort of clearing house for such information.

MR. CUMMINGS (Manager, Yellow Cab Company, Richmond, Va.): Coming right back to the Safety Council: We this year in Richmond are starting an inter-fleet contest, the same as the one last year which I was lucky enough to win, and 36 fleets will be entered in this contest. The operators of these fleets have

registered the name of each and every employee with the local Safety Council. That is one thing. And each of these men is given a registration card to carry with him the same as his driving permit. And if I dismiss a man from service for careless or reckless driving, that information goes to the local Safety Council, and is entered upon the records there, and when he goes to the bus company or the department store or somewhere else to get employment, his record is called for from the Safety Council. Now, in those 36 fleets the majority of the commercial drivers are listed. And if a man is dismissed from my employment for careless driving or reckless driving, he can not get a job in any one of these fleets.

Get behind your local Safety Council and they will solve your problems for you.

CHAIRMAN CLAIR: That is a very interesting idea, Mr. Cummings.

MR. HEAFE: In regard to the road hog, I have not heard anything about signalling. It seems to me that both as an act of courtesy and as a means of passing the information that you wish to pass, it is a good thing to do, for oftentimes you find you can see the man in your mirror clearly, and you slow down and he intends to turn right; and he will complain very vociferously if a man should pass him and then turn. If he is going to pass, isn't it a good thing to recommend that he sound his horn that he wishes to go by?

CHAIRMAN CLAIR: That point is well taken, and I am sure most of us who are trying to educate the public and drivers, are in accord that signalling is a rather fundamental safety requisite.

MR. CUNNINGHAM (Syracuse, New York): In Syracuse, New York, last year, through the auspices of the Chamber of Commerce, they formed a safe drivers club. With the cooperation of the insurance companies they enrolled a large number of drivers, and at the meetings held once a month there were speakers and also there were shown safety measures, etc.; and also I might say that we had at those meetings as many as 450 men.

CHAIRMAN CLAIR: Any further discussion, gentlemen?

MR. MINEUR: Just one little question I would like to ask, and that is in regard to the local taxicabs. I do not believe I heard anything from the taxicab operators in the metropolitan area. I wonder if there are any of them here?

CHAIRMAN CLAIR: In regard to any special point, Mr. Mineur?

MR. MINEUR: No. I was just wondering. Here, where we have a fleet of twenty-five or fifty thousand floaters, we have a real taxicab problem.

CHAIRMAN CLAIR: Is there anyone here who can give us a few words about the local situation? In just a few words.

ERNEST H. MILLER (President, Yellow Taxicab Company, New York): I am very sorry that the local taxicab men have been called on almost in vain, but I had to refuse to come here originally because I did not think I would be back in time, and I just returned from Europe last Friday, with but little new information about local taxicab conditions.

So I will give you something to think of that I saw in Europe, and that I think is going to be a matter to be considered, eventually, here. Every year the automobile manufacturer is turning out a longer car, with more horsepower, making it impossible to get as many automobiles in a single block as they could before, and making it harder to stop, because as you all know, putting on horsepower makes it possible of more speed and on the other hand it takes a little more room in which to stop. Without any thought of what it might mean from a safety standpoint or a traffic standpoint.

I think it is time that automobile manufacturers in this country began to do some of the things that they have been forced to do in Europe, largely because of the higher cost of gasoline there. That is to make cars with low horsepower and short, so that they can be handled in traffic and as a consequence, make for safer cab operation and safer car operation entirely.

I don't believe that the average length of automobiles in Europe is much over 115 inches. I know that just before I left there one of the large manufacturers came out with a great deal of pride with a six cylinder car of thirteen horsepower. You can imagine what a difference it would make if the majority of our cars in this country had under twenty horsepower and were made so that they were a little more readily handled in traffic.

That was my main observation abroad. Of course, they have not as many automobiles and not as much traffic, so they can hardly compare with here.

Now to tell you something about the metropolitan area and safety, I should like to tell you that we have done a great deal. I must admit, however, that most of it has been done by the Police Department. It is one thing to preach safety, as we always do; it is another thing to get it in as large an area as we have here and enforce it ourselves.

We have thirty-six street inspectors, who are constantly trying to regulate our own traffic. They are to our mind the greatest factor for safety that we have in Yellow Taxis. But you can readily realize that thirty-six street inspectors spread over this metropolitan area are lost. And so we owe our greatest thanks to the Police Department, who are certainly censors of too much speed and reckless driving here.

In addition to these thirty-six inspectors on the street, we have a morning and night inspection in our garage. The morning and night inspection in the garage will show what may have happened to an automobile in the course of the day. What happens in the course of a day and is closely observed by the management in an individual garage from which the driver drives, is our second greatest deterrent in careless driving. It makes for greater safety, because the driver is forced to bring in a car that looks similar to what he takes out in the morning.

Since I have come here entirely unprepared and since I have not really heard anything that has gone before, I know nothing further to say, unless somebody will ask me a question, and I will be glad to answer them if I can.

CHAIRMAN CLAIR: Any questions, gentlemen? If there are not, perhaps to keep luncheon engagements, we ought to adjourn at this time.

I again want to thank you all for coming here and the interest which you have shown.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Textile Section

New Section Officers

General Chairman—D. FRANK LORD, M. J. Whittall Associates, Worcester, Mass.
Vice-Chairman—SYDNEY INGHAM, Ludlow Manufacturing Associates, Ludlow, Mass.
Secretary—E. E. PLACE, Employers Liability Assurance Corporation, Boston, Mass.
Poster and Slide Committee Chairman—L. WM. FERGUSON, Aetna Life Insurance Company, Hartford, Conn.
Membership Committee Chairman—H. W. DONALD, American Mutual Liability Insurance Co., Boston, Mass.
Publicity Committee Chairman—ARTHUR BARLOW, Armstrong Cork Company, Linoleum Division, Lancaster, Pa.
Engineering Committee Chairman—G. W. COOK, The Travelers Insurance Co., Hartford, Conn.
Statistics Committee Chairman—JEROME GAUDET, Lorain Manufacturing Company, Pawtucket, R. I.
Program Committee Chairman—ARTHUR S. JOHNSON, American Mutual Liability Insurance Company of Boston, Boston, Mass.

Retiring Officers

Chairman, H. C. WASHBURN, New Bedford, Mass.; *Vice-Chairman*, DR. R. P. KNAPP, Cheney Brothers, South Manchester, Conn.; *Secretary*, D. FRANK LORD, M. J. Whittall Associates, Worcester, Mass.; *Poster and Slide Committee Chairman*, LEONARD HOWARD, Duncan Mills, Greenville, S. C.; *Membership Committee Chairman*, H. W. DONALD, American Mutual Liability Insurance Company, Boston, Mass.; *Publicity Committee Chairman*, ARTHUR BARLOW, Linoleum Division, Armstrong Cork Company, Lancaster, Pa.; *Engineering Committee Chairman*, G. W. COOK, The Travelers Insurance Company, Hartford, Conn.; *Statistics Committee Chairman*, HARVEY SAUL, The United States Finishing Company, Providence, R. I.; *Program Committee Chairman*, ARTHUR S. JOHNSON, American Mutual Liability Insurance Company of Boston, Boston, Mass.

October 2, 1928

H. C. WASHBURN, Chairman
District Manager, Sentinel Fire Equipment Company
New Bedford, Mass.

The first session of the Textile Section of the Seventeenth Annual Safety Congress, was called to order at ten o'clock by the chairman, H. C. Washburn, District Manager, Sentinel Fire Equipment Co., New Bedford, Mass.

CHAIRMAN WASHBURN: Because of the importance of the meeting this morning,

I am not going to call on very many members or committees for reports, but it is particularly fitting that we have a report from the Secretary of the activities during the past year. Mr. Lord.

Report of the Secretary

By D. FRANK LORD

Herewith I submit my report for the Season of 1927-1928:

There have been two meetings of the Executive Committee of the Textile Section held during the year, one at Providence, R. I., on November 2, 1927, in the rooms of the Providence Safety Council, and the other at New Bedford on March 26, 1928, in the rooms of The New Bedford Board of Commerce.

The minutes of both of these meetings are of record.

A meeting was held in Atlanta, Georgia, during the month of April, 1928, in which Mr. W. C. Wroe of the American Mutual Liability Insurance Co. showed great interest and activity. Mr. W. H. Cameron, Managing Director of the N. S. C., was present and spoke at the meeting.

Your Chairman, Secretary and several members of the Textile Section attended the Conference of The Rhode Island Safety Council held at Providence, R. I., on January 17, 1928.

Your Chairman, Secretary and Chairman of Publicity attended the Semi-Annual Conference held at the Commodore in New York City on February 18, 1928.

Your Chairman and Secretary attended the Congress of the Massachusetts Safety Council held at the Statler Hotel in Boston in May, 1928.

During the year a poster contest was held with very good results.

At the beginning of the season I was provided with a list of members of the Textile Section by Mr. W. Dean Keefer, showing a membership of 127 during the year. I have received from the Chicago Office notices of the addition of eight new members and the cancellation of 12 members, leaving a total membership of 123. A loss of four members for the year.

Committee Reports Are Dispensed With

CHAIRMAN WASHBURN: Unless any one present wants to know, in further detail, of the activities during the past year, if there is no objection, we will just waive the reading of other reports. It does seem too bad that more of the members of the textile industry have not become members of the Section. Various reasons have been given why we have failed to receive applications, and in view of the fact that interest seems to be missing among the textile industry as a whole, the Executive Committee this year has attempted to prepare a program somewhat different than those we have held in the past; one, which I think will be of interest to everybody present and which possibly may settle for all time the question of the necessity of safety and of accident reduction efforts throughout the industry as a whole.

The first speaker this morning is a gentleman who comes to us representing a body vitally interested in this question. We, as safety engineers, supervisors, personnel men, etc., are firmly convinced in our own minds that safety and production go hand in hand, and although it is a much mooted question, we certainly do believe that instead of its being a minor problem in the industry it is one of the major ones. I have the honor of presenting to you as the first speaker this morning Mr. Russell T. Fisher, Secretary of the National Association of Cotton Manufacturers, who should be in position to present a very good point of view on this important subject.

Safety in the Cotton Industry

By **RUSSELL T. FISHER**

Secretary, The National Association of Cotton Manufacturers, Boston, Mass.

The textile industry was one of the first, if not the first, to grow from a home industry into a factory industry, and was old when many of the present large industries had not made even a beginning. Our industry was not only one of the pioneers in the development of modern factory methods of production but was also a pioneer in the application of new discoveries and inventions. The steady development of light and power may be traced in the history of the textile industry for the last 125 years. Illuminating gas replaced whale oil and kerosene, and was in turn replaced by electric lights. Arc lights were used as early as 1879, incandescent lamps by 1881, individual motor drive in 1891, and the first mill completely driven by electricity was erected in 1893. Progress in manufacturing methods, adequate buildings, sanitation, accident prevention, etc., has steadily developed, and today the industry compares favorably with the other large industries of the country.

An idea of the size of the industry and its diversity can be obtained from the last census figures for four of the major groups that include the largest part of the industry.

According to the 1925 census of manufacturers, there were 1,659 silk mills, employing 132,509 wage earners; 973 plants in the wool manufacturing group, employing 206,110; 1,638 cotton mills, employing 468,352; 2,078 knit good plants, employing 161,880; or a total of 6,348 plants, employing a total of 968,851 wage earners.

In addition to these major groups there are other minor groups, such as the lace and embroidery manufacturers. The rayon manufacturers are, I believe, at the present time classified as a chemical industry rather than a textile industry.

The approximate size of the industry has been brought out to show why its welfare is of interest to so many people, and to indicate what a tremendous undertaking it would be to arrive at even approximate figures for the industry as a whole on its accident record and results of safety work.

The industry has frequently received widespread publicity of the most unfavorable nature, particularly on its accident record. Some of this is a deliberate misstatement of fact and issued to promote some personal aim. Other unfavorable reports have occasionally been published by responsible parties. Usually these reports are based on incomplete data. Within the past few months the trade papers carried a story based on a report published by the American Engineering Council to the effect that there were too many accidents in cotton mills. An examination of this report shows that the investigators based their conclusions on data from only 41 companies out of a total of over 6,348 in the industry. It is not necessary to emphasize the unfairness and probability of error in judging an industry the size of the textile industry on such a small group.

An indication of the trend of accidents in the industry can be obtained from a study of the basic rates established by the state insurance boards. In Massachusetts, for example, since the first Working Men's Compensation Act was passed in 1912, the benefits provided by law have more than doubled. If there had been no decrease in the accident experiences, it would be reasonable to assume that with the benefits practically doubled since the inception of the law, the rates would be doubled. Actually the rate today is slightly less than the rate first provided in 1912. A reasonable explanation

of this fact is that accidents have decreased at such a rate that the additional cost has been more than offset by the decrease in the number and severity of accidents.

A study of the records of the leading accident insurance companies of the country should indicate the true conditions that prevail in the industry. Through the courtesy of a number of the leading insurance companies the accident records covering the insurance of about 400,000 employees, or about a billion man hours worked, have been examined.

On the basis of these records there are 20.4 accidents per million man hours of exposure, ranging with the different insurance companies from a low of 17.4 accidents to 41.8 accidents per million man hours of exposure. Analyses of accident records of about 375,000 employees show .0418 accidents per employee per year, or 41.8 accidents per 1,000 employees per year. The severity of the accidents figured from the same source of information shows the days lost per employee to be .885 and the days lost per accident as 21.1.

In a paper read by Charles H. Clark before this Council in 1920 he raised the question "as to whether the accident hazards of operative textile machinery were not being unduly emphasized by the casualty insurance companies and by those who are directly responsible for safety work in our textile mills."

At that time sufficient data had not been collected to answer the question. Since then the tabulation of accidents by causes has conclusively shown that the operation of textile machinery causes less than 30 per cent of the lost time accidents in a mill.

The position of the textile industry in relation to accidents was brought out by the analysis that the National Industrial Conference Board made of the National Safety Conference data on accidents. These data have been used before, but are worth glancing through again.

Of the seventeen major industries of the country, the textile industry had the fewest number of accidents causing death, with the exception of the tanning and packing industry, where the information was not complete. In the number of accidents causing temporary disability the textile industry is lowest; in accidents causing permanent disability next to the lowest, public utilities being the only industry with less.

The well established fact that accidents causing temporary disability are the chief concern of the textile industry is further substantiated by this report with 30.33 out of a total of 31.48 accidents in this class. In considering the total number of accidents the textile industry is considerably below any of the other industries, the chemical industry being the nearest, with 43.81 per cent accidents, compared to 31.48 per cent for the textile industry.

Several of the insurance company's officials admit that there has been great progress in safety work in mills in the past several years. They feel that practically everything that can be done to safeguard machinery has been done, and that records show that accidents from mechanical causes are less frequent than in any other industry. They are now urging more educational work to cut down the non-mechanical accidents.

Available accident data from insurance companies has not been in all cases segregated by branches of the textile industry, so that it has been found necessary to discuss safety in the industry as a whole rather than in the cotton textile industry. Accident records, however, from a sufficient number of representative cotton mills have been gathered to accurately show the progress being made in the mills today in safety work.

One insurance company covering over 80,000 employees in cotton mills reports $4\frac{1}{4}$ accidents per 100 employees for a two and one-half year period ending Janu-

ry 1, 1928, and that this figure is one accident per 100 employees less than for the previous two and one-half year period.

Compare this record with $4\frac{1}{2}$ accidents per 100 employees for the wire goods industry, 9 for iron foundries, 7.3 for textile machinery manufacturers, 6.1 for the tanning industry, and 6.3 for the boot and shoe machinery manufacturers, and we find the hazard in a cotton mill greatly under that of other industries.

Another insurance company reports 3.4 lost time accidents per 100 employees per year.

An analysis of 19,661 lost time accidents involving 412,837 days lost showed that 3.8 per cent of these accidents were from mechanical causes, the balance 66.2 per

Accident Frequency, 1926

(Number of accidents per 1,000 workers per year)

Industry	Death	Accidents Causing Permanent Disability	Accidents Causing Temporary Disability	Total Accidents
mining	2.37	1.99	180.40	184.76
Foodworking	.75	3.13	144.97	148.85
Shoemakers and Tanners*.....		1.60	139.70	141.30

All Industries	.54	2.22	73.73	76.49

Report covers 16 establishments.

it, were from non-mechanical causes. Of the 33.8 per cent accidents due to mechanical causes, 28.81 per cent were caused in the operation of textile machinery, the balance 4.99 per cent were caused by incidental machinery, such as machine tools and wood work machines.

The same source of information shows that under mechanical causes warping and weaving machinery caused 10.19 per cent of the accidents, spinning, spooling, twisting 7.54 per cent, cards 4.02 per cent, opening and picking machinery 2.86 per cent, combers, slubbers and lapping machines 1.6 per cent, cloth room machines .5 per cent, other textile machines 1.27 per cent.

Under accidents caused from non-mechanical causes over 40 per cent were from falling material and from falls. In studying the accident reports of the insurance companies of the mills it would appear that a very large percentage of the

non-mechanical accidents can only be explained on the ground of carelessness on the part of the employee. In fact many of the accidents result from direct disobedience to instructions. Perhaps the most serious cause of lost time accidents is due to infections, the employee not reporting small cuts, scratches, or bruises when received, and paying no attention until after the infection has occurred.

A few individual cotton mill records are as follows:

Interesting Records of Individual Mills

The Luther Mfg. Co., Fall River, employing 500, went 450 days without a lost time accident, then had one accident, and now has completed another year without an accident, or one accident in 810 days.

The Lorraine Mfg. Co., Pawtucket and Westerly, R. I., has a record of less than two lost time accidents per 100 employees for the last two years.

Firestone Cotton Mills of Fall River employs about 1,000 persons, and did not have a lost time accident in December, 1927, or January, 1928. The average rate for the last six months is 4.7 per 100 employees.

The Artic Plant of B. B. & R. Knight Corp., employing 350, went from December 17 to May 22 without a lost time accident, then had one accident and has had none since. The Natic Plant employing 400 persons, went from March 5 to August 21 with no lost time accidents. The Grant Plant employing 150 persons, had no lost time accidents from November 1 to March 28, and had no accidents in April, May, or June. The Royal Plant had no accidents in January, May, and June. The Centerville Plant no accidents in January, one in February, none in March, four in April, none in May, and one in June.

The Whitman Mills in New Bedford have less than two accidents per 100 employees per year.

The Butler Mills average about two accidents per 100 employees per year.

The New England Southern Mills, employing 400 persons, have been 18 months without a lost time accident.

The Kilburn Mills, employing 1,300 persons, went through January, February, and March without an accident.

To illustrate the type of accident hazard in the cotton mills the record of the Androscoggin Mill in Lewiston is given in some detail. For the year ending July 1, 1928, the mill averaged employing 922 persons and had 7 lost time accidents, resulting in 327 days lost. This is at the rate of .76 accidents per 100 employees per year. There were no accidents from mechanical causes, all seven accidents resulting from non-mechanical causes.

These seven accidents and the time lost were as follows:

Accident Experience—Androscoggin Mill

Cause—1928	Number of Accidents	Days Lost
Falls	1	194
Handling Material	2	44
Striking against objects.....	3	68
Burns	1	21
Total	7	327

That this period was not the exception is shown by the accident summary for the past seven years, where the days lost per employee gradually decreased from 1.02 to 0.35 per employee. The frequency of accidents per 100 employees shows a low average for the seven years.

Accident Summary

Year ending June 30	Frequency accidents per 100 employees	Severity days lost per employee
1920	3.32	1.02
1921	4.73	.75
1922	5.47	.85
1923	4.46	.67
1924	4.66	.73
1925	5.70	.75
1926	3.74	.66
1927	4.28	.73
1928	.76	.35

This example illustrates clearly the problem that confronts the cotton manufacturer. The exposure to machinery hazard has been reduced to a minimum, leaving the possibility of further reduction in accidents almost entirely in the non-mechanical class, where practically all accidents are the result of carelessness, untaken, negligence, or lack of ordinary precaution on the part of the employee. Many excellent papers have been presented at previous meetings of the National Safety Council telling in detail how accident prevention work should be organized and what methods of procedure will bring results, and it would only be repeating to give them here. There are, however, certain fundamentals that are necessary for a successful safety organization.

First—The active head of the company, usually the treasurer in a cotton mill, must be convinced that continuous safety work is essential.

Second—The agent and superintendent must be made to realize that getting results from safety work is a part of their job.

Third—The overseers must be held responsible for any accident occurring in their department.

Fourth—The employee must be educated to an understanding that safety work is primarily for his benefit.

CHAIRMAN WASHBURN: There is little question but what the members here would like to ask Mr. Fisher some questions, but I am going to suggest that you withhold those questions until after we listen to the next speaker, at which time the meeting will be thrown open to discussion, and both speakers; I feel certain, will be very ready to answer any questions the members may want to ask.

We are particularly honored in having with us today, as our second speaker, a gentleman who is in a position to give us, not only data, but his own personal opinion, as to why safety should be conducted in the textile industry as well as in the others. It has been my experience that, with the exception of a few textile plants, most of the textile concerns are very ready to limit their safety work to that recommended by their carrier companies. In my own mind it is very necessary that they go farther than that. Wherever you have the human element to contend with, you are going to have accidents. It is very true that machine accidents have decreased to a marked extent during the past few years, but where you have the human element you are bound to have laxity or disobedience of orders, lack of supervision on the part of those who are in control, things which are bound to create accidents aside from the machinery hazards.

I have had it told me a number of times that as far as the machines are concerned in textile plants, they are less hazardous than those in other industries. To a certain extent that is true, but I think that all the members present will agree with me that the textile industry is a dangerous industry. Although some plants are paying more attention as the years go by to the establishment of safeguards, they are going to continue to have accidents where the human element is concerned.

The next speaker is familiar with records in all industry. The statistics which he has compiled are submitted to him by the different industries. We are particularly honored today in having with us Mr. Ethelbert Stewart, Commissioner of the United States Bureau of Labor Statistics.

Cotton Manufacturing and Safety

By ETHELBERT STEWART

United States Commissioner of Labor Statistics, Washington, D. C.

I think if I had read Mr. Russell T. Fisher's paper on "The Safest Industry" before I accepted the invitation to address this conference I probably would not have accepted. His paper was a most excellent one, and the conclusions at which he arrived are essentially the same as mine. His figures were based upon textiles, covering cotton, wool, and silk, and several other really separate industries.

In the present paper I have attempted so far as possible to segregate cotton spinning and weaving, and wool and worsted manufacture, as distinct from all other industries.

Before going into the real subject of my paper, however, I want to call your attention to the fact that it is at present utterly impossible to arrive at definite statistical facts in relation to accidents. The various States have such different waiting periods that an accident that lasts more than one day is reported in one State, while in many other States an accident is not reported unless it lasts three days, in some States 7 days, and in some States there is even a two-weeks' so-called waiting period.

In the cotton manufacturing industry the accidents are as a rule not serious; the healing period is short and hence many accidents in the industry may not be reported at all.

Even if we accept the Outwater table, which was constructed on the basis of iron and steel, where the accidents as a rule are more serious, we find that the disability in 9.2 per cent of the cases does not last beyond one day after the day of injury; in 25.3 per cent of the cases the disability lasts three days; in 37.1 per cent of the cases, five days; in 46.9 per cent, seven days; in 56.2 per cent, ten days; while in those States that have a two-weeks' waiting period 65.5 per cent of the industrial accidents would not be reported as compensable.

Again, in the cotton manufacturing industry neither North Carolina nor South Carolina furnish any accident reports whatsoever, since they have no workmen's compensation law. This in itself makes any discussion of accidents in the industry resemble playing "Hamlet" with Hamlet left out.

With this prefatory remark that there never can be any satisfactory statistics of accidents until we agree upon the facts and have a uniform set of reports, I am going to proceed to analyze such figures as exist, from a different point of view, and give you the facts as we find them. It is not my intention to read this entire paper, and certainly not to punish you with all the tables, but to hit the high spots and let you read the rest at your leisure.

I agree, therefore, in general terms that the manufacture of cotton goods is a comparatively safe industry; in fact, one of the safest. Whether cotton mills are as safe as the rather scrappy figures indicate depends on the character of the mills that furnish reports. Only partial data are available and nobody knows whether the mills furnishing data are a fair cross section of the industry. From its very nature cotton mill operation ought to be safer than some other industries. It is free from the explosion and the falling roof of the coal mine. It is free from the danger of explosions and breaking cranes of the stone quarry. It is more nearly automatic than the shoe factory and, hence, ought to have a lower accident rate.

*Not reported.

The question, therefore, is not, "Is the manufacture of cotton a safe industry?" but rather, "Is it as safe as it can be made? What more can the mill operator do to decrease the hazard of employment, and what more can the employee, on his part, do to decrease the hazard of his employment?"

It is unfortunate that complete statistics are not available for all the lines of industry. We must know what our dangers are and what our losses are in order that we may intelligently improve conditions. Greater attention should be given to statistics concerning the causes of accidents and the rate as applied to occupations. It is not enough to know the rate for the mill as a whole. Greater detail is necessary to aid in eliminating the several kinds of hazards that exist in a cotton mill.

New Hampshire, 1926 and 1927 Combined

(All accidents extending beyond-day of disability are included.
The rate is per 1,000,000 man hours)

The statistics available are at best but fragmentary. One statement may show accident rate of a cotton mill higher than some other industry, while another statement will show a lower rate for the cotton industry. One statement may show rate lower in the cotton mill than in the woolen mill. Another set of figures show a lower rate in the woolen mill than in the cotton mill. It is quite safe for either of these to quarrel between themselves as to which is the safer, both of them are comparatively safe and the nature of their process is such they ought to be about equally safe. Nor is there any reason for dispute as between the cotton mill and any other factory having only a limited risk. The question is to eliminate all of the risks possible and to educate and discipline employees as well as the employers in the "Safety First" idea.

The Bureau of Labor Statistics each year collects accident data from certain industries having a record of industrial accidents. The data are for representative industries and plants. Such figures are compiled by the bureau.

The figures for some industries are thin in many of the States and reporting conditions vary as between the States; for example, one State may report all accidents causing a loss of time beyond the date of injury, while another State have no record of accidents causing a temporary disability of less than one or possibly two weeks' duration; hence a total of the data for the several States would be something of a hodgepodge.

Pennsylvania, 1927

*Not reported.

In the several tables that follow figures are presented for the industries from which reports were obtained in States where cotton manufacturing is of any material importance. Four States are conspicuous by their absence. North Carolina and South Carolina have no accident statistics. Rhode Island has statistics but by law is prohibited giving out information. The accident records in Connecticut are decentralized; there are four or more districts in the State each having its own records.

Each State is presented by itself as it is assumed that the same degree of completeness will apply to each industry in a State, although it may not apply as between the different States.

Another table has been prepared showing the frequency rate for cotton and for woolen manufacture, and the rate for the industry having the highest rate and the rate for any industries having a rate lower than that of cotton or of woolen.

In the accompanying tables where figures for years are given, it is the sum of the establishments that report each year. For example, 14 establishments reported each of two years, and the total is given as 28. If 12 reported one year and 16 reported another year the total is given as 28.

The National Council on Compensation Insurance of New York City has furnished a table showing experience collected and tabulated by the Council covering five policy years, 1920 to 1924, inclusive. The table is attached. It shows the pay roll insured, the number of losses sustained, and the total cost of such losses. From these figures the computation has been made of the pure premium per \$100 insured. This pure premium is understood to be the amount paid back in losses without account being taken of the cost to companies in getting any business and paying overhead expenses. In mills doing cotton spinning and weaving the pure premium is 81 cents. In mills making cotton yarn and thread the pure premium was 87 cents. In mills spinning and weaving woolen the pure premium was 68

Summary of the Various States

From the tables for the several states a summary table is prepared showing the frequency rate for the cotton and woolen industries and the high and low rates reported for any industry reported.

State	Cotton	Wool	Highest	Lower than cotton or wool	Aveg.
Maine ¹	16.06	8.13	Foundries and machine shops 85.75		22.80
New Hampshire ¹	10.73	15.53	Furniture 61.49		13.27
Massachusetts ¹ ..	10.59	5.97	Brick 28.63	Carpets 2.51	11.95
				Boots and shoes 3.66	
New York ²	8.84	8.30	Petroleum refining 36.43	Carpets 3.99	15.62
				Pottery 5.15	
New Jersey ²	2.22	3.08	Foundries and machine shops 23.47		9.49
Pennsylvania ¹ ..	8.90	10.52	Lumber—sawmills 166.71	Pottery 2.69	20.27
				Flour 2.69	
				Boots and shoes 5.59	
Alabama ³	3.72		Shipbuilding—steel 32.05		
Georgia ²	5.79	14.80	Lumber—sawmills 40.58		9.70
Illinois ¹	13.18	18.42	Stoves 103.60	Lumber—planing 9.44	28.53
				Pottery 10.17	
Massachusetts ¹ ..	23.00		Structural iron 140.59		53.83
Virginia ⁴	6.85	3.06	Structural iron 84.05	Flour 2.88	14.67

¹All accidents extending beyond day of disability are included. The rate is per 1,000,000 hours.

²Accidents with disability ending in first week of disability are not included. The rate is per 1,000,000 man hours.

³Accidents with disability ending in first two weeks of disability are not included. The rate is per 1,000,000 man hours.

⁴Accidents with disability of less than 8 days are not included. The rate is per 1,000,000 hours.

s, while it was 82 cents in mills making yarn only. There is a considerable difference in wages in the cotton and woolen industries and the experience figures in and of themselves give only definite information concerning accidents. The bureau has available, however, from its own publication the average wage per man in 1920, 1922, and 1924 in cotton and woolen mills and using an average of wages for the three years as a measurement of wages throughout the period, to 1924, some interesting figures are developed.

From these figures the conclusion would be that the woolen industry is less dangerous than the cotton industry. In the statements that follow the figures for spinning or weaving, or woolen spinning or weaving are given, but not the figures for cotton or woolen yarns. The data for mills making yarn only are included because the bureau's wage figures are based on both spinning and weaving.

Cotton Spinning and Weaving

Pay roll insured.....	\$928,401,100
Number of cases.....	22,268
Paid in losses.....	7,558,600
Paid in losses per \$100 insured.....	0.81
Average payment per case.....	339.44
Average cotton mill wages per hour, 1920 to 1924, inclusive.....	0.394
\$100 pay roll pays 253.8 man hours.....	
100 man hours cost pure premium.....	0.31915

Wool Spinning and Weaving

Pay roll insured.....	\$671,471,200
Number of cases.....	11,877
Paid in losses.....	4,584,550
Paid in losses per \$100 insured.....	0.68
Average payment per case.....	386.00
Average woolen mill wages per hour, 1920 to 1924, inclusive.....	0.545
\$100 pay roll pays for 183.5 man hours.....	
100 man hours cost pure premium.....	0.37057

If 100 man hours in woolen mills at a wage of \$0.545 cost \$0.37057 pure premium, then at a wage of \$0.394 the pure premium would be \$0.30016, per 100 hours proving woolen mills less hazardous than cotton because at the same wages the pure premium would be \$0.01899 less per 100 man hours of work.

If the average payment per case in woolen mills at an average hourly wage of \$0.545 is \$386.00, at a wage of \$0.394 the average payment per case would be \$279.05.

This confirms the statement that woolen mills are less hazardous than cotton mills since at the same wage as that paid in cotton mills the average payment per case would be \$60.39 less than the average payment per case in cotton mills.

Cotton Spinning and Weaving—North

Pay roll insured.....	\$711,272,200
Number of cases.....	16,363
Paid in losses.....	5,797,157
Paid in losses per \$100 of insured.....	0.82
Average payment per case.....	354.28
Average wage per hour in 1924.....	0.460
\$100 pay roll pays 217.4 man hours.....	
100 man hours cost pure premium.....	.37718

Cotton Spinning and Weaving—South

Pay roll insured.....	\$204,519,800
Number of cases.....	5,614
Paid in losses.....	1,630,872
Paid in losses per \$100 of insurance.....	0.80
Average payment per case.....	290.50
Average wages per hour, 1924.....	0.285
\$100 pay roll pays 350.9 man hours.....	
100 man hours cost pure premium.....	0.22799

If 100 hours in the southern cotton mills at an hourly wage of \$0.285 costs \$0.22799 pure premium, then at a wage of \$0.460 the pure premium would be \$0.36800 per 100 man hours, proving Southern cotton mills less hazardous than Northern because at the same wages the pure premium would be \$0.0918 less per 100 man hours of work.

If the average payment per case in the Southern cotton mills at a wage of \$0.285 is \$290.50, at a wage of \$0.460 the average payment per case would be \$468.88 or \$114.20 more per case than in the Northern mills.

Analysis of Lost Time from Accidents in the Cotton Spinning and Weaving Industry

Furnished by American Mutual Liability Insurance Company.

Per cent of lost time chargeable to specified causes, based on 19,661 lost time accidents involving 412,837 days lost, with an average of 21.0 days lost per accident.

Mechanical Causes	Per Cent	Non-Mechanical Causes	Per Cent
Warping and weaving machines	10.19	Handling material.....	23.52
Spinning, spooling and twisting	7.54	Falls of persons.....	20.07
Card	4.02	Striking against objects.....	9.46
Opening and picking machines	2.86	Falling material.....	3.58
Elevators and hoists.....	1.89	Hand tools.....	3.09
Combers, slubbers and lapping machines.....	1.60	Plant vehicles.....	2.47

Power and transmission	.64	Vehicles	.33
Other textile machines.....	1.27	Poisonous substances.....	.28
Other mechanical causes.....	.95	Other non-mechanical causes	1.03
Total mechanical causes.....	33.80	Total non-mechanical causes	66.20
Grand Total			100.00

12.42 per cent of total time lost due to infection cases.

1.60 per cent of total time lost due to eye injuries.

.02 per cent of total time lost due to eye injuries—infection.

.56 per cent of total time lost due to loose-clothing accidents.

The table based on data furnished by the American Mutual Liability Insurance Company shows the per cent of total days lost that are chargeable to the several causes, but these figures must not be interpreted as severity rates in the several classifications, as the amount of exposure in each classification is now known.

The significant thing is that more than 60 per cent of the time lost is due to non-mechanical causes; in other words, were there no accidents in connection with the operation of machinery, there still would be more than 60 per cent as many days lost as are lost now.

Making the operation of machinery perfectly safe would still leave more than 60 per cent of the risk. The textile mill still has much to do to make machinery free from accidents and to make other lines of work entirely safe, and the worker

Analysis of Lost Time from Accidents in the Wool Spinning and Weaving Industry

Furnished by American Mutual Liability Insurance Company.

Per cent of lost time chargeable to specified causes, based on 3,415 lost time accidents involving 82,163 days lost, with an average of 24.1 days lost per accident.

10.12 per cent of total time lost due to infection cases.

1.27 per cent of total time lost due to eye injuries.

.80 per cent of total time lost due to loose-clothing accidents.

has much to do on his own part in making his occupation safe not only in connection with machinery but in other classes of work about the mill.

In a previous table I give Georgia figures as compiled by the Bureau, for the two years 1926 and 1927 combined, showing that accidents in which the disability ended during the first week are not included. In other words the 28 establishments are a combination of two years. The frequency rate as here shown was 5.79. For the purpose of this paper I wired Commissioner Stanley of Georgia requesting him to give me the number of fatal and nonfatal accidents in cotton mills for the entire State of Georgia for each of the years 1926 and 1927, with the number of employees. The result is that there were 4,173 nonfatal and 5 fatal accidents in the cotton mills of that State, a total of 4,178, in 1926. In 1927 there were 3,923 nonfatal and 2 fatal, a total of 3,925. The total nonfatal accidents for the two years were 8,096 while there were a total of 7 fatal, making a grand total of 8,103 for the two-year period. These figures cover 106 mills in 1926 and 112 mills in 1927. The hours of exposure were 392,133,000 man hours.

Here we have what I assume to be complete returns from a southern State, good, bad, and indifferent conditions, and the rate per million man hours, taking the whole cotton manufacturing industry of Georgia, is 20.7. Now here is a complete, and as far as I know, a thorough statement. Georgia it has been said is the most hazardous State in the cotton mill industry in the Union. These figures show that that is not true, for even on the same base it isn't as high as Texas,

id if you reduce Alabama, for instance, from a two weeks' waiting period to the day you would have a very much higher rate. It is not very much higher than that of Maine, and while it does weaken the statement made in this paper that the hazard is less in the South than in the North, that statement really when analyzed comes down to this—that more of the northern States report one-day accidents than those of the southern States. This Georgia statement came in after the paper was practically prepared, and I simply want to show you that even this statement covering all the little and bad plants still leaves the cotton manufacturing industry among the less hazardous.

In closing I want to say one thing—that extended disability due to infection in the cotton manufacturing industry is very great; 12.42 per cent infection in cotton spinning and weaving would indicate that that the cotton industry needs is adequate first-aid treatment for each and every kind of wound or scratch, no matter how small. I wish I were able to give you statistics that would be more acceptable, but I can say is this that your industry as a whole is a low hazard industry with tremendously high infection rate.

CHAIRMAN WASHBURN: Not long since, gentlemen, I was talking with a textile perintendent relative to his accidents based upon statistics that were received from the National Safety Council, and he immediately answered me to the effect that you can make statistics prove anything you want to. Now, to a certain extent that is true; but I think you will agree with me when I say that Mr. Stewart has shown us that the textile industry has a serious fault that should be rectified. The only means we have of knowing just how far the accident question is a major problem in the textile industry is through the reports we get from the individual plants. I regret to have to say that a very minimum number of textile plants are reporting to the National Safety Council everything in connection with their statistics on which they are able to base a fair rate for the entire industry.

Mr. Stewart has brought out the fact that there is serious need of intensive safety effort throughout the industry.

We have about three-quarters of an hour left, gentlemen, and the meeting is going to be thrown open to discussion on both these addresses and I trust that you will not allow the thing to lag, that you will come forward with the questions and statements you wish to make, so that we can have a good peppy meeting.

JOHN A. PERKINS (Harmony Mills, Cohoes, N. Y.): Would it be in order to ask Mr. Stewart if he has ever had a scratch?

MR. STEWART: Not seriously.

MR. PERKINS: I have been in cotton mills forty-eight years. There is more trouble put out about danger around cotton mills than any other industry I know of.

MR. STEWART: But the accidents happen.

MR. PERKINS: Accidents reported: I want to cite a few. I had charge of two mills in Utica some years ago. A man had a very serious case of infection. He said he was a mopper in the mill, a scrubber, and he said he was wringing out a mop, got a sliver in his finger, got infected, had to have a part of the hand removed. Later developed he was an Italian. He got some old railroad ties in the railroad, cutting the wood he got a sliver in his hand, got infected, and his mill had to pay the bill. One man had two ruptures that we paid for. It later developed that both of these were received cranking up an old Ford car. He claimed one of them was received lifting a bag of sugar we never owned, never had a bag of sugar there. The other he claimed he received lifting a box cart of 11 pounds.

In many cases people get injured in their own home, then come into the mill. I tell you that such a day they hurt their hand, scratched their hand, didn't think it amounted to anything and didn't report it. We have to pay the bill. There should be a law in every state in the Union that anybody receiving an injury should report it at once unless he was incapacitated. Every scratch and bruise and injury

should be shown to somebody. A large percentage of our bills are paid to people who are never hurt in the mills.

Speaking of falls, high heels and rubber heels, rubber heels are just as bad and worse; the majority in the mills wear rubber heels. I can go right through this hotel and find more hazards than I can find in our mill, and I guarantee as many will receive injuries as there are getting hurt in the mills. In seventeen years we have had one man lose an arm, few have lost fingers, not a person killed. There has been a score killed from our mills, who were run over by automobiles—very little said about it.

MR. STEWART: I want to say in reply that it is true that one large concern refused to hire Poles and certain other nationalities because of frame-up accidents.

A good many of the so-called personal accidents are not entirely the fault of employers. Bad economic thinking filled this country with ten million people who have not our ideas, and when the compensation law was passed, in very many cases unquestionably they did take advantage of the situation to frame up compensation cases; and even yet the cost of watching the framers-up is probably as much as the difference in the wages you would have to pay if the immigration bars had never been let down.

D. S. BEYER (American Mutual Liability Insurance Company, Boston, Mass.): I have been very much interested in the discussion of the accidents in the textile industry, which I have followed for a number of years and watched with a good bit of interest. The question of the relatively large number of mechanical accidents in the textile industry is perhaps explained, to some extent, by the fact that this industry is more particularly a mechanical industry than any other one that I recall at the present time.

A few years ago we made a study, in connection with our insurance rating work, of the number of machines per employee in different industries, and I think we found from five to ten machines per employee in the textile industry. It is some years since I have seen the figures but I know it was from five to ten, where the average industry has only one, and very many of them less than one machine per employee. That gives a very large mechanical expense and makes a very difficult matter from the standpoint of cost in protecting these machines. Take a fair sized textile plant—you have to spend \$20,000 to \$30,000 for guarding a certain type of machine. Here the economic question is a very serious matter.

I think there has been very excellent progress made in a great many mills—textile mills that we have followed personally for a good many years. One question that I think would be of interest is in connection with Mr. Fisher's discussion. Did that compilation include the boot and shoe industry and show accident frequency?

MR. FISHER: The two tables I mentioned in my report have been printed by the National Safety Council and are here.

MR. BEYER: Is the boot and shoe industry included there?

MR. FISHER: No, it is not.

MR. BEYER: One point in that connection—our experience has been that the boot and shoe, which is another mechanical industry, has a somewhat lower accident frequency; and from the standpoint of industry you will find that this is the case. I think there is a little danger of, perhaps, being too conservative. I think Mr. Fisher has given a very excellent statement of the situation from the textile standpoint. On the other hand, we don't want to exaggerate the facts. It used to be a case of when the baby cried we gave it a dose of soothing syrup. Now, we try to find whether there is a pin sticking it or something that needs to be corrected. I think we have got to face the facts clearly and without any effort to paint them in too rosy hues, because I think that is dangerous.

Also I think that there is a good bit of truth in the point the Commissioner has made in the difficulty of getting comparative statistics that really mean anything

because of the different methods of reporting. I think that such figures should come from the industry itself and I think that as this subject is brought up and more and more mills become interested in it a very splendid thing would be competition in the mills of the different types of industry, so that they would get similarity of reporting and keep their statistics on the same basis, we could then have comparative figures.

I have been in a good many competitions. That is always helpful, as giving a comparison as between one plant and another. The question is not so much the reward given the industry as whether improvement is being made in that industry and whether that particular industry is doing the best it can, or not.

The question of the falls of the workers—it is a difficult thing to control the reporting of minor injuries and little cuts and scratches that occur in mills, but in many plants they have been brought under control by very keen supervision and interest. One plant in Massachusetts recently received a letter from one of the chamber of commerce organizations. It is not in the textile industry but has over two thousand employees. For about four years now they have run with less than one accident per one hundred employees per year. So far this year, the president of that company, which has over two thousand employees, has sent me personally a memorandum every time that they have had a lost time accident in that plant, and so far they have had seven this year.

It is an industry with a great deal of machinery and hazardous work. They were running at a rate of more than ten times their accident rate at present, but on account of the keen personal interest of their manager they have made a very wonderful safety record.

The great thing is, I think, to face the facts and to get the plant that has been backward to come in line and improve its record. Just before I started to the meeting here, I asked one of my boys to pick out about a dozen charts from the textile plants just at random. They are not selected with any particular point in mind. I think they might be of interest in the discussion here as showing certain clues of how the work has been carried on. Of course the record from one plant doesn't mean anything—one swallow doesn't make a Summer—but it was rather interesting when I looked over these while the discussion was going on.

Out of fifteen plants represented in these charts, twelve have submitted below the average figure which was quoted by Mr. Fisher, and incidentally our records check very closely with them. Analysis of mills with 45,000 employees gave an average of five over a three-year period, five accidents per 100 employees per year. That is the way we keep that record. The figures of Mr. Fisher, 20.4 accidents per million man-hours of exposure, when it is reduced to 100 employees per year, it would be 4.9. This includes large plants and small plants. Here's one with 40 employees which went for one complete year without a single lost-time accident, and the average for seven or eight years is about two accidents for 100 employees. That is about one-third of the average which was quoted in those figures.

Here's one of the Southern mills which is rather high; it would need some attention I would say. Here's another plant for one year, one accident per 100 employees. For two years their rate is less than two per 100 employees. Here's another larger plant with 2,000 employees running about two to two and one-half. Here's another one which went two months without a single lost-time accident. Here's another plant that is running about half the record. Here's another that is a little bit over, and so on.

Of the entire group here I should say the average would be below and they were picked out without any selection at all; less than half the record they were about five or six years ago when we started making these studies, and I think there are sufficient figures here to indicate that real progress is being made in the textile industry. I think that the competition is not in the competitive spirit. Repeated

plans to bring in line some of the ones who have been slack have been very helpful.

D. FRANK LORD (Safety Engineer, M. J. Whittall Associates, Worcester, Mass.): It seems to me that the real need of the committee is to get the views of the man who is on the place. Suppose the textile industry is the lowest industry—what of it? What does it amount to? Aren't we going to feel a little bit as if we were smug? Aren't we going to rally just a bit and say, "well, our industry is the safest." Isn't it a false representation? Supposing we are lowest—what of it? We have to get out, as Mr. Perkins said, and clean up our own individual mill.

I would like to ask Mr. Fisher if he thinks it was well to dwell too much on the fact that the textile industry is one of the lowest industries—I don't see how we are going to compare. On the other hand, I would like to ask Mr. Stewart why he says that reports of the textile industry include everything from lip sticks to something else.

MR. STEWART: I do say that your section is composed of so many varying interests that the statistics of your section, as a section, are worthless.

MR. LORD: I suppose your information comes through the Actuarial Department of Insurance Companies.

MR. STEWART: I am talking about the section as your report shows it here.

MR. LORD: For the enlightenment of Mr. Perkins who says the mills are called upon to pay for accidents which a great many times do not occur at the plant, Massachusetts has in its compensation law the words "dire and wilful neglect" and implied the word "misrepresentation." I don't know whether New York does or not. Here's what we do. We have that same thing come before our mill continually. We have a court of inquiry and any accident that is of a doubtful nature is heard before that court of inquiry, which is composed of the workers, the overseer, or a representative from the overseer, and usually I have the pleasure, if it can be called a pleasure. The whole accident is reviewed, the cause, the result and if we find that there is that dire and wilful neglect, that accident is then taken to the Industrial Accident Board. A hearing is given and a great many, many times the Industrial Accident Board upholds the decision of our little court of inquiry.

I think of one case and I have been very active in trying to get the thing across but it hasn't gone yet, but that is a case of hernia. That is a bane to every safety engineer's existence. A man came to me out of my own department—in addition to being safety engineer, I have a department to keep up—a man came to me and says "I have strained myself." "All right, how did you do it?" He told me. I said, "Very good. Now, did you do that here or did you come to the job like that?" He had been working only one week in my department—it was a fair example. I said, "Will you agree to go to the hospital, be operated upon by any surgeon you want to operate on you, and then we will have our surgeon there, and if we find that that sack when it is removed, is an old sack, you don't stand any chance for compensation, and you don't get any doctor's bills. But if we find it a new sack that has come since you worked for us, or if work has aggravated an old sack, then we will pay cheerfully the compensation and the doctor's bills." He wouldn't agree with me, but nevertheless at the time the operation was performed we had our surgeon there and we found the old sack had been in existence for years. He may have been cranking a Ford or not, but that is something the mill has got to take up and solve.

The thing I feel we ought to drive home is that we don't want to spend too much time on statistics. Statistics are a good thing for certain purposes, but like Mr. Perkins, I believe that we can go out, go about our mill and clean up the question of accident hazards. I don't agree with Mr. Stewart in every way with regard to the cluttered up condition of mills in the North. If Mr. Stewart wants to see a real good mill, we will show him we don't have niggers wearing flat

reels and we can show him some good mills up there. It would be a great pleasure to have him come up and inspect our mills.

I want to show you the effective, from my point of view, of what I call these miserable contests. Mr. Beyer spoke of a concern in Worcester. He didn't say it was Worcester, by the way, but he spoke of a concern that got a Chamber of Commerce plaque. I was one of the committee who made the award of that plaque. The plaque was awarded, not on what I considered the statistics and the correct way of awarding a plaque, and I so told the president of that concern and the general manager. It was on the question of frequency of accidents. Many have taken issue with me on the value of frequency versus severity. Do we pay for frequency? No, we pay for severity. If we have one accident that keeps a man out one year, our record is worse than if we had three hundred and sixty-five accidents that keep a man out one day. Where does the value of a contest come, in that case? I can't see it. With all due credit to the concern that got that plaque, they are a wonderful concern and they have got one of the hardest propositions, fellows, you ever saw in your life; they are running motor trucks all around the plant and they have block signals at every turn and those trucks are run on schedule. To my mind that is their biggest hazard. Their machine shop is a wonderful development, and if any of you come to Worcester and look me up I will make a personal matter of it to take you over and show you that mill. I tell you that is where a textile mill could benefit by an examination of that mill.

Now what Mr. Stewart said in regard to these cluttered up conditions is good, and I want to cite a condition in our own mill. We have old buildings. They are from forty to fifty years old and they are not adapted particularly well to the weaving of carpets that meet the trade today. As the business has changed, instead of making a piece of fabric $\frac{3}{4}$ and $\frac{4}{4}$ wide we are called upon to make them $16\frac{1}{4}$ wide. In other words the seamless rug. Now we cannot afford to tear down a perfectly good building, and as a result we have tried to fit the machinery in a building which was not adapted to it. It ruins our cell frames, and I suppose you all know the difference between a cotton and carpet loom—we have to take space for a $4\frac{1}{4}$ loom twelve by twenty because our bobbins are all back of the loom. That leaves us so that we don't have real good aisles. Now our bobbin racks are sometimes in the way and there the question of falls comes in.

Here's the answer. After they have punched the clock that Mr. Stewart speaks of, wanting to get home and get the big potato first, they will run down the stairs. They will run out the doors; they will collide with people. What are you going to do in that case? You can't make them stop—yes, you can in a way. You can make them stop, but I really think that if the men who are employed in the handling of statistics could bring themselves down on to the earth and get around the mills once in a while they would see the difficulties we are up against.

MR. IGNATIUS MACNULTY (Department of Labor, American Woolen Company, Boston, Mass.): Why shouldn't the textile men assembled here feel very proud of the low textile record? Why should we be called smug, because we have established in an industry, perhaps one of the most valuable in the New England States, a safe place for our employees to work? In these days of efficiency and lower costs, what could be more commendable to a man seeking employment or the business itself than the low record shown? Why should you hide your light under a bushel?

Here is a large industry in which are spent hundreds of millions of dollars, its productive value too is high, and its record in sales is high. The percentage of its accidents is extremely low. A large number of its accidents, perhaps more than 90 per cent, are not compensable, particularly in the woolen industry. These gentlemen can speak better about the cotton industry. Out of thirty odd mills I have to go around, there is over one-half that have no compensable accidents, and the safety of the balance of them is hardly a very small achievement. Why shouldn't

we go out of this convention and shout from the housetops that this is one of the safest industries? It is safe for the very man that Mr. Stewart speaks of and this is not a criticism of Mr. Stewart. Isn't it a good thing that these very men we are anxious to protect make it as an industry very active? He carries his interest to his very home and the pride in his industry is very high, high in comparison to a great many other industries. The condition of his mill is a very satisfactory one.

MR. FISHER: The secretary asked me a question I would like to have the opportunity of answering now. I deliberately read from the angle I did for several reasons. I don't know why, but the textile industry and the cotton industry in particular have always been subject to a great deal of adverse comment, probably because we are one of the oldest and people have very good memories, can remember back when the textile industry was pretty backward. At the time we are practically up to date, but people still remember old conditions—before we had electric lights and running water and those things. The public has a very wrong impression. They look on it as about the lowest thing a person can do. I am not speaking of the operators, but the people of the United States as a whole. I believe it is time we came out and began to tell the truth about conditions. I think this is one of the things. Among ourselves we can admit there is a lot still to be done, but that is not to say because the industry is relatively safe it would influence a man cutting down his activities. You are looking at your own particular problem in that case, but I feel instead of emphasizing that to the public we ought to emphasize the fact that the industry as a whole is comparatively safe.

I was very much satisfied to find out how closely Mr. Stewart and I agreed on statistics and I feel a little proud of the figures I presented because at the time I thought that my figures were fragmentary. I cited the principal mills by name because I thought perhaps they would carry my study a little further.

MR. LORD: There is another thing I would like to bring to your attention that contributes to our non-mechanical accidents. There is a relatively large amount of spare time that an employee has to fill each day. We lay out the job so that we keep them as busy as possible, but if that section of the looms is running when it should run, he has five minutes. He does something in that five minutes as a substitute.

I went through a mill this summer—we went up into the spinning room. Before going in the treasurer noted how many men were sitting down. There were twelve workers—ten of them were sitting down. He said they sit that way fifteen or twenty minutes at a time. That is fifteen or twenty minutes that each mule spinner is sitting. That contributes to your non-mechanical accidents. He is looking for something to use that time for.

We went into a room of the mill—there is a big danger sign hanging up. Somebody just scrubbed the floor. There were three spinners starting down the aisle sliding, and they were using the danger sign to stop at. Whether we can eliminate that or not I don't know. We can cut them down, however.

JOHN A. PERKINS (Agent, Harmony Mills, Cohoes, N. Y.): Speaking of accidents among the foreigners: I was at the safety conference at Centreville a number of years ago. The statement was made that 90 per cent of all the accidents was by foreigners who couldn't speak English. I wasn't at the meeting—it was reported to me. I met the party who said it. The chairman of the party called his man down—"You mean to say that 90 per cent of the accidents happen to foreigners who don't speak English?" He stated, "I mean to say that all the accidents among foreigners are these who can't read or write." I said to him, "Do you mean because I can't speak a word of Italian that means that I should put my finger into a machine any time to see what will happen?" I came home and took our accident report for a year. I had it gone over very carefully.

Here's what I found: That the reported accidents among the English speaking,

long the native born, among those who could read and write English, was more than twice what it was among those who could not read and write the English language or could not speak the English language.

ARTHUR BARLOW (Armstrong Cork Co., Linoleum Division, Lancaster, Pa.): In some of the letters I sent out for the Publicity Committee, it was stated that one of the greatest enemies to safety is not the hazard itself but a wrong state of mind. Now, I only argue for the working man—I am a working man myself and I hate like the Devil to hear him run down.

As long as there is a man getting hurt (Fisher says, because he is careless) as long as that condition exists, there is a duty for such men as are gathered around the room. We shall never reach the maximum of safety, although we may in other things we desire; but I don't like anybody to come along and say that it is the workman's fault and get away with it—shifting the responsibility, as it were, to the position that he has as a mill manager or a safety engineer, as some one might have in authority. They should say, "I regret that accident happened, and wonder just how far could I have prevented it?" I think that the National Safety Council has been projecting that thought for all the years of its existence. I happen to be one who has been in the National Safety Council since it first started and I know that thought has been put first and foremost by all those who really have the problem of safety at heart. How shall we get the man to become more careful?

Such protests have been made with regard to machinery that we look upon accidents from a standpoint as negligible and we all think that the crux of the question is education. Now, speaking as the Chairman of the Publicity Committee of the Textile Section, and speaking particularly with the viewpoint of making my predecessor a more valuable man to the Textile Section, I would suggest that every man of you who have got something to say don't save it up for a year but put it to your property secretary or chairman as you call him and let him spread the news around.

To keep in mind the cause of safety, the Textile Industry ranks fourth in the industries of this country, and in my opinion, it is a disgrace to us that we are not better represented in the National Safety Council. Somebody is at fault, and a man here should accept his part of the responsibility for this membership not being greater than it is today.

These men whom I would like to have brought here, wouldn't be the kind of men who are as highly educated as Mr. Stewart and other fellows here. The men I want to see here are the men who are right on the job, the men who are in touch with the careless man, the men who can pat the other man on the shoulder and say "Don't do that, fellow." Let's get the men who can do the work. I would like to see some of these men and foremen picked out by you fellows and bring them here. Don't go and sit on them and blame them for the things that happen when you don't take them along and give them a chance to share the responsibility.

ARTHUR S. JOHNSON (Assistant to Manager, Engineering Dept., Mutual Liability Insurance Company, Boston, Mass.): I have a thought which I would like to put into this meeting. Our company covers such a large number of textiles that we feel deeply interested in their safety problem. I wish to speak for a moment of the individual plant problem, not the industry, on the proposition that the direct cost of accidents, that is, your insurance premium for the workman's compensation coverage, is so large that it represents a tremendous percentage of the net profit. The textile industry just now during this economic upheaval is working on such a low margin of profit that a plant's insurance premium equals the percentage of the net profit, and also the efficient mill which is making a profit is a safe mill and the mill which is down and out is an unsafe mill. I am

not going to prove this by statistics, but I do want to cite three mills and adapt their premium rates to the profit of one of them.

These are specific examples. They are three mills in the same state, making the same product and the mills are the same size. One of them, (a) which I call mediocre is the basis for the comparisons. It earned a net profit in 1927 of \$17,000, very low but true. That firm's adjusted rate showed a .4 per cent charge which is practically manual rate; and on their payroll of \$950,000 they paid a premium of \$7,600 which represents 45 per cent of their net profit. Could they have done better?

Example (b), which I call the good mill is similar in size, product and in the same state, had a 40.3 per cent credit on their premium rate. Applying their condition to the first mill, the premium would have been \$4,500 which represents a saving of \$3,100 or 18 per cent of the net profit. But the mediocre mill might have been worse.

Example (c), has such bad accident experience that its final adjusted rate shows a 75.9 per cent charge. Thus if the first mill had been that bad its premium would have been \$13,400 or a loss of \$5,800 from their net profit, or a diminution of 34 per cent. The difference between the good and bad conditions as measured by their premiums, represent 52 per cent of the mediocre mill's profit.

Now I am not condemning these mills and not using these figures for statistical purposes. I want you to apply the principle to your own mill. What is your premium rate? Is it manual? Is it below manual or is it way above manual? Unless you are convinced that your safety work is so effective that it cannot be improved upon, you must admit that a further reduction in your premium would reflect favorably in your profit. If your present rate is manual, can you improve it to a 40 per cent credit? If you are now carrying a 75 per cent charge you surely can reduce it to manual or better by effective safety work. A natural question is, how much will it cost to do this effective safety work? It happens that in these three mills both their mechanical accidents and mechanical conditions are identical. The cost, frequency, and severity items which show these wide differences are in the non-mechanical accidents, and they are a direct reflection of the efficiency of operation. The efficient mill is the safe mill; the safe mill makes a profit.

MR. PERKINS: The poor mill would not have to spend any money on guards to make it as efficient as the other?

MR. JOHNSON: The mill which has the 75.9 per cent charge, Mr. Perkins, shows a schedule charge on mechanical items of 5 per cent and the mill with 40 per cent credit, 3.8 per cent charge on mechanical items. The good mill had eight accidents and the bad one six on machinery. The conditions are identical and it would not cost a sou for machine guards.

MR. PERKINS: In the same town?

MR. JOHNSON: In the same state.

ETHELBERT STEWART (Commissioner, U. S. Bureau of Labor Statistics, Washington, D. C.): The Bureau of Labor Statistics gets its statistics from the manufacturers and can get them from no other source. We assume that their statements are correct and we believe they are. When they tell us the nature of the injury and the rate of injury among the foreigners, we assume that it is correct. It is very unfortunate and I am very sorry that the question came up and I had to answer it according to our figures.

Now, there is one more thing. Our figures show an enormous rate in the new man, the man who has been in the mill for one month or less, or three months or less, against the old men. Now, those figures are from the manufacturer and your turn-over is one place where you want to look for safety.

ADJOURNMENT

October 3, 1928

H. C. WASHBURN, Chairman
District Manager, Sentinel Fire Equipment Company
New Bedford, Mass.

The second session was called to order at nine-forty o'clock by the chairman, H. C. Washburn.

CHAIRMAN WASHBURN: The first thing is the report of the Nominating Committee and the election of officers.

Following a procedure which was inaugurated within the past two years and which is being followed out generally by most of the sections, they are appointing the Nominating Committee previous to the calling of the sessions. Earlier in the year I appointed on that Nominating Committee Mr. Harvey Saul, past chairman, as chairman of the committee; Mr. Glenn W. Cook of the Travelers Insurance Company, Hartford, Conn.; and Mr. Harold Donald of the American Mutual Life Insurance Company of Boston, present chairman of the Membership Committee. Mr. Saul is here. Will you report, Mr. Saul?

Report of Nominating Committee

HARVEY SAUL (The U. S. Finishing Company, Providence, R. I.): Mr. Chairman, our committee has had two or three meetings, correspondence, and we have been in touch with a number of men. We have the acceptance of the chairman. The other men are not definitely decided on; however, we have them definitely in mind and I would like to propose that our Nominating Committee present here for your consideration the chairman and leave it to the chairman and the Nominating Committee to get the acceptance of the other officers. I would like to know if that meets with your approval.

CHAIRMAN WASHBURN: You have heard the report of the chairman of the committee, is there any objection by the members?

EVERETT F. KING (Safety Engineer, H. A. Hale, Jr., Company, Boston, Mass.): I second that motion.

MR. SAUL: The motion is that we nominate the chairman at this meeting and leave it to the chairman and the Nominating Committee to appoint (I think you might perhaps better call it appoint) the other members of the Executive Committee of the Textile Section.

CHAIRMAN WASHBURN: You have heard the motion, gentlemen, which has been made and seconded relative to the nomination of a chairman. What is your pleasure?

ARTHUR S. JOHNSON (Assistant Manager, Engineering Department, American Mutual Life Insurance Company, Boston, Mass.): Mr. Chairman, it seems to be rather an unusual procedure and I think in the real workings of this Council, the Executive Committee within itself appoints certain committees and committee chairmen. I think that it would be rather unwise for us to take such a rash step as to depart from the regular procedure of calling the Nominating Committee, virtually, a board of directors to elect an Executive Committee. It is just a new idea sprung on us and I think we ought to refer it to the Council and see what the by-law requirements are for the election of officers and the appointment of committee chairman, etc., rather than to vote for the motion before the meeting.

CHAIRMAN WASHBURN: The motion has been made and seconded, gentlemen. All in favor of the motion put before the meeting, please signify by raising their right hand. It seems to be carried.

MR. SAUL: Mr. Chairman, I would like to make this statement which I think

would interest Mr. Johnson. Some of you know who we are to present as chairman. He is not going to be a figurehead, he has never been a figurehead in anything he has been asked to do. It would be very unwise for us to present any man on this Executive Committee who will be a figurehead, though it is much harder to get men on the Executive Board who will work than it is to get men who will lend their names to fill out the slate. We are not going to have a bit of difficulty in lining these up. I, for one, am very much opposed to presenting a slate here without getting the acceptances of the men we want to propose. That is why we are presenting it in this way.

MR. JOHNSON: May I ask you, Mr. Saul, if you have in your own minds a fairly definite slate worked out?

MR. SAUL: We have; yes, sir.

MR. JOHNSON: And you are withholding it because the committee has not accepted as yet, but you have certain individuals in mind?

MR. SAUL: There is one case where the gentleman has been approached and he is willing to accept but feels that he wants to present it to his employer before he gives his definite opinion. Then, there are three or four others who found it absolutely impossible to be at this meeting and whom we haven't been able to see, but we have definitely in mind certain individuals to approach and fill up the slate.

With that out of the way, I take pleasure in presenting for your consideration the nomination of Mr. D. Frank Lord, of the M. J. Whittall Associates, Worcester, Mass., to serve as chairman of this section for the coming year.

CHAIRMAN WASHBURN: Is that all, Mr. Saul? Are there any other nominations? If not, the chairman will entertain a motion.

B. F. GRIFFITH (Supervisor, J. & P. Coats (R. I.), Inc., Pawtucket, R. I.): Mr. Chairman, I make a motion that the secretary cast one ballot for the chairman, Mr. D. Frank Lord.

EVERETT F. KING (Safety Engineer, H. A. Hale, Jr., & Company, Boston, Mass.): I second it.

CHAIRMAN WASHBURN: The motion has been made and seconded that the secretary cast one ballot for and elect Mr. D. Frank Lord as chairman for the coming year.

The Secretary announced to me personally that the ballot has been cast and D. Frank Lord has been elected chairman for the coming year. Any remarks you wish to make, Mr. Lord, as the result of your unanimous election?

MR. LORD: Gentlemen of the Textile Section, I feel greatly honored in being trusted with this position, and I shall do individually what I can to keep the section at its high level; but I can't do it alone. I have to have help, and I am going to take the registration cards of the people who have been at this meeting and the one held yesterday, and I am going to analyze those cards and see where these men come from and then you are going to be called upon to do something in the cause of safety.

You come here and are all interested in safety, in your own plant—of course, it is of prime interest—and you come here and spend money to get ideas. Now, we have got to get new members. That is going to be the slogan for this year—"More Members." We lost four, as you remember from the report that I made yesterday. I want help. I can not do it all alone. The officers and the Executive Committee are far apart but I am going to analyze, as I said, these cards and then call on you for help, aid and assistance with constructive suggestions, and I know that you are all going to cooperate. If we can all pull together, then we can make this section so big that we will have to have the ball room in which to hold our meetings. I thank you for your kindness and I hope that I will be able to give you good service.

CHAIRMAN WASHBURN: Yesterday's session, gentlemen, was designed to bring

at present practices in the textile industry and the need for improvement. I think you will all agree that we had quite a peppy session yesterday morning. Also you will agree with me that it developed that there was, or is, a need for intensive safety work, not only in the industry, but in every individual plant. Granted that that is so.

Today's session will be devoted to the way in which safety work should be conducted. We are going to present a viewpoint from four different angles. You all know that it is almost impossible to get very far with your safety work unless you have the full cooperation of the man at the top of the organization. As our first speaker today, we have a gentleman who has given his sincere cooperation to the safety activities of the plants over which he has supervision. He has never appeared before us, but his name has appeared very prominently in the press in connection with a plan which we hope will go a long way toward settling the textile strike in New Bedford today. I refer to Mr. Leonard P. Frieder, Vice-president, National Spun Silk Company, of New Bedford, Mass.

Safety from the Management's Viewpoint

By LEONARD P. FRIEDER

Vice-President, General Silk Corporation, New Bedford, Mass.

There are four major reasons for conducting safety work. Humane motives dictate the effort to lessen to the greatest possible degree the human and economic suffering which unavoidably follow accidents. The creation of proper psychological conditions in a plant gains the confidence of employees in their surroundings and in the machines upon which they are working. The reputation of the plant in the community and the saving in premiums on accident policies due to safer working conditions—these offer sufficient reasons for conducting safety work. In the textile industry, premiums on accident policies range from approximately one-eighth to seven-eighths of one per cent of the payroll of the employees insured. The factors of employee confidence and public goodwill are of far greater fundamental importance to the individual plant, than the cost of insurance.

The most desirable way to gain in efficiency of production is to create such an environment for the employee that the work itself can be performed almost automatically. To permit mental retardation to the performance of the work will materially slow up the mental and physical motions required. Efficiency of production will increase with the withdrawal of causes of mental retardation, from very small to a very large amount.

An employee who has before him the ever present hazard of slipping on wet floors, coming in contact with a moving belt, or being hit by dangerous machine parts, does his work in a slow and cautious way, resulting in low production efficiency. The operator, on the other hand, who does not have before him these hazards has a free and easy manner which results in quicker motions and higher productive efficiency.

Confidence results in speed; speed results in greater production; and greater production results in lower costs.

The premium cost of an accident policy is a small portion of the total payroll. It is more important to approach the problem of safety from the standpoint of increasing labor efficiency than it is from the standpoint of premium saving. We give as a first consideration the creation of safe operating conditions under which employees may work without hindrance due to psychological barriers. Naturally, we endeavor to make all saving on insurance premiums possible. It is always well to create public goodwill for a factory; to have the employees take pride in their association, and to consider it as their plant. Essential to building the public

goodwill are safe working conditions and a record of freedom from serious accidents.

The creation of proper psychological conditions starts at the entrance gate. It involves the problem of clean yards, clean and well lighted stairways, perfect sanitation, well lighted and well ventilated buildings, and safe machinery.

Lighting is an important item in cost, particularly in those factories arranged to run more than one shift. The day of the old carbon lamp has passed and in its place have come lighting mechanisms which rival the light of the sun and under certain conditions surpass it for factory purposes.

In the design of our factories we prefer to use, wherever possible, the multi-story concrete building, using flat slab construction and totally indirect lighting. Indirect lighting is of course more expensive than direct lighting. The light from large lamps is reflected to a white ceiling as the major reflecting surface; the light is evenly distributed without shadows, throughout the area covered. Indirect lighting, even with the high lighting intensities required for a weave room on night work, approximates in our own case, less than 2 per cent of the payroll. Direct lighting of equal intensity would approximate 1½ per cent of the payroll and ordinary lighting would approximate 1 per cent of the payroll.

Indirect Lighting Speeds Up Production

The cost of installation of direct lighting is less than that of indirect, but the latter is more economical than the former because of its perfect illumination, entirely without shadows. The greatest impediment to speed is thereby eliminated with the old psychological hazards. This cost is insignificant when compared with the real benefits resulting. Several years ago, shortly after starting a spinning room in one of our new buildings, a workman came to me and said, "When you work here, you don't feel you won't see your wife and children the next morning." It is almost self-evident that employee confidence in working conditions which would justify that statement, is a sound economic result to strive for and is worth a great deal to any management.

To carry out the policy of safety work having as a pre-eminent idea the creation of sound hindrance-free working conditions, we naturally have to carry on the work which is common to so many plants—that of safety committees making monthly inspections, inspection reports, and the general checkup of the inspection standards.

We have eliminated to some degree conditions which formerly caused us greater concern, through the maintenance of a hospital staff which examines applicants for work and re-examines employees from time to time. Through the operation of a Personnel Department, which takes care of employment of workers, safety work, social and physical conditions are controlled.

A plant is really never positively safe—nor is any place for that matter—but the creation of operating conditions commercially safe is good business. It cannot be measured in terms of premium savings. It is interwoven with the larger problem of total cost which is fundamentally that of labor.

To carry out the management policy of the Company in regard to safe working conditions, it is necessary to school thoroughly the foreman and supervisory staff into management requirements. Not only is the process of education long, but it is never ending. Most men tend to get careless as they become familiar with their surroundings and to disregard the day-to-day hazards which they see so frequently.

We depend to a large degree upon our foremen to educate the employees in the details of safety, but rely as a major teacher, however, on the example which is set by management in the larger problems and more observable safety factors.

We also rely upon the moving picture machine to illustrate graphically the

ards present in ordinary work and the necessity for watchfulness; also, the ing for small bruises which are likely to occur from time to time and which, promptly attended to, are minimized in effect.

o meet the very competitive conditions of modern industry and the evident ad towards still more competitive conditions in the future, it is necessary that ry aid to increased efficiency be considered. It is our opinion that safe working ditions are a very important factor in the ultimate lowering of costs.

he present tendency is to substitute capital in the form of complex machinery the place of labor. Operatives in most industries are handling more machine is than were handled years ago and there is evidence of a continuing trend in direction.

With more complex machine units per operative, wages tend to increase; for e intelligence is required by the operator to supervise properly and operate additional machinery to the greatest advantage.

he necessity for quick action upon the part of the operator to maintain a high rating efficiency is evident. As labor becomes higher priced and with the onsibility of supervising more machine units, the indirect effect of cost of dents becomes of great moment, for the disabling of one operative makes idle rge amount of fixed capital with delays in again reaching efficient production.

HAIRMAN WASHBURN: Gentlemen, I happen to be familiar with the safety inization of the National Spun Silk Company and I think that I am safe in ng that company is certainly enjoying the fruits of a well oragnized safety inization. We know well that we have to have the full cooperation of every- r down the line, not only the president, the vice-president and the treasurer, also the agent.

he next speaker on the program is a gentleman who has appeared before us iously, a man well known to all of you, who will give the agent's viewpoint on w I Want Safety Work Conducted."

Viewpoint of the Agent on Conducting Safety Work.

By JOHN A. PERKINS

Agent, Harmony Mills, Cohoes, New York

obably the best way to begin my subject is to tell you how our safety or- zation is formed and what we do to protect the life and limb of our employees. uring the 17 years that the present company has owned our mills no person been killed and only one person has suffered the loss of an arm, this being n off at the elbow. We have had quite a few people who have lost fingers arts of fingers. In the case of the man who lost his arm and in every case e people have lost their fingers or parts of them, guards had been removed he injured persons that were put there to safeguard these people against lents.

1913 we put a force of men at guarding machinery and we complied with he requirements laid down by the State Labor Board. We have two men nually attending to safety work—repairing guards, putting on new guards inspecting machinery to see if there are any dangerous places that have not guarded.

hen we hire new employees, if they are unaccustomed to the kind of work we put them on, some one in our employ who is thoroughly acquainted with machinery on which the new hand is to be employed and who speaks the age of the new hand, instructs him fully not only in what he is to do but hat he is not to do, and every dangerous part is pointed out to him and warned against doing those things whereby he would receive injury.

Our safety organization is composed of the safety inspector, who at present is the master mechanic, and a workmen's safety committee composed of four employees—a mill wright, a plumber, an electrician and a guard repair man (employees who cover more of the whole mills each day than any of the other employees), and a general safety committee, composed of the agent, superintendent and assistant superintendent.

The safety inspector makes a weekly inspection of the mills, and makes out a report of his findings, with recommendations, which is filed in his office for inspection by the rating board inspector. He also presides at the monthly meetings of the Workmen's Safety Committee.

This committee meets in the master mechanic's office monthly and presents its recommendations and threshes out any ideas the members have on safety practices, etc. Minutes of the meetings are made out and passed on to the general committee to be approved. The general committee then holds a meeting and the minutes are returned to the safety inspector's office for filing and the recommendations are then carried out. The members of this committee are changed frequently, so they do not get "stale" on the job, and to get new blood in the organization.

Any bad practices noticed by the committee during their trips through the mills, such as horse play, fooling, smoking in the yards or any dangerous condition, is at once reported to the safety inspector who remedies the condition without waiting for the general committee's approval.

The Safety Committee Inspects New Machinery

The safety committee has taken measures to see that new machinery coming into the mills is properly guarded by the manufacturers when installed, to conform to the State laws.

Mass meetings of all the employees in the mills are held semi-annually, at which time safety motion pictures are shown or a chalk talk given.

In addition to the regular members of the safety committee, suggestions are welcome from every person in the mills. It is generally understood throughout the mills that each person in the mills is a safety committee of one to report anything that looks dangerous.

A great many of the accidents that occur in our mills are caused by falls. Notices are posted all over the mills warning people against wearing high heels or crooked heels. Whenever floors are being scrubbed a large sign with letters two inches high is carried along by the scrubbers warning that the floor is wet and to use care to avoid accidents. Each scrubber has a piece of burlap 30 feet long that he drags along the floor as soon as he has finished mopping it. By the time another 30 feet is scrubbed and this burlap dragged along, the floor is sufficiently dried so that there is no danger of slipping on it.

All accident reports are immediately submitted to our safety inspector to see if anything can be done to guard against future accidents of the same kind, and these reports are brought before the safety committee for their suggestions as to how to prevent accidents of the same kind in the future.

CHAIRMAN WASHBURN: No doubt gentlemen you will probably want to ask some questions of the several speakers, and as I stated yesterday, I am going to suggest that you hold all these things until all papers have been given, at which time you can go the limit on your discussion.

Possibly the man who is most interested from a personal point of view is the safety supervisor, and this angle of the question, the viewpoint of the safety engineer, will be presented to you this morning by Mr. D. Frank Lord, the newly elected chairman of the Textile Section.

Viewpoint of the Safety Supervisor on Conducting Safety Work

By D. FRANK LORD

Safety Engineer, M. J. Whittall Associates, Worcester, Mass.

I can say in a very few words that I want safety work conducted so as to show results.

First, by keeping the workers at their work happy and contented and with a clear mind. Second, so as to make the production of the plant as high as consistent with good practices. Third, to establish an experience rating that will tend to the reduction of our insurance premiums.

Then I want the hearty endorsement of the management. I want them to stand back of everything that is done sanely for safety. I want their suggestions and their constructive criticisms. I want the cooperation of the employment department, and its manager. I feel that a medical examination should be made of every new man employed, with record and data as to his condition, in order that he may be selected for the right place and also to avoid putting anybody at work who has an ailment that would be brought out later in the course of his employment. After the man is employed he should be given a talk on safety by the safety engineer; and then turned over to his foreman who should give him a more detailed talk on safety, and then give him a card stating the rules of safety, which he signs. Show to him the hazards that exist in the position he is about to start.

Then I want a good safety engineer. This may be a little delicate for me to talk on as it may be more or less personal, but there are many requirements that I think essential. I may have some of them, and then I may not, but as this is not a personal history, take it for what it's worth. I want a safety engineer that has enthusiasm and assurance of his position in regard to safe and sane methods. A man with the abilities to rectify faults. A man with the tact and ability to establish confidence among the foremen and the workers. A leader but not a driver. A man who can investigate impartially the causes of any accidents and suggest remedies. A man who has the capability of maintaining complete records. One who can go about the plant and locate spots where hazards exist and be able to start the necessary machinery to have them rectified. A man who is able to go about the plant with the Insurance Inspector at the time inspections are being made to establish the rating, and be able to show that all of the hard and fast rules governing guarding might or might not be applicable to the individual plant.

Next I want a safety committee consisting of men who are the leaders in the mill. And I am firmly of the opinion that foremen, overseers and supervisors are the ones to have on this committee. This committee should be changed every year, retaining of course a sufficient number of the old committee so that the work of initiating new members may be easy. Meetings should be held at least twice a month and the meetings should be conducted in a parliamentary and regular manner in order to maintain dignity and harmony. The committee should at all times be willing and ready to consider all suggestions coming from whatever source.

I believe that a suggestion box placed in convenient locations about the mill where any employee can put suggestions is a very good means of creating interest. There must be harmony in the committee and by harmony I do not mean that everybody must agree with everybody else, but under the head of harmony all should be capable of seeing the conditions as the other fellow sees them. I want to emphasize the fact that leaders are desired and that drivers should be discouraged. No workman wants to be driven, but he is willing to be led. A complete record of all the doings of the committee should be sent to the management and to each member of the committee. I have had very little experience with the contest element, and I am not ready at this time to state that I feel that a contest

can be staged with real good results unless existing conditions of the contesting departments are parallel. I believe that the results of safety work, in an individual plant are much better to be broadcasted.

In regard to the first aid department I believe that a totally modern well kept and sufficient first aid department should be maintained in every individual plant. The size and number employed will vary, of course, with the size and number of people employed in the plant. I would want a doctor with the plant for all or part of the time. This doctor should make a medical examination of new employees, care for the accidents as they occur together with redressings and keep in close touch all of the time with accident and health conditions. There should of course be in charge at the first aid room a registered nurse together with such assistants as may be required. She should keep records of all cases that come to her for treatment and submit them to the safety engineer who should be in charge of the entire safety program and he in turn through the administrative office should prepare reports for the state Industrial Accident Board and the insurance company.

I want all men and women employees to be told, and have it thoroughly driven home, that all injuries, no matter how slight, are to be cared for in the first aid room, and I want the first aid department to render the quickest possible treatment of all injuries. I am firmly of the opinion that a well balanced program on the question of Industrial Health should be carried out. No man or woman can render for themselves or for their employers the best work if he or she is not well and healthy. And this to my mind extends into the question of mentality to a very large extent. No person can leave a home in which there is sickness and trouble and come to his job able to render his best, and so to improve this condition I believe that a family health service should be rendered by the plant doctor and nurses.

The Workmen's Inspection Committee should not be too large. I find from personal experience that three men chosen from different departments of the mill can carry out the work of inspection very satisfactorily. These are men who can be spared from the position they occupy without loss to themselves or to the management. They should make notes as they pass about the mill of any place that they find unsafe, and once a month get together with the chairman of the safety committee and the safety engineer and talk over the faults which they have found and the conditions that exist. A report should then be completed and made ready for submitting at the next meeting of the safety committee for action.

Probably one of the best means of spreading safety education is by means of the bulletin board. These bulletin boards should be placed throughout the mill where the workmen are passing. The posters should be placed upon a neat and suitable kind of bulletin board. Nothing so detracts from the dignity of the board or the posters as to be placed in a slovenly and careless manner. Everything in connection with accident prevention should be neat and orderly. Posters should be selected for showing in particular parts of the mill that deal with the work that is carried on in the immediate vicinity. I cannot imagine a bigger farce than to post a bulletin dealing with railroad accidents or an automobile accident in a weave room. These should be retained and I believe that a certain number of the general service posters can be used to good advantage in the main entrance, halls, lobbies and meeting places. Nothing is so stale as an old bulletin poster and I strongly recommend that posters should be changed every week and if you have more than one plant, posters can be used intermittently.

You can post it for a week then take it down and save it for a few months and use it again. The workman wants to know something of the records of results that have been achieved through what may well be called efforts on his part and to that end I believe that a public record bulletin be posted in a conspicuous place in the mill yard giving the number of accidents each day, total for the week, total

for the month, and the total for the past year. Much interest I believe is developed in such a board.

Safety in a plant can be carried on in a practical business like manner and should become as much a part of the daily work as any other department in the institution.

With a successful safety department working safely and consistently the following are some of the results that can be achieved: 1. Increased contentment; 2. increased production; 3. decreased insurance premiums; 4. a full measure of satisfaction.

CHAIRMAN WASHBURN: We have one more speaker, gentlemen. It is my personal opinion and also the opinion of other safety men, as it has been expressed to me in times past, that all too few textile plants employ a safety engineer or supervisor, or do as much organized safety work as they should. A very great percentage of them are said to do just so much work as is brought to their attention by their carrying companies. Therefore, it is very fitting that we get the viewpoint of the insurance companies on this question, and this will be handled by Mr. Glenn W. Cook, the former chairman of the section and also a supervising engineer.

The Viewpoint of the Insurance Company's Engineer

By GLENN W. COOK

Supervising Engineer, Travelers Insurance Co., Hartford, Conn.

I suppose it seems somewhat of a paradox to say, "How do the business people want safety work conducted?" and I am going to try to explain that predicament; but we do want it conducted, and primarily successfully.

I see a number of safety men in the audience who are conducting very successfully safety work in textile plants. I want to agree with all the speakers this morning as to their method and I realize the more I see of safety work conducted, that there is no particular way of conducting it which is the best way. I have opinions of what I consider is good safety work, good methods, and what I think is not so good; what I may say is not so good, you may be following very successfully, and you may have tried what I think is good and find it faulty. For that reason, please accept what I say as merely observations of what I have made of safety, not only in the textile but in other products.

Of course the prime essential of all safety work, successful safety work, in any plant is executive interest, executive participation. That seems rather a foolish statement to make before an organization such as this, you come from plants where there is that executive interest; but I want to tell you that in the textile industry that executive interest is not universal. I was told on one occasion by an agent or manager of a textile mill in an offhand manner, "Well, we don't have accidents in the textile industry," or, "The problem is not sufficient in the textile industry to make it necessary to go to all these meetings you speak of to overcome it." In other words, they have not been sold the problem.

If the manager of a textile plant is merely conducting safety for insurance credits, he is wasting his time; because insurance credits are not a sufficient reason. You heard probably more or less of the publication which we have put forth in the last year or so on "Four to One"—that is, that the insurance cost is only one-fifth of the real cost of an industry. It said, once the manager of any industry gets the idea that safety is an economic problem, just as any other prime one is, we can get the executive interest—we want executive participation. This dele-

gating safety to some subordinate and assuming that he is going to carry it through successfully is all wrong. I have never seen it successful yet. The manager must show interest, face it, must be in on it. That can be carried to the other extreme. The agent can dominate safety in a plant to the extent that the rest of the people in the plant are not entirely frank. Though their ideas are right they are not expressing them.

I will give you a cross experiment which I undertook of slipping and falling accidents. I discussed this with the agent, his safety inspector and one of the supervisors in a shop; the manager or the agent insisted that they were doing everything they possibly could to avoid this slipping, and he described how thoroughly they were handling the subject. When it came to washing floors they put up signs and they only washed a certain space between two frames at a time. Well, we are more or less hard boiled in the insurance game, we safety men, because when we see statistics which state a definite thing we assume there must be a reason; so the engineer went down to the plant and wandered around until he found the man who was washing floors.

It is true he had a sign stuck up against the wall. This man walked along with a bucket of water in his hand and slushed it around two frames. In two or three minutes he came back with another bucket of water and he slushed that between two other frames. Pretty soon he came back again. By the time he got it all up he was past three or four frames. It took him perhaps fifteen minutes to do this. The floor was covered and there were probably ten or fifteen people who had to walk in the water. We discussed this with the overseer and safety inspector; they both knew that, but the agent was so dominating in his safety work that he didn't like to have the men express their ideas. He admitted this was all true and then said, "You realize the type of help we have to employ to do that kind of work; they don't have any brains anyway, etc." But had the safety work in the plant been properly conducted, that condition would have been corrected, it would have been brought out and discussed.

Now, next to executive interest, I would say the most essential thing in safety work in a textile mill or any other mill is foreman's responsibility or overseer's responsibility. Now, I know you don't all agree with that and you don't all carry it out, but the idea is summed up in this: that the overseer should be held accountable for the accidents in his department. A monthly meeting of all overseers in charge, in which all the accidents under each overseer are brought up and discussed should be held. The overseer has to defend himself to the other overseers. Again we don't want domination of management. It is really enough for an overseer to alibi himself when you are holding him responsible for accidents to his department, but if he alibis himself to the other overseers, he has got to be pretty near right because they will certainly bring out his faults.

In various industries today, foreman's responsibility has developed to the point where the foreman or the overseer is practically conducting all the safety work in his department. He doesn't recognize the safety supervisor or safety inspector or safety engineer as somebody with whom he is cooperating. He recognizes the safety engineer as somebody who is assisting him, cooperating with him, in conducting safety work. I believe that once we have the executive persons in a plant at the point where the foremen or overseers have accepted their responsibility, we are accomplishing as much or more than by any other means.

Of course, in every plant we should have somebody personally responsible for safety. That means a safety supervisor or a safety engineer or a safety inspector. There are so many things he can do and should do; this safety work cannot be merely to given to somebody for an hour or two a day or as something to do else besides his regular job. If the plant is of any size at all, it should be his principal job; and it is his independent investigation of accidents, which, together with your overseer's investigation of accidents, will give you some means whereby

you can get results and find out the cause of the accidents. That, gentlemen, is one of the principal jobs we have in industries today, is finding the cause of accidents.

I don't want to go into that too deeply because that will be discussed in the General Safety Engineer's Session, but you have the idea of analyzing accidents to cause. For fear that some of you are not familiar with it, we have developed this idea. In reading over accident statements, you don't get to the primary cause of the accidents. Analyze accidents to cause. If you could get everybody to do that, we would accomplish much more in eliminating accidents.

Now, to the other things. For example, our hospital. I am a firm believer in physical examination. I have seen such good results from it. On the other hand if the physical examination is not properly used by the safety department the reports of the doctor are not properly used, a lot of the efficiency of the physical examination is lost. For example, if men are examined who are not capable of doing heavy work, or men supposedly with hernia, are put on lifting, heavy jobs, all the good done by the physical examination is lost. It is done repeatedly. In other words, the overseer or the foreman should know very thoroughly what is wrong with that man when he puts him on the job, and that is not always done.

Now, I suppose pretty near every safety organization, sooner or later, advises the practice of having safety committees inspect the plant. The only thing I can say about that is that most safety committee inspectors develop into housekeeping inspectors. If the overseer is held responsible, he is held responsible for the safe conditions in his department and if your regular safety inspector is checking up on the plant, I question how much value the time consumed by these safety committees is. I can't say how successful it is in your particular plant, but I will say this—that in a great many instances looking over the reports of these men who have taken over that job and put on a job of inspection through the plant, that the results are not worth the time spent on it. I know that there are successful safety committees. I have seen some very successful safety committees made up of foremen and even workers, and when they have rotated, as I have seen them rotate, the fault generally is that when you start out you pick out four or five very good men and in rotating them you go down the line and pretty soon you have a company which isn't much good. As I said before, most of the stuff they will pick up is housekeeping stuff which should be picked up by some one else.

Now, as to the education of the employees. We tried bulletin boards, we tried slogans, we tried meetings of all the employees, moving pictures, I might name half a dozen more schemes that we tried for the job of educating the employee in safety. I have got the idea that if we go back where we were, back to the supervisor, back to the overseer, and put the job on to him of educating his employees, the value of all this stuff which we use, this propaganda stuff, will not be very great, if he does his job as it should be done. So, I can say this, that in my opinion there are two very definite essentials to all safety work, and we can build everything around those two. One is executive participation, but not domination; and the other is responsibility of the foreman or overseer for safety in his plant.

CHAIRMAN WASHBURN: You have listened to four very good papers, gentlemen, on the subject, "How I Want Safety Work Conducted." Now, the rest of the meeting is going to be thrown open to a discussion of those papers. You are at liberty to ask questions if you see fit. Let us have your viewpoint on this very important subject.

W. N. GOEBERT (Aetna Life Insurance Company, Hartford, Conn.): I understood Mr. Lord to say that he would no more put a railroad crossing sign up over his bulletin board in the weaving room than he would most anything else. Is that right Mr. Lord? All I want to know is just what his objections are based on.

MR. LORD: My idea of bulletin posting is to post in the different departments posters that refer to the work in that particular department and save the posters that refer to any general work for the halls, corridors and places of public meeting. I will give you an incident. In the carpenter's shop that is maintained at our plant, we have some thirty carpenters. One of them has nothing to do but run the band saw, and he was continually removing the guard from the upper part of the band saw. It wasn't very long before the matter was brought to my attention by one of the inspection company, and I saw the opportunity of that man getting a saw blade wound around his neck with perhaps more or less disastrous results. So I took one poster that had a picture of a saw blade wound around a man's neck and I put it directly on that man's saw guard. Sufficient to say it didn't come off. I think that he was educated. The same today with cards, loom pictures and what not—in the work place where the man is actually employed doing certain things, show him by the picture the experience that somebody else had with a machine which is similar to his.

I do believe in the posting of the general utility posters in places of public meeting, but not in the room where a specific piece of work is being done.

MR. GOEBERT: Am I to believe Mr. Lord that you would have a general bulletin board?

MR. LORD: Absolutely no. I would limit that—not a general board. We have 28 buildings and they all have entrances that the men and women go out of. In this hall is a bulletin board which is more or less general. The State requirements of Massachusetts say that five minutes' time must be allowed for the workers to wash up and get ready to leave the plant. Now, some people don't take that five minutes to wash up, and we allow them to leave their machines if they are in good shape, if they want to, but they can't go out of the building until the whistle blows. There are several minutes that can be used to go through these lobbies, which are perhaps as large as this room, and we keep the walls pretty well covered with information on safety, and that is where they get their real safety education.

HARVEY SAUL (Employment Director, The U. S. Finishing Company, Providence, R. I.): I have two questions I would ask Mr. Frieder, and one for Mr. Perkins. One question for Mr. Frieder—"Are you self insured?" and the second question is, "How much do you feel that a company is justified in spending on safety work?" I would like to tell you why I am asking that question at this particular time. Our company has this problem to contend with: We had a very serious accident a short time ago. It is one that will happen once in thirty years, but it happened. Of course, at that time we were willing to spend any amount of money not to have that happen again. We investigated it very thoroughly and we found out that one almost positive way of preventing that from happening again would require an expenditure of \$300 for a machine, and we have quite a large number of machines. We found another way which almost makes it fool-proof for \$15. We were almost tempted to spend the \$15 instead of the \$300. I know it has always been a problem with me just what is a practical amount of money to spend on safety work.

The question I want to ask is, "What leeway is given members of the safety committee which he chooses from the mechanical department?" Are they intended to approach foremen or others who have authority over conditions?

LEONARD P. FRIEDER (Vice-President, National Spun Silk Co., New Bedford, Mass.): First, we are not self-insured. The amount of insurance that we pay is not sufficient to warrant taking the risk ourselves. We have fifteen different plants scattered in several different states. Next, as to the amount of money that you are justified in spending on safety work—that is a condition which you have to analyze in each individual case. The textile industry, at least to our mind, is in such a state of adversity that it is believed that no one is really justified in spending any money unless they can get their money back in a year. The ordinary

firm undertakes it from two to five years, but our policy is that if we can't make a saving in one year we don't do it at all. We maintain a record department where things are brought out, first on the basis of insurance savings—you have to come pretty close to a year's saving on the basis of premium cost. Second, we would receipt whatever the trip of the employee we used on the job cost, the number of machines the employee was running, the amount of work which could be speeded up, whether or not an operator could handle more machines. For example, you have a spinning frame, all our spinning frames have individual motors with a direct current driven with an armature shaft—a motor shaft stuck right into the casement, so our guarding problem is very simple. But if an operator is going to walk around machines and walk around a belt line, it would pay to spend quite a good deal of money to guard that machine because, as the owner, he is bound to take precautions.

If it is a section where the operation comes through the belt substantially, a person slows up naturally. We consider the premium saving, but the premium saving has to be saved in a year.

The other reason is when the efficiency of production can be increased, frequently you are justified in making savings on making the equipment installations. I might say that as merely a variation of our year's requirement, where there is a question of quality of product we place no limit on it, even if it is a twenty year saving, because you may never determine on a cost basis what will be the economic result in improvement of quality except that costs are reduced when you improve your methods and machinery. You can reduce that by avoiding this system which causes employees to slow up as they approach some danger point. The case has to be handled individually; in some cases we would not be justified in spending a dollar and in others we might be justified in spending a hundred.

JOHN A. PERKINS (Agent, Harmony Mills, Cohoes, N. Y.): I have heard two or three suggestions that foremen be held responsible. I remember some of the accidents as I look over the items—they always come to me. One case, pulling a hose along the floor to clean the loom, he hits his hand alongside the loom. What would you do? Fire the foreman for that? Another fellow burns himself on the lathe. He had been weaving forty years. Another man cuts rough off a bobbin, strictly against the rules, and cuts his hands. Of course, the foreman can fire the hand, but what are you going to do with these people? And this physical inspector—what are you going to do with all the dead wood that nobody wants—they have to live? You have to get down to a little bit of hard facts.

In regard to that inspector, you know we don't have any in our plant. This isn't any one man job. We are all a cooperative unit. Every man there is trying to make the thing a success. The overseer sees something wrong in the room, he reports to the master mechanic to have it fixed or somebody is going to be hurt there. The inspector goes around. He reports to the master mechanic. Well, if it is something particularly out of the usual run he will go to the superintendent. If the superintendent doesn't want to take the responsibility he comes to me.

Well, now there are a lot of these guards which are controlled by the State Labor Board, they generally are. In Utica we guarded all the pick-up belts while we made a tour of inspection. A week afterward I went down and found a man cleaning up a guard, putting the belt on. Ten times as dangerous as ever before. I fixed looms for years and years and a weaver has no cause for going near the belt. If you won't touch the belt you won't hurt. It's the only way they ever get hurt on a belt of that sort unless it winds up around the shaft and the loom. Whoever is to put that belt on and off is the man who may get caught there. But get away from the weaver—then you are going to hold a foreman who has four times as much as he can do now, responsible for somebody bumping themselves against the wall or loom or stubbing their toes or a thousand and one things that can happen. Nobody can be held responsible except the person hurt.

CHARLES H. EAMES (President, Lowell Textile Institute, Lowell, Mass.): No doubt we take away many points from these papers which are remembered. It occurred to me that it might be worth while for a committee of this section to attempt to prepare a standard form of reports of accidents which may be open to corrections from time to time, but which may bring to this section or to others, printable articles, and those who are interested in preparing data concerning accidents, a form which will give the same data in all cases and which may some day be standardized.

I realize that that is open to certain suggestions, for no doubt insurance companies and state departments have their own forms which require certain reports for certain reasons. It is very possible, perhaps, to consolidate those, or if not, for this committee to set up a standard which they believe is the best one and which may sometime form a standard of report, and which will result in obtaining data which is much more reliable than any data upon which we base our conclusions at the time.

CHAIRMAN WASHBURN: That is a good suggestion certainly. There is a form which is sent by the National Safety Council, which has answered the purpose to a great extent. Are you familiar with that form?

MR. EAMES: I must confess my ignorance of such a form.

MR. SAUL: Mr. Chairman, I might add, commenting on Mr. Eames' statement, that four or five years ago our Textile Section did work up a special form for reporting statistics for the textile industry and that was in operation for a number of years and the Safety Council brought a certain pressure to bear on us to use the standard form which has brought about the condition now which Mr. Eames has reference to.

B. F. GRIFFITH (Supervisor, J. & P. Coats (R. I.), Inc., Pawtucket, R. I.): Mr. Eames can get a copy of the 1927 statistical exercises in the Exhibition Room, if you want them, and that shows about everything.

I had one or two things that came to my attention that I wanted to speak about and one was the question of environment. I have had quite a little experience of conditions in departments which result in accidents. Now, I have found that as the environment in a particular department improves—in other words, as your housekeeping of your mill improves, without doing anything else, taking everything about accidents, I believe that your accidents will reduce. I also have charge of a large recreation building. I find that if I create certain standards of environment, I am not going to have the workers who enjoy that building throwing papers all over the floor, spitting on the floor, writing obscene language on the walls and doing things to deface the property. The workers, many times where the environment is not good, will do things that they wouldn't think of doing if they were in this hotel, if they were in their own home, or if they were in a public and up-to-date theatre. You improve housekeeping in your mill, do away with the carelessness in taking care of the garbage, as far as possible eliminate cockroaches, vermin and everything of that nature, keep the aisle spaces clean, under the frames clean, and you will find that the workers are going to pull right along with you. I have seen it work out.

Now, as regards foreman's responsibility. Of course, Mr. MacNulty and I always have had different sides on that, and it seems Mr. Perkins has gone in on Mr. MacNulty's side, and I am left all alone. I believe a great deal in the foreman's responsibility and it came about in this way. We had a department where accidents were running wild. It seems to me the foreman, the man in charge of the department, is responsible. The accidents in the department are charged against that department. If the accident rate is high and it costs several thousands of dollars to pay for accidents, it costs the finished product of that department the expense of those accidents. Now, if that foreman, through ignorance, neglect, carelessness, or anything you want to say, does something in the department or

allows something to be done in the department that injures the production, reduces the production, and costs the company a thousand dollars, who is going to get it? Just the men with accidents? I believe that it is the foreman. You take away that responsibility and say, "Here, we don't care if the accidents cost a thousand dollars. That has nothing to do with production."

I think we are losing sight of the fact that that foreman is responsible for everything that goes on in that department. I don't believe that the foreman can be right there when the accident occurs, but I understand he is in a great way responsible. When you go a little further back the manager is further responsible for nearly all accidents that occur—the management makes the environment, the management creates the safety department, the management puts in the machines, the management who creates this safety department hires the man. In almost every case these men are ignorant of the conditions that surround the department where they are going to work. Proper training of the new employees will in great part reduce our accidents.

In our plant every new worker is given a little booklet in which we bring out some of the important facts in accident prevention work in that plant, and we also tell them how they can report their accidents when they do happen. They take that into the department in which they are employed and two days later the foreman asks them if they have read it; and if they haven't read it, he has them read it. In case they can't read it we have a bulletin board as big as one of these signs. There the same thing is written in French and English, as the French is the predominating language there; and we have very few who cannot speak the English language or the French language. Practically everybody is covered. If we find the person can't read English or French, they are told what is in the pamphlet, so everybody is covered.

Just one thing more. Regarding punching the clock, I thought it would be of interest to mention that at the meeting yesterday we spoke about the men running out of the plant when it came time to go home, and one man mentioned the fact that there was nothing he saw could be done to stop that. I think there is a great deal can be done to stop it. We are responsible for an accident that happens until the man gets out and off the step of the mill. If he is coming down the stairs in any part of the mill, even after the whistle blows, we are responsible, and if it is going to cost the company money, they should take care of it.

We had 38 per cent of our accidents coming from falls of persons. That percentage has been increased, but the number of lost hours reduced. The percentage is over 50 per cent, but our lost hours are greatly reduced, so that shows up a great deal more. But the most serious accidents were falling downstairs at closing time, and we had a great many of them. Now, we have stationed the foremen, the men in charge of the different departments, from the top of the mill down, on the stairways. It only takes a couple of minutes and everyone that is caught running down the stairs or any hallway, the case is severely dealt with. It has been entirely eliminated, for the last three years. To add to that we have put in proper rails and guards, etc., to prevent further accidents on stairways. When you have accidents from that cause I think they can be eliminated.

IGNATIUS MACNULTY (Department of Labor, American Woolen Company, Boston, Mass.): There is one accident particularly attributable to women who wear high heels. I thought they belonged to the ancient Egyptian period and not to a modern one in a textile mill. I am not here to advocate the wearing of high heel shoes. I am here trying to give an opinion as to what are the bases of accidents. There are very few falls of women in a modern textile mill today. I am of course referring at this time to my friend Perkins handling the cotton mills, and I have some interest in the woolen mills. In analyzing the basis of falls, we don't find many due to rubber heels. In eleven mills holding quite a large number of people, counting roughly some four thousand people, we had one woman who

fell. I think woman is balancing herself pretty well on high heels—I meant high heels not rubber heels—she is balancing herself pretty well. If you study your accidents in any state that gives complete reports on these, or check a couple of accurate reports of accidents, you will find the contribution of accidents by women is very slight. I mean her contribution to accidents by falling and not to other complaints.

As to the contribution of a wet floor to falling, I think that is exaggerated also. You will find if you analyze your causes of falls that the wet floor is a very small quantity in that contribution. So, I will take floors that are constantly wet and where the danger is continuous the whole eight hours or the entire working period. Out of fourteen mills, there were seven falls on wet floors. These are not all compensable cases. To quote all our accidents, there were 95 of these accidents, covering a period of one year, out of a number of nearly four thousand people. Where the nature of the process doesn't call for water, there was one more fall than on the wet floors. There were seven there, showing that the dry floor contributed equally to falling as well as the wet floors.

Now in washing floors, the weaving room is as good an example as I could give you, where floors have to be cleaned when the people are working; and covering the same number of mills and the same number of people in each of these mills, there were not any due to washing the floor. Every fall there was due to some fault of the individual himself, possibly carelessness. There were two out of that group serious. You will see that we are not yet reading the causes of the accident when we give old fashioned ideas. I think those of you who visit mills, like insurance reporters, will grant that the cotton mill is a reasonably safe place to work in.

I want to call your attention to the contribution of fatigue to an accident in a textile mill. This argument is largely given by Italian people and we have been interested, and I am not finding fault with them. I am going to give you these figures. There are 95 accidents covering the same number of people in the same number of mills—you can judge for yourselves whether fatigue entered largely into the cause of these accidents. There were 55 of them before the hour of ten a. m., and there were 20 of them after ten o'clock in the forenoon. There were 18 of them before three p. m. and the balance were between three and five p. m. You might say, "What about women? Does the fatigue show in the same degree among women?" So I took a number of women and found that that fatigue was affecting them more than the men. I found that out of sixteen accidents in which women had the misfortune to be hurt, again not compensable—I want that emphasized—there were seven of them before ten a. m. and three of them after ten and before 12 noon. There were seven of them between the hours of one and three p. m., the balance from three to five p. m. Out of 95 cases all together in which that small number of women were involved. In our safety card we show the hour of the day at which the party was injured. An exception is of course the exception, but usually for all practical purposes, these figures are correct.

But, you say, that is not a fair quotation. Why don't you tell us the industry in which the accidents happened—the particular phase of the industry? Would that have any bearing on it? For instance, a man working in a spooling room would be less fatigued than a girl working in the same room. Now, the weave room had their largest percentage of accidents in the mornings. There were nine of them in the weave rooms before ten a. m., and in the capsizing room where the men have to smell odors and fumes that are not the best thing because of the disinfecting that is prescribed, they were all in the morning—there were none in the afternoon at all. In the finishing where a great deal of mechanical apparatus is used constantly, seven of them were in the morning and none in the afternoon. I forgot to give you the weaving in the afternoon. Out of the total, nine before noon, five took place before ten o'clock. There were four between then and five

o'clock. In the finishing shop there were two in the afternoon and the balance of seven in the morning. In the wet finishing where the men have to use good judgment, where there is water more or less constantly flowing, accidents occurred in the morning and not in the afternoon. In the drying house, the only department of which I haven't spoken, the accidents—there were three of them altogether during the year that I gave you—were all in the afternoon during the hours of three to five.

I hold that the overseer is responsible, but I have to agree with Mr. Perkins that it would be very unjust and unfair to hold an overseer or foreman responsible for everything that happens in his department. He only exists at a particular point of space at one particular time, while his operators continue all the time and he can't tell what they are going to do, save in a general way.

In one point I would like to criticize Mr. Glenn Cook—that it would not be good to give up the education of the man in safety. If the manager of the mill in the textile industry is establishing fair conditions of labor, fair wages, fair hours, reasonable precautions to protect the man or woman, then the help is bound to contribute their share in the safety of that mill.

CHAIRMAN WASHBURN: It is very evident that we did not have enough time for this discussion yesterday. Now, the time is running along and there are a lot here who want to ask questions on "How I Want Safety Work Conducted." If there are any gentlemen here who want to ask these questions, now is the time to do it.

EVERETT F. KING (Safety Engineer, H. A. Hale Jr. & Co., Boston, Mass.): I just want to explain my position before I quote some figures here. I have been doing this safety work for nine years for H. A. Hale Jr. & Co. At present I am covering six mills, four of which are textile, and I just wanted to say one word in agreement with part of what Mr. MacNulty said about education of the employees.

It seems to be the consensus of opinion that more stress should be laid upon the length of physical hazards in the plant. I think that that work is incidental to the main safety care of the plant. You know as well as I do that after a while the physical hazards in a plant are pretty well taken care of. It remains to eliminate a large number of accidents due to what we call carelessness. These accidents can only be eliminated through the cooperation of the various employees and that does not include the newest employees alone—that includes the men who were for twenty-five years in this trade, men who have never been hurt.

We have to lay a little more stress on the education of the employee and we should also place responsibility on the foreman, although not all the responsibility on him. I think the safety committee cops in the various departments should assist their overseer in eliminating accidents.

About falls, I just want to say a word. I have some figures here that have been gathered from some of the plants in which I have been doing work, covering 24,000 employees in three different plants. Here are 643 involving some 30,000 days lost. Mr. MacNulty is quoting from his experience and I am quoting from mine. Just let me tell you about some of the accidents from falls in some of these mills.

Here's one plant of 6,000 where falls cost 12 per cent; here's another, 300 employees, 58 per cent; 6,000, 34 per cent; another mill with 1,200 falls cost 27 per cent; 1,500 falls cost 21 per cent; another, 500 employees, 60 per cent. Here's another with 3,500, 39 per cent; one with 4,000 employees, 46 per cent. A large number of these accidents occurred from falls on floors. They are not segregated into various types of falls but they occurred from falls on floors, either from wet or slippery floors or obstructions in aisles. I think our attention should be directed along the lines of preventing accidents from falls.

Just let me cite you one instance. I know a plant in Maine that employs 2,000 people, where the agent recently passed a very drastic rule regarding high heels.

He has forbidden any woman employee to come into his plant with high heels. If a girl comes in with spike heels on she is sent home for a regular pair of shoes.

CHAIRMAN WASHBURN: See if we can't confine ourselves to the subject. What this last gentleman said is O. K., but there are a lot of members here who came here to get information, so I would like the speakers to confine their remarks to the subject.

DR. ROBERT P. KNAPP (Medical Director, Cheney Brothers, S. Manchester, Conn.): I would like to find out by the consensus of safety engineers here if the opinion of Mr. Perkins is held by all. If so I would say there is a danger of accepting an erroneous statement, which I think would certainly not lead to any good results in the end.

In regard to Mr. MacNulty from falls, I could say briefly there were three falls due to high heels, because many of our female operators take off their high heel shoes.

I do agree with Mr. Griffiths in placing responsibility on foremen. I know our foremen are not so busy that they can't be held responsible.

I think it is a great mistake our friend Mr. Perkins is making. I think they should cause physical examinations to be made.

MR. PERKINS: I want to say I didn't touch on our first aid and medical department. We have one, and I would say that there is thorough cooperation between them. With all due regard to your opinion, I still have to say that we are probably having less turnover than any mill in America, and I think our accidents are as low as any mill in America. I don't hold my opinion as a theory or by statistics, but by long years of experience in going through the mills and knowing what has caused accidents. Many men have been in our employ thirty-five to forty years and want to see accidents prevented. Many of their own families are working there. It isn't theory or statistics, or it is not what we get in some cellar; it is what we got right there in the mill so the people with their fingers taken off or their arms broken can learn to know how to guard against it.

ARTHUR BARLOW (Chairman, Safety Committee, Armstrong Cork Company, Lancaster, Pa.): There were some things said this morning that I don't agree with. One of the best means of getting the foreman to recognize his responsibility, is to make him a part of the factory supervision. For the purposes of prevention of accidents, put him on the safety committee, let him familiarize himself with the conditions in the factory, place him outside his own department and by this means you gradually get that man to see things from a different viewpoint. The same thing applies to the worker. The more you can bring the foreman and the worker into close and personal contact with this accident prevention work that we are all interested in, the nearer we shall come eventually to cutting those accidents to what we would regard as a satisfactory basis.

I hate to hear you fellows say about the safety supervising work, just bring all your responsibility to the foreman. If some of you had been foremen you wouldn't talk that way. The foreman is just human like you are, and he has his own economic responsibility. Then, as a rule he has got to keep his job. The first thing that he had to do is to show the boss that he is working that department all right. Let the safety supervisor get close to the foreman. "Come along, boss, or whatever you are, let's you and I come to work together." Forget that. Let him come in and say, "Now, is there any way in which I can help you to prevent that kind of accidents." The fellow says, "Yes. You can do a lot, but I guess the best thing you can do for me is to help these people that are working for me to get educated how to take care of themselves."

C. C. KEEFE (Armstrong Cork Co., New Brunswick Plant, New Brunswick, N. J.): Our records for the last year show that about 85 per cent of our accidents were non-mechanical. We have a safety committee that inspects the mill regularly and has its meetings. About 99 per cent of their reports are for mechanical im-

provements in mechanical guards. We have state inspectors coming around. All they do is check up guards. They claim the guards are about perfect. Still 85 per cent of our accidents are non-mechanical and we are supposed to eliminate them all by education. I would like to know how you get that education to the employee for preventing those accidents in which he himself is undoubtedly responsible? We have had posters, all those things, and still people will fall and step on things and drop bricks on their feet and do those sort of things. How are you going to do it?

D. FRANK LORD (Safety Engineer, M. J. Whittall Associates, Worcester, Mass.): From experience I will answer that question. There is a motto across one of the buildings in our city, "Eternal Vigilance Is the Price of Liberty." I think that is the only answer we can make. Eternal vigilance on the part of superintendents to see that the housekeeping conditions in a plant are perfect. Mr. Cook says he thinks the inspection job is now actually deteriorating into one of housekeeping. Why isn't that a pretty good thing? If we have our guards so that we can't find any fault, let that be part of the vigilance committee. In my own committee we had 27 suggestions at the last meeting. Twenty-six of them were housekeeping suggestions—loose bricks over doors, a place where the stairs needed fixing, etc., so let that committee be a vigilance committee.

In regard to the question of the textile industry being the safest industry, we have a man here that I want to ask a question of, and I know he is thinking about it because he is the man who is handling the money; and that is, how Mr. Frieder reacted to the amount of the budget that he has to meet at the next meeting of his directors. Will he go home feeling that a reduction or an increase in the budget is going to be necessary?

For Mr. Eames of Lowell, with regard to statistics. There has been formed by the National Safety Council a standard which covers the number of accidents, lost time, and the number of days lost; and if every member of the textile branch that is a member of the National Safety Council would fill in that blank in full, leaving the frequency figures and the various figures alone, then the textile section would have a complete analysis of the accidents and statistics they could use. It seems to me that is one of the answers to Dr. Stewart's statement yesterday that his statistics "weren't worth three hoops in Arkansas." If the people would all send in the same kind of forms they would be valuable; and that emphasizes the fact that I want to make for this coming year the slogan, "Every textile plant a member of the National Safety Council." Then we will get statistics that are valuable.

We have a good chairman on the statistical committee and I think if we will all join and put in our little bit, we will get the good of it.

LEONARD P. FRIEDER (Vice-President, National Spun Silk Company, New Bedford, Mass.): In the first place, personally, I am only interested in a very general way as to what the individual plants are doing except as those things can apply to ourselves. One thing I do know about our own plant is this: What accidents cost us, what it will cost in terms of production, what efforts we make to try and prevent accident hazards. If the textile industry is in line with those that will help us, we are interested, but if we, by analysis of our own conditions, can improve our status as compared with the industry, that is where I am interested. We have to take our own condition where there is an opportunity for safety work to be handled individually, and if the textile industry were almost perfect and we still could improve our own conditions why those conditions would go into our own budget to correct the hazards and reduce our own expense whether it is direct or indirect.

GLENN W. COOK (Supervising Engineer, Travelers Insurance Co., Hartford, Conn.): So many of the gentlemen present disagree with me today, I had better say something before it is too late. Foreman's responsibility—it is easy to reduce

any idea, if you are antagonistic to it, to its absurdities. All I know about foreman's responsibility is this—that where it has been tried they like it and use it. We don't mean by foreman's responsibility that the foreman is responsible for the accident. He is responsible for the conducting of safety in his department but the fact that somebody gets hurt in that department doesn't mean we are going to hang the foreman for it.

On the subject of education, I am not condemning the education of the employee. The only brief I have is that on education of the employee we should not try to bring the foreman on the accident work, which could just as well, or better, be done by the manager. I have come over my desk every month bulletins of the National Safety Council, the Insurance Council, etc., and as I see all those bulletins come across my desk, I wonder how much value there is to these bulletins that are posted. Yet, we have found no way of measuring just what value that particular form of education has been; even though we can't measure it, I do not think we should give any of it up. My only thought in criticizing education is to bring ourselves to let these efforts be put into constructive safety work, to act as an assistant to the things the foreman and the manager should be doing.

C. N. YOUNG: Mr. Frieder spoke a few minutes ago to the effect that he thought a safety investment should pay for itself in one year. I would like to ask if he expects any other item of his plant investment to pay for itself on that basis? Why should safety be put on any other basis than any other item of plant investment?

MR. FRIEDER: The reason is this. It sounds very nice to say an investment cost you 6 per cent a year, but it doesn't—I have kept records of it—I have amended that—every investment cost is 20 per cent a year, that is at first. The reason we don't make it five years is this. For instance, if you want to increase your production, it is hardly possible that you could get it other than by an investment that would yield much less than that basis, but when you come to equipment, etc., we find so many opportunities, we feel that a one year basis is wise. Some people put it at two years. When I say one year you must bear in mind that our plants are two or three shift plants, and we have much better opportunity for making accidents than others have. Another plant may have to say two, another three, before they can be superior to us, but in our own case one year is plenty.

MR. PERKINS: One gentleman said he wondered how effective those bulletins were. Back in war time there was a bulletin posted about a man who stepped on a nail, and he had the worst looking foot that I have ever seen. That is something I have tried to guard against because I was brought up on a farm and it would turn a whole place into confusion to step on a nail. I said, "You put a carpenter on and have these bulletins put up all over this plant." I saw the man doing the work. A few days later I was up in the spinning room and he was repairing floors that were partially worn out. He was throwing the nails down—he had spent a day and a half putting up these bulletins and here he was doing the same thing himself. I didn't speak very gently and I don't know that I confined myself to the Scriptures. "Didn't you go around here putting bulletins up to guard against that?" He said: "That is for the help."

HARRY D. IMMEL (Bureau of Inspection, Department of Labor and Industry, Harrisburg, Pa.): One of the gentleman said something about state inspection being entirely a matter of machine guarding. I think it might be of interest to him to know that the Department of Labor and Industry of Pennsylvania is preparing to try it. The idea is no more than this: Our state inspection, beginning in a month or two, is going to be based on individual plant experience largely. Heretofore, our state inspection, just as other state inspection, was a matter of routine—block by block system, door to door for the factories almost. And then our Bureau of Registration, which gets a record of every accident, we are going

to have prepared every month and sent to our supervising divisions a record of lost time accidents in every trade. They will be kept intact as a permanent record and will largely be the basis for routine inspection. Mechanical safeguarding will of course be a large part of our work, because we are the most interested in that phase of the work, but education is going to be second and a considerable amount of work will be done in bringing in an interchange of ideas. As far as possible, enterprise is going to be a part of our work and we think the textile industry is going to appreciate that method of inspection.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Woodworking and Lumber Manufacturing Section

New Section Officers

General Chairman—J. M. BISSELL, Marathon Lumber Company, Laurel, Miss.
Vice-Chairman (Manufacturing)—M. C. GOODSPEED, General Electric Company, Erie, Pa.
Vice-Chairman (Sawmills)—H. R. ORCHARD, Marathon Lumber Company, Laurel, Miss.
Vice-Chairman (Logging)—W. L. WALLACE, Edward Hines Lumber Company, Lumberton, Miss.
Secretary—O. J. OLSEN, Fisher Body Corporation, Detroit, Mich.
Program Committee Chairman—JOHN B. GRIER, American Car and Foundry Company, Wilmington, Dela.
Membership Committee Chairman—I. W. ROWELL, Wisconsin Land and Lumber Company, Hermansville, Mich.
Publicity Committee Chairman and News Letter Editor—A. O. JACKSON, Aetna Life Insurance Company, New York City.
News Letter Associate Editor—H. STEERE-CLARK, British Columbia Loggers Association, Vancouver, B. C., Canada.
Poster and Slide Committee Chairman—F. W. BRAUN, Employers Mutual Liability Insurance Company, Wausau, Wis.
Engineering Committee Chairman—G. A. ORTH, American Car and Foundry Company, New York City.
Statistics Committee Chairman—H. J. KELLEY, American Seating Company, Grand Rapids, Mich.
Executive Committee: THE FOREGOING AND
G. E. SANFORD, General Electric Company, Schenectady, N. Y.
H. G. WIBERG, Lumber Mutual Casualty Co. of New York, New York City.
E. ROSS FARRA, Grand Rapids Safety Council, Grand Rapids, Mich.

Retiring Officers

Chairman, JOHN B. GRIER, American Car and Foundry Company, Wilmington, Del.; *Vice-Chairman (Manufacturing)*, J. M. BISSELL, Marathon Lumber Company, Laurel, Miss.; *Vice-Chairman (Sawmills)*, E. K. PRICHETT, Prichett-Powers Company, Grand Rapids, Mich.; *Vice-Chairman (Logging)*, H. STEERE-CLARK, British Columbia Loggers' Association, Vancouver, B. C., Canada; *Secretary*, M. C. mittee Chairman, E. ROSS FARRA, Grand Rapids Safety Council, Grand Rapids, Mich.; *Publicity Committee Chairman and News Letter Editor*, O. J. OLSEN, Fisher Body Corporation, Detroit, Mich.; *Poster Committee Chairman*, H. D. HERRON, International Harvester Company, Chicago, Ill.; *Engineering Representative*, G. A. ORTH, American Car and Foundry Company, New York City. *Executive Committee*: THE OFFICERS AND G. E. SANFORD, General Electric Company, Schenectady, N. Y.; A. O. JACKSON, Aetna Life Insurance Company, New York City; H. C. WIBERG, Lumber Mutual Casualty Company of New York, New York City.

October 1, 1928

JOHN B. GRIER, Chairman

**Employment and Safety Manager, American Car & Foundry Company
Wilmington, Dela.**

The first luncheon and afternoon session of the Woodworking Section at the Seventeenth Annual Safety Congress was called to order at twelve-thirty o'clock by the chairman, J. B. Grier, Employment and Safety Manager, American Car & Foundry Company, Wilmington, Del.

CHAIRMAN GRIER: Gentlemen, we had this luncheon meeting arranged today so as to become acquainted. Today I would like you to meet your neighbors on both sides and across the table and become acquainted, so that when we gather in these sessions we will know one another and not be standing in the lobby looking for some one of our personal friends.

I started last night in the Congress. We had a little dinner to President Niesz. There were a lot of nice things said about President Niesz, and there was a lot that was not said that could have been said. President Niesz is a very likable man, and anyone who has known him for a year, and has worked with him, can't help but acquire a love for him. He is an ideal man and has made us a wonderful president.

What we are going to do here today is just sort of hash things over and try to get you fellows to give us some of your experiences which are odd, and we will call on two or three of our members here for a short talk. We have a man with us who has evolved in his mind the super-excellent safety plan for preventing all accidents. That is a big offer, and I am going to let him put it across. I don't know how well he will get away with it. One thing that struck me rather funny last night, was that Dr. Stewart said that the Jonah-and-the-Whale incident was an accident that was reported but there was no lost time. He also said that that accident could have been prevented had the whale not exceeded the speed limit. If he hadn't exceeded the speed limit, he would never have caught Jonah.

To start our meeting off, I am going to ask Dr. Leroy P. Kuhn, Chief Surgeon of the Lumbermen's Mutual Casualty Company, Chicago, Ill., to give us just a few minutes' talk. It is just a talk on his personal experiences in accident prevention work.

Address

By DR. LEROY P. KUHN

Chief Surgeon, Lumbermen's Mutual Casualty Company, Chicago

I feel just a little out of place in this meeting of safety engineers and safety men. A physician or surgeon usually tries to mend what happens as the result of accident. That has been my work for perhaps twelve or fifteen years, and especially in the woodworking industries of Chicago. During this time, in treating

patients, of course, one would naturally obtain a definite history of how the accidents occurred, and with the more serious types of accidents, we become very much interested in the cause, as the history is taken of each patient brought to us for treatment.

In the last ten or twelve years I have become especially interested in the more serious accidents from their etiology; first, the physical condition of the man; second, the mental condition of the man—whether his mind is slightly confused or whether he is balanced so that he can carry on the kind of work that is given to him.

I have found during the last three or four years, that the mental attitude or the illness of a man's mind (if I may so state—of course, there are so many different types of mental illnesses that I won't attempt to classify them) but if a man's mind is wrong, he is a fit subject for an accident. In other words, if he leaves home in the morning mentally confused, perhaps by nine or ten o'clock he is going to be over at the hospital or, in the doctor's office. If this man is depressed, if he is melancholy, if he has financial worries, if he has domestic troubles at home that started him away to work wrong in the morning, he is just the type that comes to us later in the day.

It has occurred to me during these past few years that we ought to give a little more time in our accident prevention work to the mental condition of men about the plants. I don't know how much it is worth to you men in accident prevention, but from a medical standpoint, it appears to be as something that ought to be given more consideration.

Then, too, in these more serious accidents that come to physicians, the question of guards, the type of machines used, is something that the doctor is interested in. He finds that from a certain class of machines, certain types of accidents constantly occur, some of them serious—a small percentage serious, possibly three-fourths not of much importance.

During this woodworking experience that I have come so closely in contact with in the past years, I have a good many abdominal injuries come to me for attention. I would say that a third of them have been very serious, while two-thirds were just minor injuries to the abdominal or the chest portions.

There was a time when men did not wear glasses—no goggles were used at all. Then, finally, the workman was interested in glasses to prevent eye injuries, so that in the Detroit session in 1922 of the Safety Council, I brought to the attention of the Woodworking Section, some abdominal form of protector for the revolving rip saw or planer or any type of woodworking machinery that might cause an employee to receive an abdominal injury. I thought that the average guard that is used was very good—especially when it is used.

We have gathered a good deal of statistics from guards, the number of different types of guards used in the woodworking industry, and we find that there are some very good, some standard guards used, and then there are other places where guards should be used where they haven't been used at all. It is from these sub-standard guards and the industries that have guards but do not use them, that we obtain so many serious abdominal injuries.

So it has occurred to me, during the past years, that it might be advisable to have some form of abdominal protector that a man could wear, similar to wearing glasses for injuries to the eyes. I am very much interested in that particular subject, so much so that during the last three or four weeks, I have gotten up a sort of abdominal protector that I believe will deflect or make the blow to the man's chest or abdomen less serious, so that he will not receive an injury to some internal organ in the abdominal cavity. If you had gone through some of the experiences that I have at the operating table, if you had seen some of these men who have suffered from a kick-back of the rip saw or the planer, you would find that a sub-standard guard was used, or else no guard at all; and you would find that man has

to have four or five inches, maybe four or five feet of intestinal tract removed, because he has been so seriously injured. You would begin to think of some way to prevent that type of accident if it is possible to do it. As a physician and surgeon, I don't know whether it is possible or isn't possible, but I do know from the statistics that we have gathered, that some of the guards that are on the market now do not protect. A first-class guard does protect. We have found that very few accidents occurred with these saws where a good guard had been used.

I am indeed glad to be here at this meeting, and to see the interest that is taken generally in the physical examination of employees, and especially what the last speaker emphasized this morning in the general meeting. It seems to me it was one of the best addresses that I ever heard.

CHAIRMAN GRIER: Thank you, Dr. Kuhn.

I would like to hear now from anyone. Bring up any of your accidents or any of your strange experiences—something that is unusual. Let's get acquainted and have a general roundtable discussion.

R. C. BARR (Manager of Safety Instruction, Lumbermen's Mutual Casualty Co., Chicago, Ill.): I would like to ask how they have prevented the kick-back accidents in rip saws and planers. I would like to ask the different individuals collected here how they have prevented kick-back accidents in their plants?

W. L. WALLACE (General Attorney, Hines Associated Lumber Mfrs., Lumberton, Miss.): I am going to ask my able, efficient associate, Mr. Buchanan, to give you—not the experience of our operations, because we no longer have that character of accident—but I am going to ask him to give you an explanation of a device that the J. J. Newman Lumber Company has evolved and adopted, which in my mind, from seeing it in active operation, makes a kick-back accident impossible.

MR. BUCHANAN (Safety Engineer, Edward Hines Lumber Co., Lumberton, Miss.): Mr. Thompson, the safety engineer for the J. J. Newman Lumber Co. interests in Mississippi, had two kick-backs last year—one of them on a two by four straight through a man, another one a week later. They thought at first it was dull saws. They said the saw file was at fault. They got good saw filers, the same saw filers who had been filing in those mills for years and never had any trouble at all, and they knew there was something wrong. Mr. Thompson told me that he had worked and worked, trying to devise some way. They got a planer foreman by the name of Mr. Buckley. Joe asked all his foremen to think up something to help stop these accidents. Mr. Buckley went to work on it, and I believe that he contrived the first, but it wouldn't work. They put it on the back of the edger instead of the front. It is a device that has four teeth, and the feeder stands like this (indicating) and as the lumber comes through, the minute she hits that, these teeth rise and ride this lumber, and you couldn't get it out of there if you took a tractor and pulled it. You couldn't get that piece of lumber to kick back. That lumber will not kick back. It is an absolutely fool-proof device. You can put them on planers, on re-saws, on edgers, you can put them on anything.

Several people have been trying to buy the patent on it, and Mr. Buckley will not have it patented at all. He has had it copyrighted, I believe, and had it fixed in the patent office so that nobody can commercialize it. But, if any of you are interested in that and want to see that thing, Mr. J. I. Thompson of the J. J. Newman Lumber Company of Hattiesburg, Mississippi, will furnish you blueprints of it, gratis. The president of the J. J. Newman Lumber Company was so well pleased with it that he told Mr. Thompson to have a number of blueprints made up, so that if anybody wanted them they could have them.

I notice in all the lumber magazines—in the American Lumberman, and Southern Timberman and National Timberman, and all the big magazines all over the country—they are all featuring this device. It is not a publicity stunt of the Newman Lumber Co. at all. It is a sound proposition, and one that is absolutely fool-proof. So, if you want to stop your kick-backs, that is the thing that will stop them.

M. J. MCCARTHY (Fisher Body Corp., Detroit, Mich.): Mr. Barr, I think if you will just bear with me until Mr. Olsen gives his talk on Wednesday, you will see both of the questions illustrated.

G. A. ORTH (Chief of Safety Dept., American Car & Foundry Co., N. Y. C.): That device has been in the plants of the American Car & Foundry Company since 1915. It has been illustrated in the *National Safety News* by the National Safety Council. We have been using that for about 13 years. We have never had a fatality since its use.

MR. WALLACE: Mr. Orth bears out what Mr. Buchanan has said—that device makes a kick-back accident impossible. That is what we are all trying to do. Now our Newman people declined to even try to patent it. Why? Because they want to spread safety throughout the universe.

CHAIRMAN GRIER: Are there any other questions? Is there further discussion on this subject?

MR. BARR: In connection with the same subject, many times you find that in sawmills they can use non-kick-back devices, but in the box manufacturing plants where the saw operator has to retrieve the saw again, we find there is some objection to using that form of non-kick-back device, that is, in sending short pieces through the machine. It is really our problem in the box manufacturing industry to find something that will prevent kick-backs and not use that form of dog. I think that dog mentioned by our friend from Mississippi is a very effective dog to use in the sawmill. I don't know whether the address to be given later will cover box manufacturing or not, and that is the reason I bring that up again.

M. J. MCCARTHY (Fisher Body Corp., Detroit, Mich.): It covers that kick-back guard in two or three different forms.

O. B. FREDERICK (Safety Supervisor, Dierks Lumber & Coal Co., Dequeen, Arkansas): Is this kick-back guard used on edgers?

MR. BUCHANAN: It is at the present time. It can be rigged on any saw, rip saw, planers, edgers, and I am going to begin to use it on table saws. I am fixing for that now. They told me it couldn't be used on rip saws. Nevertheless, I rigged one on a rip saw and got it working.

MR. FREDERICK: One other question: Is the dog put in front of the saw?

MR. BUCHANAN: In front of the saw.

CHAIRMAN GRIER: Any further discussion on the same question?

A. W. BLOIS (Foreman, Owens Bottle Co., Huntington, W. Va.): After the board passes through the saw, what effect does that have in preventing an accident after it passes through to the back of the saw where you get your kick-back?

MR. BUCHANAN: Probably I didn't make myself clear. The saw teeth are like that (indicating). They hang down like that with a slight curve, as you will see by the blueprint. As the lumber goes under it, these teeth fall down on the top of this board. That is the front edge of the board. I have seen kick-backs from knots in the middle of boards. We had one of them caused by a knot in the middle of the board. The board broke and flew back. But, if that device had been there, it couldn't have happened. The knot is the only thing in the world that is going to cause you to have a kick-back with that device.

MR. BUCHANAN: Understand me—I have had this device working only about two months, but I see the feasibility of it, and it is a good device. I think it is the only solution that I have seen so far that will absolutely stop it. Now, you can't control the knot hazard, but very few timbers that you get in your industrial plants outside of the mills have knots in them. The mills themselves are subject to the knot hazard. We class that as No. 3 common lumber, and there is very little of it sold.

CHAIRMAN GRIER: I think probably what would explain it a little more clearly is the fact that the dogs are long and the bar holding the dogs in front of the

saw prevents any material from coming back over the top, if the board ~~should~~ break in the back.

MR. BLOIS: My experience has always been after the board passes through the saw, if that lumber happens to lie there a few minutes, and your vibration happens to bring the lumber in contact with the saw tooth, that is where you get your kick-back.

MR. MCCARTHY: It can't do that. The lumber comes right down on the table. While the lumber is not being fed in, the dogs are practically on the table. These dogs, you understand, are loose. As the lumber is fed in, it goes right straight through. After she passes the dog, the dog drops down and lies on the table.

MR. BUCHANAN: Another thing is: The modern plant layout today doesn't call for an offbearer of lumber. If you keep up with the *Engineering News*, you see that the offbearer of lumber is a thing of the past. It is all done by chains and automatic conveyors. In our planers we have one man, and no man ever touches that lumber until it is 300 or 400 feet away from that planer after it comes out the other end. It falls and is automatically taken away.

CHAIRMAN GRIER: Probably you are not clear on just which is the front of the saw, or which they are considering the front of the saw.

MR. BLOIS: I call the front of the saw the part which the operator faces.

MR. BUCHANAN: That is the back of the saw. The feeder stands in back.

CHAIRMAN GRIER: Where do you have your guard placed?

MR. BUCHANAN: At the front of the saw.

CHAIRMAN GRIER: And the guard gets hold of the material after it passes through the saw?

MR. BUCHANAN: Yes. It won't work on the back.

MR. BLOIS: I misunderstood that. Does that also apply to planers?

MR. BUCHANAN: Planers and everything.

CHAIRMAN GRIER: Is there any further discussion?

DR. LEROY P. KUHN (Chief Surgeon, Lumberman's Mutual Casualty Co., Chicago, Ill.): The gentleman from Mississippi made some remark about knots in the wood or knots in the board being sawed. I have noticed in getting histories from employees' kick-backs that most of them will describe something about a knot in the wood that caused the kick-back. If I understand you correctly, you said your guard wouldn't work where the saw hit a knot.

MR. BUCHANAN: Kiln-dried lumber is subject to shrinkage. It wouldn't do it on natural dried lumber. You take a knot in a board, kiln-dried lumber, and it will shrink so that you could take it and hit it with a hammer and knock it out, practically all the lumber. It is tight, but it is not as tight as it should be. Sometimes the moisture dries up so much in that lumber that that knot becomes loose, and if that saw is just a little bit dull, it is going to cause trouble on that knot, because that knot is going to fly as soon as it touches it, and if it hits just in the right place or if the board is turned over, you are going to see the knot come out of there. I have noticed it time after time. I have spent days in the planing mill down there watching just that one thing. We had a knot in a board—the board was about three inches on one end and one inch and a half on the other, and about three feet long—and it went right through a man right here. It was caused by nothing but that knot breaking. A piece of that board kicked back while the main part of the board went on.

DR. KUHN: Then you have no guard for that particular situation?

MR. BUCHANAN: No sir, we have nothing for that.

O. B. FREDERICK (Safety Supervisor, Dierks Lumber & Coal Co., Dequeen, Arkansas): We have had some kick-backs due to the fellows feeding the lumber in crooked and raising the rollers when they saw that they had made a mistake. We have had a few kick-backs from that.

W. J. CULLEN (Safety Engineer, Royal Indemnity Co., New York City): Speak-

ing about these saw guards: Is the blade of the saw guarded with a cage guard on top?

MR. BUCHANAN: You say a table rip saw. It is an automatic feed rip saw.

MR. CULLEN: I am talking about a manual feed rip saw on a table.

MR. BUCHANAN: The majority of these rip saws that you push lumber through are practically obsolete anyway.

MR. CULLEN: As far as I can see, in one industry alone they are not obsolete, and in practically all the plants around here they just stand in front with a board and shove it through.

MR. BUCHANAN: I am speaking now of the modern methods is running a shop. I say that the rip saw (of course, there are a lot of those things still) as they are renewed, are going to be automatic. There is nothing open except just the drop guard.

CHAIRMAN GRIER: I think the discussion has centered around a particular operation. This kick-back device can be put on almost any type of rip saw, and the hood guard and splitter in addition to that. It doesn't interfere in any way with the operation of the hood guard which covers the top of the saw entirely and the splitter which is the biggest safeguard of all.

H. R. ORCHARD (Supt., Marathon Lumber Co., Laurel, Miss.): In connection with a kick-back device on edgers, it is well to keep in mind the point that the gentleman brought up about the operator raising up the rollers after he has put the board in. It is very essential to keep that in mind when you are considering safeguarding any piece of machinery, because there would still be a lot of troubles coming from the operator not using the safeguard provided for him. Of course, I know that is true in every industry.

Now, in connection with these edgers, while it is a splendid idea, and our plant expects to equip our edgers with this kick-back device, fortunately we haven't had a kick-back accident in our mill in five years. We do not manufacture as much lumber as the plant this gentleman here is connected with, but we do manufacture around forty-five to forty-eight million feet of lumber a year, and we have only two edgers in that machine, and they have to handle a lot of material.

After the last kick-back accident, our people insisted on close attention being paid to the edgers. That includes the sawmill people, they understand it—that it applies to all machines; that includes the condition of your saws, the condition of your feed-in rollers, the condition of your out-feed rollers and all of your devices, and what I think is most essential is to inoculate in the mind of the feeder not to take that chance; when he gets a board in there (naturally, we don't want him to put a board in crooked) but if he does put a board in crooked, let it go on through and lose that piece of lumber; and if he gets a piece of lumber in there hung up, not to lift up those rollers or interfere in any way with the device until he gets the machine stopped and can take it out. I think that is one point we have all got to keep in mind: That while mechanical safeguarding is absolutely essential, we shouldn't think it is going to solve all of our troubles, because the operator is still the most important factor.

W. A. WILSON (Personnel Manager, Frank Graves Sash Door & Mill Co., Los Angeles, California): I would like to know if there is a guard that would properly operate on a railroad or dado saw, where we are cutting and dadoing fairly wide material, 12, 14 or 16 inch sills. I would like to know if there is such a guard.

R. C. BARR (Mgr. of Safety Instruction, Lumberman's Mutual Casualty Co., Chicago): I can't answer that myself, but I can refer Mr. Wilson to Mr. McKiel, who represents the Wisconsin Industrial Commission, who has worked out a satisfactory guard for that.

CHAIRMAN GRIER: I am sorry he is not in the room with us, and if he is later, we will call upon him.

MR. FREDERICK: We have, I think, fairly successfully solved that problem of

the dado with an overhand guard which swings or, in other words, bounces when the lumber is fed under. It raises the lumber and as the timber goes through, it drops down. We also have a hand for clearance to hold the lumber, so that the man doesn't necessarily have to put his hand anywhere near the dado head, and he merely clamps the lumber on the table with this and shoves it through.

MR. WILSON: May I ask if that is done with a foot lever that will bring the saw into contact with the wood?

MR. FREDERICK: No, it is not done with a foot lever. We have a sliding table.

MR. WILSON: I have in mind where the saw is moved by a foot lever.

MR. FREDERICK: That is different from our operation.

CHAIRMAN GRIER: I might say that we have covered that operation fairly well with an iron bar clamped to the carriage of the saw that travels with the saw and carries the guard overhead. The guard is tapered so that when it strikes the material it rides up over it and as it comes back, it comes down and covers the head.

MR. WILSON: Does that operate for all widths of wood? We are thinking of this to take a fairly large curve coming back.

CHAIRMAN GRIER: It operates within a limit. It can be set for the large operations or the small.

MR. WILSON: This is a large piece.

CHAIRMAN GRIER: It would operate for that if you made the guard for that operation. You would have to make a guard for an exceptionally large operation. The bar which carried it would have to be heavier than would be necessary for the lighter operations. It would be governed entirely by the amount of that work which you would have to do.

Is there any further discussion? Does anyone else have any question?

MR. BARR: With this guard, does the guard extend out far enough to strike the operator?

CHAIRMAN GRIER: It does not; it clears.

Are there any further questions? If not, I am going to ask Dr. Lucian W. Chaney, Economist, of the U. S. Department of Labor, Washington, D. C., to give us some of his experiences.

DR. LUCIAN W. CHANEY (Economist, U. S. Department of Labor, Washington, D. C.): I inherited a job for which I am not particularly fitted. I happen to be the chairman of the committee which is operating a division of the National Standards for Woodworking Machinery. I would like, in that connection, to ask the members of this section for any information which they may have with regard to a request which has come to the committee from the manufacturers of woodworking machinery. The code, as you probably know, contains a statement of maximum speed which should be adhered to in the operation of the saws. This has stood unchanged for a number of years. The Manufacturers' Association has presented to us a request that we raise the limit on saw speeds about 67 per cent. The members of the committee almost unanimously are very doubtful as to the safety of this procedure. We have already conducted some investigations as to the relations between speed and the strength of the mounting and the strength of the steel which the saw is made, but the most noticeable thing which turns up in connection with our investigation is that after all, we don't know very much about it.

There are a considerable number of technicalities which we are entirely at sea about, and I was authorized, as chairman of the committee, to appoint a sub-committee which should deal with this question.

Now, if the members of this section have any wisdom on the subject of saw speeds, we would like to have you give it to us. If you will set down what you think about that, I shall be glad to furnish you with copies of the statements made by the manufacturers, and in any way cooperate with you in clearing up the matter

so far as your views are concerned. We need this information badly in order to make an intelligent modification of the speeds prescribed in the present National Standards Code.

CHAIRMAN GRIER: Has anyone developed some questions now?

R. WILLIAMS (Thomasville Chair Co., Thomasville, N. C.): If the gentleman will take it up with our organization, I think he will probably get some information along that line, as we have a number of saws that are running at probably twice the speed at the present time, of the code of which he speaks.

M. B. GATHMAN (Plant Manager, Fisher Body Co., Detroit, Mich.): For twenty-five years at least, there has been a rule for figuring the saw speeds. That is, dividing 36,000 by the diameter of the saw. That is a rule they all went by until all saws today are motor-driven (or practically all of them). Now the motor is applied right to the saw and there is no way of changing the speeds. The speeds are set, and it is now left up to the judgment of the man who runs the mill as to how big a saw he can run either at 3,600 or 1,800 r. p. m., because those are the only two speeds you can get with alternating current motors at 60 cycles.

On that basis, a 12-inch saw would run 3,000. Now they are running 14 and 16 inch saws at 3,600 and they are not having any trouble with them.

CHAIRMAN GRIER: Are there any further experiences along that line?

M. C. GOODSPEED (Safety Engineer, General Electric Co., Erie, Pa.): I would just like to suggest in that connection—it appears to me that there should be a definite relationship between your speeds, the set of your teeth, the sharpness of the saw, and a few of those conditions, that will possibly run you into considerable trouble if they aren't watched more carefully at the higher speeds than at the speeds that we have been accustomed to. Those points should be very carefully developed by this committee, and brought to the attention of the users of the saws, if the higher speeds are permitted.

CHAIRMAN GRIER: There is one question that came up during my administration as chairman, which I have not been able to check up. In one of our Safe Practices Pamphlets there appears a statement, "Do not use a cracked saw whether or not it has been drilled." I was asked to furnish some definite proof that accidents had occurred from that source. So far, I have been unsuccessful. I have written to quite a number of large woodworking concerns, asking them if in their experience they have ever known a saw which was cracked and drilled at the end of the crack to prevent it from cracking farther and breaking. Is there anyone here who has had that experience?

R. G. BUCHANAN (Safety Engineer, Edward Hines Lumber Co., Lumberton, Miss.): Do you mean that a saw that has been cracked and the saw filer had cut it off and braced it and drilled it?

CHAIRMAN GRIER: No. I mean a saw that had cracked from, say, the perimeter of the saw, in probably an inch and a half or two inches toward the center, and then at the extreme end of that crack, a hole drilled to prevent it from going on further into it, and no bracing done.

MR. BUCHANAN: We had a band saw that the saw filer tried that on, and it broke.

CHAIRMAN GRIER: I am speaking of a circular saw. This is the experience I have had: The same answer to all of my letters, no one has ever had that experience.

MR. GOODSPEED: The National Safety Council has had a committee working on that particular question.

CHAIRMAN GRIER: The committee was after me, as chairman of the Woodworking Section, to furnish them proof of an accident to substantiate this clause, "Do not use a saw whether or not it has been drilled." We have never had any and our plant has been in operation for 65 years, and we have used drilled saws. We don't at present.

A. W. BLOIS (Foreman, Owens Bottle Co., Huntington, W. Va.): At what depth crack do you consider drilling the saw?

CHAIRMAN GRIER: Personally, we do not consider drilling a saw at all, regardless of how far it is cracked, but I have found them around our plant which were used, drilled in as far as three inches from the edge of the saw, in a 14 to 16-inch saw.

If we have no further questions, I am going to call on some one else, perhaps he can give us this information. Is Mr. Harold S. Norton in the room at present? Mr. Norton, I would like you to give us something.

H. S. NORTON (Safety Engineer, Bureau of Standards, Washington, D. C.): I believe I am in the same position with Dr. Chaney, regarding actual experience. We gather our experience from the industry and from the manufacturers, and I was about to ask the same question here regarding the maximum speeds of saws which, of course, we haven't received a good answer on as yet. Realizing the fact that the motor is directly connected with the arbor on the saw, and that the motor speeds are more or less constant. Of course, there are all kinds of difficulties that arise as far as the steel is concerned in the saws, and there was a question in my mind whether the steel in saws made today is any better than that made 20 or 25 years ago. I hear from some old-timers that it is not, but I am inclined to think that that is not an accurate statement.

CHAIRMAN GRIER: Thank you, Mr. Norton.

Next we will hear of our Safety Plan, of which I spoke in the beginning, and we will let the father of this plan explain it to us—Mr. A. L. Bussing, or rather, "Al be Careful!"

A. L. BUSSING (Al be Careful, Inc., New York City): I feel quite healthy—I am sure I look quite healthy, and I am almost proud to be the father of this plan of mine.

For the last 35 years I have been interested in accidents and accident-prevention. Some 20 years ago I did my first job in accident-prevention, and that was as an insurance man in New York City, in the putting up of notices to drivers of horse-drawn vehicles, to "be careful."

Since that time, I have seen losses, accidents and suffering continue, so that even now those who do not live in metropolitan areas know of the seriousness of these accidents which befall you, me, your mother and your children. I have told you that I was in the insurance business, and I hated to see these premiums for accident-prevention grow and abound; whereas 20 years ago an employer paid a rate, perhaps, of 30 cents to protect himself against an employee, today, to give him the benefits of the Workmen's Compensation Law, the average rate is beyond 3½ per cent. When we consider and know that there is over 2 per cent in the State of New York paid out in indemnities alone, we must realize and we must know that the cost is great.

Several years ago, I had several large concerns that I insured, and irrespective of their premiums, the casualty company said to me, "Bussing, there is nothing wrong with your risks—morally they are O. K.—but we can't make any money out of them." I started in to place those risks elsewhere and I learned that the other companies did not want them because of the system of rating by debit and credit.

I went back to them, and I said, "Give me a chance to make those risks safe" (this was some seven years ago) "and I will show you what I can do." I started in, and my first impulse was to get to the home, to the mother and the wife and kids of these men who were causing the accidents and the suffering from them. That is no new story today. My first line of approach was a lot of postal cards, followed up by meetings, bulletins and everything else that the casualty companies and myself could devise, but I did not have at that time the full force to approach these people in the way that I wanted to approach them. I wanted to send a

message home each day, each week, whereby the mother, the child, the father, would say, "Daddy, don't get hurt—come home—don't get hurt—and bring me something."

We all know of cash awards, but what to give to these people I didn't know. I wanted to give them something that didn't cost the boss all of his profits; I wanted to let the boss live and, at the same time, I wanted to cut down the terrible experiences that these people were having. It resulted in my getting out a plan known as the "Al be Careful" plan of premiums, getting out a catalogue to get to the homes, the catalogue filled up with the previous messages that I had sent, which would cost the boss two cents per week or more, whichever way he might feel that his accident needs required.

With this plan being started, I realized that I needed to build up an experience, to find out how it was working. I went out to Chicago; I showed it (not in elaborate form as it is today) but I came back here to New York and have been plugging on it ever since. We have been running in connection with the use of the premiums and the rest of the work which we do, and which each and every one of you could do, and we have been obtaining results that are far beyond anything that I had expected.

I just got through a "No-Accident-Month" with a concern which has been paying some \$70,000 or \$80,000 in premiums, and in August of last year (which was a month which resulted in some 71 or 72 accidents and a cost of over \$5,000 for losses and reserves), with this plan we have come through that month of August this year with the same number of accident reports, accident frequency—for you all know that there is none of us who can run an accident program without having our accident frequency keep up—but in the last analysis, we have five lost-time accidents on compensation this year as against five lost-time accidents last year.

I haven't the comparisons here, but the actual comparisons are a minimum as against last year, for last year, while the total losses and reserves were over \$5,000, using the casualty companies' figures, the total loss and reserves on their entire losses was \$1,348, and with it all, this concern had increased their business over 20 per cent.

But with it all, I have learned that we need to educate the men in the factory, first. Secondly, we need the assistance of the fathers and the mothers and the children by having them say, "Daddy, don't get hurt—don't have an accident. I want that pair of roller skates."

CHAIRMAN GRIER: Gentlemen, this plan came to my attention at the Congress last year, and I have looked it over, and I bring it here not as an advertising scheme, but, as Mr. Wallace said, to put it before you. He claimed that Mr. Orth didn't put our program before the others on our kick-back device. Here is something before you. It is something that I, myself, believe is good and am giving you the benefit of looking into Mr. Bussing's plan—"The Al be Careful Safety Plan."

Mr. Farra, will you give us a word?

E. ROSS FARRA (Manager, Grand Rapids Safety Council, Grand Rapids, Mich.): There are being formed now, and have been formed in some of the local council cities, what we call a "Women's Home Department," and I have been convinced for a great many years that a good part of the success of industrial safety can be helped by Home Department work. It seems to me that the industrial men who are living in local council cities can well make use of this Home Department work.

We organized in Grand Rapids last spring, the Women's Home Department, with one of the prominent club women as the chairman. I will show you my point when I finish what I am going to start to tell you—last spring we carried

on a series of Home Safety lessons with the professional home visitors, such as the visiting nurses, the community health nurses, and so forth. The topics taught those nurses were such as: The Home to Live In, Engineering the Home, Fire Prevention, and such other topics as would touch Home Safety entirely.

But my thought, and the thing I am selling to our industrial men in Grand Rapids, is this: That I am doing a real job for industrial safety when I am putting over a good Home Safety program. We are planning a Thanksgiving No-Accident Month in Grand Rapids, in November, similar to what they have been holding in Pittsburgh for many years. I am going to ask the Home Department to put on a program in the homes for industrial safety. Yet we have a very low industrial safety record in Grand Rapids. We had 24 home fatalities last year; 22 motor vehicle fatalities; 17 public and only 11 industrial, and yet, I believe, the solution is in having the folks in the home interested in industrial safety.

I think that part of the program (I haven't seen the program) is very good, and I think all of you who are living in local council cities or close enough to feel the effect of local council cities, can well cash in on their Home Department work. Possibly the manager of your city hasn't thought of that particular phase of it, and you have an opportunity to bring it to his attention.

Just one other thing: I have humbly tried to serve this organization for the last year as chairman of the Membership Committee, and I am going to say something that will hurt. There isn't a single member of the Membership Committee, and only one or two members of the section that have got a single member for the Woodworking Section in 1928. Now, friends, the success of this section (and I have been tied up with it as many of you know since 1920) or the success of any other section, depends entirely upon you gentlemen. Your chairman can't do it, neither your present chairman nor the one to come; and I am going to ask you again as I asked you last year at Chicago, if you will go home and make up your minds to send to whoever is your new chairman one industrial membership for the National Safety Council between now and the 1929 Congress? I don't know where it is going to be held—I haven't any inkling of it. But, if you will do that, we will have twice as many members in this section as we have now, and the Woodworking Section a couple of years ago was the second largest. I think we are the third now.

Of course, some cancellations were due to the fact that the logging mills were closing down, so you couldn't have any sales argument to get them to renew. But we ought to cover that with the re-manufacturing, and I beg of you men to go home to your communities and get just one member for the National Safety Council. You will be doing yourself a favor in this, for every other industry close to you which is not now a member of the National Safety Council, whose interest and support you get for the National Safety Council, will help your industry, because you are bound to employ some of their men sooner or later.

If you had a community where every single industry in that community was a member of the National Safety Council and doing safety work (just being a member of the Council doesn't mean anything—but doing safety work does), I am sure that accident-prevention would be much easier in your industry than it is today.

CHAIRMAN GRIER: Thank you, Mr. Farra. I am sure that will help us wonderfully. Mr. Farra has a right to talk that way, because I know of seven memberships that he sent in through his own efforts from in and around Grand Rapids.

MR. FARRA: They took work, too. They didn't come easy.

CHAIRMAN GRIER: Have we any further questions?

MR. G. A. ORTH (Chief of Safety Dept., American Car & Foundry Co., New York City): I want to say in connection with the "Al be Careful" Plan, our company, the American Car & Foundry, is putting this plan into two of our departments in two plants—the Berwick Plant, employing some five or six thousand men,

and the Wilmington Plant. While we have no record on its workings, having just gone into effect several weeks ago, I do say for it, after my investigation of the plan, that it has merit, because it brings up the one thing that Mr. Farra very clearly stated, and that is: You are getting the message to the families, to the wives and to the mothers, and there is no doubt in my mind but what the little kiddie at home, when he gets these coupons which are part of the plan (similar to the plan that we have here in the United Cigar Stores and which is broadcast throughout the country) he will save these coupons and then have them redeemed for prizes or awards. I think Mr. Bussing has hit upon a very excellent scheme to reduce accidents in industry.

Before I consented to putting the plan into our plants, I talked the matter over with able safety engineers, and without exception, they have arrived at the conclusion that it has some merit to it.

We know in our plants that we have got to keep up the effort of the man. All of you know of the Andy Gump cartoons which appear in many of the newspapers. I wrote to Mr. Smith, asking his permission to use Andy Gump in a series of cartoons in our plant, just in order to get the men interested in safety and to have the continuance of this effort in safety. We had the men in our 18 plants draw up something that would apply in this series. They have responded and some of the messages are excellent. I would say that nearly all of them are, and they relate to our particular industry. If any of you would care to have a copy of this, I shall be very glad to have them made up and sent to you, if you will just let me know.

CHAIRMAN GRIER: Any questions on this plan?

MR. BUSSING: Might I make a further explanation? In regard to the cancellation and collection of the coupons, we insist that the employee make the application through his employer. In other words, we are not going to allow these coupons to be sold around the streets. We propose to have the employer in direct control of the whole situation, and when Mr. Employee cashes in the number of coupons, Mr. Employer will know just where they are going. In addition to that, we have an award that goes to the employee pronouncing that he has been a safe employee for a certain period. I forgot to state also that this year and a half—that is, these coupons that are coming in at the present time have been saved for periods of from six months to a year and a half, meaning that that family has been working to get enough coupons to get some one of these awards. I claim that no family can work to get any of these awards, from the silverware to the roller skates or kodak, without looking through the calendar, and by so doing they cannot help but obtain some idea as to safety.

L. GLAZER (Manager Safety Dept., Dierks Lumber & Coal Co., Kansas City, Mo.): In regard to getting safety in the home, we have used a little scheme that I think has been quite effective. Of course, it is difficult to trace tangible results.

A short time ago, we started a little campaign among the school children in our communities. It was a literary contest with the subject, "Why My Daddy Should Be a Safe Worker." I do not think the plan is original with us. It has probably been used by other people, but we instituted that contest in every one of the country schools, tributary to our operations, and we received, from some schools, as many as 70 essays, written on the subject, "Why My Daddy Should Be a Safe Worker." We offered a prize of \$2, I believe, for the first essay and \$1 for the second, and it was really remarkable to see what thought the children gave to the subject. We feel that that has served to bring Safety into the home, because these children in making up their essays will probably speak to their daddies and ask them why they ought to be safe workers. Most of the essays brought out the point that daddy should be a safe worker because, when he gets hurt, the children suffer. Now, that is a point that we have been trying to

hammer into the minds of our workmen for many years—that they are not the only ones to be thought of when you try to impress safety upon them. As a matter of fact, we know that it is really the children and the mothers who suffer when the wage-earner is laid up.

So, that is a suggestion that perhaps many of you could use—institute a contest in your communities on that subject, and I feel that that will serve to bring safety into the home in a way that perhaps it has never been introduced before.

M. C. GOODSPEED (Safety Engineer, General Electric Co., Erie, Pa.): I would like to emphasize what Mr. Farra said about this work in the home. I have been sold on the idea for several years. I believe if you could take the kids and teach them safety, when they get into the shop they are going to be better off, for their own good, and for the good of us, who have to work with them, than would be the fact if they have no idea of what safety means before they get into the shop.

The idea of home safety can be put across whether you have a Safety Council at work or not. You can do that for your own employees only, or several shops can join together and put a safety home campaign across as a group. In any case, you can get these safety lessons already prepared which give you the outlines from the National Safety Council, and I can tell you just exactly how you can work it out to make a success of it.

You have got to have somebody who is interested to follow the work, first. That person will have to get enough people who will go through those lessons, learn them themselves and then give them to the groups, so that they can properly present the subject. This spring, we operated in approximately 16 groups of women, with over 45 speakers following these lessons. Those speakers were all volunteer teachers, you might say, or speakers secured from the insurance people, from the utilities, and whatever the subject of the lesson happened to be, we pick the speakers from the city to handle that lesson, the speakers best able because of his knowledge of the subject. Any of you can do the same thing and you are going to secure results that will surprise you.

You will get the results and the attention of the women's organizations and work back through them right into the homes, carrying these safety lessons, and it is absolutely worthwhile.

ADJOURNMENT

October 2, 1928

JOHN B. GRIER, Chairman

**Employment and Safety Manager, American Car & Foundry Company
Wilmington, Dela.**

The second session was called to order at nine-thirty o'clock by the chairman, Mr. J. B. Grier.

CHAIRMAN GRIER: According to the program, I see there is a report and an address due from your retiring chairman.

It is with a great deal of pleasure and honor that I welcome you to the Seventeenth Annual Congress of the Woodworking and Lumber Manufacturing Section of the National Safety Congress.

This section, during the past year, has moved to the third place in membership, due to the loss of several industries in the Western states, caused by ceasing operations. I will bear on that just a little later.

Another year has passed, during which time safety activities have been carried on with success which cannot be measured. We do not know how many lives or how much suffering has been saved or prevented during the past year. Our accident records are not yet to the place where we can definitely say ten lives have been saved or fifty accidents have been prevented. We do know, however, that lives have been saved and that accidents have been prevented. Everywhere we read of wonderful no-lost-time accident records. Our accident experience covering the past eight years has not decreased in frequency, there is a slight decrease in severity. These reports, however, are very inaccurate as the number of concerns reporting to our Section has increased steadily from year to year. There were thirty more establishments reporting in 1927 than in 1926 and so on down the line. Combating this statement, of the 167 establishments reporting during 1927, 10 of them completed the year without an injury causing loss of time.

We are receiving reports now from numerous sources which have been closed to us in past years. Industries have accepted their burden in the accident problem and are handling it as they do a production problem. They realize that accidents are far more reaching than they seem to be on the surface, particularly since the interpretation of our Compensation Laws have been stretched far beyond the realization of the sponsors.

It is my duty to present, as chairman of the Section, a report of the activities during the past year. We have had quite an active list of officers. In order to conserve time, it was moved at our meeting held in March that the Chairman would make a report covering the activities of all of the officers.

I have a letter from Mr. J. M. Bissell, vice-chairman in charge of Sawmills, expressing his inability to be with us, and in Mr. Bissell's behalf, I wish to state that he has been of invaluable assistance to me in the past year in carrying on the work of this Section. He is thoroughly sold on safety work and has brought into the Council a number of members during the year. He has also been instrumental in retaining several memberships which would have been cancelled in the Southern States but for his activities. He is devoting considerable time to the safety work in the South particularly in the interest of the lumber and of the Section. He was one of the leading men in the Gulf States Regional conference held in New Orleans last June. He has been instrumental in having the Southern Loggers Association devote part of their annual meeting to the discussion of safety measures in the logging operations and has attended all meetings of the officers of your Section.

Mr. E. K. Prichett of the Prichett-Powers Company, Grand Rapids, as vice-chairman in charge of Sawmills, has been quite active in the furniture manufac-

turing interests through the state of Michigan. He has been instrumental in putting on safety programs through the Grand Rapids Safety Council and has himself assisted with the membership by securing new members in and around Grand Rapids.

Vice-chairman in charge of logging, Major Harry Steere-Clark of the British Columbia Loggers Association, Vancouver, B. C., Canada, expresses his regret in not being able to attend this Congress, but you will realize it is well out of his latitude. However, Mr. Clark has sent us quite a number of bulletins applicable to the Logging and Lumber Manufacturing side of the Section and has, himself, advanced logging safety throughout British Columbia, where he is in charge of safety work of several large logging concerns.

Secretary Goodspeed of the General Electric Company, Erie, Pa., has been in attendance at several of the Executive Committee meetings of the National Safety Council as well as the meetings of the officers. You have heard from him, no doubt, several times through the minutes and general topics he has sent out.

Mr. W. L. Wallace of the Edward Hines Lumber Company, Lumberton, Mississippi, as chairman of the Program Committee and a member of the 1928 Nominating Committee, has been the outstanding officer of the year. He has devoted considerable time and thought to the Section. He has the interest of this Section at heart and has been of invaluable assistance to the Chairman during the past year. This program which you will listen to has been arranged by Mr. Wallace, with the help of the other members. He has also been instrumental in securing for us a reputation throughout the Southern States, and has sold the National Safety Council to numerous Associations. He worked with Mr. Bissell in the Gulf States Regional Conference, the Southern Loggers Association, and is at the present time, advocating the holding of the next National Safety Congress in the South, where we have never gone to spread our gospel.

E. Ross Farra of the Grand Rapids Safety Council, as chairman of our Membership Committee and a member of our Nominating Committee, has been quite active. He appointed regional officers to assist him in this work and through his efforts has been able to keep in the Council quite a number of members which would have sent us their cancellations. He has also sent us several new ones in and around Grand Rapids, through his personal solicitation. Mr. Farra is now manager of the Grand Rapids Safety Council, and must spend most of his time in that section. However, he is very much interested in the Woodworking and Labor activities.

Right here I want to divert just a moment, from the regular routine of reporting our Executive Committee, and state that it has been my experience that we are paying entirely too much attention to safety in our small plants. Safety does not only deal with men in our own particular plants, and when we asked these people to sell National Safety Council memberships, they said they did not have time—the safety program in their own plant was too large. I often wonder just what caused the safety program in their own particular plant to be so large. I wonder if it isn't the new employee who comes in from another plant, a neighboring plant, which has not put on an attractive safety program, who are not members of our local council, and not members of the National Safety Council. Those men, therefore, in coming into our plants, are not trained in the ways of safety and present our greatest hazard. They are unskilled in our method of working, and even though the plant from which they come has nothing in common with our plant, a man who is drilled in safety will be on the lookout and be a much better employee. Therefore, I say that we have been devoting entirely too much time to our own Safety program. We can sell Safety to our brother and in that way, benefit ourselves. It has worked out in numerous cases.

Mr. O. J. Olsen, Safety Director, Fisher Body Corp., as chairman of the Publicity Committee and *News Letter* Editor, has gotten out for us five first-class *News Letters*. You have all received copies of these, and, when you realize that Mr. Olsen had very little assistance from the 400 and some members of our Section, you will feel, as does your chairman, that the job was well done. It is quite a feat to write a *News Letter* applicable to four hundred members and not have any more come back than he has had.

H. D. Herron of the International Harvester Company, Chicago, Illinois, as chairman of the Poster Committee, has been successful in producing 23 posters for this Section, 12 of which applied to the lumber interests and 11 to the woodworking manufacturing. He was assisted in this work by Major Harry Steere-Clark of the British Columbia Loggers Association.

Chairman of Engineering Committee, G. A. Orth, of the American Car and Foundry Company, New York City, has attended the meetings of the Engineering Society and kept us informed as their activities as well as given us advice in the conduct of this Section. He has made several addresses during the year, one of which was reproduced in the July issue of the *National Safety News*. He also is a member of the Nominating Committee.

Messrs. Sanford, Jackson and Wiberg, members of the Executive Committee of the Section, in addition to the ones just mentioned, have been very active in their work, serving as members of our Nominating Committee, and have given their advice freely as to the conduct and activities of the Section.

Your chairman has, to the best of his ability, carried on the work of the Woodworking and Lumber Manufacturing Section during the past year. As a member of the Executive Committee of the National Safety Council, he attended all but four of their monthly meetings, and passed out to the membership of the Section, the outstanding activities of the parent body.

It has been my pleasure to attend the meetings of the Foremen's Safety School in Grand Rapids, Michigan, and address them, as well as several of the industries in their individual plant safety meetings. Also to represent this section at Newark, New Jersey, and talk before the safety school there on the activities in which we are so much interested.

The program, which will be carried on, following my remarks, has been arranged to the best of our ability. This morning we cover the activities of the woodworking and lumber manufacturing interests and tomorrow has to deal with the re-manufacturing interests. We hope that this program will meet with your approval, but also look forward to any suggestions for its improvement and betterment.

Your officers, which will be elected tomorrow, cannot carry on successfully the work of your Section unless each man lends his support. It has been my experience that we are too attentive to safety in our own individual industry and do not spread the safety gospel outside of our plant. We should talk safety to our fellowmen and endeavor to sell the Safety Council membership to them in an effort to make industrial safety as far-reaching as possible.

Men trained in safety in one plant will be a valuable asset to any other plant in which he may become employed. By spreading the gospel of safety and getting safety installed in our neighboring plant, we will in a way, reduce accidents in our own industry for eventually will not some of the employees of our neighboring plants become employees of ours?

I was, at this time, going to call on the chairman of our Nominating Committee or his slate which he has prepared, but I am going to just delay that until before our Luncheon Meeting. After that slate has been presented by the Chairman of our Nominating Committee, it is not closed. It is open until our election which will be held tomorrow morning, in this room, and any additional nominations can be made from the floor. If there are no additional nominations, this time will

give you an opportunity to become acquainted with those in whose hands it is planned to place the operations of this section next year.

Judge William S. Bennet, who was to talk to us today, has sent his regrets at his inability to be with us. He has, however, sent his paper, which will be read by his safety engineer in the operations—Mr. R. G. Buchanan, of the Edward Hines Yellow Pine Lumber Company, Lumberton, Miss.

Mental versus Mechanical Factors in Accident Prevention in Woodworking and Lumber Manufacturing Industries

By HON. WILLIAM S. BENNETT

General Counsel, Edward Hines Associated Lumber Interests, Chicago

Before results can be obtained from any efforts looking towards the prevention of accidents it is imperative that the management do their part and show the sincerity of their purpose of seeing that safe machinery and tools are supplied; that is, that the machinery is fit for the purpose intended; that it is in proper condition and kept in a proper state of repair and equipped with adequate and sufficient safeguards.

Quite naturally the first thought that presents itself in the matter of "Injury and Accident Prevention" is the danger from unguarded machinery, and the first step generally taken is to see that adequate guards are placed wherever necessary or possible.

When suitable machinery, tools and appliances, equipped with the proper safeguards have been furnished then about all that can be, has been done to overcome the true mechanical hazards. Of course, there are hazards incident to the place and manner and method of work that are the responsibility of the management which strictly speaking, are neither mechanical nor mental, but to a certain extent may said to be both. In making the place of work safe both thought and labor are required. The method or manner of doing the work is a mental process inaugurated by the management and transmitted to the labor; but be a place equipped with the most efficient and the most perfectly safeguarded machinery and all surroundings of the place in which the work is done be made as safe as possible and the method of doing the work be the safest that can be devised, the job is just about begun.

It is my view that in a systematic and intelligent effort to eliminate industrial accidents, or personal injuries, it is essential that the cause of each one should be ascertained, and for several years at our Mississippi operation, we have made careful investigations of each one that has occurred, and the cause or reason for its occurrence and have kept a record thereof.

Our investigation has included not only lost time injuries, but those of the most trivial nature, a scratch, bruise, abrasion no matter how slight, is required to be reported, and we endeavor to ascertain the cause of each one. The cause of a most superficial hurt today might be the cause of a major injury tomorrow; in other words, the same cause can and might produce vastly different effects.

Our record of "Causes" is divided into four general classes: First: those purely accidental; Second, those caused by the fault of the man injured; Third, those caused by a fellow workman; and, Fourth, those which may be said to be caused by some failure or negligence on our own part.

In logging and lumbering operations, there are certain types of injury, hazards of the very nature of the work, which no guard, plan or forethought can avert and which are truly accidents. These are of the first class.

Those due to the negligence or lack of proper care of employees are included in the second and third classes, and the fourth class covers not only those caused

improper guards or failure to guard machinery, but any injury which any act the company could have prevented.

We assume the duty of providing safe machinery, safe ways and safe methods work and for any injury due to our failure to meet these obligations, we think e responsibility is our own.

Our records for a number of years have shown comparatively few injuries are rely accidental. By far the greater number are either rank carelessness or failure think, and very few are caused by defective or unguarded machinery.

Record for Two Years

Total Accidents	1926	Days Lost	Total Accidents	1927	Days Lost
	Lost Time			Lost Time	
1218	688	8890	761	344	4622

Lost Time Accidents Divided Into Classes

	1926	1927
Class A	445	173
Class B	189	137
Class C	43	21
Class D	11	13

This record brings us to the inescapable conclusion that the human equation is it most essential to be considered in accident prevention, and to my mind sup-rts the further conclusion, now I think universally reached by all those who ve given the subject thought, that education of workmen in safe practices and fe thinking is the answer to the Safety Problem—that is to say workmen must taught to protect themselves and their fellows—taught to surround themselves th a safe guard of mentality, and depend upon that rather than upon mechanical ards.

As I have suggested there are dangers that cannot be overcome by mechanical ards—there are latent hazards and those inherent to the nature and place of rk, in the machinery and even in the guard itself. It is almost a truism that machine, nor guard for that matter, can be made "fool proof" nor can I imagine y character of work incident to the Wood working and Lumber Manufacturing lustries in which the careless man is not liable to severe injury, and a constant nance to his fellow employees. The most perfectly designed mechanical guard i itself become an element of danger when improperly placed or when not laced on a machine when it has been removed. We are all familiar with the uries resulting from the operation of various types of saws caused by failure replace a guard which has carelessly been left off.

Several months ago we had a most severe injury occur because a guard on a dder had been left off while the machine was in the shops. The foreman con-ued the use of the machine with the guard off—did not report it and the safety ineer had not discovered it. The result was that in gying the skidder a man rking along side two large gears which should have had the guard over them, ped, caught his hand in the gears, and part of his hand and three fingers were shed off. Here the mechanical guard has been supplied—would have prevented : mutilation of the man if in use, but the true cause of the injury was the lure of the mental factors to work and not the failure or lack of the mechani- device.

Another case that comes to my mind is the loss of a man's leg just below the ae. We use for loading logs on to the cars in the woods a movable machine,

which might be termed a derrick. A pin holding the boom had broken and the boom had fallen to the ground. Several ineffectual efforts had been made to raise it; men were standing all about and around the fallen boom when a fireman stepped up and volunteered a suggestion, went in and fastened a cable about the end of the boom, and signalled the man on the loader to lift. The boom in rising, swung around, struck the front of a man's leg and mashed the leg against a stump. We think the cause of this injury was the failure of the mental factors, and not the failure or breaking of the pin. The pin was between two pulleys, and out of sight; the boom on the ground and its liability to swing when raised was apparent; the men in its possible path and the stump were in plain view, and had a plan of work been mapped out, each man helping assigned to his place and the others of the crew kept out of the arc of danger, the injury would not have occurred; had the safeguards of mentality been in use the man would have been spared the loss of a leg.

Just another case: These log loaders when in operation—indeed at all times—are fastened to rails affixed to the cars on which the loaders stand to hold them stationary. When one car is loaded the machine moves ahead, or back, under its own power, to the next car. It is, of course, necessary to unfasten the stay chains before it should move; to do this a man stands on the ground alongside and out of sight of the operator on the machine. We call this "transferring," that is, transferring the loader from one car to another. At the time referred to the man was unwrapping the chain with one hand and holding on to the rail immediately in front of the loader wheel with the other. The operator assuming the chains were released and without notice started to move the machine; the man's hand being over the top of the rail over which the machine must pass; the result is self-evident. The mental safe-guard was not at work.

Another case: From a different angle: In felling timber for sawlogs men work in pairs in different "drifts" or strips of timber. As sometimes happens a tree from one drift will fall across or into another, frequently falling or crashing into another tree and when this occurs often a limb is broken or left hanging in the standing timber. A pair of sawyers go to fell it without seemingly thought or care as to the broken or hanging limb. The shock of the ax or the vibration of the saws, or perhaps a gust of wind dislodges the limb and a broken head, shoulder or arm results. It seems that ordinary common sense would prompt a man to look up, and see a situation as wide open as this, but sometimes it does not. I have known it to happen in five minutes after the foreman had not only warned them of this very thing, but pointed out the exact danger—and no foreman, nor could a dozen stand over 40 or 50 pairs of sawyers and direct each stroke of the saw or ax in the felling of each particular tree. Foremen can but give general instructions and warn of dangers and beyond that each man must work out his own salvation, and if he be not working with the safe guard of mentality the best mechanical devices merely lessen his danger.

Instances can be multiplied indefinitely where the failure of the mental factor to work was the direct cause of injury despite perfect mechanical safe guards, but the foregoing seem sufficient to illustrate my position. Where the mind of the foreman and the workman are not running in a channel of safety—which is one of the safe thinking—accidents and injuries are going to occur.

Every modern manufacturing plant is planned for efficiency and safety. Every builder of a machine now designs it for efficiency and safety. When a machine leaves the factory, it is now equipped with adequate safeguards. Industry, society and statute law now demand this, but these things are not enough. They will lessen the toll of course. Both man power and machine power are necessary to manufacturing, industry, and the best of each is demanded. "Best" includes efficiency and safety—Intelligence is necessary for both efficiency and safety. The producer can in the market buy the best machinery and material, but he has to

educate the intelligence to use it properly, in the supply of labor that is available.

The inefficient and careless man is a menace to himself and his fellows, far greater than is an unguarded machine. In the machine the danger is visible, but that the particular hazard may be from carelessness is unknown and cannot be anticipated, and it can only be guarded against by changing the man himself, converting him from a liability to an asset of the organization. Accidents will, of course, always occur, but preventable injuries will not in an organization of men trained in safe practices and safe thinking.

On the other hand, some people believe that if you put on an intensive safety campaign without guarding your machinery to a practical standpoint, that is enough to reduce accidents, but I have found that both safeguards and education are necessary. It has been proven that a plant mechanically safeguarded in strict accordance with the Underwriters standard, still has accidents and it has also been proven that plants with non-mechanical, or safety education, work alone still have accidents, so neither is wholly effective without the other. For example, I have been told of one plant that spent very close to fifty thousand dollars putting in mechanical safe-guards on saws and belt; taking out open set screws and replacing them with set-in set screws and every other form and make of safety device that anyone told the superintendent of the plant would reduce accidents. After he got all that work done, he sat back and said "Well, our accidents are going to decrease now," but one week after he had all this work done but had done no safety education work to provide mental safe-guarding, he had the loss of three hands and several other men laid up with serious injuries caused by not knowing how to effectively operate these mechanical safety devices. Why? Because this superintendent sold himself on the idea that mechanical safeguards were all that were needed and that no safety education was needed among the men, as he had, or thought he had, intelligent men working for him.

It is very easy for you, as safety men, to understand what should have been done—after the guarding was complete. The big job is to convince such people as his superintendent that you must have both mental and mechanical guards. I am not a fanatic on non-mechanical guarding alone, nor am I a fanatic on mechanical guarding, but I have seen the effects of both and am convinced that both are necessary. I do not believe that any plant, regardless of how small or how large it may be, or the number of men employed, can successfully cope with the Safety problem if they do not use both methods. I have yet to see saw guards that can be put on a saw and stop entirely all accidents or stop a man from getting his hand caught in it if he has not some safety knowledge to work with that saw guard. Around a sawmill I believe that large drive belts that will fly if they break, open sprockets, wheels, open gears, frictions, horizontal or vertically inclined belts, walkways or passageways, should be guarded fully. As to saws, I believe that the guard that will work to a practical standpoint with the work or job that this saw has to cut is the best guard for that saw, but I repeat that this saw guard is of little use if the man operating it has not some safety education to go with this guard.

Let me cite to you what both mechanical and non-mechanical or safety education combined have done for our company in its Southern mills. Up to June, 1926, we did not go in for an intensive safety work and we had no safety engineer. We guarded our machinery as best we knew how and preached safety as best we could, in without systematic direction. Our safety engineer spent his first six months in our southern mills getting acquainted and learning how lumber was manufactured. Beginning January 1, 1927, our safety engineer went into an intensive safety education or non-mechanical program. No additional mechanical guards have been added on our machines or around other places since that date, but an intensive safety campaign has been carried on—by personal touch with the foremen and the workmen themselves; use of moving pictures; starting a publication of a house

organ, that is distributed monthly to every employee; the foremen's meetings and most of all, the personal touch with the workmen themselves. We have also in our plant what is known as the "One Year Club" among the foremen, which entitles any foreman who has gone a year in his department without a lost time accident, to automatically become a member of this club and receive a gold watch fob stating that he is such, with his name engraved on the back of it at the end of his year. Also in our mills there is a thermometer that keeps the men informed as to how many accidents the mill has had and it is a daily sight to see men gather around this thermometer counting the number we have had and talking among themselves as to the reduction that has been made.

These figures that I am going to quote are for the two sawmills only. These mills are two-band sawmills, one works night and day, working about 750 men, and the other works days only, working about 400 men. For the year 1926 we had a total of 1036 injuries, out of which 388 were lost time. In 1927, we had 447 total injuries, out of which 145 were lost time, or a decrease of 56.85 per cent in total accidents and a 62.63 per cent decrease in lost time accidents. And for the first six months of 1928, we had a total of 164 accidents, out of which 103 were lost time, which shows that in 1928 we will show a still further decrease in our year's total.

May I add this, that no two locations can carry on exactly the same safety educational methods. The man who has charge of the safety work must use his brain in studying the men and understanding them to know what they will absorb and how much of it they will absorb.

CHAIRMAN GRIER: Are there any questions on this paper as presented by Mr. Buchanan for Mr. Bennet, of the Edward Hines interests?

O. B. FREDERICK (Safety Supervisor, Dierks Lumber & Coal Co., Dequeen, Arkansas): May I ask Mr. Buchanan why the loaders are chained to the rail?

MR. BUCHANAN: They have 30-foot booms on them and they reach out and turn completely around and pick up the logs. In order to hold that, you have got to chain them.

MR. FREDERICK: Your loaders, then, are of a lighter type than the ones we use.

MR. BUCHANAN: They are the heaviest American loaders they make.

MR. FREDERICK: It isn't necessary for us to chain them to the rail. We have the heavy American loaders.

MR. BUCHANAN: I may be wrong about that, but it has been done since I have been there.

W. L. WALLACE (General Attorney, Hines Associated Lumber Mfrs., Lumberton, Miss.): Our operations are over a very rough territory. It may be at an angle, this way or that way, and it would be an impossibility to maintain it in a state of equilibrium if it were not chained.

CHAIRMAN GRIER: Are there any other questions on this paper?

Let's get the good out of it. If you have any questions, bring them up, and Mr. Wallace will discuss the paper for us. Mr. Wallace, probably you have a few remarks to make on the paper that would be enlightening, without questions.

MR. WALLACE: I don't know that I could add very much to what has been said. I am somewhat of a fanatic on the question of mental safeguards rather than mechanical. I had hoped I might get the benefit of somebody else's ideas as to the advantages of the mental safeguards. I had an experience this summer that made a very great impression on my mind. I was in the mountains of Tennessee, where, in certain places, there is a 45 per cent grade on the roads. I was there for about four or five weeks, and not during that time was there a single automobile accident on any one of those mountain roads. I live in country that is

most as level as this floor. I can hardly walk across the street without hearing crash of a car. My 16-year-old boy was driving a heavy car on those untain roads as safely as we walk around this room. The point is that people lize and appreciate the conditions, and so are careful. I have always tried bring such influences as I could to get the man into a safe frame of mind. other words, to get them to think safety. I would have been glad, instead of ing something to say, to listen to somebody else on that subject.

ROBERT TOMS (DuPont Co., Portland, Maine): In that report of the accidents, understood that one of the firemen made a suggestion regarding booms. Was part of his work to look after that?

MR. WALLACE: No sir.

MR. TOMS: Was he the man injured, or was it some other man?

MR. WALLACE: Another man.

MR. TOMS: That is the point I brought out: That it seems to me it was lack supervision on the part of the handling of the crew, to allow a man who was xperienced to take part in work which he wasn't supposed to do, and allow 1 to make suggestions and follow them, is unsafe practice, whereas, if the man o was accustomed to handling this job and was cognizant of the risks and of danger of that boom swinging, he probably would have seen that his men re out of danger before the boom was attempted to be lifted.

That, I think, is the mental hazard which has been stressed in this paper, and ink it is very pointed, that frequently these accidents come from men attempt- to do things which they are not assigned to and for which they are not fitted, l do not know the risks.

n our business we try to have every man handle his own job and not let ebody come in and run it for him, because he is trained for the special risks the job at which he is working. He recognizes it, he knows there is a safe y of doing it, and he is instructed and trained to do it in the safe way.

GLAZIER (Manager Safety Dept., Dierks Lumber & Coal Co., Kansas City,) : In the wood operations, the point was raised about mechanical guards. ur operations, we find it practically impossible to provide any mechanical rds against the most prevalent accidents which are those which occur from handling of axe and saw. We have often wondered if it would be possible provide a guard when a man is carrying a saw from job to job, or when he carrying his axe over his shoulder, but it would be practically not feasible put a guard on that saw or axe to keep him from getting cut. We have had n carry cross-cut saws on their shoulders, and some were foolish enough to the teeth towards their neck—then they stumble and fall and the teeth cut shoulder or neck.

ome time ago we thought we would investigate to see if it would be possible put a guard on that saw while it was being carried. I wondered if the Edward nes Lumber Company had ever thought of that, and if they had ever gone o it?

CHAIRMAN GRIER: Before calling on Mr. Wallace, I will answer your question m my own viewpoint which is not logging. We do handle cross-cut saws in plant, cutting finished lumber. When I say "finished lumber" I mean logs t have been sawed to the square, probably 12 x 14, 40 feet long, in-constructing ges or work of that kind. We have provided our men with a stick of wood an h and a half wide and about an inch thick, which has been grooved in a sticker. ey set the saw teeth into this groove and either carry it without any retaining e or string, or they can tie it with a string and hold it in place. That is re- red when we are carrying our saws from one operation to another.

Mr. Wallace, do you have anything on that?

MR. WALLACE: We have had the same proposition that Mr. Glazer has. Most

of the sawing injuries, however, in our operations, occur while the men are actually engaged in cutting. They catch the saw in something, or they fall.

We have thought of the same problem and we think it would be impractical to use any guard at all while the men are actually engaged in the work. In the course of five years I remember only one injury to a man from carrying a saw when he was not actually engaged in the work.

R. G. BUCHANAN (Safety Engineer, Edward Hines Lumber Company, Lumberton, Miss.): Some time ago, down at the Southern Lumber Association, I had occasion to have a talk with a Simon Saw man. I went around to their local distribution house, and saw a strip of wood that had a groove in it, just the curve of the saw. There was a little strip of metal that clamped on the other side, around the saw. I asked our purchasing agent to insist that each one be equipped, when we bought saws in the future.

The problem I now have to contend with is getting the men when they are carrying these saws, to put these guards on, in going to and from the labor train. We have a labor train four cars long and it has a baggage car on it.

Our bridge foreman who is a very active safety man, told me some time ago of a man who had occasion to leave the logging camp. He had a bridge to work on that the labor train had to go over. He went out and got an automobile truck and loaded the men into it. In loading the saws, one man cut his leg. He told me that he stopped right there and made that man show him five different ways that he could have loaded that saw so that he wouldn't have hurt himself, and he only found one way that he could cut himself. He said, "I made an illustration of it right then, before my whole crew—showing them how to handle the cross-cut saw."

H. R. ORCHARD (Superintendent, Marathon Lumber Co., Laurel, Miss.): We are very much interested in saw accidents. We have had more saw gang accidents this year than we have ever had, and we have about reached the conclusion that it is a matter of discipline. One of the troubles with saw gangs is that the men like to go out there in the morning on the work train the same time as the regular crew, but they find ways and means to get back into camp ahead of the other men.

A good saw gang in the timber that we are cutting now would probably cut up 70 to 80 trees—maybe more. They like to go out there and do their work in a hurry, get through about two or three o'clock in the afternoon and get back into camp ahead of the rest of them. It is the personal element in the saw gang accident—the haste to get through. Most of our accidents, as Mr. Wallace said, do not come from carrying the saw or the axe, but through carelessness. They throw the axe, something deflects it and they cut their legs. The saw accidents mostly come from cutting through, frequently after the tree is down—they just pull right on through and cut themselves on the knee or leg.

We had a safety meeting at our camp about a month ago. We had 18 reportable accidents in our saw gang in July, and when the figures went on our manager's desk, he got worried about it and said, "I am going up there to talk to those boys personally." We have a saw gang foreman who is much above the average. He wanted to know what we do after we hire a good sawyer, to prevent him from continuing to cut through the tree until he cuts himself. The only thing we could say was, "Educate them; keep after them." In order to put over safety in those cases—if you can't do it by kindness and reasoning and education, the only thing I know to do is to take the man off the pay roll or put him somewhere else. We let one saw crew go, after a good deal of talk and thought about it, but we intend to reinstate them a little later if they apply for work. This crew had seven reports in 60 days, four on one man and three on the other, and we just got afraid of them.

The saw gang accident is a management problem. You have to put backbone

> your foreman and then he has got to stand pat, in order to eliminate a at number of them.

L. LOCK (American Mutual Insurance Company): About 15 years ago, I working in the lumber woods in British Columbia, surveying. I noticed re that all those men carrying their saws out from camp into the woods, had m strapped onto a board. This board was about six feet long and about width of the saw. I asked the manager why his men carried their saws that way, and he said that it was to stop accidents. While we were iding there, a man came along without the board on his saw and the manager ed him where it was. He said he forgot it. Well, the man was sent back r it. The manager told me that they had reduced their accidents from carry-saws almost to a minimum. That was quite a while before we thought much ut safety—and it was just through supervision.

TOMS (DuPont Co., Portland, Maine): Speaking of another class of saws—band saws in band mills—I operated a band mill for four years in conjunction my other work, and when I took the management of this mill I had absolutely experience in operating a mill, but I did realize those heavy band saws were element of danger. I watched the men handling them, taking them off and ing them on, which we had to do quite frequently; and I noticed they were g unsafe practice. I made a study of it and I decided that there was a safe to handle the saws without a mechanical guard. I attempted mechanical rds but found they were not practical. They hindered the work and really e an element of danger, because they taught the man to believe that with this rd, the saw was harmless.

he idea that I wanted to get into their heads was this: That a saw is always gerous; it is a very sharp instrument and has a great many teeth. It is apt lip and cause a very jagged wound and quite frequently carries infection in eeth. That was the thought that I instilled into the minds of these men. One he things they would do in taking the band saws off for changing was to turn teeth out, invariably, so that everybody walking back and forth would run risk of cutting himself on those teeth. I told them to turn the saws around hat the tooth side was toward the wall, otherwise there was the risk that a might trip and fall, and strike the teeth of the saw.

he result was that they used safe practice in handling those saws in taking off and on the machines, for four years, without a single lost-time accident. lieve you have to train the men first and instill in them the idea that it is gerous, that they must handle the saws in a safe way and always "think ty" and in that way, you will avoid nearly all the avoidable accidents.

CHAIRMAN GRIER: In handling band saws, we have always found the board safe and the easiest way to handle them.

B. FREDERICK (Safety Supervisor, Dierks Lumber & Coal Co., Dequeen, Arkansas): I would like to ask if you are ever troubled with wedging accidents wood—the making of wedges by the men while they are on the job.

R. ORCHARD: Yes, I think we have had two instances this year where a man red himself by making a wedge. As I say, it is a matter of supervision. ardless of what you say about accidents, the idea gets through an organiza-sometimes that if it doesn't cost you anything there is no harm in it. We t subscribe to that theory at all in our management. We handle our claims in tle different manner. A lot of our foremen get the idea that an axe injury saw injury wouldn't cost anything, because that is the only thing we can use fissippi without being liable. An axe or a saw is still a simple tool in fissippi. So they get careless in those things. We consider it in just the class as the actual cutting in working on the tree, because it is due to the idual carelessness of the man. The tools these men use, they purchase them-s. They are on piecework. They buy the tools from the company, although

they can buy them anywhere they want to. The condition of the tool does not really enter into it. We keep a filer there for them, and keep their saws sharp.

CHAIRMAN GRIER: The next paper will be presented by Mr. F. W. Braum, manager of the safety engineering department, Employers Mutual Liability Insurance Co., Wausau, Wisconsin.

Snags in the Safety Stream

By F. W. BRAUN

Manager, Safety Engineering Department, Employers Mutual Liability Insurance Company, Wausau, Wis.

When I was asked to go on this program, I requested Mr. Bissell to change the title, and he said, "No, you won't have a chance." I wanted the title to read, "From Stump to Car," but he said you can go right ahead with that idea.

I am not a logger, as I told Mr. Bissell, and I want to tell you, but we have had considerable experience with loggers and their methods. Every establishment that uses lumber as a raw product should be interested in the manufacture of that product. The steel mills of Pennsylvania and Indiana are vitally interested in the safety of mining of iron ore in Minnesota and Michigan. You furniture men from Grand Rapids, Michigan, buy your lumber (a good share of it) in Northern Michigan and Northern Wisconsin, and should be interested in the safety of the mills from which you buy that lumber. Incidentally, you ought to interest those mills and loggers in this section of the National Safety Council. There should be more loggers represented here. You have made a good start in putting it into this section, but you ought to continue.

Logging presents so many different hazards that it is difficult to portray them all. The main factor and the first danger point in logging is the lumberjack himself. Nothing is so important in industry as personnel. Good, sound, healthy lumberjacks are the biggest asset in the logging industry. You should conserve that manpower. Everybody loses when timber burns and everybody loses when a lumberjack is injured. If they were to desert us, all the woodworking industries would have to shut down their plants.

Another hazard is terrain—the logging territory. If it is hilly, it is doubly difficult. In Northern Wisconsin, where I live, the logger has the road problem—ice roads. Much has been said about ice roads, as to the safe material to put on ice roads on hills. Some use sand, and sand is all right if the hill is very steep, but if it is long and gradual, sand is not so good, because the runners get hot and then when you get out on ice again—you know what happens. A good many loggers now use hay. Don't pile the hay down in big piles, but a gradual sprinkling of hay. Some use fertilizer, but that has its drawbacks on account of eating up the ice.

The weather in our section has a lot to do with the logging hazard. The small logging contractor who is contracting to deliver a certain amount of logs to a sawmill, gets about three-quarters done when the weather breaks. About the middle of February, it suddenly gets warm for a few days, and he rushes his work, hires anything and anybody as a lumberjack, to help him out, and then you have the lumberjack hazard.

Where do they happen? Nothing is so convincing as a fact. I am going to give you just a few statistics:

In 1925, we had reported to us 425 axe accidents, and axes take first place every year in logging. In 1924, 251; in 1923, 245. The second and the most serious cause is trees in felling. Then slipping, being struck by objects, and spring poles are the cause of many broken teeth.

I cite these figures because every lumberman ought to know where they are happening. You cannot begin to do anything in accident prevention unless you know where they are happening. If you expect to get anywhere, you have to start from where you are.

I am going to give you briefly some of the methods that some of the lumbermen in Wisconsin use to prevent these accidents.

The first and most important thing is management or executive backing. The management must be sincere, because nobody is so superstitious as a lumberjack. If he is led to believe one thing, and the management does not back it up, he will never lose faith in that particular management.

The woods foreman and the logging superintendent are the management. You can't find the executive or the president of a logging concern very intimately acquainted or in daily contact with his lumberjacks, and the lumberjack looks to the woods superintendent and the foreman on his particular job as the management, and they must be sincere in their purpose.

There are two kinds of leadership that these foremen or woods superintendents must exercise. One kind of leadership is that which the men follow willingly; the other is the driver. Cooperation can not be demanded nor commanded. It must be won. The hardboiled woods foreman, with a jaw like a snowplow, with sand in his bladder, can never command the respect of a lumberjack. Much has been said about these jacks in novels and in movies, but they are human just like you and I.

The woods foreman should place his men. Do not put a club-footed fellow at sawing. You have to have fast, snappy men as sawyers. Do not put a lumberjack to work with an axe who is bothered with rheumatism. Do not take the lumberjack's word as final. If he hires out to you and you ask, "Have you had experience in the woods?"

Sure!"

What have you been doing?"

I do anything."

All right, I need a sawyer."

A lumberman told me just last week that they do not have drivers in the woods any more—they just have boys holding the reins. Whose fault is that? It is the fault of the management, the woods foreman. Show him how to drive if you are a woods foreman. Tell him what is expected of him.

That holds true with a new man. You might say, "We don't get new men in the woods." Oh, yes you do! The city employment agencies are sending men into the woods in Northern Wisconsin and Michigan, out of the Twin Cities, from now until spring, every single day, and some of these fellows have never handled an axe before. A lumberman told me not long ago that he hired two men as expert sawyers. He sent them in to cut, and this is what happened: They were cutting a large birch that was leaning. They started to cut without notching the tree. Soon the saw pinched, they started on the other side. What happened? The tree split to the top. A beautiful birch that took nature years and years to produce, was spoiled by the hand of man in two or three minutes. That tree is probably rotting there today, because a woods foreman hired these men as sawyers and never investigated whether or not they could saw.

The new man should be instructed as to how and what he should do, and it should be put to him in such a way that he knows if he is not doing it that way, he is expected to leave. If you had every logger sold on that idea, the lumberjack would not wander from camp to camp because of the privileges that he has in one place and not in another.

Every logger would be educated to the fact that there is only one way to it, that is the safe way, and every camp followed that plan, you would reduce the accidents.

Safety education, safety bulletins, safety talks to the men are prime factors in reducing woods accidents.

I have some pictures that we had taken, showing the right and wrong way on several woods operations. We get out safety bulletins to our logging interests, highly-colored like that, because a lumberjack likes pictures.

This is the correct way to carry an axe. You do not need to put on all kinds of explanations, but show a lumberjack that picture and he will understand it. Here are two fine illustrations—stumble either way and you will cut your head—you will cut it plenty. You will see men carry it this way and that way and they will slip and fall, whether you have snow or not.

Here is a fellow ready to cut. He has plenty of brush in which his axe can get caught, and anything might happen then. The proper way is to clear that brush and then chop the tree. The right and wrong way of doing that operation.

Here is a swamper and his helper standing too close. If the axe should slip as shown on the lower picture, something must give, and it is always human flesh that does.

Here is a picture of a spring pole—it is a small one, but remember that we had to get out and make these and we used the small ones, but you have larger ones than that. Look at this operation to the left. Lots of men do it that way. What is the result? The axe doesn't clear the cut, the tree snaps, and then you have an accident.

Here is an operation—(one of these boys that holds the lines) standing between the team and the log instead of in back of the log as it should be properly hooked.

Here is an operation with the tongs and the lines and everything tangled up—his feet too—the horses start and away he goes. It should be done in this manner. Safe position at the end of the log and you can do better work. Never get ahead of your log when tailing down.

Here is an operation that is right and wrong, either picture, depending entirely on the circumstances. A good many loggers will disagree with this picture where the man rides the roll. Some say he should stand on top. In this picture, the safest thing to do is to stand on top, because it is a small load, but where you have four or five thousand feet on a load like that, the fellow is way up here, and your wrapper must be safe. If it becomes unhooked, he has to be an A-No. 1 log roller to get out of all that mess.

Down here the road is rough, he is half asleep, he falls, and the team keeps right on going.

I have any number of these sets. I am sorry I did not bring them along, but I would be glad to mail the Safety Bulletins and these pictures to anyone who is interested.

I want to talk briefly on the sawmill hazard. The sawmill, with its high speed-belts, pulleys and machinery, is a difficult problem to guard practically. Some men have recommended, having gone into a transmission room basement in the sawmill and counted the belts, that all the belts and pulleys, shafting and everything be guarded. That is not practical. You might just as well nail the doors to the transmission basement from the first floor to the basement, and call it guarded. But, you can do this: You can guard every single gear. There is absolutely no excuse under the sun for an open gear at any location. I remember an incident in which I was talking to a sawmill foreman and I recommended that a gear be guarded. It was 9 feet from the floor, above the platform on which stood the hog. The sawmill foreman said, "Nobody ever goes there, except the oiler." That is the trouble. If he is a good oiler, why not protect him? Three days later that oiler was in a hurry. He threw up a ladder against the hog platform and instead of going around, he reached through a sprocket to oil the cup, standing on a little 2-inch board. He slipped and left his left arm hanging in the sprocket. Then they guarded that sprocket—they enclosed it. Now that man is doing oiling,

and that is all he ever will do—that is all he ever can do, and “nobody ever goes there.”

Live roll gears in a sawmill represent a hazard and have taken fingers and toes. We had a young fellow do the Charleston in one of the sawmills, kick his foot underneath the live roll gears, and it took his toes off. The foreman was watching him do the Charleston. A fine foreman! Was he sincere in his safety work? He is foreman no longer in that particular building.

Live roll gears can not be completely enclosed on account of the fire hazard. You can not begin to box these things up so that all the sawdust and dirt accumulates—that causes friction and then a fire. But you can do this: You can put a board over the top, a board far enough down on the sides, and then put one on an angle this way, so that your gear is up here—all the sawdust and dirt and everything can fall down, and a man would have to deliberately get in there—he cannot get in there accidentally.

There isn't a guard made that guards a hazard in a sawmill 100 per cent. If he wants to get in there, he can get in.

Saws should be sharp to be safe. A dull saw is a bad hazard. They should be gummed and hooked, sharpened and changed regularly. A sharp saw sings and a dull saw grunts. Your sawmill foreman should see to it that they are changed. Keep your filer busy. He hasn't enough to do as it is. Make it the duty of your filer to get out in the sawmill and look these saws over. That is a good safety measure, and a lot of sawmills in Wisconsin are doing that now—making him responsible for the saws.

The layout of sawmills should be considered in the safety of a sawmill. Frequently a one-band mill changes to a two-band mill, and then you have a conglomeration of machinery which they try to put into a small space, and you have a hazard.

Maintaining interest should not be a difficult problem in the woods or in the sawmills, if the management provides that interest. If they are sincere in their purpose, the battle is won. If the management would exert as much effort and zeal in accident-prevention as they do in production, the accident problem would be solved.

CHAIRMAN GRIER: Have we any questions on Mr. Braun's paper? Is there any discussion?

I think Mr. Braun handled the subject in a masterly way, and I feel that he can answer some questions along that line.

L. GLAZER (Manager Safety Dept., Dierks Lumber & Coal Co., Kansas City, Mo.): Just about two weeks ago, we had one of these gears that we didn't think needed to be guarded, down in the basement of one of our sawmills, pulling a mule chain. This gear, I suppose, was about three or four feet in diameter. It was open underneath so that the oiler could put his grease in there, using a wooden paddle, and while he was carrying on his work, his paddle got hung up. He tried to get it out and the gear, slowly moving, pulled his hand up against the timber. He lost four fingers of that hand. While trying to disengage his hand, he reached in with the other hand and lost a finger of that hand. We thought that it was impossible for a man to get his hand in that gear. The oiler claimed that his foot slipped. We didn't see how his foot could slip at that particular place. There was no slipping hazard there as far as we could see, but it just illustrates the point brought out by Mr. Braun that no gear should be left unguarded. It doesn't make any difference whether or not there appears to be a hazard there, a gear is a dangerous instrument and should be guarded in every possible way.

That accident is going to cost us about \$2,500, under the provisions of the Oklahoma Compensation Law. It need not have occurred at all if we had had that idea in our minds that every gear should be guarded, regardless of whether or not there appears to be a hazard.

ROBERT TOMS (DuPont Company, Portland, Maine): Might I ask Mr. Braun a question? In regard to guarding, I don't think that he meant us to infer that he didn't believe in guards around the belt, but I would like to ask if this is safe practice—to fence off or board off dangerous sections where nobody goes—absolutely nobody, not even the oiler—parts of the machinery that are oiled when the machinery is shut down and to guard all moving shafts or moving pulleys or belts that are adjacent to passageways where men have to pass to and from. Would you agree that that would be safe practice?

MR. BRAUN: Yes. I am glad you brought that up.

Passageways should be guarded. The shafting should be guarded on the top and sides and the sides to extend well below the shaft, and the belts and pulleys in those passageways should be protected so that anybody stumbling or slipping can not fall into them.

R. C. BARR (Manager of Safety Instruction, Lumbermen's Mutual Casualty Co., Chicago, Ill.): I don't know whether Mr. Braun intended to cover live rolled shafting in that statement or not. It is my impression that a good deal of attention should be given to the guarding of live roll shafting, even though it is smooth in character. We have had two serious injuries during the past year, one resulting in death, and the other resulting in the loss of a man's right arm, including the shoulder blade that was pulled entirely separate from the body. The man whose arm and shoulder blade was removed is still in fair shape and working again.

Another thing that we can give consideration to is long distance oiling. There are some sections of the sawmills where it is difficult to get in and get the oil to the proper bearing. We have worked out, in several instances, tubes leading to the oil cuts or oil bearings where the oiler does not come in contact with the hazard. He introduces the oil at the end of the pipe and oil runs through the bearing, and they tell me that they are able to keep track of the bearing without feeling it to see if it is hot.

O. B. FREDERICK (Safety Supervisor, Dierks Lumber & Coal Co., Duquoin, Arkansas): We have had in our plant, a number of accidents due to the carriage slipping down while the men were working, and I am glad to say that it has been overcome. We have a sawyer at one of our plants who has designed a carriage hook. I understand that he has it patented now. However, anyone can fix one up himself by using a chain, if necessary, to hook the carriage back because the steam, more or less, especially when your valves begin to get old and worn, will leak into the drum. This man who designed this guard last year was awarded, I think, \$100 by the Southern Pine Association for the best device to eliminate waste, and he also received \$50 from the National Lumbermen's Association. I think that it is very, very good and the carriage is locked at the proper end and there is no danger of the carriage slipping down on the man while they are making the necessary repairs and changing saws. A chain or a hook and eye can be fixed there. At one of our plants, we have a large hook and eye, similar to a screen door hook.

MR. BRAUN: I failed to mention one thing that might be of interest to the logger and the sawmill operator, and that is the proposition of camping. Wisconsin is noted as the playground of the Middle West, and thousands of campers camp in these forests. They put up improvised washlines, by pounding nails into trees, taking the rope off and leaving the nail in the tree. Fifty years from now, they will log that section of timber, cut down that tree and find that the bark has grown over and around that nail. The saw will hit that spike and you men all know what will happen. Allow no campers in your timber.

CHAIRMAN GRIER: We have a few moments yet for general discussion of the papers presented this morning, or for any other questions that you might care to bring up.

I will now open the meeting to discussion and questions. If you have a question on your card, kindly hold the card up and we will get it.

W. S. CLARK (American Mutual Liability Co., Boston, Mass.): There was one point in Mr. Braun's talk that I wanted to ask a question on. Just what bearing does good light or inefficient lighting have in the transmission basement, and further, what bearing would self-oiling bearings have in preventing hazards of that type?

MR. BRAUN: There are so many things I can take up in a sawmill, that it is good that you bring these things out in the discussion. It has been my experience that sawmill basements are not very well lighted, and they should be well lighted; any establishment should be well lighted. The self-oiling bearing, of course, is a time-saver, and if it is placed properly, so that the oiler doesn't have to creep around a lot of stuff to get to it, it is certainly a good thing to install.

G. A. ORTH (Chief of Safety Dept., American Car & Foundry Co., New York City): Reference was made by one of the speakers in connection with an accident on smooth rolls. I am not familiar with the logging business, but we have on rollers in our rolling mills, an electrical shutoff, so that if any of the operators of this roll should get their hands in the rolls, they have a rod that they throw over and automatically shuts off the power. I wonder if that could not be applied to these smooth rolls that were spoken of a moment ago?

R. C. BARR (Manager of Safety Instruction, Lumbermen's Mutual Casualty Co., Chicago, Ill.): The accident that I referred to was on the live roll shaft and not on the rolls.

CHAIRMAN GRIER: On the straight line of shafting?

MR. BARR: Yes.

CHAIRMAN GRIER: Mr. Braun, I believe, referred to the live rolls.

MR. BRAUN: The live rolls are not rolls as they are machined, they are rolls that take the lumber from the band saw and convey it down through the mill to the different operations.

CHAIRMAN GRIER: A conveyor is what you have in mind.

MR. BRAUN: It is a small roller conveyor, driven by a small gear. As to the point brought up by this gentleman on the shafting, it would of course be taken into consideration at the top and sides and the board at the bottom. If that were placed, it would take care of that hazard.

R. G. BUCHANAN (Safety Engineer, Edward Hines Lumber Co., Lumberton, Miss.): In our lumber, we have got to keep pine lumber from bluing when it is put on the yard. It is run through a solution of caustic soda before it is stacked in the yard for air drying. This caustic soda eats the hands of our men who handle this lumber. I want to know if anybody ever heard of any solution to keep that from ruining his hands—an oil of some kind or a glove or something that these men can put on to keep their hands from getting sore and so that the caustic soda will not eat into their hands?

H. R. ORCHARD (Superintendent, Marathon Lumber Co., Laurel, Miss.): I would answer Mr. Buchanan's question in this way: A good many of the mills are dipping their lumber in a solution which does not affect the men's hands. We dip our lumber; about 60 per cent of our cut, which makes it somewhere around 78,000 feet a day, goes through a solution, and we believe that it is as effective as any solution on the market.

CHAIRMAN GRIER: Do you know just what that solution is?

MR. ORCHARD: We buy bicarbonate of soda. We have tried other preparations which I would not care to name, but we did not find that they were any more efficient or any more economical than straight bicarbonate of soda. I may get in bad on this, but I think we carry this at a temperature of 120 degrees—about 4½ per cent.

ADJOURNMENT

October 2, 1928

Luncheon Session

JOHN B. GRIER, Chairman

**Employment and Safety Manager, American Car & Foundry Company
Wilmington, Dela.**

The second luncheon session of the Woodworking and Lumber Manufacturing Section was called to order at twelve-thirty o'clock, Mr. J. B. Grier presiding.

CHAIRMAN GRIER: Gentlemen: We have concluded our work this morning, and as I promised, we will have a report now from our Nominating Committee, who will name the officers they have selected as logical men to lead this section during the next year.

This Nominating Committee is appointed early in the year to look over the prospects, select those men who they think will be able to handle the work of the section, and to secure from those men, their acceptance or promise that they will serve, provided they are elected. This committee is not appointed with the idea of railroading through a slate. It is appointed so that we will have active officers and men who will devote time to the work of this section, and it does take time to carry on the work of this Woodworking and Lumber Manufacturing Section.

Mr. G. A. Orth, a member of the Nominating Committee, will make the report, in the absence of the Chairman, Mr. Jackson.

Report of the Nominating Committee

G. A. ORTH (Chief of Safety Department, American Car & Foundry Company, New York City): The Nominating Committee reports as follows:

Chairman, J. M. Bissell, General Manager, Marathon Lumber Co.

Vice-Chairman (Manufacturing), M. C. Goodspeed, Safety Engineer, General Electric Co.

Vice-Chairman (Logging), Hon. William L. Wallace, Attorney, Edward Hines Lumber Co.

Vice-Chairman (Sawmills), H. R. Orchard, Mill Superintendent Marathon Lumber Co.

Secretary, O. J. Olsen, Safety Director, Fisher Body Corp.

Chairman, Program Committee, J. B. Grier, Safety Engineer, American Car & Foundry Co.

Chairman, Membership Committee, I. W. Rowell, Wisconsin Land and Lumber Co.

Chairman, Publicity Committee & *News Letter* Editor, A. O. Jackson, Supervising Engineer, Aetna Life Insurance Co.

Chairman, Statistics Committee, H. J. Kelley, American Seating Co.

Chairman, Poster Committee, F. W. Braun, Mgr. Safety Engineer Dept., Employers Mut. Liab. Ins. Co.

Chairman, Engineering Committee, G. A. Orth, Chief of Safety Dept., American Car & Foundry Co.

Executive Committee, E. Ross Farra, Mgr., Grand Rapids Safety Council, Grand Rapids, Michigan; G. E. Sanford, Chief Safety Engineer, General Electric Co.; and H. G. Wiberg, Lumbermen's Mutual Casualty Co.

CHAIRMAN GRIER: The election of officers will be held immediately following the reading of our first paper tomorrow morning, in this room. If there are any nominations, suggestions, or corrections, we will be glad to have them at that time. If you find it convenient, I would say, make yourselves acquainted with these men and you will concur with the Nominating Committee.

At this time, and to start some little discussion such as we had yesterday, I will call upon Mr. Barr.

R. C. BARR (Lumbermen's Mutual Casualty Company, of Chicago, Illinois): I don't know what the members here want to hear about, but perhaps some of the experiences of an insurance inspector will interest them.

Our company deals with a great number of small risks, and in dealing with small risks, it is probably different from the average man's connection who attends these meetings. But I think the purpose of the National Safety Council is to cut down accident frequencies in woodworking trades, and you have got to consider the experience of the small risks in measuring the results of the work of the Council, because the good work that you build up can be torn down considerably by the bad experience of the smaller risks.

I think the insurance men present will agree with me that the insurance companies are not after the smaller risks. We carry a good number of them because of the necessity in insurance work. They must have the insurance and somebody must carry it. But, the small risk is a hard one to reach from the standpoint of safety because of their isolation from the business districts, and they are hard places to work on in the matter of safety, because it is a slow process of building up education.

I might submit one experience we had down in a little town in Alabama two or three years ago. I stopped at a small sawmill and they had a boiler in operation—no roof over it—out in the open, and I noticed there was no water gauge glass on the boiler. I made a remark about it, and the superintendent of operations said, "No, our water is too muddy here, it covers up the glass, so we can't tell where the water level is anyway, so we took it off." I said, "How do you tell where your water level is," and he said, "We open up the bottom pet cock and we know we have enough." On the same boiler, I noticed they had an old-fashioned safety valve with a lever on it, in addition to the regular weight, they had a couple of castings from a well-known automobile engine and I asked him the reason for the additional weight. He said that steam kept coming out of it and they had to keep the steam in the boiler, so they put on the additional weight.

To cite another case in the state of Georgia, where our company had experienced a great number of accidents and they sent me down to find out why. I spent about an hour and a half in the plant, talking to the various foremen, and while I was there, I noticed a great number of cabinet-makers coming out from the cabinet department and operating the saws, the joiners, stickers, in the woodworking section. I noticed they had a full complement of machine men and wondered why the cabinet-makers thought it necessary to conduct those machine operations themselves. Naturally, the person to go to would be the foreman of the machine section.

He said, "I can't stop those fellows from coming out here. They just come out and take possession of the machine and shove my men aside." When I went back

to the office the superintendent of the operations asked me if I had any recommendations to make and I said, "Yes, one." He said, "That is rather unusual for an insurance man to make one recommendation." I said, "The only recommendation I can make is that you give some attention to the supervisory force in your mechanical department." He said, "We have a foreman out there." I said, "You have a man out there, but he is not a foreman." He asked me what I meant; I told him that the man seemed to have no power over the cabinet-makers using the machines. Well, a week later they changed foremen in the mechanical department, and our

accidents were reduced to almost nothing. I made a checkup of the accidents six months later, and there had only been one minor accident in that department, whereas we had been having five and six a week.

In insurance work, we run into a good many problems that probably have been worked out in the large plants; but in the smaller plants, it is a little more difficult, because of lack of finance to take care of proper safeguards.

In another mill, a sawmill in the South, I was standing on the sawmill floor one day, when the whole building was shaken violently, creating considerable scare on my part. It was caused by a piston ring in the shot gun carriage breaking, the end of the piston ring dropping down into the feed pipe and lodging itself in the valve so that a quiet shutoff could not be handled by the saw operator. The shot gun carriage went down to the end of its travel and struck the large timbers which acted as buffers at the end and dislodged them entirely. In fact, set them back six inches. They overcame that difficulty by introducing a screen in the pipe so that if any pieces dropped down in the pipe they would be caught by the screen instead of lodging in the valve.

I have a note here, "Right Man on the Job." That occurred to me while one of the speakers was talking this morning. The Atlanta incident that I spoke to you about is only one example of it. We find on insurance records that too often men are injured because they are not acquainted with the machine they are operating. A yard man will come in from the yard and operate a saw (this is a small plant where they don't have the supervision that you have in the larger plant) and because of his unfamiliarity with the machine, he is often injured. The use of men of advanced ages in lumber yards which are connected with some of the larger sawmills and some of the smaller sawmills, is something that ought to be watched very carefully. A man of advanced age will climb to elevations, and he is not so sure of his footing as a younger man; if he does fall and sustains a fracture of any bones, it takes a good deal longer to heal than it would in the case of a younger man.

I expected somebody in the discussion of safety subjects in the Woodworking Section would mention the new saw that has been gotten up by one firm called the "non-kick-back" saw. Every other tooth is a bumper tooth. The sharp end tooth only extends about one sixty-fourth of an inch above the bumper tooth and in plants where this has been tried out, I believe they have had absolutely no kick-back accidents. You could take a piece of timber and throw it on top of the saw and very seldom is there enough force from the contact to throw it off from the saw table.

One more point is the device you use (it is known under different names) for the loading of lumber into box cars and the unloading of lumber from box cars. Usually this device consists of a rod with a right and lefthand thread on it. When it is introduced into the car door, it depends for its support upon the wedging between the sills of the door. We have had two death losses from the use of that device. Men depend upon it to hold the lumber as they load it into the car and load it out of the car, and it fails and the man is precipitated to the ground below. He is very likely to receive a broken neck as a result; in fact, that was the death loss we had.

CHAIRMAN GRIER: Does anyone have any questions to ask on Mr. Barr's remarks?

ROBERT W. TOMS (E. I. DuPont de Nemours & Co., South Windham, Me.): I would like to ask in regard to that death loss that you spoke about in connection with the device that they had for loading lumber into the cars, do I understand that was wedged into the car door and there was a roll on top for handling the lumber over the roll?

MR. BARR: Yes, it consists of a right and left hand thread, so that when it is

placed in position, one end is turned so that it wedges itself between the sills of the door.

MR. TOMS: The reason I asked was this: We use a device similar to that for loading lumber, but we don't use the friction that way to hold the roll in the door. It is a bar going across with a long slot on either end and in that slot is a hook. That hook hooks around the jamb, where this timber is large enough to go around the outside of the door. These hooks are made adjustable for different width doors, and then there is a handle on either end that brings that up.

The idea is: Here is your bar, and there is a hook that goes through and around the jamb of the door on each side. Then you screw up on the outside, making that bar absolutely rigid in that door, any height you want. You raise it and lower it quickly. Then you have your roll on top. In that way, there is no chance of that falling. It is held very rigid in the door and you would have to break the bar before you could get it down. I can easily understand how just the jamb against the side of the door would get loose very easily. Ours is very easily moved, higher or lower, and can be taken off very quickly, and we find it very serviceable. In the sense of this, we have an attachable roll that moves back and forth on this, that is hung in the center. That can be moved back and forward on this load to change the angle of it. In that way, you can handle a lot of lumber with very much less labor and with safety.

O. B. FREDERICK (Safety Supervisor, Dierks Lumber & Coal Co., DeQueen, Arkansas): Mr. Barr, I would like to know the name of that saw which you mentioned. I believe it would be enlightening for the members to know the name of that saw you spoke about that had the anti-kick-back device.

MR. BARR: It is called the Dubrule.

CHAIRMAN GRIER: I am going to call on a gentleman who has honored us by his presence at our luncheon today, and in return for that, we are going to ask him to say a few words to us. I am going to call on Mr. Ernest Hartford, Chairman of the New York Chapter of the A. S. S. E. and General Secretary of the American Society of Mechanical Engineers.

MR. ERNEST HARTFORD: It is good to be here to join in your luncheon and I am glad to be able to tell you one or two things about the Metropolitan Chapter of the A. S. S. E. I imagine most of you come from other cities, but we would like you to know that we have established a policy this year in the Metropolitan Chapter of having our monthly luncheon meeting regularly on the third Thursday of each month at the Fraternity Club, which is at the Southeast corner of 38th Street and Madison Avenue. We had our first meeting the third Thursday of September, and we had Commander Elsberg of the U. S. Naval Reserve there, to speak on Safety as it applies to submarines. Commander Elsberg had charge of the work of the raising of the S-51 and was also called back, although he had left the service, to assist in the raising of the S-4. He told us a very interesting story—one which was so attractive, that I believe we are going to get rather a large attendance at the next meetings. We are going to try to put on a program through the winter that is going to help the Safety movement in New York, where, as perhaps all of you know, it is very badly needed.

I can't tell you in detail regarding the remainder of the program, but there is another matter that I would like to speak about while I am on my feet, and that is, the possible relationship between the work of your particular section and the A. S. M. E. where I spend most of my time. We have, in A. S. M. E., as perhaps you know, a Wood Industries Division, as we call it. You call it "Section" in Safety work—we call it "Division." The Wood Industries Division, would, I am sure, be delighted to have an opportunity to cooperate with the section, and in so far as the Safety work is concerned in making suggestions, we would be glad to have you get all the credit for anything that is done in that connection. In other words, I am not merely trying to suggest something which will help to put

A. S. M. E. more in the limelight, but rather to give you an opportunity to utilize something which is pretty well organized.

In that connection, we have organized groups working actively in 69 cities in 38 states of this Union. We would like to see each of those local groups utilize more of the material which could be brought into these meetings from the Safety viewpoint, and we think it is rather up to you gentlemen to take the initiative in telling us what we should do to bring Safety into the woodworking industry or Safety from other points of view, because I imagine some of you are interested in it from other aspects than purely the woodworking.

We place freely at your service and disposal anything that we have in our organization, in the hope that you will take it in that spirit and, as I say, take advantage of a well-organized proposition.

We have in the Engineering Societies Building on 39th St., which was made available to the whole engineering profession through the generosity of Andrew Carnegie, a very wonderful collection of technical literature. That includes, of course, everything on Safety as well as other branches of Engineering. You may not realize that there are something like 1,400 technical periodicals published in various parts of the world, these being printed in 26 different languages. Now, I mention that because there is available for any of you men, regardless of whether you hold membership in any of the societies that occupy space in that building (and by the way, the Metropolitan Chapter of A. S. S. E. has its headquarters in that building) you have access to this wonderful fund of information, and should you care to get it, there is being conducted a card index service whereby you can get every week, on a 3 x 5 card, very convenient for filing, information in any of these 1,400 publications that applies to Safety or specifically to the Woodworking Industries. That is a service which is being rendered to the entire engineering profession, and although it was started only last January, its value is already widespread, still there are only a small proportion of the engineers and industries that can use it that, I think, have even heard about it.

So, Mr. Chairman, I am very glad of the opportunity that you gave me to say a few words. I want all of the men who are here interested in any kind of engineering work, to feel that when you are coming to New York (and there isn't a convention or a congress such as this, which offers the opportunity to get into contact with various industries here) that you will feel perfectly free to come to the Engineering Building and feel that that is your headquarters, that you are wanted there, and that anything we can do for you in any way, to place at your disposal these facilities of a number of engineering societies, is yours for the asking. Thank you very much.

CHAIRMAN GRIER: I am sure that all of us here appreciate the generosity of the Engineering Societies of New York, and that some of us will avail ourselves of the privileges and facilities that Mr. Hartford has so generously extended to us.

Mr. Farra, our past chairman, has a word for us.

E. ROSS FARRA (Manager Grand Rapids Safety Council, Grand Rapids, Mich.): I want to back up what Mr. Hartford said, that the Wood Industries Division will cooperate with you, because I have appeared before them in New York City twice, and in Providence once, and in Grand Rapids once, regarding the Woodworking Code, and I have promised that either myself or one of the directors of the Safety Council will be on the program of the Wood Industries Division in Grand Rapids this coming month.

I also want to say that I have sat in a great many of the Engineering Society Executive Committee meetings, and there has always been the cry that you can't get the Engineering Societies to cooperate. I want to say this to you: We have a pretty hardboiled Engineering Society in Grand Rapids—a good many of them are the older type of engineer—not the younger men—but I find that if you go after these fellows, it is surprising how much you can get out of them to help you in

your particular work. That, of course, applies more to the folks in community work. The Grand Rapids engineering work has been right back of me, and they are putting on for me (not solely, but as the main sponsor) an electric illumination institute which begins there about the last week in November, and they are doing the brain work of it at least. I am doing the printing work—that is about all I am doing. The Engineering Society is going to sponsor that with the Light Company and the Gas Company, and I think it is going to be an outstanding change in our industrial work. It has never been put on there before. I couldn't have put it on without the Grand Rapids Engineering Society of which Mr. Spindle, of the Gas Company, is chairman.

CHAIRMAN GRIER: Are there any further questions or any comments that anyone desires to bring before the meeting?

If there are no further questions, I am going to call on Mr. Sam Fowlkes, manager of the New Orleans Convention Bureau to tell us something of the South. Mr. Fowlkes is here in the interest of New Orleans, and New Orleans is trying to get the National Safety Congress to meet there next year. We are not backing up Mr. Fowlkes as a body—we are just giving him a chance to tell us something of the old South.

MR. SAM FOWLKES: First, it is a great privilege to be able to have lunch with you gentlemen today. I appreciate it very much.

Mr. Grier has told you my primary object up here is to look over the Safety Congress, to see what you have, what type of meeting it is, and also to accompany my local delegation, of which we have quite a number of gentlemen—not only from New Orleans and the immediate section, but from all over the South—who are working with us and with our people in trying to convince the officers and the members of the National Safety Council that the South needs this wonderful organization to meet in her territory.

We feel that it would not only be of great benefit to the South, but would be of great benefit to the organization as a whole. Our people are just beginning to realize what the safety movement means to them.

To give you an illustration: In New Orleans, there has never been a safety movement at all, up until about last spring, and we organized a little sectional meeting and had an attendance of some 400 around New Orleans and the immediate vicinity, who went on record as being in favor of the movement and wanted to invite the Safety Congress to meet in future years in New Orleans. Our section down there is really in its infancy, regarding the industrial plants; our schools are just beginning to take up the safety movement, and our city (which is also directly interested) and Mayor O'Keefe, chairman of my board, who sent me up here, have all taken an active part in it. I assure you that we will appreciate your support and cooperation and some of these days, we hope that we will be so fortunate as to have this wonderful organization meet within our city, so that the South will benefit greatly from it and help us out in this movement, and we also feel that it would be of much benefit to you.

G. A. ORTH (Chief of Safety Dept., American Car & Foundry Co., New York City): I should like to ask a question. First, tell us something about where we can place the Congress, should we vote to put it down there, and about your hotel facilities, and whether or not the hotels can take care of the visiting delegates.

MR. FOWLKES: That is one of the reasons why I am in New York City today. This morning I have gone over the situation quite extensively, trying to take in all your meeting rooms and the number that you require. Among our four hotels and our three theatres which would be available, (they adjoin our leading hotels, in New Orleans) we will be able to take care of the Congress and the meetings, and from our exhibit standpoint, we have a large Government warehouse which is a 10-minute drive from the center of the city, which would be available. However, we also have another proposition which we are going to offer the directors, and that

is, housing the whole thing under one roof. That is, at the International Trade Exposition, which has its own restaurant, can give you all your meeting halls and your exhibits, has your telegraph service, your taxicab service and everything out there under one roof. We feel that we have the proper accommodations. However, we also know that you won't have the attendance at a Southern meeting that you would have in the East or the Central West, and we feel sure that we can take care of you very nicely.

MR. FARRA: How far is the Trade Building from the main hotel?

MR. FOWLKES: It is a 10-minute drive. We have a taxicab concession that always has taxis at the hotel and out of this building which makes a minimum charge of twenty-five cents and that will take you to any hotel. We have just recently had the Bottlers—they had 100,00 square feet of exhibit space, and all of their meeting rooms, and about 50 per cent of the gentlemen had lunch at the restaurant that is open every day in the year out there, and they were very well satisfied. We had an attendance of 6,000 delegates at this meeting.

ADJOURNMENT

October 3, 1928

JOHN B. GRIER, Chairman

**Employment and Safety Manager, American Car & Foundry Company
Wilmington, Dela.**

The Wednesday morning session of the Woodworking and Lumber Manufacturing Section was called to order at nine-fifty-five o'clock, by the chairman, Mr. J. B. Grier.

CHAIRMAN GRIER: This morning we will have talks on Wood Re-manufacturing, and the election of officers for the coming year. We will also have discussion after each of the papers, and at the end of the session, if we have time, we will have a general discussion for any questions that anyone cares to ask, pertaining to this Section. We will have them answered at that time.

Last fall it was my pleasure to be in one of our mid-western cities and visit a number of the furniture industries located in and around Grand Rapids. While I was there, I made a visit through a plant which attracted my attention. The plant was clean, well-guarded, and being chairman of the Section, it furnished food for thought.

I believed that if the factory was kept in such a condition, that man who was responsible could tell us something about accident-prevention work. So, it is with great pleasure this morning, that I introduce Mr. H. J. Kelley, manager of industrial relations of the American Seating Company of Grand Rapids, Michigan.

MR. H. J. KELLEY: Mr. Chairman, ladies and gentlemen: I prepared a paper because I believe that I can stay with my outline much better by sticking to this paper, and if there are any questions at the close of the paper, I will be glad to amplify any points that you may be interested in.

The Fourth Cornerstone

By HARRY J. KELLEY

**Manager Industrial Relations, American Seating Company,
Grand Rapids, Mich.**

It has often been said that the foundations of society rest upon three great institutions, the Home, the Church, the School. To these I would add another, the Factory, the fourth great cornerstone of our modern civilization. In a factory a man spends one-third of his adult life, one-half of all his waking hours. The factory exercises a considerable influence on his character.

What society is today and what it is to be tomorrow is to a degree a reflection of what your factory and mine are. Is there any greater responsibility, then, than that of making these factories fit places in which to live and work? the sort of places whose influence on the father will compare favorably with the influence the schools are exercising on the children?

In discussing this subject I expect to show:

1. That men are less likely to be injured in a plant which is clean and orderly because:
 - a. Disorderly conditions are the direct cause of more industrial accidents than any other one thing.
 - b. Carelessness in upkeep of the plant engenders careless habits among the workers.
2. That better morale is maintained among the workers through maintaining a clean and orderly shop and that this results among other benefits in fewer accidents.

3. I shall discuss some of the common difficulties in the way of good housekeeping.
4. I want to tell you about an interesting experiment which we have carried out in our plant, solving the problem of housekeeping in a most satisfactory manner.

Direct Cause of Accidents

First, then, bad housekeeping is the cause of more industrial accidents than any other one thing. Falling objects, stumbling, bumping into objects, stepping on nails, are familiar terms to all of you while defective wiring, spontaneous combustion, and dust explosions are common causes of plant fires too often augmented by blocked exits and failure of sprinkler systems, evidences of lax inspection and bad housekeeping.

Statistical evidence of this can be found in almost any tabulation of accident reports. Here, for example, in a tabulation of all reported industrial accidents in the state of Pennsylvania for the year 1924, I find:

Twenty-one thousand injuries out of 83,000—somewhat over one-fifth of the total—were listed under the following causes:

Falls of persons.

Stepping upon or striking against objects.

Falling objects (mines and quarries not included).

Hand trucks.

It is safe to assume that a very large share of the injuries in this list were caused by bad housekeeping of one sort or another. It is also certain that a lot of accidents caused by bad housekeeping were listed under heads other than these. For example, "handling objects," causing about one sixth of all reported accidents, had in it a great many cases in which disorderly surroundings contributed to the injury. Likewise, accidents charged against motor vehicles, explosions, and cranes and derricks are often caused in reality by bad housekeeping. These caused 6 per cent of all accidents while our old friend "Miscellaneous" which covers among its other multitude of sins "Bad Housekeeping" was responsible for another sixth. According to Michigan figures for 1926-27, about 14,000 out of 30,000 compensable accidents were caused by:

Falls of persons.

Stepping on or striking against objects.

Falling objects.

Trucks.

So we may safely deduce that from a fourth to a half of all reportable industrial accidents are caused directly by bad housekeeping in one or more of its many forms.

Quoting Boyd Fisher's "Mental Causes of Accidents," Lewis DeBlois says in his admirable book, "Industrial Safety Organization":

"There was an automobile body manufacturing plant in Detroit which had so many accidents in the woodworking department that it became known as 'the slaughter house.' In running circular or band saws, workmen frequently made false movements and cut their hands instead of the lumber. In one particularly bad month, 27 fingers were lost. This brought matters to a crisis. The management was more or less conscientious. They faced the situation humbly and came to the correct conclusion that the real trouble did not so much lie with the workmen as with the fact that scheduling and plant housekeeping were both as bad as possible. Trucks of material blocked all of the aisles; finished pieces were not removed promptly, or in proper sequence; stock chasers were running all over the plant for what they needed. The workmen on piece work at one time were laboring under the double pressure of the foreman's demands and their own desire to boost their earnings. At other times they were waiting for

material blocked at previous machines. A general atmosphere of physical and mental confusion prevailed. Periods of hurry and anxiety kept men distracted when their attention should have been fixed in an orderly and peaceful way upon the dangerous task in hand.

"At last the company introduced an efficiency engineer who had done good work in a neighboring plant. In a very brief time he straightened out the scheduling and the material movement. There followed promptly a noticeable reduction in the accident rate. The unsavory reputation which the plant had had with its workmen was improved and the company was saved from being dropped as a bad risk by a mutual compensation insurance company."

So much for the direct physical effect of Bad Housekeeping on accident frequency.

Let us consider for a moment the indirect but none the less significant effects. Go back for a moment to the fundamentals of accident prevention. You have heard repeatedly at this Congress the statements, that "Safety is a matter of education," that "Eighty per cent of all accidents are caused by carelessness," that "The best safeguard is a careful workman," and the like. If it is true, and we know it is, that the price of safety is constant care, then carelessness is the arch enemy of safety and the problem of accidents will be whipped when we train our workmen to be everlastingly careful.

Can we train our workmen to be careful when they live in a plant which, because of our carelessness, is unclean and disorderly? Will they be careful workmen when you permit them to be slovenly in the care of their workplace? If you and I are going back to our plants with the message that 80 per cent of all accidents are caused by someone's carelessness and that we want the workmen to join us in preventing such accidents, then in all consistency, if we hope to succeed, it is up to you and me to lead the way by cleaning up the place and putting it in order. Not until we have done that can we produce any very serious effect on the minds of the workmen whose carefulness we solicit.

Morale

Long ago we learned that accident prevention could not be accomplished if safety work were made to stand by itself as a separate activity or "movement." Safety work, if it is to succeed, must be a part of a whole program of satisfactory relations between employer and employee. High turnover, excessive illness, absenteeism and tardiness, insubordination, unrest and dissatisfaction, and a high frequency of accidents are all evidences of failure on the part of the employer to maintain cordial industrial relations. It is futile to attempt to correct any one of these without going to the root of matters and so changing our attitude and that of our men that there is a mutual feeling of confidence and common interest between us.

Through long experience in working to maintain satisfactory relations with our men we have found that disorderly and insanitary working conditions are a destructive force in morale building and that regardless of what else we do to promote good feeling among our men, bad housekeeping has the effect of creating a dissatisfied worker and destroying pride in their workmanship and their company.

If we believe this it follows that among other things we will look about and give intelligent thought and planning to the working conditions of the men in our plants.

It is not my purpose here to go into great detail as to standards of order and cleanliness. These standards are discussed at length in *Safe Practice Pamphlets* of the National Safety Council under the following heads:

	No.
Industrial Housekeeping	45
Stairs and stairways.....	2
Floors and flooring.....	11
Yards	17
Woodworking machinery and equipment.....	20
Shop lighting	22
Drinking water, wash and locker rooms and toilet facilities.....	27
Exhaust systems	32
Industrial ventilation	37
Health service for small plants.....	57

Many of you have a complete file of these pamphlets and all of you should have them.

Too often employers are satisfied if their plants conform to the legal requirements of the states where they are located. A study of state codes and experience with state inspectors has shown that the standards enforced by them are intended to relieve only the very worst cases of labor exploitation and are entirely inadequate from the standpoint of progressive employers. It is indeed far more to our interest to maintain working conditions which make for highest efficiency of our labor than for the benefit of any other, even the state. So a study of some of these *Safe Practice Pamphlets* and a critical study of working conditions in your plant will be advisable if you hope to maintain the standards we talk about when we speak of Good Housekeeping as an aid to production and accident prevention.

Difficulties in the Way of Good Housekeeping

Now since I have said that a substantial share of industrial accidents are caused by bad housekeeping and can be prevented by good housekeeping, it is pertinent to ask just what do we include in housekeeping. Good housekeeping includes three main functions:

1. Orderliness which pertains to the arrangement of space; marking out of aisles and storage of stock, raw, in process and manufactured.
2. Maintenance including floors, stairways, trucks, power and light lines, transmission equipment, sprinkler and other water lines and steam pipes, compressed air equipment and exhaust system, and elevators.
3. Cleanliness from a sanitary standpoint and the cleaning of lights and windows.

Covering as wide a scope of activity as these, it is not surprising that housekeeping presents a vexing problem. Not only are these functions many and varied but they are the sort of things which do not come to the every-day attention of foremen, and any one of which can be neglected from day to day without the actual stoppage of production. Pressed as he is by the ever present necessity of crowding through orders and keeping down costs, even the best foreman is more than likely to neglect the things which are not of immediate necessity. As he neglects them he becomes used to working in a house badly kept until presently he is not even conscious of such conditions and an unsatisfactory standard of housekeeping prevails. That is one reason by the way why industrial engineers can come into a plant and make a wonderful show of progress by cleaning up the things which have been going on unseen before our very eyes.

Another thing which causes neglect of housekeeping is the fact that everybody's business is nobody's business. Our company has centralized control of production, centralized control of costs, centralized control of employment, centralized control of methods, centralized control of research and time study and centralized control of housekeeping.

Our Experience

The history of improved housekeeping in our plant constitutes a successful experiment which is so thoroughly practical and satisfactory that I wish to repeat it here as a possible solution to similar problems in other plants.

A few years ago we were confronted with an apparent shortage of trucks and a lack of space in our wood shop brought about, we thought, by increased production.

The floors were cluttered with truck loads of stock in process, departments were held up one day waiting for stock to work or trucks to load it on and were working overtime the next day in a frantic effort to catch up with an accumulation that had been dumped on them all at once. Instances are remembered of loads of stock being lost for weeks at a time. Stock chasers rushed about trying to move first one order, then another depending upon pressure from the sales organization.

The situation got so bad that we assigned one of our engineers to study the job. He put on an assistant who acted as a labor foreman. This foreman hired a crew of men whose main job it was to unload trucks. This we knew to be uneconomic but in the emergency there was nothing else to do. There were times when this crew unloaded stock from trucks to the floor and back to trucks again the same day. Then gradually order began to come out of the confusion.

The first step was to introduce lift trucks and platforms wherever possible. This at once forced us to mark out aisles and storage spaces because you can't use a lift truck unless your loads are in orderly arrangement. The lift trucks were eventually followed by electric lift trucks which further emphasized the need for clear aisles and orderly arrangement.

Next came the centralized control under the labor foreman, who had proved himself well fitted for the job, of all interdepartment transfer. There was no longer any chance for shifting of responsibility from one foreman to another for the movement of stock. The transfer foreman was responsible from the moment the last operation was completed in one department until he had a receipt from the foreman of the next department. This did a great deal to keep stock moving through the plant instead of standing about. Incidentally it was a great aid to our scheduling department because the records of the transfer department practically eliminated the stock chasers.

Success of this plan finally brought forth the suggestion that the transfer department assume control of transfer within certain departments where lugging, as we used to call it, had gotten to be too much of a job for the department foreman. The first place this occurred was the upholstering department. During a rush period the foreman of this department had so many extra men on lugging work that they were in each other's way and the lugging cost per productive man hour ran as high as 16 cents. Now it ranges between 4 cents and 6 cents. The transfer foreman, who by this time was becoming somewhat of an expert, took charge of the movement of stock within this department and in a few months had the transfer cost budgeted and the work organized so that without confusion stock was flowing through the department and the accumulation of loaded trucks had entirely disappeared.

Following the excellent experience in this department, other departments were rapidly added to the list and within a few months all transfer of stock both within departments and from one department to another was brought under the control of one good foreman. There is an incidental saving here which I am sure will interest you. It used to be the practice on the part of foremen to assign idle men to lugging. It didn't matter if there were already enough luggers to take care of the work, when a man ran out of a job temporarily he was put on lugging. In some instances this was so bad that when our production went down our lugging cost went up. With a foreman whose sole job it was to handle transfer work and keep the cost down, this was stopped at once.

This foreman, as I said was working under the supervision of the engineering department and this arrangement made easy the installation of mechanical handling devices, conveyors, cranes, special trucks, etc., many of which have been installed in the past four or five years. In that time incidentally we have had only one accident with a conveyor while we used to have several every year with hand trucks.

So much for orderliness. Now as to cleanliness. Cleaning and sweeping has always been done in our plant about as in every other where only superficial attention was given to it. Each department had its sweeper or sweepers as the case might be or in the case of small departments maybe they shared a sweeper. He was under the supervision of the foreman who had him keep the place swept up according to his own standards, some good and some bad of course. In addition the sweeping job was used as a miscellaneous account into which idle time of operators could be thrown, just as I described to you in the case of transfer work. Sometimes the sweeper, who was probably superannuated, would be asked to relieve a man on a machine and in one instance we had a sweeper lose a thumb relieving on a job for which he was unfitted.

Then there was the problem of stairways and other places which were in nobody's department and were always the subject of controversy. Toilets used by men in more than one department were also no man's land and in settling discussions as to who should keep them clean they sometimes got pretty bad. And worst of all, the foreman's supervision would become most lax during periods of rush at the very time when we could least afford to have the men distracted and dissatisfied with unclean working conditions.

Window cleaning and electric light cleaning were done partly by a cleaner under the supervision of the steam engineer and partly by department sweepers on request of the department foreman. We found on investigation that some foremen did not even know the procedure of requesting windows cleaned.

We have safety committees in our plant, one consisting of rank and file workers, one of foremen. These committees make monthly inspections and reports and there was hardly a report for a long time that did not include an item or two about unclean toilets, drinking fountains, washrooms, windows or lights, sometimes all. And finally the foremen's safety committee made the recommendation that all cleaning and sweeping be placed under the supervision of the department of internal transfer.

Since we had at first encountered some resistance getting foremen to relinquish transfer work, it appeared that this was a compliment to the success of the changes we had made and it looked like too good an opportunity to let pass. So we placed all cleaning and sweeping under the same control as transfer work and the results have been gratifying. Since the change we have not had a complaint from either safety committee about dirty conditions and we are complimented by visitors of wide experience on the cleanliness that prevails throughout the plant.

By way of illustration here are two comments of which we are rather proud, the first by Dr. Ernest Levy—one of a party of German executives who visited the plant in this country—as follows:

"We have visited many plants in the United States and Europe, but the like of yours we never saw. For cleanliness, modern construction and sanitary consideration and care of your workers' health your plant stands as a model for other woodworking factories. We recall with great pleasure our visit to your establishment."

The second comment is by Dr. Dokoff, head of the Department of Labor and Industrial Hygiene of Bulgaria, who spent over a year in this country visiting all types of plants:

"You have attained a remarkable degree of cleanliness in your plant. I have been in many woodworking plants but in none have I seen so little dust and dirt."

Now, of course, you are interested in the cost. Well we were prepared to pay more for cleaning to get a better job. As a matter of fact our cost per square foot is exactly the same now as it was before.

What is the effect on accidents? Our accident frequency rate has gone from 107 accidents per million hours in 1920 to 21 accidents per million hours in 1927 and 1928 will be around 18 or 19 if we continue through the year as well as we have gone the first nine months.

Negligent housekeeping still claims about one-fourth of our cases, but bear in mind that we have attacked accidents from all angles, and accidents from all causes have decreased materially. The point is that accidents from bad housekeeping have been kept in line and that we have made progress in this just as we have in machine guarding, prevention of infections, and other phases of our safety work.

I have tried to cover a very important subject in a suggestive manner, hoping that someone who has overlooked this vital subject may be caused to give it thought.

More accidents are directly caused by bad housekeeping than by any other single cause. In addition carelessness in this breeds carelessness of habit and leads to still other accidents.

Morale is built by good housekeeping and destroyed by bad housekeeping. We have reduced our accidents, improved our morale, and increased our production by centralizing the control and execution of the most important housekeeping activities.

The Question of Foreign Labor

CHAIRMAN GRIER: Thank you, Mr. Kelley. I think that was a very enlightening paper, and there should be some questions. We will take about five minutes for discussion before going to the next paper.

Are there any questions? Mr. Kelley, I am sure, will be glad to answer any questions that you have concerning his paper or concerning housekeeping in general. We are not going to waste too much time waiting for questions.

FELIX WEILL (Indemnity Insurance Company of North America, New York City): What do you do in regard to foreign labor? That is, if you have any that don't talk the English language very well? Their homes are not as clean as some of the average ones.

MR. KELLEY: Our plant personnel is probably a little unusual in that the average education of the group is above the eighth grade. That explains your question, partly, because people who have received an eighth grade education in our country, as I noted in my paper in the beginning—the factory is one of the fundamental institutions of our country, but the school has taught most of our people, we feel, the early fundamentals, or I should say, sir, early training in the fundamentals.

W. S. PURDY (Hartford Accident & Industrial Co., New York City): How long were these innovations in an experimental stage—that is, over a period of how many years have you effected this change into working order as you have it now?

MR. KELLEY: We have been operating on the basis of years, but just as soon as this engineer was assigned to a survey of the situation, conditions began to improve, and it was but a short while after we were able to assign this labor foreman to the task, and he has carried on ever since. So I would say that in a period of a year, one ought to make good progress.

CHAIRMAN GRIER: Are there any further questions?

If not, we will go on to our next question.

We will now try to put on the first paper by Mr. O. J. Olsen, who has charge of the Safety work of the Fisher Body Corporation, of Detroit.

Accident Prevention in Wood Mills

By O. J. OLSEN

Safety Director, Fisher Body Corporation, Detroit, Mich.

The Fisher Body Corporation is one of the largest single units of the General Motors Corporation, with a production of over 1,250,000 bodies per year. A considerable amount of the total manufacturing space for wood mills of the corporation is located in the state of Michigan in plants at Flint, Pontiac, and four plants in Detroit. There are also large wood mills at Cleveland, St. Louis, Memphis and Fleetwood.

The Fisher Body Corporation is one of the world's largest users of fine lumber. In order to supply its demand it buys three-quarters of the total lumber which it uses; the other fourth it gets from its own forests.

Fisher uses about 300 million board feet of lumber a year. In other words, at least between 40,000 and 50,000 acres of timber land must be cut over a year to supply Fisher with the lumber it needs, or, to put it in other words, about 133 1/3 acres of timberland are cut every day for the use of Fisher.

The lumber manufacturing operations in the Fisher Body Corporation are carried on by a subsidiary, the Fisher Lumber Corporation, which owns more than 100,000 acres of timberlands in the northern part of Michigan and about 100,000 acres in Ferriday and St. Joseph, Louisiana. It operates saw mills in Ferriday and Wisner, Louisiana, and in Memphis, Tenn.

Slide No. 1.

At all times there are kept in the various Fisher lumber yards and kilns over 25 million feet of lumber. Most of this is hard wood, and approximately 16 million feet is kept on sticks in the yards where it remains 90 days or more for the first seasoning, or as lumber men term it, air-drying.

The yards are kept scrupulously clean and every precaution is taken to prevent fire hazard. The yards are protected throughout by their own individual fire protection system, while the saw mills and the parts plants are protected by sprinkler systems.

Slide No. 2

The plants in Memphis consist of a double battery saw mill and a large factory which manufactures all of the wood body parts and assemblies for Chevrolet bodies, these being shipped for final assembly into the complete body framework to Fisher plants operating in conjunction with Chevrolet plants throughout the United States. The saw mills in Ferriday and Wisner are single battery saw mills, each with a daily capacity of about 90,000 feet of lumber with about half the capacity of the double battery Memphis saw mill. In St. Joseph, Fisher has about 30 miles of lumber railroad, in Ferriday about 21; in Wisner about 14.

It is interesting to know that, exclusive of interior trimming, window mouldings, etc., there are approximately 100 wood parts in the smallest body Fisher builds, viz. the Chevrolet, and in some other bodies there are more than 200 wood parts used in the manufacture. Upon these 200 parts, some 1,200 operations are performed preparatory to their setting up on the assembly of the body framework. On the

roof rail alone, there are between 15 and 20 operations. These figures show the work necessary on a wood body as distinguished from the absence of such detail work on a steel body, and the length to which Fisher goes to give the best possible kind of a body from the point of service, appearance and safety.

In the average door of a body by Fisher, there are $9\frac{1}{4}$ board feet of lumber and $15\frac{1}{4}$ square feet of sheet metal.

The framework of Fisher Bodies is of high grade lumber, reinforced by metal, and for the purposes of this article we wish to state a few of the salient features in making and fabricating wood parts with the inherent risks in wood-working operations.

Slide No. 6.

It is obvious to those who are familiar with wood-working operations from the time the timber is felled, transported to the rough mill, then the finishing mill, where the lumber is cut to dimension for automobile body parts and the proper dimensions for veneering for use in furniture manufacturing, each stage has its individual hazards which have been difficult to overcome. This is true especially in such cases where it is a question of guarding the point of operation. Although the equipment used in the various industries where wood-working is a part of the product is essentially the same, each one has its own conditions to be overcome, due to the method and requirements of the product.

Slide Number 1—Shows a Table or Mitre Saw. No doubt you gentlemen who have been operating mills know that the usual protection for a table saw was to make up a guard entirely of wood, same generally being a section cut so that it

would act as a spreader, with a flat board placed on top of this to extend over the saw, and a piece of canvas or rubber over the front edge of the flat board.

This was primarily used to stop saw dust from flying around, but did have some value as a protection, having been improved upon by making an apron on each side of the flat board, which prevented blocks ricocheting if they should happen to catch on the back of the saw when cutting off small blocks. I know of cases where this has happened, resulting in serious injury.

In order to make our guards on these saws of a more permanent nature, we purchased various types from manufacturers of guards and wood working machinery; have also been experimenting with guards of our own design, and you will note from this slide our first step towards a guard combining metal with wood—slide being of wood with a height adjustment, and having a metal shield over the saw. The guard is pushed back by the fence and returned by means of a counter weight.

Slide No. 8.

Another important point I would like to bring out, although not shown in this slide, is to have a box built on the back of fence so that when same rides over the saw it does not project through. Accidents occur quite frequently at this point, and I might add that fence should be securely fastened to the table and should not have too many saw cuts—particularly when using a Dado head for cutting a blind recess in flat stock that does not cut through. When board is held against the Dado head, if, for some reason, a kickback occurs, hands would drop on top of head. In order to prevent this happening, it is better to slide stock under a pressure bar which keeps operator's hands off board while it is passing over the head.

Slide No. 2—Shows a Table or Mitre Saw with an improvement on the guard, inasmuch as we use metal entirely on cross-cutting and mitering operations, and a hard wood bar with a spreader for ripping operations. You will note that this guard is supported so that wide stock can be run over the saw, and has adjustments three ways.

Slide No. 6—Shows a Gang or Multiple Spindle Boring Machine. This machine is also considered a hazardous one and difficult to guard properly. You will note that we have arranged slides to fit on the spindle support, and the picture shows guards at the low and high limits. These guards are actuated by the movement of the table.

Particular care must be taken in placing the screws in the spindle support so that they do not clog the oil passages. In addition to this we place a bar around the spindle, midway between the upper and lower bearings, to prevent spindles from swinging out in the event that the pin in the universal joint breaks. We have

Slide No. 10.

had several cases where this has happened, but were fortunate not to have anyone injured.

I have noted in my travels that other plants use, as an additional precaution, a cut or boot placed around the lower universal joint, but this can only be used on cases where spindles are not tipped too far from a vertical line. In adjusting these guards, we have them extend one-half inch below the bit point.

These Gang boring machines represent about 10 per cent of our wood-working machinery, and I believe that 90 per cent of the operations on same can be protected.

Slide No. 8—Shows a Jointer with a swing guard, which we have installed on practically all our jointers, and this can be obtained in the open market. It is not only necessary to cover the jointer head on one side of the fence, but it is also necessary, when fence is moved in on the table, that a permanent guard be attached

to the back of the fence, so that regardless in what position the fence is on the table, the jointer head will be covered.

We have had accidents of a serious nature when the jointer head was not covered in back of the fence, and we try to have the operator remain at his machine until the head has stopped revolving.

I have recently seen in a wood-working machine tool manufacturer's plant a braking device which I believe could be incorporated on such machines as jointers, shapers and moulders.

Slide No. 10-A.

Slide No. 10—Shows a Band Saw. This is what we consider our best guarded band saw. We have designed a number of guards to cover the band saw blade below the wheel and the table, but, of course, on some of our older equipment it was also necessary to cover not only the exposed part of the saw between the wheel and the table, but also the front and back of the upper wheel. However, this part of the guarding is usually taken care of by the manufacturer of the new machines.

There is also provision for guarding the exposed saw blade between the wheel and table, but it is usually fastened with machine screws, and is not always adjusted to follow the saw guide bar. We, therefore, made a guard as shown, which covers the saw blade at all times without regard to the changes made in the height of saw guide bar. On the newer machines, the lower wheel is enclosed

in a solid box with an outlet on each side wall for the saw dust exhaust, and it appears to work out much better than the old method of removing the saw dust from the bottom of the machine.

Slide No. 11—Shows a Shaper equipped with "U" shaped sheet metal guards covering the heads above the cutting edge of knives. These are fastened to the post and are adjustable in a vertical line. Some of these guards were purchased on the open market and others are of our own make.

You will note that we have a box hung on the shaper for tools, as we found that tools were being left on top of the table between the heads and there is a chance of their crawling into the heads as a result of the vibration, and we therefore aim to keep tables clear.

Slide No. 11.

You will further note that the machine is entirely enclosed with corrugated metal partitions. These can be placed as shown, or can be made up of sheet metal, allowing proper clearance, and attached directly to the machine.

Slide No. 14—Shows a Planer with a kick-back device, and a sheet metal shield on the tail end of the machine. The shield reduces the hazard of accidents to eyes from flying chips.

Goggles. Employees in our mills are wearing goggles while engaged in any operations where there is possibility of eye accidents. Recently all persons employed around wood hogs were equipped with goggles containing special lenses, and shortly after this had been made effective a flying piece struck an employee's goggle, crushing the frame and shattering the lens. There is no doubt but what the goggles prevented a serious injury.

Education in Safety Work. We all know that education is an important factor in accident prevention work, and our efforts in this direction have been the placing of bulletin boards at the clock entrances and in conspicuous places throughout the plants, using National Safety Council posters and other bulletin service—changing the bulletins at frequent intervals. In addition to this we hold monthly safety meetings for all foremen which are of an inspirational nature, and in turn the foremen hold their own departmental meetings of all employees, where they give 5 to 7-minute talks and invite suggestions from the men. We also supply each workman with a pamphlet describing what we consider safe practices in the mills,

Slide No. 14.

and we set same up in the way of suggestions rather than rules, as we believe that reasonable persuasion is preferable to arbitrary dictation. Of course, this preference is kept within reasonable limits.

At periodical intervals, fire drills are held, and so far we have been successful in conducting same in an orderly manner in a minimum time.

As an additional incentive, we have installed what we call an "Accident Prevention Bonus Plan" payable to foremen on a quarterly basis, with a minimum of \$5.00 and a maximum of \$100.00 for any one foreman per quarter. The basis for establishing this bonus is a hazard rating applied against each machine or operation in the mills. These ratings are relative, ranging from 10 to 100—the most hazardous, such as shapers, mitre saws and jointers, carrying a rating of 100, while bench work is rated at 10.

I am just injecting this briefly at this time, but if you would like to have full details regarding our bonus plan, get a copy of the Proceedings of the Automotive Section of the 1927 Congress held in Chicago.

Further, as a part of our educational program, a first aid course, under the supervision of a trained instructor who is endorsed by the American Red Cross, is carried on. One or two classes of ten men each are running in each plant at all times, and we feel that this is of value to the individual receiving such instruction as it develops a sense of consciousness in the employee as to the serious effects of accidents. It is not our thought to have any first aid work done by these men, as we have a well-organized Medical Department—consisting of a main hospital and first aid stations in each plant. However, there are emergency cases, such as electrical shock, asphyxiation, etc., where the knowledge of first aid and quick action is essential to prevent a fatality.

In conclusion, we believe that employees in our mills realize the necessity of working safely, and this has been demonstrated to us by reason of the fact that some of our mills employing approximately 800 men, have gone through a period of from 3 to 6 months without a time-losing accident, while we have had 55 foremen in various departments of our mills, each with an average of 30 men, go through a period of one year without a lost time accident. A portion of these have gone through two years without a lost time accident.

I am very pleased to state that we have not had any great difficulty putting into effect any reasonable proposition we might have in the way of "Safety."

(Mr. Olsen's paper was illustrated with numerous lantern slides, some of which are reproduced in these pages.)

CHAIRMAN GRIER: Thank you, Mr. Olsen. That was another very good paper, I think, if I am permitted to express the opinion of the group.

Are there any questions at this time?

MR. PURDY (Hartford Accident Indemnity Co.): I would like Mr. Olsen to inform us here just to what extent are guards removed from these machines, and also goggles removed—the men failing to wear these goggles during hot, torrid weather?

MR. OLSEN: To my way of thinking, we are always going to have guards removed from machines, and we are always going to have the men forget to use their goggles. I don't think that we are going to correct the human element to the extent that we are going to have them 100 per cent functioning on wearing of goggles or keeping guards in place on the machines.

F. B. FIELDING (Western Electric Co., Kearny, N. J.): Mr. Olsen, do you have setup men for making the major setups on those machines?

MR. OLSEN: We do not classify them as setup men. We pick our best men to do that. That is, we pay a good shaper operator a fair wage, and he sets up his job. We have isolated cases where we have a foreman or a setup man but in our big mills it is done by our key operators.

We have put in an intensive campaign on accident-prevention in the last two years. We do not want to brag about disciplining men. After we have given them a reasonable time to accept our policies and our requirements, if they do not seem to want to accept them, we give them a layoff of two or three days—sometimes a week, and if that does not cure their trouble, we take a more extreme measure, but we are not so strong for that method of getting results. We expect the men to follow our requirements on safety, the same as they do in any other plant policy. I am not going to say that we do not discipline them, but that is only in exceptional cases.

In connection with guards we have had a number of serious accidents on jointers in back of the fence, so now we have arranged to have a guard placed in back of the fence as well as in front, so that when the fence is moved forward on

the table, the exposed part of head is covered. We have had a number of fellows (not supposed to be in the mill at all) walk along, and inadvertently put their hands on table to feel the bright surface which would result in the loss of the end of their fingers.

CHAIRMAN GRIER: If you have further questions, gentlemen, I will ask you to put them on the cards, and we will take them up at the end of the next paper. Our time is getting short, and we have another paper and some business this morning.

At this time, our program calls for the Election of officers for the coming year. As was explained yesterday at our Luncheon Meeting, early in the spring we appoint a Nominating Committee to look into this subject of officers for the coming year, and ask them to prepare a slate. This slate is not to be railroaded through, but it is a slate of active men who will accept the responsibility in case they are elected.

Officers of the Section are Elected

Mr. A. L. Jackson, Supervising Safety Engineer, of Aetna Life Insurance Co., New York, is Chairman of this Committee, and we will call upon Mr. Jackson for his report at this time.

(Mr. A. L. Jackson read the report of the Nominating Committee as previously given during the luncheon meeting.)

CHAIRMAN GRIER: Gentlemen, you have heard the report of the Nominating Committee. What is your pleasure?

Are there any other nominations?

L. GLAZER (Manager, Safety Dept., Dierks Lumber & Coal Co., Kansas City, Mo.): I move that the nominations be closed and the report of the Nominating Committee be accepted as a whole.

(The motion was seconded and carried.)

CHAIRMAN GRIER: I will instruct the Secretary, Mr. Goodspeed, to cast the unanimous ballot of this body in favor of those named.

(The Secretary announced that he had cast the ballot and the Chairman declared them duly elected.)

CHAIRMAN GRIER: I suppose, in the absence of Mr. Bissell we should call upon our newly-appointed officers to take charge of the meeting. Mr. Wallace and Mr. Orchard are in the room, and I will ask Mr. Wallace to come forward and take the place of his cohort, Mr. Bissell.

(Mr. Wallace assumed the Chair.)

CHAIRMAN WALLACE: Gentlemen, in undertaking to fill the position temporarily vacated by our able, efficient and much beloved chairman, it gives me a very great deal of pleasure, and the pleasure is lessened only by the fact that Mr. Bissell, who will be your chairman next year, was not able to be here. I have been closely associated with him for the last several years. I pledge him to you as able a chairman as you have had, one who has his heart and soul and his interest in the safety promotion, not only in the Woodworking Section, but in the world at large, and who will serve you to the extent of his ability. I ask that you pledge him, on your part, your cooperation and assistance.

On behalf of these newly-elected officers, we have already given our assurance that we are your servants, to do what is possible in any manner, shape or form, to answer any demands to try to make this Section what it should be—one of the most efficient and powerful in the National Safety Council.

The next paper on the program is by Mr. H. G. Wiberg.

Saws

By H. G. WIBERG

**American Mutual Liability Insurance Company
Boston, Mass.**

I suppose most of you wonder where I come from, in view of the fact that there is a different name on the program. I must confess that it is somewhat of a surprise to me to find myself here. I feel also that I am a sort of a casualty—not the sort of casualty that is discussed in these conventions, but a political casualty. I think Mr. Gernon, who was to give this talk, found that he had to go to Rochester, and so I am substituting in his place. I am sorry, in a way, because Mr. Gernon has had a great deal of experience and has had a great deal of opportunity to observe saws all over the State of New York, at least. I am quite convinced that he would have been able to give you a great deal of information from his experience.

Of course, those of you who have attended Congresses for the past four or five years, know that we have had a great deal of attention given to saws. That seems to be a perennial bloom with the Woodworking Section. For a couple of years, we turned over (as I recall it) an entire morning to saw guard manufacturers and had them come with their products, explain them, demonstrate them, point out the advantages that they claimed for them, and then the members of the Section fired questions at them, brought up their problems, and tried to get a great many of the difficult points in the operations of saws straightened out.

Then we had had, in addition to that, talks on saw guards by people from manufacturing plants, Safety Engineers, Safety Inspectors, and discussions by the representatives of the various manufacturing concerns at the Congress.

So, I was somewhat at a loss as to what to say about saws.

I don't know whether any of you recall the paper presented by a Mr. Fuller, of the National Council on Compensation Insurance, a few years ago. He presented quite a voluminous analysis of accidents in seven or eight woodworking industries, the principal industries, and he laid quite a bit of stress on saws in that analysis. I thought I would like to go back to that analysis and point out some of the principal facts which he brought out, which I think have a very important bearing on the question of the saw guarding and saw hazards.

This analysis of his covered a period of six years—1918 to 1923, inclusive, and involved payments for the accidents in question, of about \$16,000,000. He covered 3,038 accidents, including a total of 570 deaths and 30 permanent total disability cases.

Now, let's come down to saws right away. He found that rip saws alone, produced 422 accidents and that these accidents cost 14 per cent of the total cost of all accidents. He found furthermore, that the accidents in the case of all other types of circular saws, amounted to 22 per cent of the total cost of all accidents in the seven or eight woodworking industries which he was working on.

There you have saws producing or causing 36 per cent of the total accident cost of all injuries in these woodworking industries, which indicates at once, the importance of saw accidents and the necessity of concentrating and continuing to hammer away on the circular saw.

These percentages of cost varied in some slight degree with the different industries, that is, they were higher in sawmills, for instance, than in sash and door mills, and in the case of furniture plants, the rip saw accidents were more costly than in plants of other types.

Just for the sake of comparison, I want to indicate the comparative cost of some of the other machines. He found that planers caused only about 3 per cent of the total, joiners about 3 per cent of the total cost, shapers about 6 per cent, which

would again reinforce the statement that I have made as to the importance of concentrating on circular saws and giving them our first attention.

He also found that the principal cause of accidents in the case of the rip saws was due to kick-backs. He had a record of 120 kick-backs, 73 of them resulting in a fatality. In other words 61 per cent of the kick-backs killed somebody.

That indicates that the kick-back is certainly a deadly proposition, and that we can't attach too much importance for the use of spreaders, pressure bars, non-kick-back devices, or any other means which will prevent that particular type of accident.

As I recall it, I haven't seen an exhaustive analysis of the causes of kick-back accidents, but I recall several that relate to the question of housekeeping which was mentioned here this morning. Several of them were due (that I know of) to material being on the saw table, being brushed into the saw, picked up and thrown.

Later I would like to have someone—or a number of the gentlemen in the audience—discuss this question of kick-backs and give us the benefit of whatever steps they have taken to reduce that hazard. I, myself, feel that in case of rip saws, either hand-fed or self-fed, the hazard can be taken care of very well. There are rip saw guards on the market now which absolutely prevent a kick-back. There are undoubtedly a great many homemade devices which do the job just as well.

I have heard of kick backs on self-fed rip saws, but I must confess that they have been very rare, and it seems to me that it is almost an impossible thing to happen, if the self-fed device on the rip saw is in good working shape.

I think that we have made commendable progress in the guarding of most types of saws, either by homemade devices in the various plants, or through the ingenuity of insurance engineers, or through the methods adopted by manufacturers, and that brings me down to a question which I think is a very important one on the question of saws, if not on the question of all woodworking machines.

I don't know whether you have noticed it, but I have observed for the last two or three years, the woodworking machine manufacturers are beginning to put real guards on their machines. It seems to me that that has been a rather belated development. I have, several times, talked to manufacturers of woodworking machinery at these Congresses, and have found that they didn't know anything about standards. They tell me that they didn't know where to get them, they didn't know of any organization that had drawn up standards giving the requirements. I have been very glad in each case, to tell them where they could find code books put out by different organizations such as Labor Departments, insurance companies, and engineering committees, and I took the opportunity in each case, to tell them that I thought that they were certainly asleep at the switch—that when they put out a machine which is a dangerous machine, they certainly should put it out completely guarded in so far as possible, instead of trying to compete with some one else's simply on a question of a few dollars' difference in price.

I don't know whether any of you have seen or have noticed the swing saws recently. There are at least a half-dozen manufacturers that I know of that turn out a swing saw now which has the blade completely guarded as far as the upper half is concerned, and the arbor nut. You know, we used to have quite a bit of difficulty in getting anybody to do anything on the swing saw, because they said there was a piece of metal on the inside, and that kept a man's hand away when he pulled out the saw. But we did educate the employers and it seems that finally the machine manufacturers have taken it up and they have taken it up in good shape. You can very conveniently remove part of the guard and change the saw. The guards they put on are solid, substantial, and very good.

I think that employers, before buying machine equipment, should require the manufacturers, by contract, to furnish machines which will pass the safety requirements of the states, the labor departments or industrial commissions of the state

in which the employer is operating, the insurance companies and the American Engineering Standards Committee.

I know of a number of cases where they have done that with entirely satisfactory results. I know of one installation of 35 or 36 machines where four out of the 36 were all that had to be changed, and in those cases, entirely new guards had to be bought, without, however, costing the employer one cent of money, and when those machines were installed, they met the approval of every labor inspector that walked through the place; they secured him credit in his rates from his insurance people, and there was nobody, in fact, who could take exception to them.

It seems to me that that is where a great deal of progress can be made in the future. I recall that in the laundry industry, the employers got together at some convention of the Laundry Machinery Manufacturers and said to them, "We don't propose to buy any more machines unless they are guarded, unless they will meet the inspection of the state authority and the insurance companies." That happened several years ago, and the latest that I have heard from it is that the manufacturers got together and gave the employers 100 per cent cooperation, so that every machine that they turn out now, that is, the machine manufacturers who are in the Laundry Machinery Manufacturers' Association, is completely guarded, and there is nothing for the employer to do to meet the requirements of the state authorities or the insurance companies.

There is one other thing that I think enters into this question of saws and saw guards—in fact, it enters into the entire question of safety. It has been borne in on me more and more as I attend these Congresses. I wonder if some of the men who come to them don't get the same idea that I do—that we hear somewhat the same thing over and over again. That is true, but I have come to the conclusion that the biggest thing in this safety proposition is the continual and everlasting hammering and pounding away at it. You have got to be on the job every minute of the time that a machine or a device or a plant is in operation. I don't think that all of us give consideration to the fact that you have got the employee working on a machine, you expect him to turn out a certain amount of work, and he has got to, naturally, give the biggest part of his attention and his effort to getting out that work. We say, after an accident has occurred, because the man didn't think, that it was carelessness or thoughtlessness. Possibly it was, but still I think that there is some measure of excuse for the man being thoughtless, and the way to get away from that is to keep at him, keep reminding him of it, so that he will get into the habit of thinking safely and carefully.

CHAIRMAN WALLACE: Gentlemen, Mr. Wiberg's address, I feel sure, has been interesting, instructive, and I trust helpful to us, and as a pinch-hitter, I think his batting average is about a thousand. This question of saws and saw guards has been one of abundant prolific discussion, and I am sure that we would be glad to hear any discussion or any inquiries now that you may have.

H. W. GABOR (New York State Insurance Fund, N. Y. C.): I agree with Mr. Wiberg that the tendency today is for manufacturers to safeguard their machines whenever they can be sold that way to the users of those machines, but we must never lose sight of the fact that a machine manufacturer builds his machines, in the first place, to sell them, and if the purchasers of those machines specify a circular sawtable, a swing saw or other type of saw, without including in that specification, the necessary guards, the manufacturers will sell that machine to the purchaser, if he can. It is very often a matter of price with the purchaser of a machine, and naturally, if there is competition between two manufacturers, they are all glad to sell their product.

If there is a matter of a hundred dollars' difference in the price of a machine, very often the user of the machine will purchase the cheaper machine, even today, although it is true that that tendency has been overcome to some extent.

I want to say this: That if the purchasers of the machines would specify in all

cases, as Mr. Wiberg brought out, that the machine should be fully-guarded, the machine manufacturers, whether it be woodworking machines, metal machines, or others, would do precisely the same as they did in the case of the laundry machine and that is to build their machines with automatic stops, and so on, including all the necessary safety devices. I would like to hear Mr. Wiberg give us the benefit of some of his experiences with variety sawtables, that is, that type of rip saw which, because of the miscellaneous operations performed on it, is termed a variety saw, and the methods which he has seen and which we know he has recommended for safeguarding those saws for certain operations.

MR. WIBERG: Mr. Gabor has brought up a thorn in the side of most of us, in trying to get saws guarded. I have in mind, a few questions, or at any rate, one, that I was going to ask Mr. Olsen, but I don't want to turn off Mr. Gabor's inquiry in that way. I think the variety table is a question of education and continually hammering the man who is using the saw. There is only one way that I know of that you can guard a variety table for all of the various operations, and that is, to have a guard for each of the various operations. I don't know of any one guard which will take care of it—in fact, I know it is impossible, because if you are doing a ripping job, you have a splitter or a spreader or a riding knife, whichever you call it. Then if you are going to do dadoing on that machine, you have got to remove the splitter, so it is obvious at once that you can't use one guard for all of the operations that can be done on that table. But you will have separate throats provided with the splitter or with the entire rip saw guard mounted on it, for use when ripping. You have pressure bars for dadoing or grooving, or you can have a foot to use, if you are grooving a board in the center or some precise distance. Otherwise, it would be necessary to hold that board just by the main force of the hand, and you wouldn't have anything to stop it in case it started to come back.

I was going to ask Mr. Olsen whether those miter saws, for instance, are used on that particular job practically all of the time. I was very much interested in his guard and I am going to talk to him afterwards about it to see what we could do toward adapting it for variety table work.

MR. OLSEN: Well, Mr. Wiberg, I think you explained the story on guarding of variety or miter saws or table saws, fully, because it is a rather difficult thing to do, to design a guard that will cover all operations—I will say, we found that out. We have shown three different guards that we used on a variety saw, one is the metal shield and the other is the bar with the splitter or spreader, and the other is a kick-back finger pressure device. The dado head and cut-off saw guard that we use does not even cover all the operations of that nature in our mills. In our pattern mills—we use the standard type of circular sawguard that you can buy in the open market, but we did not think that they would be the thing to use in a production shop—they were too slow. So, that is why we tried to develop something of our own design.

M. B. GATHMAN (Plant Manager, Fisher Body Co., Detroit, Mich.): In regard to Mr. Gabor's question here on the matter of putting on the guarded equipment, I think that is only a matter of time. In the past, the manufacturer has attempted to supply guards and go out into the plants later on and found them thrown aside, and has become discouraged. But now, the efforts that are being made for safety at the present time, are eventually going to bring them in line. The manufacturer is working all the time to provide guards.

There is one point that Mr. Wiberg brought up that I think should be investigated and that is this: Sixty-one per cent of fatalities in rip saw accidents. I think that should be investigated, to find out whether the accidents occurred from old-time methods of operations or whether they occurred on machines of up-to-date manufacture. I think, in the old days say 15 or 20 or 25 years ago, there were more rip saw accidents due to the way rip sawing was done. Today, with the

power-fed machine, chain driven, and with kick-back devices on it, we have very few rip saw fatalities. In fact, I do not know of any in six years with the great number of rip saws that we operate, and I think the accidents referred to should be looked into and that we should find if they are using obsolete methods, so that we will know whether we are talking about something that has already been taken care of or whether it is something that still exists.

MR. WIBERG: I will be glad to answer that question, at any rate, in one particular; those accidents occurred during the years 1918, 1919, 1920, 1921, 1922 and 1923.

CHAIRMAN WALLACE: I think that almost answers your question.

MR. GATHMAN: That may have been on equipment and method of doing things that have been obsolete for ten or fifteen years.

MR. WIBERG: That brings up another question which I might have touched on. I believe it was mentioned here yesterday, and that is the fact that a lot of these kick-backs are due to the condition of the saws themselves, irrespective of any guards.

CHAIRMAN WALLACE: That is dull saws.

MR. WIBERG: At a meeting last week, the statement was made that the Underwriters Laboratories in Chicago had tried to produce a kick-back. They had a saw which was in first-class shape, properly sharpened, set and gummed, and they couldn't get a kick-back. The thing absolutely refused to come back. The wood went through without any trouble at all. So they finally got a dull saw and a piece of wood that had been soaked in water for about six days, and they immediately got a kickback.

Someone here yesterday, I believe it was, said that in their plant they had turned over the responsibility for the proper condition of saws to the flier, and the understanding was that he would not sit up in his room and wait for them to be brought to him, but that he was to go out through the plant and see that they were in proper shape while they were working and to stop any machine on which the saw was not in good shape, change it, put on a sharp saw, and bring the other one up in good shape.

It seems to me that that is a mighty good thing and will be a big step forward if everybody should adopt that practice in cutting out the kick-backs and probably other accidents.

CHAIRMAN WALLACE: Here are two or three questions that have been presented. One is: Is there a practical shaper guard on the market? Mr. Olsen, can you answer that?

MR. OLSEN: Well, there is a practical shaper guard on the market to cover a part of the shaper-head, but I do not know of any guard that you can purchase on the open market that will cover the entire head. There are some concerns that have been experimenting with the automatic shaper guard the same as ourselves, and they have been more or less satisfactory. If you want any information on our guard, we will be glad to give it to you. We think it is rather expensive.

CHAIRMAN WALLACE: Mr. Olsen, I have two other suggestions—both seem to have been propounded to you. Mr. Norton, of the U. S. Bureau of Standards, asks this question: What is the gauge of sheet metal which Fisher Body uses on dust exhaust hoods, on molders, and so forth?

MR. OLSEN: I am not in position to give you that. I could take a guess at it. I think it is about 16-gauge.

J. B. GRIER (Safety Engineer, American Car & Foundry Co., Wilmington, Del.): I wish to state that we use a heavy gauge metal in all our hoods for all of our woodworking machines, with the idea that it will at least break some of the force of the flying knives or cutters should they come out.

CHAIRMAN WALLACE: Through Mr. Gunn, of the Pullman Company, Chicago,

this question is asked: What protection or device do you use to hold knives on heads of planers?

MR. OLSEN: We try our best to get the best bolts and nuts that we can buy on the open market, and put them through a rigid inspection before we use them. I do not mean that we are going to inspect every bolt or nut, but if you have established a reliable source, they will probably take care of the job of inspection for you.

FRED THOMAS (Rossman Corporation, Beaver Falls, Pa.): I have a particular hazard in a plant I am at, that isn't directly a woodworking question, but we happen to use a considerable amount of sawdust and shavings that come from the different woodworking industries. We find that the man using that shaving is subject to irritation, something like eczema, on the hands. These men are sent to the medical men who, in some cases, have the men patched up, but that same eruption or eczema, always shows a recurrence, and we are having that as a real hazard among thirty or forty men. I just wondered if anybody else had had that experience and could tell me what might be the best procedure.

MR. GRIER: We have had some cases of eruptions such as you mention. We found it particularly in wood that had been exposed to a chemical of some kind, and not in a particular wood. We have not had much annoyance from that source, and I am wondering whether or not you have eliminated everything else but the sawdust? I don't believe that the recurrence of this eczema, or whatever you find, is due to the sawdust. We never have a recurrence of that eruption. It is always on a different employee, or we soon discover the cause of the eruption. One time (I might just deviate from that a bit) we had hemorrhages from our band sawyer's nostrils. We took the band sawyer off and put on another man. The same thing happened with him, and we found that in sawing the wood, teak, that sharp particles irritated the nose membrane and caused the hemorrhage. We eliminated that by putting a blower system over our band saw. We have found that teak is a very gritty wood, and in high-speed machinery, at times you can see sparks fly from the teeth of the saws or cutters as you are making a cut through this wood. A good bit of it grows under water, and it is full of grit.

CHAIRMAN WALLACE: I don't suppose there is any place in the world where there is more sawdust than in a real, sure-enough band sawmill. Now, you operate two or three band sawmills, Mr. Orchard—did you ever have anything of that kind occur in any of your operations?

H. R. ORCHARD (Supt., Marathon Lumber Co., Laurel, Miss.): No, sir; we have never had any trouble of that kind.

CHAIRMAN WALLACE: I am thoroughly in accord with what Mr. Grier says. I don't think it is inherent in the sawdust.

MR. WEILL: The only experience I have had—the only wood that seems to cause a lot of trouble is Brazilian Walnut. A lot of the furniture factories have discontinued the use of it.

CHAIRMAN WALLACE: That comes back to the same question. It may be some peculiar property in some kind of wood, but I don't think, generally, it is true.

S. L. KENNEDY (Royal Indemnity Co., New York): Just a word of general observation on today's and yesterday's discussion. A couple of days ago, I said to my wife, "Tomorrow I am going up to the Convention of the National Safety Council to see what they are doing toward preventing accidents." And she quickly rejoined in a rather naive way: "Why," she said, "I am doing as much to prevent accidents as they are. Every time I cross the street, I look this way and that way."

The point I wanted to bring out is that the consciousness of a person that there is an inherent danger impending, whether it is crossing a street or in the mill or factory, or on a saw bench, is important. One of the speakers yesterday brought out the fact that the superintendent of one particular mill purchased every safety device that was recommended to him, to prevent accidents, spending a total of about \$60,000, and when he had them all installed, he said, "Well, now, I guess

that will cut down or prevent accidents." That was the end of his progress. The following week, there were about three hands lost and several other serious accidents, which only goes to show that unless along with your mechanical guards, your safety devices on your various hazards, you organize a comprehensive educational program which will instruct the operators how to use these guards (which in themselves, may be an inherent source of danger) you haven't completed your safety program. In other words, it is my idea that it is a very important thing to get the operators to think in a conscious way, that there is always an impending danger in the operations that they are conducting at the time.

That organization that I suggest is a mental organization, an organization of the operator's mind, along safety lines.

CHAIRMAN WALLACE: Some of the papers tried to bring that out. One of the subjects we had was "Mental versus Mechanical Safeguards."

I have one other question here from Mr. Weill: What is the method you use to guard large circular saws for ripping logs? What method do you use for guarding the carriage? I might say before I propound that question that I know of no modern sawmill that uses circular saws. There may be such; I don't know one.

MR. WEILL: They use them out in the woods, and that is what I mean.

CHAIRMAN WALLACE: I know of no industry that rips logs in the woods. There are none in our operations.

MR. WIBERG: Of course, you still have the carriage saw used in a great many large lumber yards and large sash and door mills and large furniture plants. They don't have logs actually, but they get large timbers and they re-saw them, and a great many of them do that on a circular saw.

For instance, you take the cigar box industry; they always prepare their veneer on circular sawmills. They bought these Brazilian Cedar logs which came here squared up and then they cut them up on the circular sawmills with the carriage. As I recall it, they usually cut down thin stock right on that large sawmill. I don't know offhand how you could guard them, but that brings up a question with a great many of these guards. I might have touched on that before in speaking, and that is the inclination of the man toward guarding—does he really want to guard it, or does he just simply want to ask somebody here where he can purchase a guard that will come already prepared, that he can slip over that? We had that same thing with the swing saw—simple as that appears now. There was a great deal of objection to covering the outside of the circular saw blade. How can we do it? How can we do it without stopping production? We would have to take the guard apart and take five or ten minutes to do it when we want to change a saw blade. That problem was solved very simply when somebody came along with the determination to do it, and that same thing exists to a large degree, in guarding all types of saws.

I know the railroad saw, as some people call it, or the foot-treadle saw, that was considered impossible to guard, for a while, but now you have several guards being turned out by commercial guard manufacturers. It is a question over and over again, of whether the man is fully determined to guard it.

I recall that in the chemistry profession that, as you know, you have certain principles for combining substances and they are supposed to unite and give you a certain definite compound, and it is supposed to be impossible to do it any other way. Well, several very important, far-reaching discoveries have been made in chemistry by some young chemist who, as it was put later, was damn fool enough not to know that it couldn't be done that way, and so he went ahead and did it.

G. A. ORT (Chief of Safety Dept., American Car & Foundry Co., New York City): There is one statement I would like to make in connection with the operation of saws. In our 16 plants, we have over a thousand pieces of woodworking machinery. All of the machines are equipped with safety devices. We have spent

over a million dollars in 17 years, in the application of safeguards. We have, however, in our employ, men who sometimes refuse to use the guards, throw them back, or take them off. Now, to prevent injuries to these men who can not see safety, we dismiss them, explaining why we put on the floor, a rubber mat to prevent slipping. I also don't know whether any of you have accidents due to slipping. We have had some. We have had fingers cut off, and I just bring that up thinking that it might be a suggestion that you may want to adopt in your own plants.

CHAIRMAN WALLACE: I have known that to be used successfully.

WM. FINDLAY (E. I. DuPont DeNemours & Co., Portland, Me.): To go back to this question of the gentleman over here about the guard for a circular saw in the woods—if anybody knows of one, we want to get the information on it.

CHAIRMAN WALLACE: Let's put that this way: Does anybody know of one?

MR. FINDLAY: We don't use many of them, but we use them in the woods in Maine, and we would like to know a way to guard them.

CHAIRMAN WALLACE: Does anybody know of an efficient guard for a circular saw in the woods?

ROBERT TOMS (E. I. DuPont DeNemours & Co., Portland, Me.): The discussion this morning has always come back to the point as to the efficiency of a guard and whether the manufacturers should be compelled to place them upon the machines, and the fact that after the manufacturers do place them upon the machines they frequently find them discarded and not used. It seems to me that the burden of having those guards used is entirely upon the management of the mill. A guard is placed upon the machine, and a man is asked to use that machine, and quite frequently you expect him to use that machine with that guard and turn out the same amount of stuff immediately, that he did before. He sees in that guard, a hazard, or something that is in his way, something that prevents freedom of action, and it is absolutely necessary, it seems to me, on the part of the employer, to give that man sufficient time to learn to use that guard increasingly and well and to teach him that to use that guard is really part of his job, that he is getting paid to use that guard upon that machine, and if he learns to use that guard efficiently, he is considered a more efficient man and should be a better man for the company, and better paid, and that part of his compensation will depend upon the efficiency with which he uses that guard. It seems to me that is one of the things that should be stressed in using all mechanical guards.

I know the attitude of the men, as a rule, and you can't change it unless you give them some incentive to use that guard when they have it.

Regarding guards on saws, I really don't know of any efficient guard for a circular saw, but we had an accident (fortunately, nobody was hurt). A band saw broke, as they frequently do. I was sitting in the office at the time, about 150 feet or 200 feet from the mill, and I heard the crash. I knew something had happened. I went down there and everybody was standing with his mouth open and looking scared, and I didn't blame them, because that jagged, broken saw lay across the carriage, less than a foot from the man who was operating the shifting of the carriage, and had that carriage been a foot from its position, we would certainly have had a fatal accident.

That led me to devise, if possible, some guard to prevent that saw from throwing itself over the carriage when it broke. Anybody who has used band saws, knows that they run at a high speed and there is a lot of potential energy released there if that saw breaks. We built down not a cast guard, but a steel guard and suspended that from the frame of the saw, so that it came down, as we thought, to a point that would never be touched by any log passing under that carriage. It came down so far in this position, so that it came out from the saw, followed to a certain extent. While we have never had a similar accident, I feel sure that should that saw break again, it would give a measure of protection to the man who was on the carriage.

CHAIRMAN WALLACE: Gentlemen, it is getting a little late. Our attendance is diminishing. Is there anything else that we have to take up before adjournment?

JOSEPH HONSA, JR. (Aetna Life Insurance Co., N. Y. C.): I would like to know something of your method in the maintenance of your guards in your plant—what procedure do you take? Do you let the operators operate those saws while the guards are being repaired or do you shut the machine down?

MR. OLSEN: We are in the position that we do not have our equipment guarded 100 per cent, so, to give you a direct answer to your question, I will say that if it is out of commission, they will not operate the machine. You know, guarding is only a small part of the job, anyhow. It is having the man properly instructed, and if you have got him sold on the idea of safety, the guard is only a small part of the job. You know, talking about equipment being guarded as it comes from the manufacturers, I think, that the manufacturers have gone a long way in the guarding of equipment and this applies to guarding of equipment in the mill, too. The reason they do not have guards that cover it better is because no standard has been developed.

One thing that I thought was always necessary was a brake on a jointer. They have made a move in this direction on the new type machines. They have provided a mechanical brake. It is only a question of standardization, and of course, that is a pretty hard thing to maintain, too, because, as we go along, our processes change and we develop new ideas. It is a pretty hard matter to maintain a standard.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Public Safety Division

October 1, 1928

HOMER E. NIESZ, Chairman

President, National Safety Council; Manager, Industrial Relations, Commonwealth Edison Company, Chicago

The first session of the Public Safety Division at the Seventeenth Annual Safety Congress was called to order at two o'clock by the chairman, Homer E. Niesz, President, National Safety Council, Chicago, Ill.

CHAIRMAN NIESZ: This is a general joint session of the Public Safety Division with Electric Railway, Public Utilities, Steam Railroad, and Taxicab and Fleet-Owners' Sections. Mr. Matthew S. Sloan, who is scheduled to preside at this meeting, was unable to be present, although he expected to be up until noon. Circumstances over which he had no control compelled him to be elsewhere this afternoon.

The first speaker on the program is chairman of the Public Safety Advisory Committee of the National Safety Council and is Vice-President of the Council for Public Safety. Mr. Miller McClintock, Director, Albert Russel Erskine Bureau of Street Traffic Research, Harvard University.

Facts vs. Guesses in Solving the Traffic Problem

By MILLER MCCLINTOCK

Director, Albert Russel Erskine Bureau of Street Traffic Research,
Harvard University, Boston

There are obviously very great differences between facts and guesswork, not only in the problem of traffic regulations but likewise in all human problems. Guesses are so easy that we fall into the habit of relying upon them. They come to us readily and we reach conclusions easily from casual observations. Sometimes guesses are right, and that further encourages us to do things in an easy sort of way. Guessing is easy. It is the principal way in the past in which traffic control matters have been handled, largely due to inherent laziness and the difficulty men have in forcing themselves to go to the trouble to acquire facts.

Facts afford a basis, not for casual conclusion but for accurate conclusion. They do not come easily. In any problem, as soon as one makes up his mind that he is going to find out what underlies that problem he is immediately confronted with the necessity to spend energy, time, and frequently money in obtaining those facts. When a problem becomes sufficiently important in economic and social aspects to justify the expenditure of time, energy and money, then the collection of facts as a basis for the solution of that problem becomes justified, and I submit to you,

that if there is any problem confronting American cities today which justifies time and energy, it is the traffic problem with its congestion, delay, economic loss, and the tremendous social aspects which result from the killing of citizens.

The National Safety Council has gained a position of importance and has come to have a position of leadership in industrial safety, because it has been unwilling to draw conclusions on the basis of guesswork and has insisted that careful organization and adequate funds be provided to make possible the investigation of the conditions which it attempts to solve.

I am sometimes impatient, as I go over the United States, to hear people say the matter of public safety, the solution of the traffic problem, is, after all, only a problem of education. It is obvious that education is no better than the facts on which education is based. It does little good to jump to conclusions and run to the press to gain some immediate publicity. That is too frequently done in the United States and, as I say, the National Safety Council and those associated with it have gained a reputation for themselves because they have looked at the problem as one which deserves the taking of pains.

I want, without being critical, to illustrate some of the facts that have come to my attention in the past few years of traffic activity in the United States which show the necessity of having sound control methods. This aspect of the problem invades all factors of the traffic situation. I will only pick out the two most generally interesting to illustrate this subject. In the first place there is the matter of the use of automatic traffic signals.

Signals are installed in American cities in many cases without consideration for the need of stop and go control, without consideration as to the need of signals at particular intersections, or the type of control and timing which will best relieve the situation.

It has come to my attention through studies, before and after signal installation in several cities widely separated in the United States that they did not, in fact, improve safety at all, but increased accidents. Yet I can assure you that the persons who installed those signals would have told you without the slightest question that those signals had improved the accident situation at those intersections.

It was my duty some years ago to undertake the study of traffic conditions in one of the largest American cities. I was informed by important merchants that the matter of parking must not be considered for legislation. I asked why and was informed that parking along curbs was so important from the standpoint of retail business that any change in the status of free or unlimited parking would be detrimental to business. I asked these business men who were thoroughly informed on their business how much patronage came from curb parking. The replies varied from 25 per cent to 50 per cent. Some months later I asked these men to cooperate with the agency I was serving and they were amazed to find that instead of 25 per cent to 50 per cent, they could only attribute 1½ per cent to this source.

Naturally, the question arises, how can we get facts? How can we organize agencies sufficiently intelligent and responsible to get the facts and when obtained to analyze them and draw from them logical conclusions? After you have facts you can guess about conclusions, in which case your facts are valueless.

There has been a movement in the United States during the last five years which promises to put the problem as it relates to accidents on our streets on a sound engineering and scientific basis. Two types of agencies have been used during the last five years which were intelligently financed and supported and have given valuable results.

The traffic survey is a temporary affair. It is an organization of the traffic agencies in the city who have decided that they need to take an inventory of their situation. A traffic survey is an inventory of traffic conditions designed to show

the city what are the facts in all aspects and ramifications of the problem and to build on the basis of those facts a fundamental system of traffic control. That is all that a traffic survey can be and all that it ought to purport to be in the beginning. Where properly conditioned it gives the community a new idea of what can be done in the way of sound engineering practice. It is temporary and, of course, of no value unless the methods used in solving problems of this kind are perpetuated in that community.

I wish I had time to tell you of the splendid work being done in a dozen cities by the street traffic engineers. I will mention two or three to show you how they are organized. San Francisco has a traffic engineer, a member of the Department of Public Works. That traffic engineer has been in office for one year. He went into a political situation, the kind in which you would think facts would not prevail. Today no action is taken in San Francisco without referring it for investigation to this engineer.

Chicago has Mr. Leslie Sorenson, and conditions from a political point of view have not been entirely favorable. This agency has made substantial progress and there again few things are done without a reference to this agency for investigation. I might go ahead and mention several similar agencies which are thus solving our problems on the basis of facts and not on the basis of guesswork.

CHAIRMAN NIESZ: Mr. McClintock's presentation of this subject is now open for discussion.

E. K. EASTHAM (St. Louis Public Service Co.): Mr. McClintock spoke of some particular study made with reference to parking in which it was shown that merchants derived about 1½ per cent of their business from customers who utilized parking space in front of those places of business. I wonder if Mr. McClintock could tell us whether that would be a fair general average.

Mr. McClintock: I am fearful it would not hold true for all cities. The studies reveal a wide variation. The percentage of trade varies according to the automobile characteristics of the retail district and the size of the city. In Boston we find that 8 per cent of the total patronage could be attributed to curb parked cars. No two cities would be alike.

MR. EASTHAM: Have you struck any cities where the percentage has been greater?

MR. MCCLINTOCK: Yes, San Francisco. The curb parking patronage was 11 per cent. The total amount of automobile patronage ran, as I recall, about 16 per cent.

CHAIRMAN NIESZ: Any further discussions on Mr. McClintock's address? Then we will proceed with the next speaker, who is Mr. Ernest W. Corn, Field Representative, National Safety Council, Chicago.

Community Safety Leadership

By ERNEST W. CORN

Field Representative, National Safety Council, Chicago

If it were possible to adequately map or diagram the organization structure of the average municipality, it would be found to possess an interesting mosaic of interlocking and overlapping community organization structure, a large portion of which is ineffective and to a certain degree unnecessary. This has allowed the initiated to cry "over-organized" both in season and out of season. It is my conviction that the average community is not so much over-organized as it is wrongly organized, and the reason for this is very frequently due to the type of leadership that has inspired the organizations.

In every community there are various forces assuming leadership either in or-

ganization work or in the molding of public sentiment. Some of these forces are constructive, and, if properly put together in a community set-up, would add materially to the well-being of those living in the community; but many of them make use of their leadership powers for selfish purposes or for ill-conceived ends. The faddist finds a fertile field in most communities. It has been said that you can organize anything, or sell anything, at least to a certain portion of the gullible public in the average city. This is the fertile field for the fanatic and the crank and frequently brings organization efforts into disrepute.

Then we cannot overlook the social or political climber who finds in the promotion of an organization the opportunity to place him or her before the people in the hope that such recognition will give additional community prestige that may be used either socially or politically, as the case may be, in the furtherance of their own particular selfish end. There is, of course, also the copyist who in the course of his or her travels finds some new type of organization, some new problem being solved or some new group attempting to solve a problem and feels that in view of the fact that this is being done in some other community it should be done in their old home town.

We could illustrate at length the results of such sentiment in the average community. I am of the opinion that there are a good many traffic lights installed in the United States without any particular knowledge as to the need but largely because they seem to be the proper thing in Pumpkin Corner or Penobscot. But, fortunately, in all of this mosaic of ill-advised community organization, we have the cropping up from time to time of organizations which are the product of careful study and well-defined ends. It can almost universally be said that these organizations are the ones that have been inspired by business men, promoted by business men and in the final analysis of their program financed from the same sources.

In the matter of community safety, there need be no question in the minds of anyone relative to the need of some kind of concerted community action in this field. Preventable accidents are prevalent everywhere. While street and highway accidents may vary with congestion and the number of cars registered in a particular area, and while industrial accidents may naturally be commensurate with the importance of the industrial community, at the same time it can very safely be said to follow reasonably well the per capita ratios of the whole country. But this is even more nearly true in the case of home accidents. The home is a home. The hazards of the household are substantially the same whether it be the farmhouse standing individually and alone on the plantation or the ranch, or whether it be tucked in, in the midst of apartment houses, paved streets, hotels and factories in the center of our great industrial population. It is entirely a reasonable conclusion that the prevalence of home accidents varies but slightly. So we do not need to study the accident situation to establish facts, but rather to adjust the program for accident prevention to the picture of the general community, and to locate its most important field of activity.

There are three things that we can always add to the fact of the universality of accidents; they are always costly in life, limb and human suffering; they are always preventable, and we have proven through years of experience that they are always amenable to organized effort. With this experience back of us, it would seem that we are justified in the conclusion that whatever may be the mosaic of organization of the average community, it is not over-organized nor completely organized until some concerted effort is being made toward the reduction of preventable accidents.

The history of the organized safety movement in the United States under the leadership of the National Safety Council appears to justify the conclusion that a year-round program of organized propaganda and education as well as engineering can be justly expected to have a very definite effect upon the frequency of

preventable accidents. The National Safety Council is an organization of national scope. When it serves industrial plants, it has the industrial organization as the medium through which it can function. Very early in the development of the program of the National Safety Council there grew a recognition of the need for a certain association of National Safety Council members in the large cities. Representatives of these various firms got together, exchanged their ideas and began to interest themselves in the general problem in their communities. These were called local safety councils.

At this time there was no idea of the larger function of the safety council as we see it today but these groupings began naturally to evolve certain community programs, with the result that in a few years we had the demand for a community organization that would function under expert management and would address itself to the entire problem of accident prevention wherever it happened to lie, whether in the shops or plants, on the streets and highways, in the homes or in other public places. This program has met with considerable favor and in sixty cities in the United States to a greater or less degree it has been worked out. City administrations have welcomed such organizations; Chests and Chambers of Commerce have frequently incorporated them in their general budgets and programs of work and in many places, due to particular local situations, the community has been willing to support them independent of all other organizations and give them a free hand in their accident prevention work.

The question has frequently been asked whether this form of organization is applicable to a small community or not. Many of the smaller cities do not feel the need of such an organization due to the comparatively small number of people who are killed by accidents each year. While this number may be just as large per capita as in the larger cities, it does not loom as important when evaluated in cities of from 25,000 to 50,000 as when looked upon in cities of 500,000 to 1,000,000. It has been a serious concern of the National Safety Council just what form of organization might be used in these smaller municipalities to at least impress the need for this kind of service. In the smaller cities the organization structure is very much more apparent, due many times to the fact that only a few men and women can be relied on to head up the various organizations necessary in their community set-up. The addition of a new organization in a city of this kind immediately meets with opposition. Additional financial campaigns or financial obligations are also met with opposition and it is a serious question in the minds of a good many whether a full-time executive is needed to handle the comparatively limited program that would be possible in a city of less than 75,000. In spite of the fact, therefore, that we contend that many cities are wrongly organized rather than overorganized, it is a fact that a saturation point of community organization is more easily reached in the smaller than in the larger city, and any additional groups organized find considerable difficulty in maintaining a healthy, active program that will keep them from being a drag on the community and more or less of a reproach upon the service which they undertake.

It has occurred to us that there is one group of business men in every community who should be intimately and vitally interested in accident prevention in all of its phases. This group of business men is comprised of those who head up the service corporations very largely and such community associations as really get the vision of the value of accident prevention as a community function.

In many ways the service organization is a very specialized form of business. Service is a perishable commodity. The handling of the business of this kind is a day-to-day program depending for its success upon community confidence and the repeated willingness of the constituency to buy the service. We sell electricity by the KW hour, gas by the 1,000 cubic feet, transportation by the ton mile or the man mile, telephone and telegraph by the word or minute and even do the family washing by the pound or piece. The life of any of these companies and many more

of a similar nature depends upon a continuous purchase of the public. In practically every instance their capital investment is comparatively worthless except as it is operated for the services of the public. This is unlike a store of goods which, if the public refuses to buy, might be resold and remerchandised. A gas plant is not worth much except when it is in operation and even a laundry becomes a building with a bunch of junk when there are no clothes to wash. Public relations, therefore, and public confidence are very essential to the success of the service corporations. Anything that tends to build this up is of direct and important concern.

Aside from inefficiency in delivery of service or a general spirit of discourtesy to the community, I can think of nothing so potent in breaking down this willingness on the part of the people to purchase continually and repeatedly as a feeling on the part of the public that the service is a hazard. Electrical and gas hazards have set up resale resistance. Delivery systems have been almost barred from certain parts of cities because of the hazardous driving of their automobile operators. Anything in the way of a devil-may-care attitude upon the part of a service corporation will immediately militate against its ability to properly sell its commodity. On the other hand, there is a certain human interest in accident prevention, and the service corporation that not only privately but publicly allows it to be known that it is interested in not only the safety of its own employees and its patrons but that it is interested in the safety of the public; that its operations are courteous; that it has the proper public attitude, will find this attitude very effective in turning public sentiment toward such a corporation.

In safety council cities, almost without exception service companies, both utilities and others, are our staunchest supporters. They support our programs with their finances, with their staff and with the prestige of the company in the community. In many instances our councils owe their inception to the leadership of just such corporations. It seems to me that in the smaller cities and in a relatively smaller way the same type of corporations should assume the leadership and that it would mean much to them as business institutions as well as render a much needed service in the community in which they do business.

Why not crystallize in the non-council city, even from a few thousand population up, all of the service corporations into a community committee? Why not get them together, talk the problems of preventable accidents over and see what sort of a community approach could be had by bringing the forces of the existing organizations face to face with the problem? I would call into such groups the utilities, the transportation companies, both rail and others, the insurance companies, the dairies, the laundries, the dry cleaners, and I would not forget that in a very definite sense the chamber of commerce, the automobile club, and the women's organizations are service corporations.

Diagnose the problem, see where its greatest need lies, secure the volunteer secretaryship of some interested employee of one of the corporations whose boss will give him the time to devote to this form of community activity. Then divide the field and allocate the leadership of the various types of accident prevention work to either individual corporations or classes of corporations and let them assume as their own program the action in that particular field. Do not forget, of course, that some of this work can be done by the automobile club, chamber of commerce, the women's organization or any other of the community associations already existing.

Then, under the leadership of the National Safety Council, lay out this field, so organize it and engineer it that each one participating stays in his own back yard and have the results clear through a common secretaryship to avoid overlapping, and we have not a new organization but a community function with activities allocated to existing organizations that should in the large do much for the prevention of accidents. It will be found in certain communities that the chamber of commerce will be willing to add at least the part time of an additional staff man

to function as the secretary and the director of such activities. My suggestion would be that in such instances, due to the technique involved in accident prevention leadership, this man should be chosen because he is a safety man and then have him do some chamber work rather than a chamber man to do safety work. In many instances, it has been our experience that the work has been sloughed by chamber staff men and has not been given the interest and enthusiasm that it deserves. I am convinced that no community of any size can afford to be without some type of accident prevention organization. It will not do the job of a large, well-financed Class A safety council but it will do something and that is more than is being done in many of our cities today.

In the above discussion I have not mentioned the industrial corporations as such. I would leave these organizations out of any community picture. Many of them, in fact, are members of the National Safety Council and many who are not have ample safety organizations and are doing a strong accident prevention job in their plants. Most wide-awake industrial corporations are now interested in community welfare. They are members of the chamber of commerce, they subscribe to the community chest, they give to the capital fund campaigns and many of them have their own welfare departments that follow the sick or injured employee to his home, advise him relative to economic maladjustments and in every sense of the word endeavors to tie him in to an industrial community in fact as well as in name.

These corporations are interested in accident prevention as it affects their employees outside the shop hours as well. Certain research work that we are making now confirms the opinion that in well organized safety plants it is not uncommon that three to four times as much time is lost due to preventable accidents outside of the plants as from those occurring inside the plants. These accidents occur on streets and highways going to and from work; they occur in the homes and in public places during the recreational hours of the employees. The man is just as dead, whether he is killed on the streets and highways or in the shop. The hole he leaves in the working gang has to be filled just the same. Labor turnover costs the same and the disruption of gangs and intensive operation results in the same loss whether this lost time is due to an accident in the industrial plant or whether the man is run down by an automobile on his way home. And so these corporations are interesting themselves in public safety, and rightfully so, the community will find them ready to cooperate and they, too, should be tied into the picture as described above.

And now just what do we expect to get out of a thing of this kind? Where do we come in? Must it be set down as a matter of philanthropy upon the part of the service corporations or industrial companies or even the associations in the community? Or is it possible for us to realize when we look at the situation more carefully that it is merely another expression of good business? I am convinced that it is not unreasonable to enumerate among the values to be expected from a program of this kind better public relations for the cooperating companies. Public relations is an asset, a reduction in sales resistance to certain commodities, from the installation of gas in the home to a feeling of safety upon the part of the man who buys his transportation by the mile in a taxicab. We might add to this a profitable protection of employees and their families whether during the hours of employment or while they are off duty. The experience of the safety councils has been that intensified community action under proper organizations and leadership results in a substantial reduction of preventable accidents in the average community.

Accidents are no particular respecters of persons and the innocent as well as the guilty are often the victims. Anything that increases the chance of protection and safety of the employee of any concern or his family is playing directly into the hands of that corporation. If I were in the executive offices of some large corporations I have known I would seek by any means under the sun to protect my corpo-

ration from the odium of the reputation of public carelessness. I would certainly see to it that a very radical change took place at once and I am sure that the executives of these companies would do the same if it were possible to hear the criticism that is directed at them many times by the general public. The cost of this change may never show on their books for they have never realized the advantages of such a reputation, so they cannot figure the loss, but it is there just the same.

Granting that a corporation is willing to do such things as I have described above, if they were to go out and undertake to discharge their obligation to the community, but to discharge it over their own men instead of through the medium of a community organization they would find the effectiveness of their program discounted due to the prejudices of the public who would contend that it was purely a selfish movement in behalf of public favor. The same results can be had and an increased preventive effected through a community movement without being discounted. And so we have the values of proper community relationship and in addition we have a very definite accrual in financial returns due to the reduction of preventable accidents. It, therefore, does not need to be classed in the category of the philanthropic but rather as a forward step in good business for any corporation that depends for its success financially upon the good wishes of the general public.

This brings us to the perfect analogy with the relationship of the National Safety Council and its service contact with its corporation members. When we get ready to do a job of accident prevention leadership for an industrial corporation, the first thing we will want to find out is who will be our representative in that organization, who will receive our material, who will put it across and who will help to crystallize into shop sentiment the ideas and suggestions that go out from our office. This has been comparatively simple because all corporate bodies are organizations. There is a natural crystallization of leadership here and, therefore, an increased efficiency in the relationship of the national organization with such concerns. But how shall we reach the community? Who shall we write to? Who will function by proxy for us in getting over the program we recommend for the reduction of accidents in a city? The only answer to this question is the formation of a community group which will assume the leadership and direction of an accident prevention program related to the community just as the personnel men or safety engineer of an industrial concern assumes the leadership for the accident prevention work in a plant. The program will always be more indefinite. It will be harder to make it 100 per cent efficient. It will be more difficult to get the cooperation of all of the elements of the city than it has been to get the cooperation of industrial employees. But be that as it may, if we are to do our job and if we are to render the service that we wish to give to cities of all sizes and in all locations, it must be either through the addition of this particular function to the present program of an association, community in scope and unselfish in purpose, that already exists, or the crystallization of a community group which will take the responsibility and discharge this leadership in an adequate manner.

This approach must necessarily be flexible. We have consistently refused to state a national policy upon it due to the very great variety of existing community organizations. In some cities we can confidently lay this obligation upon the Chamber of Commerce and realize that it will be efficiently discharged. In others, the Community Chest will be glad to make it one of its many duties. The automobile club is interested in street and highway safety especially, and relating its work to all ages from the school child to the adult driver, functions efficiently in certain fields of accident prevention, and it is not uncommon for a manufacturers' association to be very much interested in the work of its own plant's members. But relating the program to the individual community in whatever manner may seem feasible and wise, it still is the function of the community and if the provision for accident prevention in all of its phases does not exist and cannot be made to exist

through the present organization, then such a community has not fulfilled its entire obligation to guarantee, in so far as possible, life, liberty and the pursuit of happiness to every man, woman and child in its bounds until it has done something sincerely and unselfishly to protect them from the hazards of modern life and to preserve them whole in body, unhampered by economic maladjustments due to preventable accidents, and free from the worries and uneasiness caused by community hazards, by reducing in so far as possible those risks which are incident to modern society.

CHAIRMAN NIESZ: Mr Corn's paper is now open for discussion.

NORVIN E. GREEN (Louisville Car Wheel & Ry. Supply Co., Louisville, Ky.): Mr. Corn has told us about getting cooperation of street railways, public utilities, etc. We did that in Louisville and ran into great trouble because the general public thought we were a cat's paw for the taxicab company, gas and electric and street railway. We had for our first president, the president of the taxicab company and today we have the lowest rates on taxis in the world but the people were still suspicious. We could not get along without the financial cooperation of these organizations but I would suggest that they be kept in the background if possible.

CHAIRMAN NIESZ: The next talk is to be presented by Mr. Robert I. Catlin, Secretary of the Aetna Life Insurance Company, Hartford, Conn.

Why Insurance Companies Are Interested in Automobile Accident Prevention Work

By ROBERT I. CATLIN

Secretary, Aetna Life Insurance Company, Hartford, Conn.

I consider it a privilege to address you on this subject, as I believe the attitude and interest of insurance companies concerning this particular matter may be underestimated as well as misunderstood. Insurance companies are, I believe, doing far more toward promoting the saving of lives and property than the public realizes and I wish I had the time to tell you of some of the things which the Life, Casualty and Fire Insurance companies are doing in this direction.

Why are insurance companies, like the Aetna, which I represent, interested in automobile accident prevention work? Primarily for two reasons; first, they want to be, and, second, they must be. On the one hand, it is a matter of choice; on the other, a matter of compulsion.

Using a word recently popularized by President Coolidge, we "choose" to be interested in automobile accident prevention work because, recognizing the seriousness of the situation and appreciating to what extent our organizations, scattered over the length and breadth of this country can help, we desire to put our shoulder to the wheel along with other agencies, such as the National Safety Council, in order to see what can be done toward solving a serious problem; and, believe me, it is a serious problem.

When one stops to consider that during 1927 over 26,000 persons were killed and approximately 800,000 seriously injured through automobile accidents, and that the showing for the first six months of 1928 indicates at least 27,500 persons will be killed during this year, or approximately 100 people killed or seriously injured every hour of 1928, it can readily be seen the situation is not only serious, but that automobile fatalities and non-fatal injuries continue to climb at an alarming rate.

It is rather significant that 1927 is the first year that the number of deaths and injuries caused by automobile accidents increased faster than the number of cars

registered. The population of the country increased approximately $1\frac{1}{2}$ per cent, the number of automobiles registered increased 5 per cent and the number of motor casualties, 8 per cent. I believe these figures speak for themselves.

While I feel much can be said in commendation of the quality of work being done towards improving the automobile accident situation, certainly there is much room for improvement in the direction of quantity of work. Without, in any way, impairing the quality of work, we should bend our united efforts towards placing both the quality and quantity of work on a higher level and, in this direction, here are some of the things to be striven for:

- 1—A keener appreciation of the value of human life.
- 2—More efficient and courteous operators of automobiles.
- 3—More interest on the part of owners in keeping their automobiles in good operating condition.
- 4—Adoption of uniform laws and ordinances regulating the use and operation of automobiles.
- 5—A stricter enforcement of motor vehicle laws.
- 6—Education of the public, especially children, as to the effect of a growing congestion of automobiles.

Speaking of increasing the quantity of work, I should like to see the press of the country encouraged to give greater space to the presentation of facts and figures concerning automobile accidents, especially those occurring locally. If this data is presented in such a way as to attract attention, it is bound to create interest and, possibly, a determination to improve the situation. Legislative bodies should be encouraged to adopt much measures as have been suggested by the Hoover Conference on Street and Highway Safety and especially does this apply to the matter of the proper examining and licensing of *all* automobile operators.

Only twelve states: Arizona, California, Connecticut, District of Columbia, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, Pennsylvania, Rhode Island and Vermont require an examination of drivers before granting a license to operate an automobile. In six other states: Delaware, Maine, New York, Washington, West Virginia and Wisconsin, the examination is optional. I believe that considering the matter from all angles, it can be truthfully stated we have been very lax in the enactment of proper legislation which would require *all* operators to pass an efficient examination before obtaining a license to operate an automobile.

Lastly, there is the matter of more adequate information concerning automobile accidents. Aside from the States of New York, Connecticut and Massachusetts, very little is being done toward procuring and compiling data which show under what conditions automobile accidents are occurring. If we are to tackle the problem efficiently, we should have the necessary detailed information on which to base the attack.

As I have already stated, we are interested in safety work because, through compulsion, we must be. However, I am pleased to say the chief reason for our interest is a matter of choice.

Selling automobile insurance as we do, it is our desire as well as our duty to sell insurance protection to as many owners of automobiles as possible. To accomplish this, it is only reasonable to assume the more attractive we make our charges for insurance, the more easily the coverage can be sold.

Not over 25 per cent of the automobiles operated in this country are insured, i.e., from the standpoint of insurance affecting personal injuries and property damage. Furthermore, most of the automobiles insured are those located in cities and the territories immediately adjacent. Entirely too few automobiles in the smaller centers and rural districts are insured. Undoubtedly, the present cost of carrying adequate insurance protection is causing many to attempt to get by without it.

Now, what effect is the increase in motor casualties having on the cost of insurance? There can be only one answer, i.e.,—it is forcing the cost upward. In order to show you why this is true, I shall outline as briefly as possible the plan followed in the making of automobile rates or premiums.

Automobile rate making is essentially a problem in cost accounting. It consists in accurately measuring those elements which make up the rate. Generally speaking, the automobile rate is made up of two elements, one of which may be designated the loss and expense element, and the other, the overhead and profit element. The loss element represents that part of the premium dollar necessary to defray losses incurred under the policy contract and the expense of investigating, defending and settling claims. The expense element, sometimes referred to as "overhead loading," is necessary to defray the cost of acquiring the business, the administration of the business, the expenses of taxes and, at the same time, provide a profit to the company. It may be well to state that the profit allowance in the automobile rate is but $2\frac{1}{2}$ cents of the premium dollar.

The loss element of the rate, which is commonly referred to as the pure premium is determined from the detailed statistics of the insurance companies. For rating purposes, the United States is divided into approximately 250 territories and statistics are maintained along the following lines:

First, a separate experience is kept for every city in the United States with a population of 100,000 and over and for certain areas suburban to the larger cities.

Second, a group experience is kept on cities of 25,000 to 100,000 population in each state.

Third, a group experience is kept on all towns and villages of less than 25,000 population in each state and this is what is commonly known as "Remainder of state" territory.

It has been determined that a city ought to develop an annual exposure of 5,000 cars with attendant losses of about \$100,000 before its individual experience can be given any credence. Communities developing less than this minimum exposure are grouped together with other communities of proportionally the same hazards, so that a dependable volume of experience may be used for establishing rates. Separate statistics are maintained for each line of automobile insurance and within each line, a statistical division is made for the type of car insured, be it private, passenger, commercial, public or dealer or garage. Under each of these divisions a record is kept of the number of cars insured, the premiums received, the losses paid and outstanding and the number of claims arising in connection with the operation of those cars.

The pure premium or the loss element to which I have already referred, is really the foundation of the rate and is obtained simply by dividing the sum total of the losses incurred, inclusive of all claim expenses, by the number of cars exposed to risk. In calculating pure premiums, the experience for four years is usually taken into account, modified, however, by such trends as may be evident.

A knowledge of local conditions is invaluable to the rate maker. Local business conditions, the political situation, the existence of public safety activity, the legal situation, the prevalence of ambulance chasing and other things of a kindred nature, are particularly valuable in the interpretation of the available statistical data. Specifically, they give concrete meaning to upward and downward trends that may be indicated by the experience.

After pure premiums have been calculated for various territories and classifications, the next step is to work out the rate, which is done through adding a reasonable loading for the overhead or expense element.

It is hard to conceive of any other business that analyses its costs so minutely and which is willing to have the result of that minute analysis publicly known.

Now that I have sketched briefly the basis on which automobile rates are made,

I want to emphasize this particular point, i.e., the fact that individual communities with a dependable spread of experience are rated on their own individual experience. Therefore, in a very large measure, such communities have in their own hands the power of making their insurance rates. It naturally follows that if the number of automobile accidents increases, the rates must naturally show an upward trend. On the other hand, if such communities get back of an efficient safety program and thereby improve their automobile accident situation, lower rates may be anticipated.

According to information recently released by the National Automobile Chamber of Commerce, twenty-five of our larger cities show more than a 10 per cent increase in motor fatalities for the first seven months of 1928 as compared with the same period for 1927. Considering the amount of safety work being done in some of these cities, the showing, I feel, is rather discouraging.

What are some of the things the insurance companies are actually doing to improve the automobile accident situation?

First, through the establishment of Safety Engineering Departments, a great deal of study is being given to an analysis of the causes of accidents, especially those applying to risks insured.

Second, at every opportunity company employees, agents and other representatives are being encouraged to tie in with the work of local Safety Councils or any other safety movements and appreciating that these representatives are scattered throughout the cities, towns and rural districts of the whole country, it would seem that much might be accomplished through this medium.

Third, through the National Bureau of Casualty & Surety Underwriters, effort is being made, especially along educational lines, to assist in the plans laid out by the National Safety Council.

Fourth, through the rendering of accident prevention and safety engineering service for motor fleets. Usually, this safety service is so flexible that whatever conditions surround a particular risk, it can be readily adapted to fit the situation. Among the features which have been designed to assist fleet owners in carrying on a regular campaign for safe driving are the following:

- Safety slogan cards for installation in each automobile.
- Drivers' lessons to inculcate the principles of safe driving.
- Safety bulletins for posting on garage bulletin boards.
- Drivers' meetings with talks by experts and round-table discussions.
- Accident report forms.
- Vehicle defect report blanks for the convenience of drivers in reporting any repairs that may be needed.
- Accident analyses charting any accidents that may have occurred, showing cause and nature.

Recommendation on personnel, based on our records and specialized experience.

Routing so as to avoid danger zones and increase efficiency.

When urging owners of motor fleets to tie in with accident prevention and safety engineering service, we point to the fact that considering the matter purely from a selfish standpoint, they cannot afford to disregard the issue. Here are at least nine reasons why accidents involving the fleet owner's automobiles affect his pocket-book and business:

- 1—An abnormal depreciation of the equipment.
- 2—Increases in monetary investment through the necessity of procuring extra equipment.
- 3—Cost of making repairs to damaged automobiles.
- 4—Damage to merchandise transported.
- 5—Loss of trade caused by unreliable deliveries.
- 6—Loss of the advertising value of well-kept and operated equipment.

7—Adverse effect of damaged equipment on drivers.

8—Loss of good will which is so essential to any well-run business.

9—Increased cost of proper insurance protection.

It is indeed gratifying to be able to report that through each of the four mediums which I have mentioned, satisfactory results are being obtained and the outlook is promising.

In closing, I should like to refer briefly to compulsory automobile insurance concerning which there is much discussion today. Time will not permit my saying more than this.

The chief concern and effort of the public should be directed towards the elimination of automobile accidents, rather than towards providing a monetary compensation for those affected by the effect of automobile accidents. In other words, placing first things first, let's tackle the cause of automobile accidents and I am sure the effect will take care of itself.

While there is much to be said for and against compulsory automobile insurance, I believe that wherever and whenever the subject is considered, first attention should be given to ways and means of eliminating automobile accidents. Then, that problem has been properly attended to—careful study should be made as to the proper way of compensating innocent parties whose person or property has been injured or damaged through an automobile accident.

It is far more important to save a life than to compensate for one.

CHAIRMAN NIESZ: Any discussion or question on Mr. Catlin's paper?

HARRY RAINES (Director, Washington Auto Driving School of Brooklyn, N. Y.): Have you ever made any studies of a group which is not insured and a group that has been insured?

MR. CATLIN: I do not believe that the carrying of insurance increases accidents. I believe a relatively small proportion of automobile owners become more careless when they carry insurance. That has been borne out in Massachusetts by the experience under their compulsory automobile law. We try to eliminate those persons whom we insure if we find they are irresponsible or careless.

MR. RAINES: Does insurance check up the driver to see what experience he has?

MR. CATLIN: Our Company spends \$100,000 a year investigating prospects for automobile insurance. We investigate them as far as we can.

MR. RAINES: I think they should investigate the driver to show proof of his experience before his insurance is issued. Under my experience when they enter our school, a fellow says, "I want a few lessons, how long will it take?" We tell him it will take so long and he says, "Oh, I only want a few lessons, I am insured."

MR. CATLIN: I do not think it is our duty or responsibility to weed out the irresponsible drivers. I think that is a duty that belongs to the State. (Applause.)

PERCY C. ABELL (Mgr., British Columbia Safety League, Vancouver, British Columbia, Canada): May I ask what is the fate of the widows and orphans of people suffering from irresponsible automobile drivers?

MR. CATLIN: I believe a study should be made as to proper compensation to those who are hurt through no fault of their own but this is certainly not the right way to approach the accident problem as I see it. Let's get at the cause. I believe all of you realize that it is only right and fair that those who do suffer through no fault of their own, a personal injury or damage to their property, should receive compensation and therefore we are urging owners to carry insurance protection so that when it comes to a matter of compensating someone they will get it.

F. H. WYSE (Canadian National Safety League): What results have been obtained by compulsory automobile insurance in Massachusetts?

MR. CATLIN: It is too early to state definitely the effect of the Massachusetts Law. We have not seen sufficiently the effect of that law to comment very intelli-

gently upon it. However, I believe that persons sustaining personal injury in Massachusetts are receiving compensation in many instances even though they were contributory in causing the accident. We know that the number of accidents, the number of fatalities, the number of non-fatal personal injuries have increased but whether or not these are caused by the law I cannot say.

LOUIS MCBRAYNE (Massachusetts Safety Council): For personal injuries under compulsory insurance I think there are no legitimate unpaid claims. There are pending a great many cases where the motorist did not carry property damage and claimed under \$100 personal injury. When it is difficult to prove that anyone suffered, we investigate. An investigation brought out the fact that there was a downward trend in fatal accidents as against last year; a downward trend in injuries to pedestrians and an increase, apparently, to occupants of the cars. The motorist did not hit as many pedestrians but apparently injured more people in cars.

MR. WYSE: I would like to ask if there is any better reason for compensation for the industrial worker hurt in an accident than for compulsory automobile insurance?

MR. CATLIN: Several plans are being tried out: the Massachusetts plan, the New Hampshire plan, the Connecticut plan, all of which have in mind the same purpose and I feel that it is entirely too big a problem to jump at conclusions. Some of those states that have enacted compulsory laws are now already inclined to believe that they acted too hastily. I personally feel this way: Instead of following the Massachusetts plan I believe that the logical plan is the one being tried out in New Hampshire and proposed in New York and Pennsylvania which plans were passed by both legislatures and were not signed by the Governor for certain reasons. That law provides that anyone causing a personal injury or damage to property shall either compensate that person or surrender the operator's license pending a disposition of that claim. That is the most economical and practical way to go at this problem. I do think it is wrong for us to go into a plan of this character with such far reaching effects without first analyzing and studying the effects in those places where it is being tried out and fairly tried out.

CHAIRMAN NIESZ: This subject is a very interesting one and might be carried on for some time. It will be necessary to proceed with the next paper on the program, which was to have been presented by Mr. John W. Lieb, Vice-President and General Manager of the New York Edison Company, New York City. Mr. Lieb was unavoidably detained on account of having to attend another convention this same week. His paper will be presented by Colonel J. P. Jackson of the New York Edison Company, New York City.

The Contribution of the Electric Light and Power Industry to the Safety Movement

By JOHN W. LIEB

Senior Vice-President, The New York Edison Company, New York City

The electric light and power industry has been a dominant influence in the United States in promoting safe living and working conditions, by having provided the means for effective lighting, relatively safe industrial working conditions, and the reduction of heavy muscular labor.

After the early scientists and discoverers, Volta, Ampere, Oersted, our own Joseph Henry, Michael Faraday, Benjamin Franklin, and a long line of distinguished investigators and inventors, had wrested from Nature a sufficient knowledge of electricity and its practical applications, electric lamps, arc and incandescent, were invented and made easy the lighting of pitfalls and dangerous or dark places.

Largely because of the availability and knowledge of electricity, the application of the electric motor and electric drive has resulted in the creation of the labor-saving machines and appliances of today. These machines, through the medium of ingenious, power driven, materials handling contrivances, constitute the modern facilities for the orderly, economical, and relatively safe chain of operations from raw material to finished product required for America's enormous mass production.

The contribution of the industry to the safety movement also includes active service in the development of safe practices in the generation, distribution, and utilization of electricity for the protection of its own workers and the public; cooperation with the medical profession in studies of the effects of electrical shocks, methods of resuscitation, and other needed treatment for those who have been shocked; and aid through its electrical service in the effective equipment of hospitals and sanatoria with ultra violet light, X rays, fluoroscopes, etc., and in the use of a large number of electrical instruments which now form part of the resources of the medical profession.

Attitude of the Industry

The attitude of the electric light and power industry toward the safety of its employees, and of the public which it serves, was well set forth in an address by your chairman, Mr. Matthew S. Sloan, delivered before a group of safety experts at a recent meeting of the Empire State Gas and Electric Association in Albany, New York. He said:

"In considering accident prevention or safety work, there are two points of view which come to any public utility executive. The first, and to my mind the dominant one by long odds, is the moral obligation involved. I hold that we are morally obligated to do everything possible within our companies and within our industry to prevent accidents and to assure the safety of life and limb of our workers on the same basis as we are morally obligated to be honest in our business transactions. A basic human relationship is involved. It is our responsibility, and it is our privilege. In an industry which has ideals such as ours, and which serves the comfort and happiness of human kind, we could not evade if we would this responsibility for saving the flesh and blood of our own people.

"We have also a responsibility in this respect to the general public—a responsibility as companies to safeguard members of the public as well as our own people so far as our operations carry or tend to carry any hazard affecting the public; and a responsibility as an industry to do our part with other community agencies in general safety movements."

The electric companies of the United States have accepted the obligation and responsibilities to which Mr. Sloan referred, and are giving to them the same intelligent attention that is applied to problems relating to engineering equipment, good service, continuity of operation, and economy in electrical production and distribution.

Electric Illumination

Probably the greatest single step in the direction of safety was taken when Thomas A. Edison invented a practical, flexible, and portable electric incandescent lamp, and shortly thereafter started operation of the first central station for the generation and distribution of electrical energy for light and power purposes, in Pearl Street, New York City, in 1882.

The combination of the generating station and a practical system for the general distribution of electricity which rendered the incandescent lamp commercial, made possible the introduction of safe lighting units in the workshop and the

home, and made available their application in widely varying sizes and adaptation to all possible situations. The effects of this have been almost revolutionary in nearly every phase of life.

In the home the electric lamp has promoted the prevention of accidents by making unnecessary the use of the candle, kerosene lamp, the fish tail gas burner, and other open flames used for lighting, and its ready use for illuminating stairways, cellars, attics, closets, and other dark places.

In the factory and shop the application of electric lamps has made possible industrial production in pleasant environments with adequate general illumination, with effective local illumination over the machine tools, and with portable lamps for close inspection of delicate processes, all of which are contributory not only to better safety conditions for the worker but result in greater output and better quality of product.

In the days before electric service had become common, the large and usually dull and unattractive interiors of shops were difficult to light; today, good lighting is the rule in all properly equipped industrial establishments. The localized intense illumination needed for safety and efficiency in industrial operations requires not only intensity and concentration of light on the work, but lamps which can be placed at any point and moved around to any position, with appropriate shades and reflectors to project the light and protect the eye. Electric light is particularly well adapted for such service, especially in the units provided by incandescent lamps. Railroad or shop yards, and other work places not under roof were relatively unilluminated before the electric arc light became available. Kerosene lanterns carried by workmen were almost the only form of lighting, with the result that such places were often quite hazardous. Today, in the yards of establishments where work is carried on at night electric illumination of high intensity furnished by arc lamps or now usually by large gas filled incandescent lamps is the rule. In underground work in mines and quarries use of the electric lamp in drifts, shafts, mine "rooms," etc., has proven particularly valuable as a safeguard to life and limb through avoidance of the terrible explosions of mine gases. Mine haulage by electric locomotives and trains has contributed not only to the more efficient handling of coal and ores but has produced safer and more satisfactory conditions for the mine worker.

Those who have studied the subject state that many industrial establishments have failed as yet to obtain the full advantages of electric illumination for promoting production and safety. This is a weakness that should be quickly rectified, for the cost of adequate illumination is so moderate compared to the total cost of the product that a small improvement in lighting brings most abundant returns in improved production.

The immeasurable advantage in the prevention of accidents by the use of electric lights on the streets of our cities needs no argument or illustration; it is self-evident. Those who can remember the conditions existing before the days of electricity, or those who were compelled to go about in the darkened cities of Europe, during the great War, must have a vivid conception of the improvement in safety which has been gained by efficient, modern systems of street lighting. The need of light where traffic is heavy, is rapidly causing roads to be lighted for long distances out into suburban territory, and it seems likely that this practice will gradually be extended until all important, heavily travelled, through roads have been covered. With the rapid networking of the country with electrical transmission and distribution lines, this result is yearly becoming more easy of accomplishment.

The Illuminating Engineering Society, the American Institute of Electrical Engineers, the National Electric Light Association, lamp manufacturers, and others have given much study to the best illumination for different purposes.

Thus, as an illustration, in shops good lighting intensities may be found to vary between 1 to 20 or more lumens per square foot at the point of use, depending upon the character of work to be done; in outside construction, from $\frac{1}{4}$ to about 5 lumens per square foot may be needed on the work; on streets it may vary from a few hundredths to one or more lumens per square foot at the road surface, depending upon the kind and character of the thoroughfare. The lumen is the amount of light that will fall on one square foot of a sphere one foot in diameter with a unit candle at its center. Each lighting project, however, must be carefully studied separately to obtain the best results required for local conditions. Of course, shading, reflection, absence of glare and quality of light, as well as volume, enter into such studies.

Incidental to safety on the highway, rail or water, electricity has been fundamental to the development of effective signal systems and satisfactory head lights for moving vehicles. Modern lighthouses, with their extremely strong lights, channel buoys, and automatic colored street signals are developments resulting from the extended use of electric power. Undoubtedly, signalling and high power beacons for landing fields required in the air service will be equally dependent upon it, making night flying safe and expeditious.

The sessions of the International Congress on Illumination held at Saranac Lake during the week just closed were largely taken up in the discussion of signaling systems for streets and highways, standardization of signal colors, head-lights for passenger automobiles and trucks, illumination of streets, highways, and factories and relation of lighting intensity to output and avoidance of fatigue.

Power in Industry

The electric light and power industry has contributed greatly to the safety of industrial work by making it possible to substitute electrical power for mechanical power and human brawn.

In a plant driven and operated by mechanical means alone, the power must be transmitted and applied in the individual machines through the use of rope-drives, shafting, pulleys, belts, gearing, clutches, or other mechanical transmission and speed changing contrivances. Many accidents have occurred because of these mechanical devices. The substitution of the direct connected electric motor permits the transmission of the necessary power through insulated and protected electric wires; and the finest changes of speed of electrically driven machines can usually be made without the use of cone pulleys or gears, or at least a substantial decrease in their number is possible. The result of this has been that the production hazards in American factories, when electrically equipped, have been much reduced. Any attempt to use mechanical power alone for the huge mass production, as developed in the last few years largely through the practicability, flexibility, and convenience of application of electrical power, would be found impracticable from the stand-points of operation and economy and would also offer hazards to the life and limb of the worker which would prove a serious if not prohibitive obstacle.

One of the most useful characteristics of electrical power, for promoting safety, is its easy control and flexibility. Thus, in a train of operations, such as in paper making or newspaper printing, it is possible through electrical control to shut off the power at many points. By this means a workman may protect himself by cutting off the power instantly from the place where he is at work and preventing its being turned on elsewhere. In handling materials, the ease of control and ready application of electricity to cranes, hoists, conveyors, industrial motor cars, etc., has been especially useful. Handling materials is the greatest source of accidents in most industrial plants. Nevertheless, the number can be kept down. Thus, an organization of about 800 men, which stores large quantities of light and heavy

machinery and other supplies, had an accident frequency of only 8.54 per million man-hours during the first six months of this year. This excellent record must in part be attributed to the work of an active safety organization in the works, but a large part is due to the equipment of easily controlled, electrical, materials handling apparatus.

Often the possibility of remote control of electrical machinery is of substantial value in the prevention of accidents. Such control is to be found in the use of electromagnets in connection with a crane for handling scrap iron by an operator placed far out of danger. The handling of hot metals in foundries and steel mills is another illustration of such control. The extent to which remote control may be carried is shown in the newly opened, automatic sub-station, the so called Robot Sub-station at Spuyten Duyvil, New York City, which is sufficiently large to serve as a center of electrical distribution to cover a large city. In this automatic plant the numerous operations of switching and control are performed by operators located at a distance of several miles.

The reduction of fatigue among workmen is another salutary source of accident prevention resulting from the application of electric power for industrial operations, handling and conveying materials, etc. Today many of the most burdensome duties, earlier done by hand, are performed by electric power. This makes the workman, to a much greater extent than has ever been the case before, a controller of power rather than a producer of power. Parallel with this, therefore, is a reduction of over-fatigue, which dulls the senses, induces inattention, and is considered a prolific source of accidents.

The Extent of Electric Utilization

The extent to which the safety features, accompanying the use of electricity, have been made available in the United States, are indicated by the following figures:

Generation of power by the central stations in this country, as tabulated by the Electrical World, for the year 1927, was approximately 75,600,000,000 kilowatt hours or a little over 100,000,000,000 horse power hours. The same authority states that there were, during that year, about 17,600,000 domestic lighting customers of the power companies, who received power from the central stations, and it estimates that 63 per cent of our population had the advantage of electric service in their homes. In addition to this, practically all of the residents of the United States are, more or less, incidentally and indirectly protected from accidents by means of electric light through its use by commercial and industrial establishments and on our streets and highways.

The amount of electric energy consumed per capita in the United States far exceeds that in the three largest nations of Europe as indicated by further figures from the Electrical World, given below for the year 1925.

United States	680 kilowatt hours per capita
Germany	320 kilowatt hours per capita
Great Britain	220 kilowatt hours per capita
France	220 kilowatt hours per capita

The National Industrial Conference Board has tabulated data from the United States Census of Manufacturers which give the following significant information in regard to the large and growing use of electricity in American industrial production:

1899	Total electric power used in manufacture, 493,000 horse power
1925	Total electric power used in manufacture, 26,000,000 horse power
1899	Per cent of electrical power in manufacture, 4.9
1925	Per cent of electrical power in manufacture, 73.0
1899	Per capita horse power per wage earner in manufacture, 2.11
1925	Per capita horse power per wage earner in manufacture, 4.27

The trends indicate continued increase in the electrification of industry, and in the amount of power placed at the service of each worker.

This availability of electric power at the beck and call of the worker, by the simple pressure of a button, lies at the very foundation of the economic efficiency of labor and this great advantage is undoubtedly one reason for the high production per worker and the possibility of paying high wages, which constitute one of the great advantages possessed by American industry.

Safe Practices

Electric power itself, as supplied by the electric light and power industry to its customers, is undoubtedly safe when properly installed and used. However, like any other power, such as a moving fly wheel, grinding machine, or motor truck, it is dangerous if wrongly used.

From the early days of the Pearl Street station much attention and concern was given to the proper installation of electric wires and equipment. At first, however, efforts were largely confined to promoting good service and preventing hazards from fires. As voltages have increased for transmission, and the distribution and utilization of power have become more wide-spread, greater consideration has been given to the development of safe practices and safeguards designed to protect the worker in the electrical industry and the general public.

These safe practices are recorded and published in printed codes. Thus, very early in the history of the industry, in fact at its very inception, it joined with the Fire Underwriters in building, and keeping in pace with the times, a safe code of good wiring practice. This code, called the National Electrical Code, has become generally recognized and is commonly accepted as representing safe practice. Though it has been directed primarily toward the prevention of fire, it has served admirably also, in most cases, as a guide for the maintenance of good service and the protection of life. In about 1914, especially for the purpose of protecting against personal accidents from electricity, the industry joined with the United States Bureau of Standards in developing the National Electrical Safety Code, which supplements the National Electrical Code, spoken of above. These two codes taken together furnish an excellent compendium of safe practices, which, if followed carefully, may be depended upon largely to eliminate hazards and prevent accidents in the nature of electric burns or shocks; they have both been approved as American Standards by the American Engineering Standards Committee.

The electric light and power companies, in addition to providing the safe practices and guards called for in these codes, and as otherwise found desirable, often at large expense, have fallen into line with the safety movement of the country through the medium of effective safety education and organization. This phase of activity is beginning to be quite fruitful and some of the electric companies are making safety records within their organizations which are highly commendable. In fact the electric light and power industry can justly lay claim to having been a pioneer in the safety movement and a leader in the introduction of safety devices, protective devices, and the promotion of effective company safety organizations.

Safety for Central Station Employees

In dealing with high voltages, probably the most difficult problem the electric light and power industry has had to meet is that comprised in human proneness to carelessness, abstraction, and inattention.

Thus, to protect the workman from his own weaknesses it has been found necessary in power plants to have each high voltage switch (often called a circuit breaker), and each of the other pieces of high voltage equipment, installed in an individual fireproof compartment. These compartments are placed in locked switch

galleries. (This excepts the cables which are in protected tunnels or ducts.) Each compartment in a switch gallery is closed in front by doors and is carefully numbered and marked with danger signs. The high voltage switches are operated from "control boards." On these boards are low voltage, hand operated, switches for operating motors or other appliances, by remote control wires, which in turn close or open the high voltage switches in the compartments.

Before a workman is permitted to remove a door of a compartment containing a high voltage circuit breaker or other apparatus, he must receive written authority from the operator in charge, with information that the apparatus on which he is to work has been cut off the circuit and is "dead." The authority is given only after the operator at the control board has blocked open and tagged the control switches on the control board, which open such main switches in the compartments as are necessary to isolate the high voltage apparatus to be uncovered, and any other steps necessary to safety have been taken. The control switches cannot be closed without removing the blocks.

In taking off doors to apparatus it has been found desirable to have two experienced men sent together in order that they may check each other. These men both follow the written instructions of the operator in charge. For further protection they make such additional tests, while in the switch galleries, as are necessary to prove the circuit dead upon which work is to be done. One of the common tests used, for ordinary generating station voltages, is by means of a "test stick." This consists of a fuse and proper resistance or reactance, one end of which is directly connected to a ground, the other end connected through a flexible wire to a metal piece at the end of a long insulated handle, which the workman may safely use to touch the apparatus to be tested.

When the workmen open the doors of a compartment in accord with instructions, and after the tests have been made, they block the switching mechanism, if the apparatus in the compartment is a switch, so that it cannot be closed even from the control board. They then, as required, place ground connections, for further protection, in such a way that it is impossible for the equipment to be made alive even if the switch should be accidentally closed. They also attach tags to the apparatus, after it has been made safe for workmen, which show it to be dead and, if such is the case, that men are working upon it. Workmen wear rubber gloves in all operations involving high voltage equipment.

In spite of the careful procedure set forth above, the safety numbering and markings, and the use of two men, mistakes now and then occur due to the failure of the human element. The power companies are thus finding it desirable to use locking systems on their high voltage compartments, whereby an employee can only get into the compartment for which he has a key and, by means of interlocking arrangements, into others in the right order of progression.

The New York Edison Company is at present installing a system of interlocks, controlled by radio appliances, so that a compartment cannot be opened, if apparatus contained within it is alive, even though the workman has the right key.

The industry has been equally thorough in developing safe procedure for working upon high voltage distribution circuits both underground and overhead. It has also given much thought and attention to developing and supplying safeguards, such as rubber gloves, rubber protectors for covering wires, asbestos blankets for protecting workmen from cable explosions, especially designed protective tools, etc. The safeguards are periodically tested and inspected. It is seldom that wires carrying more than the commercial distribution voltage are worked upon when alive, and then only when urgent necessity demands and with the exercise of very great precaution. Nevertheless, when working on disconnected or dead apparatus, many of the same precautions are taken as though it were alive to protect against danger should the apparatus be made alive accidentally.

The principal requirements of this safety procedure are set forth in detail in the National Electrical Safety Code, referred to earlier, and it is included, in addition, in the detailed written or printed safety rules of the individual companies. Employees must learn and follow these rules. They are taught to understand them by individual instruction and through the medium of formal, scheduled classes.

The result of all this safety work has been that fatality rates in the industry among electric light and power employees have been reducing steadily.

Asphyxiation

The industry has been deeply interested in methods of resuscitation for application in cases of electric shock. In 1911 the National Electric Light Association arranged for a commission of eminent physicians and scientists to study the subject.

The result of this and later studies has been the general adoption, by those interested, of the prone pressure method of artificial respiration, such as originally devised by Sir Edward Sharpey Schaefer. The method is quite simple and applicable for reviving cases of drowning, gas asphyxiation, and electric shock. It is recommended that the employees of all industries should learn this method. Indeed everybody should be familiar with it. The following figures show the field for its use:

Fatalities in the United States in 1924 as given by the United States Census are,	
By drowning	7,158
By carbon monoxide gas	4,166
By electricity	975

The electrical and gas companies are very generally teaching their employees the method. The New York Edison Company, with an employee enrollment of 13,234, gave instructions in the prone pressure method to the extent of 35,541 employee-instruction hours in 1927.

As in the Consolidated Gas Company and its other Allies, the teaching is done by trained employees in classes of about 20 men each.

Despite past studies, but little is known of the physiological effects of electricity in cases of electric shock. To promote further study of the subject, a National Research Committee has been organized under the general direction of Dr. Simon Flexner of the Rockefeller Institute consisting of eminent medical and scientific experts to carry on research concerning electric shock, electric accidents, and resuscitative and preventive measures. This committee in addition to other activity has already advanced its research signally, by having developed in the laboratory a method which gives hope of ultimately being able to restore a fibrillating human heart to normal movement. Heart fibrillation is one of the frequent consequences of electric shock and has heretofore been considered a fatal condition. The work of this committee, already advanced on animals, leads to the hope that we may obtain the knowledge necessary to save human life in accidents of this kind.

The National Electric Light Association awards the Insull Medal to the employees of the electric light and power industry for saving life by the prone pressure method of resuscitation; the American Gas Association awards the McCarter Medal for similar service by employees of the gas industry; and the National Safety Council gives a medal for the successful use of the method, to persons who are not eligible for other resuscitation medals. The first makes awards in cases of electric shock, the second for cases of asphyxiation, and the third for any saving of life by the prone pressure method. These awards have proven to be an aid and inspiration in life saving.

From the foregoing, the members of the National Safety Council will recognize that the electric light and power industry, by the nature of its business, its resourcefulness, and its progressive spirit has contributed largely to improved safety conditions in the United States. Also that it has been an active agent in accident preven-

tion through education, study, and development of safe methods for using and controlling electricity, and by cooperation with the medical profession, the police, fire departments, and other interested bodies.

The cost of accidents is high: an insurance organization reported in the case of a group of rather hazardous occupations, for an annual payroll of over \$76,000,000, that the compensation costs, based on the New York law, amounted to slightly over three per cent of the payroll. Another study by an insurance expert indicated that total costs of accidents were about four times the compensation payments. The activities of the industry, however, so far as they relate to accident prevention and safety, have not been carried on so much for the immediate economic advantage they secure, as for the purpose of meeting the high ideals the industry has set for itself, the discharge of its moral obligation toward its own workers and the general public, the doing of its part toward the advancement of the general welfare, and the furtherance of the comfort and happiness of mankind.

CHAIRMAN NIESZ: We were fortunate in having this paper printed and distributed to those attending this meeting. We will now have an opportunity for discussion or any questions you may wish to ask Colonel Jackson. If there is no discussion of the paper, I would like to express as Chairman on behalf of those represented at this meeting our grateful appreciation for their presentation of the subjects on which they have spoken and the very interesting contributions and valuable material they have given us for this meeting of these sections jointly.

ADJOURNMENT

October 2, 1928

Accident Facts—How to Get Them

LOUIS I. DUBLIN, PHD., Chairman

**Chairman, Statistics Committee, National Safety Council; Statistician
Metropolitan Life Insurance Company, New York City**

The session was called to order at ten o'clock by the chairman, Dr. Louis I. Dublin, Chairman, Statistics Committee, National Safety Council.

CHAIRMAN DUBLIN: It has always seemed to me that the National Safety Council was to be commended because it was one of the few service organizations that realized, very early in the game, that there was a place for the gathering of facts in the development of their program. I think the characteristic of most workers that serve the public—the so-called welfare agencies—is that they are moved more by considerations of goodwill than by considerations of knowledge and direction by fact. But the Safety Council is not one of those. At the very beginning in its campaign against the industrial accidents, it realized that if it were to get anywhere in the development of a campaign, it would have to gather facts, and so facts were gathered as to the number of industrial accidents and the time and the place and the how of those accidents, and it was an inspiring fact to see how under these auspices industrial accidents came very largely under control. It is to the everlasting credit of the Safety Council that it started that campaign that way. So when the proper time came to take notice of the equally important situation with regard to public accidents, it was necessary to organize a campaign first for the gathering of facts, and, so, some seven or eight years ago a committee of this section was appointed, a Statistics Committee, whose business it was to not only gather facts, but to develop methods for the proper gathering of them.

I have been associated with this committee some five or six years as the chairman. It has been a joy to me to be so associated with a group of men who have given unstintingly of their time to develop a methodology for the gathering and the analysis of facts with regard to the public accident situation.

Year after year we have reported to you an annual statement covering the situation as best we could. We have developed a system by which the facts of public accidents can be gathered. We have developed that system by constant agitation and change as the situation showed it necessary. We have also propagandized, developing interest on the part of the authorities, both state and municipal and federal, in the adoption of this system, and I am very glad to say to you that at the present time a registry corresponding to fifty millions of people are covered by the system which this committee has evolved.

This thing is no longer an experiment. A very simple and effective method for the gathering of the facts with regard to public accidents has been developed; one hundred cities and some seven or eight States are following this system, and it is our hope that before very long the entire country may see the wisdom of this method, and we shall have then a unified and comparable and simple method of gathering the facts as these accidents occur, and have these facts sent to a central agency—at the present time the central agency is the headquarters of the Safety Council—where these facts will be tabulated, analyzed, and the essence of them developed into a series of precautions for the prevention of accidents.

That has been the history of your committee. It feels so good about its work and the urge has been so great for it to expand these efforts, that it has seemed wise for this committee to take on the form of a Section, and at the session this afternoon we shall have more to say to you about the desirability of this expan-

sion; that is, the development of a Section to be called a Statistics Section of the Council, whose business it will be to coordinate the statistical work of the various sections of the Council, but more especially at the present time to engage in the gathering and analysis of public accident facts.

More particularly this morning we are to consider how these facts may be obtained; how to get them. It is very logical that we should begin with the organization of a City or State Accident Statistics Bureau. No State in the Union has gone further probably than the State of New York in the gathering of these facts, and Mr. Aronowitz, who has done more than anyone for the development of a methodology, will present to you the work of his office.

Organization of a Statistical Bureau

By **LEON ARONOWITZ**

Statistician, Bureau of Motor Vehicles, Albany, N. Y.

A Statistical Bureau of a Safety Division has three functions: first, securing data; second, compiling and analyzing that data; and third, suggesting safety practices in conformance with the knowledge so obtained. I will briefly discuss how the first two of these duties can be performed by a motor vehicle bureau.

Statistics become valuable only when they present a true picture of conditions as they exist, and indicate the magnitude of the problem which is to be studied. Lack of complete information leads to erroneous conclusions which seriously impair investigation and solution of the problem. Dangerous conditions will continue to exist in localities where the accident cause is not known, and no aid in eliminating these accidents can be offered when information is lacking.

It has been the experience in New York State that to secure complete reporting of all accidents, it is necessary first to secure legislation requiring the filing of accident reports by the operator of the motor vehicle involved and by those officials (police officers, justices of the peace and coroners) to whom the accidents are reported. This legislation should provide a penalty for failure to report accidents. In New York State, failure to report an accident is the basis for the suspension of a license; and a conviction for this offense is a misdemeanor. Such penalties for failure to report have a most salutary effect.

Preliminary to the law becoming operative, a campaign of publicity should be inaugurated to advise all motorists and public officials of the provision of the law and also of the safety uses for which these reports are to be used. The accident problem should be presented to enlist the sympathy and aid of the motoring public, and the necessity of accident reports as a basis for studying the problem should be stressed. The law requiring merely the reporting of accidents is not sufficient, as many persons are unfamiliar with its provisions and fail to comply, not intentionally or through contempt of the law, but due to ignorance of this requirement. This publicity should stress the importance of complete, accurate information if the loss of life and property is to be lessened—rather than merely compliance with the law to avoid the penalty for failure so to do.

Publicity can be obtained in many ways; first, through the press; second, from talks at safety rallies before commercial and civic organizations; third, by obtaining the cooperation of the school authorities and having them devote a brief period each day to teaching safety to the children, who will in turn repeat these safety warnings to their parents; and fourth, by printing the provision of law requiring the reporting of accidents on driving licenses, or by issuing pamphlets of instructions to operators when they secure their license plates.

Accident report blanks should be clear, simple, and concise so that the person filling out the report will clearly understand what information is wanted. Involved

blanks have a tendency to puzzle to such an extent that the owner or operator becomes discouraged or bewildered as to how to complete the report. Wherever possible, the information which it is necessary to obtain from the report, should be set forth on the accident report in tabular form and the applicant requested to check those items which apply to the particular accident in which he was involved. Thought must be also given to the size of the form so that it will be convenient for public officers to carry in their pockets. If the form is involved, long, or bulky, police officers will refuse or purposely forget to carry them. In many instances persons who are desirous of complying with the law, will be at a loss as to how the report is to be filled out, and will be so discouraged that they will not file a report unless the blank is easily understandable.

To determine if reports are being filed in accordance with the law, special investigations must be made. One of the most effective means of determining this fact is to subscribe to a newspaper clipping service, which furnishes items of all accidents occurring in the jurisdiction. Another method sometimes employed is to delegate one or more employees to read the newspapers and check all references to motor vehicle accidents against the records in the bureau to determine whether reports are being received. If no report is found, a letter should be written to the operator or operators involved, advising them of the requirements of the law with respect to filing reports and requesting them to fill out the blank report enclosed. If a reply is not received within a week or ten days, a follow-up letter should be written, advising the operator that failure to report an accident is an offense which may result in the suspension or revocation of his license, and also that conviction of this offense is a misdemeanor.

It is most important to compare the fatal accidents which have been reported to the motor vehicle bureau with those reported to the bureau of vital statistics, or the health department. This check will be of great value to both bureaus, and will result in each department conducting investigations to secure these reports. In New York State for the year 1927, the Motor Vehicle Bureau checked monthly with the Health Department, and at the end of the year the records of the Motor Vehicle Bureau disclosed 2,424 deaths resulting from motor vehicle accidents, whereas the Health Department disclosed 2,435 deaths, a difference of eleven. This difference is accounted for by those injured in accidents occurring outside New York State, being brought into the State, where death occurred. In other instances death resulted from heart trouble or some other illness while the person was riding in an automobile, and was not the result of an automobile accident. Publishing the number of deaths is not effective unless the records of these two bureaus agree.

Wherever possible, the statistical section should establish contact with police units, safety directors, or other organizations interested in accident prevention, and obtain reports from them of accidents occurring in their communities. This affords an additional course of information and, in many instances, will assist the bureau to obtain reports which otherwise would have been unknown.

The proper agency to receive these reports is the one delegated by the statute to administer the law. In states, this is usually the bureau of motor vehicles, or a similar bureau, while in local communities it is the police department. Upon receipt of these reports they should be so filed as to be accessible when needed. Reports may be filed alphabetically under the name of the operator involved in the accident, or geographically according to the street intersection. The method adopted depends, to a great extent, upon the use to be made of the reports and the authority which the bureau receiving them possesses. If the bureau has the power to suspend or revoke licenses, it is perhaps desirable to have the records filed alphabetically, so that the record of all violations and accidents which are filed against a particular individual, will be in one folder. If, however, the records are not used for the purpose of removing reckless drivers from the streets, and the

primary purpose is to use these records as a basis to determine dangerous hazards in the city, the second method of filing by street intersection is suggested.

The reports, then, will quickly indicate those locations where particular hazards exist, and enable investigations to determine if there are any conditions existing at this point which should be remedied or corrected. This study may reveal the fact that traffic lights should be installed, traffic officers stationed at this point, left turns eliminated, parking banned, or some such similar remedy. The hazard of the locality will be brought to mind and a remedy can be suggested through study.

Having discussed the methods and means of obtaining accident reports, I will now turn to the internal organization of the statistical section, and explain the procedure of analyzing, tabulating, and filing of reports.

The first step is to determine what information is to be studied. This will vary from year to year. Experience may indicate that one group of facts is more valuable than another, or that certain types of information have no value from a safety point of view. Only data of possible use should be collected.

In determining the classes of information to be tabulated, your attention is directed to the following tables suggested by the National Safety Council:

1. Type of accident, which sets forth the object with which the motor vehicle came in contact; such as, motor vehicle with motor vehicle, motor vehicle with railroad train, motor vehicle with pedestrian, etc.

2. Circumstances surrounding the occurrence of accidents, which table is subdivided into:

- (a) Direction of travel, that is, turning right, turning left, going straight.
- (b) Act of motorist, such as exceeding the speed limit, wrong side of road, without right of way, etc.
- (c) Physical condition of the driver.
- (d) Sex of the operator.
- (e) Condition of vehicle, this table indicating whether there were any mechanical defects.
- (f) Acts of the pedestrian, such as crossing against signal, crossing diagonally on street, etc.
- (g) Condition of pedestrian.
- (h) Road condition—This table sets forth whether the roadway had defects or was under repair, or contained an obstruction which was not lighted.
- (i) Road surface—Indicating whether the pavement was dry, wet, snowy, muddy or icy.
- (j) Weather conditions.
- (k) Light conditions.
- (l) Railroad crossings.
- (m) Road location.

3. The type of vehicle involved. This table classifies accidents as to commercial cars, taxicabs, motorcycles, busses and passenger cars.

4. Day of week.

Having determined upon the matters concerning which it is desirable to secure data, it is necessary to prepare a code for each type or table to be tabulated. For example: if it is deemed important to know the day of the week on which the accidents are occurring, each day will be given a separate code number. This information is entered on analysis sheets, which contain headings corresponding to the type of information being coded. Under the proper heading on the analysis sheet the code number of the item analyzed will be entered. These analysis sheets are then sent to a key punch section, where tabulating cards are punched with the information entered on the analysis sheets. These cards are then run through a tabulating machine and totals are obtained. These totals are entered on charts and complete information is available with respect to the reports which have been analyzed.

The method which has just been described applies primarily to those bureaus where the volume of work warrants the use of tabulating machines. If the volume is not sufficient to procure such machines, the analysis can be obtained by tallying by hand each item of the report under its proper heading.

The report is now ready for study to ascertain the various circumstances surrounding accidents, and to indicate the line of safety work which should be undertaken.

It is not my intention to discuss how these statistics may be used for safety purposes, as this topic will be covered by another speaker later in the day.

Throughout the discussion of the organization of a statistical section of a motor vehicle bureau, I have refrained from discussing minutely the organization of the bureau, and also I have eliminated special problems which apply only to New York State. I realize that the accident problem is one which affects cities as well as states, and for this reason I have eliminated detailed information and attempted to explain the outlines of a practical statistical bureau, rather than outline in detail the plan which is in effect in New York State.

TABLE I

Deaths and Death Rates per 100,000 Population from Specified Types of Accidents and from All Other Causes: New York State, New York City, and Rest of State, 1915 and 1927

Cause	Deaths		Rate per 100,000 Population		Per cent of Change of Rate
	1915	1927	1915	1927	
NEW YORK STATE					
Accidents (total)	7,343	9,333	74.1	81.4	+9.9
Automobile accidents	677	2,555	6.8	22.3	+227.9
Accidents (except automobile)	6,666	6,778	67.3	59.1	-12.2
All causes (other than accidents)	139,549	131,673	1408.1	1148.4	-18.4
NEW YORK CITY					
Accidents (total)	3,558	4,604	68.1	77.1	+13.2
Automobile accidents	346	1,095	6.6	18.3	+177.3
Accidents (except automobile)	3,212	3,509	61.5	58.8	-4.4
All causes (other than accidents)	72,635	65,826	1390.3	1102.5	-20.7
REST OF STATE					
Accidents (total)	3,785	4,729	82.8	86.1	+6.6
Automobile accidents	331	1,460	7.2	26.6	+274.6
Accidents (except automobile)	3,454	3,269	75.6	59.5	-19.3
All causes (other than accidents)	66,914	65,847	1427.9	1198.2	-16.1

CHAIRMAN DUBLIN: This paper is now open for discussion. There must be a host of questions that you want to put to Mr. Aronowitz as to the details of his method. We shall be very glad to hear from anyone.

HOWARD BROWN (Detroit Automobile Club): I would like to ask the speaker whether or not that information is open to people facing civil liability suits.

MR. ARONOWITZ: So far in New York State the reports are confidential. We have given out information with respect to the name and address of the parties

involved, the license numbers; but how the accident has occurred has been considered private material and not divulged. There is a case in the courts now, going through two courts, and they have ruled against the Commissioner. They claim this information is a public record and must be given to the public, but he has taken an appeal to the Court of Appeals, and until that is decided, we are ruling that the information is confidential; his basis being that if this information is made public, people will not give complete reports, not state the true facts, and the purpose of having the statistical information recorded would not be attained.

DR. L. W. CHANEY (Bureau of Labor Statistics, U. S. Dept. of Labor, Washington, D. C.): Does New York forbid the use of all accident reports in court?

MR. ARONOWITZ: No, but the Bureau does not produce the report. In case of a subpoena, the Bureau has appeared in court, but not with the record.

G. C. HUBBELL (Registry of Motor Vehicles, Boston, Massachusetts): I would like to ask our friend, Mr. Aronowitz, what experience you have had in New York in getting reports from the police as compared with the reports from the operators.

MR. ARONOWITZ: We found in New York State that in the larger cities we have very good success. In New York City I should say that we get pretty near one hundred per cent, and also in Buffalo. In the smaller towns it is a question of educating the police, and they are gradually coming to the point where they are beginning to make fairly complete reports.

MR. BROWN: Does the operator also make a report when the police officer makes a report? Is that in duplicate?

MR. ARONOWITZ: No, our law provides they must report to a police officer, and also to the Commissioner of Motor Vehicles. The law further provides that any police officer to whom an accident is reported must file the report with the Bureau, and in those cases resulting in death, the Coroner must also report the death. So in some instances we get reports from four sources; from the operator, from the State police, from the local police, and from the Coroner, if it results fatally.

CHAIRMAN DUBLIN: How do you manage to get the material down to the locality where the accident occurs? I am thinking of the cities of the first class, and even down to the smaller cities. Is there any attempt to get the facts out to those cities, so that they may use them?

MR. ARONOWITZ: We have adopted a plan of supplying every city having a population of ten thousand or over with a complete report for the year, and if at any time they want special reports for the month, we tabulate them. The Commissioner at one of his talks before the Mayor's Conference, offered the services of the Bureau to prepare a spot map for any city requesting it, in the solution of their traffic problems, and in the past year we have probably made twenty-five spot maps in cities ranging from ten thousand to one hundred thousand, showing where the accidents happened. Our reports monthly are not only the State reports, but they are sub-divided into up-State, and all cities of ten thousand or over.

CHAIRMAN DUBLIN: Would you tell us, Mr. Aronowitz, what your Bureau costs?

MR. ARONOWITZ: Well, in the statistical section there are eight employees, a stenographer and myself. I should imagine the total cost of the Bureau would be around \$35,000. That would count printing, equipment, rental of space and everything else.

CAPTAIN A. J. MURRAY (Milwaukee): I would like to ask in reference to the accident reports, if those accident reports include all accidents, property damage, or just where someone is injured?

MR. ARONOWITZ: In New York State the law provides they only have to include accidents resulting in death or personal injury. We have no report of property damage.

L. E. McBRAYNE (Massachusetts Safety Council): The statement was made in one of our sessions that there were only three States which had an adequate analysis of accident information, and while that figure may be small, certainly

seven would be the maximum. I had occasion in Virginia in the spring to go into the capitol at Richmond and see how their experience compared with that of Massachusetts. On the books they had apparently a law which required them to report all these accidents. I found they had no information. They were receiving only a very small number of accident reports, and yet they were assuming that that was their accident experience, because they could not prove otherwise.

I wish we might have from the States that have no adequate information their point of view on how they know what's happening and whether they have any true basis for carrying on a campaign for accident reduction.

FRANK MATSON (Minnesota Safety Council): We have just organized a Safety Council in Minnesota. We have had in our three principal cities systematic accident reporting more or less by voluntary action. We are now working through a committee on a plan for state-wide accident reporting. The committee have not got to the point yet of deciding whether we will have to do it by legislation or whether we can accomplish it voluntarily. I would like to hear from some of these experts as to whether we can hope for any success from voluntary reporting, or whether we will have to work through a law.

CAPTAIN EUGENE CASEY (Supervisor of Traffic, New Orleans): We have in the State of Louisiana a State act that compels the driver of a motor vehicle in the case of personal injury, to report to the nearest police station; also to make a report of collision damage to the extent of \$25 or over. We have not a great number of large cities in the State of Louisiana. In the city of New Orleans our reports are almost 100 per cent, because every police officer will have charges preferred against him if he fails to report an accident or the condition of property damaged over \$25, and if there is no police officer present in a collision, no matter how trifling, the drivers must exchange names and addresses. In the event of personal injury he must report to the nearest police station. The State law, just passed by the last session of the legislature, makes that compulsory all over the State of Louisiana.

Of course, in the absence of police officers, I do not know how well that law is going to be observed and enforced. It is rather difficult to enforce a law of that kind in rural communities. In cities I think it is possible to do it. There is no excuse why it should not be done in the larger cities of the country.

MR. ARONOWITZ: I doubt if a voluntary registration system would be effective. Unless you have a law requiring it and also some penalty which is going to be inflicted unless they comply with the law, you are not going to get reports. It has taken us in New York State four years with the law, and we are still not getting complete reports. Every month when we check with the Health Department we find over twenty fatal injury accidents that they have which we have never received. We do not even get it through the newspapers. At the same time we have some reports they do not have. So unless you have a strong law requiring the reports, I doubt if you would be very successful.

CHAIRMAN DUBLIN: I will assume that the subject has been carefully discussed and we will proceed with the second item.

Now, long before it was conceived necessary to organize a State Accident or City Accident Statistics Bureau, the State and City Health Departments were reporting accidents, but only of the fatal type. Every death that occurred was registered in the States and cities that were in the registration area, and as a result we have had for a great many years a fairly complete record of deaths that resulted from accidents. Now, that's a very important item at the present time in the campaign for the development of a national accident reporting system, for we have an agency which is engaged in doing that very thing, but of course for fatal accidents.

Another point is this: that the method of analysis used by these State and Municipal Health Departments is of a type little different from that which seems to have grown out of the necessities of the accident prevention campaign. The system of classification used by the Health Departments has emphasized the type of accident; that is, whether the accident that resulted in death was due to a fall or was due to a poison; or was due to a collision in a railroad wreck, or whatever it might be, emphasizing the type of accident, but giving no information, or rarely, with regard to the location of the accident or the circumstances that resulted in the accident.

In other words, we have recognized that while we have a system of accident reporting in the Health Departments, the method used is not exactly adapted to the best uses of the material, and so there has been developed an attempt to so coordinate the methods of the Health Departments with those of the Accident Bureaus that information can be exchanged and information obtained which can be used in the campaign for prevention.

One of those who has been most active in this attempt to coordinate the two sets of agencies is our next speaker, Dr. DePorte, the Director of the State Bureau of Vital Statistics. He has on various occasions in meetings of the Vital Statisticians of the Health Departments, discussed this subject, and I know he comes to you with a good many excellent suggestions.

What State and City Health Departments Can Do in Gathering Accident Statistics

By J. V. DePORTE, Ph. D.

Director, Division of Vital Statistics New York State Department of Health,
Albany, N. Y.

Any effort to reduce mortality from a specified cause must be based on accurate information regarding the loss of life ascribed to it and an analysis of its death rate according to time, place, and other pertinent factors which vary with each cause. Deaths from accidents are, of course, no exception to this postulate. Here, we should know the volume of mortality in the area with which we are concerned, its movement in terms of the population over a sufficiently long period of time, and the type and circumstances of these deaths.

The sub-title of this paper tells us indirectly that the statistics made available by health departments are inadequate for accident prevention work. In order to learn in what respects these statistics are, at present, wanting, we must acquaint ourselves with their scope, learn about other official sources of information, and then attempt to suggest a procedure which will make the facts gathered by health departments more satisfactory. Since my knowledge of this subject, limited as it is, pertains to conditions in the State of New York, I shall concern myself in this paper with the situation in this State.

Movement of Mortality from Accidents in New York State, 1915-1927. Fourteen years ago, in 1915, accidental deaths in the entire State numbered 7,343; last year the total was 9,333. The corresponding death rates per 100,000 population were 74.1 and 81.4, an increase of 9.9 per cent. Among the several types of accidents, the greatest rise was recorded in mortality from automobile accidents—the deaths under this head numbering 677 in 1915 and 2,555 in 1927, the death rates being 6.8 and 22.3 respectively and the increase in the rate equalling 227.9 per cent. The death rates from all other types of accidents were 67.3 and 59.1. In other words, in 1927 the rate from the last group was less than in 1915 by 12.2 per cent. This reduction, however, was not so great as that recorded in mortality from all other causes. In 1915 the death rate in the entire State from all causes other than

accidents was 1,408.1 per 100,000 population, in 1927 it was 1,148.4—a drop of 18.4 per cent. The situation in the entire State and its two main subdivisions is summarized briefly in the accompanying Table, No. 1:

TABLE No. 1

Deaths and Death Rates, per 100,000 Population, from Specified Types of Accidents and from All Other Causes: New York State, New York City, and Rest of State, 1915 and 1927

Cause	Deaths		Rate per 100,000 Population		Per cent of Change of Rate
	1915	1927	1915	1927	
NEW YORK STATE					
Accidents (total)	7,343	9,333	74.1	81.4	+9.9
Automobile accidents	677	2,555	6.8	22.3	+227.9
Accidents (except automobile)	6,666	6,778	67.3	59.1	-12.2
All causes (other than accidents)	139,549	131,673	1,408.1	1,148.4	-18.4
NEW YORK CITY					
Accidents (total)	3,558	4,604	68.1	77.1	+13.2
Automobile accidents	346	1,095	6.6	18.3	+177.3
Accidents (except automobile)	3,212	3,509	61.5	58.8	-4.4
All causes (other than accidents)	72,635	65,826	1,390.3	1,102.5	-20.7
REST OF STATE					
Accidents (total)	3,785	4,729	80.8	86.1	+6.6
Automobile accidents	331	1,460	7.1	26.6	+274.6
Accidents (except automobile)	3,454	3,269	73.7	59.5	-19.3
All causes (other than accidents)	66,914	65,847	1,427.9	1,198.2	-16.1

In New York City the death rate from all accidents in 1927 was higher than in 1915 by 13.2 per cent. The automobile rate increased by 177.3 per cent while the death rate from all other accidents decreased by 4.4 per cent. The decline in the death rate from all causes other than accidents amounted to 20.7 per cent. In the Rest of State the 1927 death rate from accidents was only 6.6 per cent higher than in 1915. The increase in the automobile rate, 274.6 per cent, was considerably greater than in New York City. At the same time, the reduction in the death rate from all other accidents, 19.3 per cent, was more than four times the corresponding figure in New York City. In 1915 the rate for this group of accidents was 73.7 Upstate, or 20 per cent higher than in New York City, while in 1927 the two rates were practically equal. In fact, in the State, exclusive of New York City, the drop in mortality from accidents other than automobile was greater than from all other causes.

The estimates of population employed in this table and in all other tables in this paper were computed on the following bases: for New York City we employed the returns of the 1910 and 1920 federal censuses, since the City Health Department did not accept the figures of the State Enumeration of 1915. For the Rest of State we used the returns of the federal censuses and of the State Enumeration of 1915. The figures for the entire State were obtained by adding those for its two main subdivisions.

We shall now trace in some detail the movement of the accident death rate in 1915-1927 according to the basic factors involved—age of decedent and type of accident. In the following tables and diagrams, for the sake of simplicity, we deal with the initial and terminal years of this thirteen year period. Detailed tables for the years 1915, 1920, 1925, 1926, and 1927 appear as an appendix to this paper.

TABLE No. 2

Deaths and Death Rates, per 100,000 Population, from Accidents, by Age:
New York State, New York City, and Rest of State, 1915 and 1927

	Deaths		Rate per 100,000 Population		Per cent of Change of Rate
Age at Death	1915	1927	1915	1927	
NEW YORK STATE					
All ages	7,343	9,333	74.1	81.4	+9.9
Under 5 years	866	687	89.3	62.1	-30.5
5-14 years	838	988	47.5	46.8	-1.5
15-24 years	917	996	51.5	57.9	+12.4
25-34 years	1,053	1,107	59.1	54.4	-8.0
35-44 years	986	1,328	68.0	77.0	+13.2
45-54 years	892	1,227	84.4	91.7	+8.6
55-64 years	647	1,157	102.3	136.2	+33.1
65-74 years	501	896	152.5	224.1	+47.0
75 years and over	641	935	466.4	555.5	+19.1
NEW YORK CITY					
All ages	3,558	4,604	68.1	77.1	+13.2
Under 5 years	503	371	93.9	64.8	-31.6
5-14 years	493	527	51.8	47.6	-8.1
15-24 years	374	430	37.6	44.9	+19.4
25-34 years	544	575	53.8	49.6	-7.8
35-44 years	522	721	67.0	77.5	+15.7
45-54 years	464	699	89.8	105.0	+16.9
55-64 years	303	593	112.3	158.8	+41.4
65-74 years	212	416	180.6	284.9	+57.8
75 years and over	143	272	358.7	526.6	+46.8
REST OF STATE					
All ages	3,785	4,729	80.8	86.1	+6.6
Under 5 years	363	316	83.8	59.2	-29.4
5-14 years	345	461	42.6	45.8	+7.5
15-24 years	543	566	69.2	74.2	+7.2
25-34 years	509	532	66.0	60.8	-7.9
35-44 years	464	607	69.1	76.4	+10.6
45-54 years	428	528	79.3	78.5	-1.0
55-64 years	344	564	95.0	118.5	+24.7
65-74 years	289	480	136.9	189.0	+38.1
75 years and over	498	663	510.4	568.2	+11.3

In New York City the mortality curve according to age starts with a slight peak in the group "under 5 years," declining to a minimum at 15-24 years, rising with age to an absolute maximum in the oldest group "75 years and over."

While the curves for the two years 1915 and 1927 are of the same general form, the rates in the three age groups "under 5 years," 5-14, and 25-34 years were lower in 1927 than in 1915, while the death rates in the other age groups were higher (see also Diagram 1). The greatest reduction was recorded in the youngest age group, "under 5 years," whose rate was less than in 1915 by almost one-third. The maximum increase, 57.8 per cent, occurred in the group 65-74 years, followed by a rise of 46.8 per cent in the oldest group, "75 years and over."

In the Rest of State the curves of mortality also have a slight peak in the youngest age group, "under 5 years," with a minimum point in the next group, 5-14 years, and, with the single exception of the group 25-34 years, rising to an absolute maximum at "75 years and over." Here, too, three reductions were recorded among the several groups: "under 5 years," 25-34, and 45-54 years. As is the case in New York City, the reduction "under 5 years" was greatest—about 30 per cent. We find that an 8 per cent *decrease* in the death rate of the group 5-14 years in New York City corresponds to an *increase* of almost equal size Upstate, while a 17 per cent *increase* in the 45-54 years' group is coupled with a 1 per cent *decrease* in the Upstate rate. It is particularly interesting to note that while in New York City the 1927 rate at "75 years and over" was higher than in 1915 by 47 per cent, the corresponding increase in the Rest of State was only 11 per cent. We may say, in general, that in New York City the changes in the rates of the various age groups were more accentuated than in the Rest of State.

We have also expressed, according to age, the mortality from accidents in 1915 and 1927 in the State and its two subdivisions in terms of the deaths from all causes.

TABLE No. 3

Deaths from Accidents, per 100 Deaths from All Causes, by Age: 1915 and 1927

Age at Death	New York State		New York City		Rest of State	
	1915	1927	1915	1927	1915	1927
All ages	5.0	6.6	4.7	6.5	5.4	6.7
Under 5 years.....	2.6	3.8	2.5	3.7	2.7	3.9
5-14 years	18.6	23.7	18.0	21.9	19.4	26.1
15-24 years	12.3	16.0	8.9	11.9	16.7	21.4
25-34 years	9.4	12.4	8.2	10.8	11.3	14.6
35-44 years	7.0	10.3	6.1	9.4	8.6	11.5
45-54 years	5.3	6.8	4.7	6.8	6.0	6.9
55-64 years	3.4	4.9	3.1	4.7	3.7	5.1
65-74 years	2.5	3.4	2.5	3.7	2.4	3.3
75 years and over.....	3.3	4.1	2.5	3.7	3.6	4.2

We shall call attention to several important facts brought out by the preceding figures. First, the relative mortality from accidents was highest in the group 5-14 years. In 1927, in New York City, one in five deaths in this group was ascribed to some accident while Upstate the ratio was one in four deaths. The proportion was lowest in New York City in the two oldest age groups 65-74 years and "75 years and over;" Upstate, in the group 65-74 years. In calling attention to these figures we must, at the same time, keep in mind the fact that the general death rate in the

group 5-14 years is, of course, lower than in any of the other ages, while at the farther end of life the general mortality is highest.

The figures for 1927 were, without exception, higher than in 1915 which means that the trends of accidental mortality did not follow those of the general mortality

DIAGRAM 1-A
Death Rates, Per 100,000 Population from Accidents, by Age—1915, 1927:
New York State

curves and even in the several instances where the specific death rates from accidents declined, the reductions were less than in the general death rates.

We shall now compare the mortality in 1927 and in 1915 from the several types of accidents specified in the International List of Causes of Death. (See also Diagram 2.)

TABLE No. 4

Deaths and Death Rates, per 100,000 Population, from Specified Types of Accidents: New York State, New York City, and Rest of State, 1915 and 1927

Type of Accident	Deaths		Rate per 100,000 Population		Per cent of Change of Rate
	1915	1927	1915	1927	
NEW YORK STATE					
Accidents (total)	7,343	9,333	74.1	81.4	+9.9
Poisoning (gas excepted)	222	176	2.2	1.5	-31.8

Excessive heat	28	20	.6	.4	—33.3
Other accidents	332	388	7.1	7.1	—

*Data for 1915 not available, included in "other accidents."

In New York City the death rates from three groups of accidents were higher in 1927 than in 1915 by the following percentages: accidental absorption of irrespirable, irritating or poisonous gas—67.6 per cent, accidental traumatism by firearms—50 per cent, and automobile accidents—177.3 per cent. The second group was numerically unimportant, the deaths increasing from 11 to 15. The deaths under

the first rubric rose from 355 to 683, while those from automobile accidents increased by more than 700—from 346 to 1,095. The rates under the other heads were lower in 1927, the reductions ranging from 3.4 per cent under accidental traumatism by falls, to 84.6 per cent in mortality from accidents involving "other vehicles." The numerically largest decrease was recorded in mortality from accidental burns, from 422 in 1915 to 289 in the later year.

In the Rest of State we also note three increases—in the death rates from conflagration, 54.5 per cent; accidental traumatism by fall, 12.9 per cent; and auto-

DIAGRAM 1-B

Death Rates, Per 100,000 Population from Accidents, by Age—1915, 1927:
New York City

mobile accidents, 274.6 per cent. The numerically largest increase was under automobile accidents, from 331 to 1,460. Deaths from falls increased from 802 to 1,062 and those from conflagration, from 53 to 95. The recorded decreases ranged from 6.7 per cent in the death rate from accidental traumatism by firearms to 64.7 per cent in mortality from street-car accidents. The numerically largest drop occurred in fatalities from railroad accidents, which totalled 636 in 1915 and 331 in 1927.

The outstanding differences in the changes recorded in the two main divisions of the State may be summed up as follows: the death rate from conflagration and falls increased in the Rest of State, while in New York City decreases were recorded. On the other hand, an increase of two-thirds in the death rate from accidental absorption of gas in New York City was coupled with a decrease of

DIAGRAM 1-C

Death Rates, Per 100,000 Population from Accidents, by Age—1915, 1927:
Rest of State

about 30 per cent in the corresponding rate Upstate. And again, as already mentioned earlier, the rise in mortality from automobile accidents was much higher Upstate than in New York City—the rates of increase being 274.6 per cent and 177.3 per cent.

In 1927 automobile accidents held first place among the several specified causes of death in both divisions of the State, followed by falls. Next in numerical

importance were, in New York City, accidental deaths from the absorption of irrespirable gases, while, Upstate, the third place was held by accidental drowning.

Official Sources of Accident Statistics

The State Health Department has the custody of all certificates of death in the territory under its jurisdiction, i. e., the State, outside of New York City. The certificates for New York City are filed with the City Health Department.

DIAGRAM 2-B

Death Rate Per 100,000 Population from Specified Types of Accidents—
1915, 1927: New York City

* Rate for 1915 not available

Other State Departments collect statistics of mortality from specified types of accidents—the range of these activities, in brief, follows:

Industrial Accidents. All deaths occurring in industries in New York State for which workmen's compensation is paid are reported to the Department of Labor. These reports are made by the employer and the necessary additional information is also supplied by the dependents of the person killed.

The facts furnished to the Labor Department include the place and time of accident, age, sex, occupation, wages, length of service, the circumstances of death as described by the employer (if medical report is required, a doctor's description of the nature of the injury), hospital, if any, and physician.

DIAGRAM 2-C

Death Rates Per 100,000 Population from Specified Types of Accidents—
1915, 1927: Rest of State

* Rate for 1915 not available

There were 1,042 compensated deaths during the year ending June 30, 1927. This figure undoubtedly includes some accidents reported to the Motor Vehicle Bureau and to the Public Service Commission.

Motor Vehicle Accidents. Every motor vehicle accident which results in the death of a person must be reported within twenty-four hours to the Commissioner of Motor Vehicles by: (1) the operator of the motor vehicle if he is able, or by some other participant, (2) the police officer who investi-

gated the accident, and (3) the coroner or medical examiner. The sum of information from these sources includes the date, place, and time of the accident, character of road and road surface, traffic and weather conditions, names, sex, and age of persons killed and injured and of the operator and owner; also nature and extent of injury together with a clear account of the accident. In 1927, deaths in motor vehicle accidents numbered 2,424. Some of these may possibly have been included in the Labor Department's total of compensated accidents.

Railroad Accidents. Reports of railroad accidents are made by the corporations involved to the Public Service Commission in Albany if the accident occurred outside of New York City, and to the Transit Commission in New York City if it occurred within the limits of the City. The reports show, among other items, the date, time, and place of accident; weather conditions; cause of accident; name and address of the victim; and the nature and extent of his injuries. Accidents occurring in railroad shops are reported to the Labor Department. During the year ending June 30, 1927, deaths in railroad accidents numbered 474 in the State, outside of New York City, while during the calendar year 1927 the Transit Commission reported 248 deaths within the limits of Greater New York.

The three State Departments mentioned above—the Labor Department, the Bureau of Motor Vehicles, and the Public Service Commission have, therefore, detailed information regarding all fatal accidents which occur in industries or through the operation of motor vehicles, steam and electric railroads. The facts regarding all other types of accidents are available only in the limited compass of the records of the State Health Department. In order to learn how these records could be made more comprehensive, we shall review briefly their content and the several important factors involved in their compilation.

The certificate of death employed by the State Department of Health is of the standard type used in all States of the Registration Area. The Public Health Law places the responsibility for the recording of this certificate upon three persons: The *undertaker or person in charge* of the burial is responsible for the actual filing of the death certificate. He obtains the personal items on the certificate from some member of the decedent's family, then presents the certificate to the *physician, health officer, or coroner*, who fills the medical part. The undertaker files the certificate with the *local registrar*, who, in turn, forwards it to the State Department of Health on or before the fifth day of the following month.

In accidental deaths, if a physician was in attendance and there were no suspicious circumstances which might point to the possibility of a homicidal or a suicidal act, the medical part of the death certificate is entered by the attending physician. If no physician was in attendance at the time of death, the Public Health Law (Section 378) prescribes that "it shall be the duty of the undertaker or other person to whose knowledge the death may come to notify the local health officer of such death. When so notified the health officer shall immediately investigate and certify as to the cause of death; provided that if the health officer has reason to believe that the death may have been due to unlawful act or neglect he shall then refer the case to the coroner or other proper officer for his investigation and certification." When the certificates are received in the State Department of Health they are carefully examined for possible omissions, incomplete or inaccurate entries. Requests for necessary additional information or corrections are sent to local registrars. If no replies are received within two weeks, in the case of places with a population over 10,000, second and third requests are sent to registrars while in the smaller places and rural communities, these requests are addressed directly to the persons responsible for the particular item—the undertaker, physician, health officer, or coroner.

A large proportion of the certificates of accidental deaths are quite unsatisfactory for statistical analyses. Last year, for example, in 21 per cent of them the information given regarding the cause was too fragmentary for purposes of mere classification, while the corresponding proportion of unsatisfactory certificates of death from all other causes was only 2 per cent. I hasten to add, however, that the physicians and coroners to whom requests are sent for additional information are most cooperative, and satisfactory replies are received in practically all cases. Those physicians who failed to supply the necessary facts in the first instance apparently did not know what constituted an acceptable statement. In the eyes of some medical men the type of injury is the important matter, the circumstances of the accident being of secondary significance. In July, 1927, for example, forty-two death certificates gave one or another type of fracture as the cause. Our query in each case asked for the manner in which the fracture was sustained. From the replies we learned that in thirty-one cases the fracture was caused by a fall and these deaths were, therefore, classified as No. 185 of the International List, "accidental traumatism by fall." In eight cases an automobile was involved and these deaths were placed under 188c, "automobile accidents." Two fractures were caused by falling trees and were entered under 188g, "accidental traumatism by other crushing;" and one person was struck by a train, which was a "railroad accident," No. 188a. Our aim in making these inquiries was to learn enough about the cause of death to permit us to classify it according to the International List. This tabulation, particularly as regards the major group of falls, clearly, is not sufficiently comprehensive to form the ground-work of accident prevention activities. There are falls and falls. Let me list in greater detail the additional information given to us regarding these thirty-one cases:

Fall on floor.....	7
Accidental falls.....	7
Fall downstairs.....	3
Fall from chair.....	3
Fall in home.....	2
Slipped and fell on floor.....	2
Fall from stoop.....	2
Fall from bed to floor.....	1
Fall from ladder.....	1
Decedent blind—stumbled and fell.....	1
Slipped on rug in home.....	1
Fall on sidewalk.....	1

The details shown in the preceding outline were, of course, entirely lost in our tabulation.

A health department is obliged, in the nature of things, to limit its additional inquiries to a few essentials. We cannot ask a busy practicing physician or a local registrar, whose compensation in many instances amounts to only a few dollars a month, to take the time that would be necessary to fill a long questionnaire. We have, therefore, prepared a concise form which, I believe, will enable us to obtain a necessary and sufficient minimum of information regarding deaths from accidents. In this connection, it is a pleasure to acknowledge my indebtedness to Mr. E. W. Kopf, Assistant Statistician of the Metropolitan Life Insurance Co., for many helpful suggestions.

**NEW YORK STATE DEPARTMENT OF HEALTH DIVI-
SION OF VITAL STATISTICS, ALBANY, N. Y.
SUPPLEMENTAL INFORMATION FOR DEATHS FROM
EXTERNAL VIOLENCE**

For all deaths resulting from external violence, please fill out this form, supplementing data required in items 17 and 18b of medical certificates of death.

Name of decedent	Date of death	Place of death
_____	_____	_____
Was death due to accident..... Suicide..... Homicide.....		
If an accident, what was decedent doing when injured:		
At work in factory or workshop..... in office..... at work elsewhere (specify).....		
At home..... on the street..... on railroad..... elsewhere (specify).....		
How did accident happen?.....		
If any vehicle was involved, state whether motor vehicle.....		
horse-drawn vehicle..... common carrier—railroad: steam..... electric		
Nature of injuries sustained.....		
If burns were involved, state whether through conflagration of buildings.....		
The questions above are applicable also to all instances of septicemia or infections following injuries.		

The business of securing this additional information could be carried out best through the agency of state and not city health departments because city health departments are often dissociated from the offices of local registrars. In this State twenty-two registrars are also city clerks and in some cities their offices and those of the local health departments are in different buildings. The health officers, therefore, often have no convenient access to the vital records; besides, the average health officer has neither the time nor sufficient clerical help to take up any additional functions.

Commencing with January, 1929, these blanks will be put into use in the State, exclusive of New York City. The local registrars will be instructed to secure the indicated items whenever a certificate of an accidental death is filed with them and to attach the blank to the corresponding death certificate.

Accidents differ from most of the other causes of death in one important aspect; namely, that they are all, at least theoretically, preventable and that within practical limitations they can be controlled to an effective degree. The need of more light on the circumstances of various accidents is axiomatic and we hope that our more comprehensive statistics will be of service to safety workers in their great task.

*Data not available.

CHAIRMAN DUBLIN: I would like to draw your attention to a few items on this blank. You see it says, about half way down: "If an accident, what was decedent doing when injured? Was he at work in a factory or work shop, in an office, at work elsewhere, at home, on the street, on a railroad?" The point of that is to bring out the very deficiency that heretofore existed in the records of Health Departments. They gave us their best information on the type of accident; they did not tell us where those accidents occurred. It is obviously of the first importance, from the prevention standpoint, to know where the accidents occurred—Were they industrial—that is, did they occur while the man was at work?—Were they home accidents?—Were they vehicular accidents?—Public accidents on the streets?—Railroad accidents?

By this very simple device we are enabled to obtain a fund of information State-wide, which is of tremendous importance to the accident prevention campaign. It would be so important to have the State Health Departments and State Registration Departments do this work, as Dr. DePorte suggests he will do in his State, because until systems like Mr. Aronowitz's are established, we shall have to rely on the Health Departments for any information that we have.

I sincerely hope, moreover, that Dr. DePorte will develop this system so as to include serious injuries as well as fatal accidents. I don't know what the chances of that are, but it would be of tremendous importance for the Registration Divisions to include that type of information. I don't mean trivial accidents, but very serious ones.

Is there any other comment?

JOHN V. LONG (Pittsburgh Better Traffic Committee): There is one type of accident that I imagine you are going to find rather hard to discover: That is, where the certificate recites the cause of death, which occurred after possibly two or three months, but was superinduced by an automobile accident. We find we have not been able to trace anything back in Pittsburgh, and it is a subject which I believe will have to be taken up through the Medical Society to get that information.

MR. KELSEY (Boston): Don't you also want to know what the decedent's state of mind was; whether he had his full faculties about him while he was in the place where he got injured, or whether he was asleep at the switch?

CHAIRMAN DUBLIN: There's lots of information we should like to have. I wonder whether we could get that. Was there someone else who would like to ask a question?

MR. HUBBELL (Massachusetts): In glancing at this report sheet, I was wondering if Mr. DePorte would be interested in deaths by carbon monoxide gas. We have found in our Motor Vehicle Bureau that we have quite a few of those.

DR. DEPORTE: October 1st we began classifying deaths from carbon monoxide gas, as a special study of our own.

E. W. KOFF (Metropolitan Life Insurance Co.): Do you expect to send this form to the coroner or doctor or the local registrar?

DR. DEPORTE: Just the local registrar. The local registrars are directly responsible to us, and that's why we want to concentrate the work through them, because we have the power to force them to supply the information, whereas a coroner will or will not just as he pleases.

CHAIRMAN DUBLIN: Do you pay them anything extra for the report?

DR. DEPORTE: No, but accidental deaths average about five per district per registrar; so the average registrar in the average district probably will not have more than five a year, and even though they are very poorly paid, we can expect them to obtain information in detail for these five deaths, one death in two months on the average.

CHAIRMAN DUBLIN: We will now proceed to the third and last paper which will be presented by Mr. Burnham, the Research Director, Motor Vehicle Department, State Board of Public Roads of Rhode Island.

Can the "Probable Cause" of an Accident Be Deduced from Accident Reports?

By **HARRY C. BURNHAM**

**Research Director, State Board of Public Roads, Motor Vehicle Department,
Rhode Island**

There is no question but what it is possible to do so if the accident report is so designed to secure complete information.

The foundation of a successful analysis to determine the fundamental cause of a highway accident is an accident report blank in the form of a complete questionnaire so laid out as to provide for the checking of one answer against another.

A most important item is to secure from the person making the report the full story as to his impressions of the occurrence.

The next important consideration is that the analyst be a person who uses every day "horse sense," who is a practical and experienced motor vehicle operator, who has a good understanding of human nature and has, at least, a rudimentary knowledge of physics.

The analyst should also be a student of highway conditions. This knowledge can easily be obtained by the establishment of observation posts at points of varying locale. Here, first hand knowledge can be had as to the habits of humanity awheel and afoot. In fact, the knowledge obtained by actual traffic studies and observations will be found to be of the utmost value.

Observing traffic, we shall find that highway users have a certain few bad habits. These will be noted in the so-called "near accidents" which can be seen anywhere on the highway.

We shall see motor vehicle drivers failing to slow at intersections; at points where their view is obscured, and at curves; trying to outguess the other traffic, cutting corners, attempting to beat pedestrians to a passage or endeavoring to move the pedestrians out of the path of the motor vehicle by nervous blasts of the horn. We shall also observe innumerable drivers who are not paying the slightest attention to their job of the moment.

Pedestrians will be seen to enter the street or path of traffic from behind obstructions such as parked cars, street cars and other vehicles. Some pedestrians will be noted who run into the street suddenly or who use the street in such a manner as to indicate no realization as to the danger incurred.

We shall see a composite picture of human carelessness, egotism, ignorance and thoughtlessness.

Finding these conditions to generally exist, we shall have no difficulty in tracing the brilliant thread of carelessness through the warp of fact and fancy of our accident report.

The analyst's knowledge of human nature brings the realization that rarely ever does a human being deliberately proceed to endanger his or any one's life or limb. We have to admit that whenever actual danger is definitely known to exist we stop and think it over.

Therefore, we must consider as our first point the fact that no highway accident is ever deliberately brought about by any of the parties involved.

We shall soon find in our quest for a cause that the average person feels that he or she is an expert driver. We shall quickly separate expertness from overconfidence. Our driver will tell us that so many years of driving experience

rest to his credit. We shall, reflecting on our own experience and knowledge of human nature, know that this experience has bred bad driving practices that have become automatic habits. We must look for these in analyzing our accident reports.

Our participants will be found to blame everybody but themselves for the accident, or will state that it was caused by the weather, or street corners or something else. Never will they incriminate themselves if they can help it. And the peculiar part of it is this: You will find that in the majority of cases they honestly believe their statements to be entirely truthful. More human nature.

Our driver will state on the accident report that he did everything to avoid the accident. He was going slowly, or slowed down, blew his horn, put on his brakes, swerved his vehicle, in fact we soon find that our driver was indeed a superhuman person. He did several more things than he actually had time to do.

The analyst knows that at any certain speed a motor vehicle travels a certain number of feet per second; that it takes a definite time interval for registration of an item in the human mind and to secure a motor reaction; that it requires a certain time interval to stop a motor vehicle; that pedestrians have certain average rates of movement whether walking or running, and will apply these sharp, cold facts in dissecting the truth from the statements in the accident reports.

Surrounding every highway accident are factors which are easily checked; the weather, locale, time of day, volume of traffic, course of vehicles or pedestrians, condition of highway, etc. We can call these our common factors. They are present in every accident.

We must not forget however, that none of these factors actually caused the disasters. In digging out our real cause we must consider them as merely corroborative factors only.

Perhaps it is well to drag our "corpus delicti" into open at this point. We must remember that there is no such thing as an accident being caused by an inanimate object. Disaster only comes with the entrance of the human factor with its almost incalculable capacity for errors. There must be conscious thought directing anything inanimate.

The motor vehicle is not a motor vehicle until we have consciousness at the wheel or some conscious act to set it in motion. Our common factors enter into the accident only to the extent that the human factor failed to take notice thereof and guide his course or actions accordingly.

For instance, to aver that a blind corner caused an accident is patently absurd. The same thing applies to skidding and a host of other fallacious beliefs as to accident causation.

Our trail is approaching its goal. We study our accident reports and dig out therefrom the thread of human carelessness, which, like the far reaching tentacles of dry rot, reach into the uttermost human activity.

We shall find that one or perhaps all of the participants just failed to be alert, or on the job. They failed to see the proximity of danger or heed the dictates of caution because they had met with similar conditions countless times before and nothing had happened. But, in this instance the time margin was a bit short or reaction was sluggish and the inevitable occurred.

We, as analysts, must bring forth from our analysis of highway accidents the errors of commission or omission so clearly that the picture can be vividly presented to highway users as to the real dangers incurred.

We must remember the fundamentals of human nature typified in the person who will deny recklessness but who will admit he made a mistake.

As we go deeper and deeper into this analysis we will find greater simplicity. It finally will dawn upon us that the basic cause of any accident of any type

is absolutely the same, the only difference being in the background, and the instrument at hand at the moment of disaster. The same basic error leading to the dropping of the best china cup might lead to a fatal highway accident if the person were seated at the wheel of a vehicle in motion instead of holding the cup.

Use what terminology we will, this is what we must bring forth from our study of accident reports and use the facts so obtained as pigments to paint such clear pictures that even the lowest intelligence using our highways can see and learn much thereby.

Until we are able to bring to each highway user the realization as to the scope and extent of his or her own responsibility for accident prevention, and to emphasize it as a personal matter of great moment to such individual, we shall be unable to effect any real lasting diminution in the terrible toll now being exacted as the price of individual carelessness.

We must not attempt to consider in our analysis either civil or criminal responsibility. We must not be swayed by sentiment or fallacious beliefs; we must disregard technicalities. We must uncover the human errors which were the real cause of the disasters so that they may be broadcast far and wide.

No attempt has been made in presenting this paper to consider detailed analysis technique as the limited time prevents more than a general coverage of the subject.

MR. BURNHAM: I shall be very glad indeed to supply any information upon request. I have not attempted to give you details. I have attempted to emphasize and bring out to you that it is possible to secure from any accident report a very good idea as to the failure of the human element to see a condition developing before him or her which led to a final accident.

We can stand at this window here and we can see potential accident after potential accident. The only thing that keeps the accident from occurring is the fact that one of the human elements involved probably was alert or that the time element was sufficient to prevent.

To point out the time element, I would like to tell you about an accident which was deliberately staged. We hit a Ford touring car with a Pierce Arrow limousine. We had a great number of persons there just merely to observe it. They knew what was going to happen. They saw the accident. I took their comments. I then examined the film, one of the motion pictures being made at the rate of 16 pictures per second and the other at 128 pictures per second; and, gentlemen, there was not one of the fifteen persons that described the accident accurately, because that accident took place in $\frac{3}{16}$ of a second, and the average human being has no opportunity to get more than one impression at the time that accident took place. Each one of the fifteen individuals had a different impression, but by taking the fifteen impressions we could piece the accident together again, and it was the same as it showed on the film. But there were fifteen different impressions of the accident, and your average automobile accident happens in less than one second from the time it is first perceived to be a potential accident until it has happened.

I might mention that your average automobile travels at an average rate of speed on the highways of about 22 miles per hour or a little over 30 feet a second. Your average human being reacts in about seven-tenths of a second. In other words, it takes seven-tenths of a second to perceive something and get reaction through the motor nerve center. We are traveling say 30 feet a second; it takes us seven-tenths of a second to react. Therefore, we have to figure on going 21 feet while we are thinking about what we are going to do. Then we have got to stop the automobile after that. We will find upon studying we must allow

at least 45 to 50 feet to see something and stop before being involved in an accident, if we are traveling at 20 miles per hour. We have got to sell that idea.

I could go on telling you a lot of other things we have dug out in Rhode Island through the combination of a very comprehensive mass of accident statistics, the establishment of 54 observation posts upon the highways, taking in all kinds of highway conditions, traffic, the studies which we have made there and the compilations

CHAIRMAN DUBLIN: Mr. Burnham has presented a very interesting and a very stimulating paper. Here is a clear-cut issue which is involved in this paper. I am sure you all got it. His thesis is that it is possible in a large number of cases at least, to determine the basic responsibility of the individuals concerned in the accident. He is, in effect, saying that it is possible to place fault and blame in the causation of accidents, and that of course is quite contrary to the idea that has motivated the Committee under whose auspices this symposium is taking place. The Committee of the Safety Council concerned with public accidents, vehicular accidents, has definitely taken the stand not to attempt to place responsibility for the causation of accidents; that is, not to get behind these human elements that Mr. Burnham has referred to, but rather to get as complete a picture of the facts of the situation, of the physical conditions surrounding the accident, so that those at least might be correctly reported and controlled in the accident prevention campaign.

This is a clear-cut issue, and I sincerely hope that those of the Committee who were largely responsible for the development of that point of view—that is, for the elimination of the human element of responsibility from the picture of the accident, will have something to say, or will ask questions in regard to the system that is in operation in Rhode Island, so that the rest of us may be able to draw a fair conclusion with regard to the value, the advantages, of either stand.

I am taking pains to bring home to you the significance of Mr. Burnham's paper. It is a vital question, and we ought to have a very full discussion on the merits of the two systems. I hope Mr. Aronowitz will have something to say about it.

LEON ARONOWITZ (Statistician, Bureau of Motor Vehicles, Albany, N. Y.): There are a few points I would like to bring out. In analyzing the reports, one needs to have some familiarity with traffic conditions, to analyze the report thoroughly and use proper judgment. In New York State we have approximately 90,000 reports a year. With our staff of employees, getting anywhere from \$1,000 to \$1,2000 a year, you cannot expect them to possess the ability that Mr. Burnham would like to have people possess. In a small locality, one or two men can probably go over all the accident reports and determine just exactly what happened. We have got ten or twelve girls and they are changing every three or four months—two or three leave and two new ones come in—it would be impossible to get people of that type.

Then the next factor—Mr. Burnham mentioned about the accident that they staged. There were fifteen people and they all got a different impression. If fifteen people viewing the accident all get a different impression, how is a person sitting at a desk in an office to be able to draw any conclusions as to how the accident actually happened?

Then there is another phase of this problem that comes up. I have mentioned this to some of the other members of the Committee before. A man is driving a machine; he is intoxicated. As a result of his intoxication he is speeding and he is on the wrong side of the road, and he runs over a pedestrian who is jay walking. What particular factor caused that accident? What particular act of either the motorist or the pedestrian? If he had not been intoxicated it would not have happened; if he had not been riding on the wrong side of the road it would not have happened; if the pedestrian had not been jay walking it would not have happened.

It seems that the Statistics Committee's function is to get facts and not draw conclusions. If they get the facts and find out what is actually happening, then from these facts they can draw conclusions which will help this general campaign. They will know that certain drivers will speed; that a certain number of drivers are failing to observe the right of way. They will find out, for example, that taxicabs, while they only represent a small percentage of the cars registered, represent a large proportion of the accidents. Facts such as that can be drawn from your statistics.

In New York State in 1925 we licensed what were known as Junior Operators, people between sixteen and eighteen years of age. As a result of our statistics we found at the end of the first year that 15 per cent of the Junior Operators that were involved in accidents, caused deaths, whereas in the case of senior drivers, only 3 per cent caused deaths. That immediately brought home to the Commissioner that there was a dangerous element that must be controlled. So the following year the law was amended, so Junior Operators could drive only in the rural districts. That cut the fatalities down to 8 per cent, and that percentage even was 2-2/3 times as high as for the more experienced driver; and this year we are considering presenting to the legislature to have that law repealed. Facts such as that can be drawn from your study of statistics, rather than attempting to put the blame on any particular man.

L. E. MACBRAYNE (Boston): I would like to speak a word in support of Mr. Burnham. We try in Massachusetts to keep up with Rhode Island, and at our State Conference last May we assigned to Professor Parke of the Institute of Technology the discussion of a problem similar to this. We gave him the title—What is the Relation of Momentum to the Human Element in the Accident? I think what Mr. Burnham desires to bring out is this: That the average man involved in an accident does not know why it occurred. He does not know the failure of the human element. He does not know, as Professor Parke pointed out, that when he takes a certain car and drives at a certain speed, he has a momentum of five cars going five miles an hour, or a railroad train at a certain speed, and he does not know the variation in the mental reaction in a small group of even ten drivers so that in that group of ten drivers one man will do the thing within a limited range of time that will cause the accident.

It is not necessary for every community to make an analysis that will prove what may be discovered in any one important city; that is, if we find in a group of ten individuals there is a variation, then the idea we want to sell to our million drivers in New England, or your larger number in New York, is the fact that unless you know as much about yourself as you do about your car, you have no right to take chances on the highway above a certain speed. We have a phrase that says, "Driving too fast for conditions." Professor Parke said there should be added to that the words, "Driving too fast for the man behind the wheel;" that a large number of men are driving, just as a large number of pedestrians are walking, without a proper understanding of how they will act under certain conditions in which the time element is vital.

We were holding some road races on a track where if you don't go one hundred and twenty miles an hour you fall off, because the track is at an angle of some 45 degrees. Right in front of the grand stand one of the well-known racers approached so close to another driver that it looked as though he had struck him. Of course he had not struck him. Otherwise the accident would have occurred there. But in a fraction of a second after the first car had passed the second, the message came to the brain of that driver, "He is striking me," and so he made not an easy turn but a quick turn and went off the track; the car went into the air, turned over three times, and hurled both occupants over the fence, killing one of them. I talked with a dozen people who saw the accident and made this discovery; that those who

saw the first part of the accident were not able to describe any of the second part, and those who saw the body tossed over the fence could describe accurately only what occurred when the body struck, but had no picture at all of what happened before the body left the car.

Now, when confronted by a situation that may cause an accident, the average individual receives that same shock. He does not get the whole picture. Consequently, seeing only a part of it, he is a part of the accident, and may do the unexpected thing. If he has a narrow margin of time, which does not allow him to work out the whole problem, as Mr. Burnham says, he must react in a fraction of a second. I think Mr. Burnham has developed a very important thing, and it is not that each community should undertake to find these facts, because not every town would have the facilities; but once having established these facts, we should take them into our local campaigns, because, after all, too many of us are stopping with the statistics; we do not know what to do with them.

When we discover that there is an increase in elderly pedestrian accidents, when children's accidents go down, then we ought to increase our campaign in that five months' period, or four months' period, according to the geographic location, when the older people are getting hurt, because there is a direct relation between our Northern States and the upward curve of the elderly pedestrian accidents, and at the same time our children's accidents are going down until they reach the lowest point, when the old people are at the highest. There's where we should put the statistics to practical information and education in our campaign.

A. J. BAMS: I want to say first that it seems to me Mr. Burnham handled these subjects very, very well, but I think there are some adverse criticisms—not criticisms of the manner in which he handled the subject, but criticisms of the subject itself. In my experience in life, in compilation of any and all information, wherever the human element enters into it, we begin to get results which are usually based upon the ability of the individual who compiles these statistics to interpret, rather than on the facts which are presented, and if we develop too far the subject of probable cause, we reduce to a minimum the number of questions which we might ask about an accident, and when we do that we get nowhere. We get the result that we get in all other activities requiring the human element; that it varies accordingly as we vary the person; from person to person. I want to throw out these suggestions as counter to the thought of probable cause.

If we increase the number of questions, and of course ask the proper questions, we reduce the need for asking the probable cause, as it might be presented by the one who reports the accident. And, accordingly as we reduce the need for interpretation of conditions and facts relating to the accident, we get accuracy. Aren't most of our accidents, or a large percentage of them, accidents on which the facts will give the cause, without trying to develop a line or a column of remarks for an interpretation which is not needed?

My thought is that we ought to increase the number of questions to the point where probable cause would not enter into the discussion by the person reporting the accident, and when we do that, we eliminate the interpretation, which is a hit-and-miss job.

SMITH R. BRITTINGHAM (Seaboard Air Line R. R. Co., Norfolk, Va.): I had occasion some years ago to run down most minutely the causation of one particular accident. It was a case of serious injury and loss of an arm. I came to the conclusion that the accident was primarily and in its last analysis due to the fact that the injured person had had a fuss with his wife that morning before going to work. It put him in a mental frame which prevented his giving the proper attention to his work. If it is possible to ascertain from the report just what the fundamental cause of the accident is, when it involves such fine points, such elusive mental elements as that, I really want to know something more about it.

I am particularly interested in accidents on railroads. Sometime ago I had figures made up to try to ascertain the fundamental causation of crossing accidents, and I was astonished to learn that on our own railroad 46 per cent of all accidents at crossings were due to the automobilists running into the train rather than the train running into the automobilists, and I believe, that back of that 46 per cent of accidents were mental causation which it is absolutely impossible to learn from any statistical reports, howsoever finely it may be devised.

MR. HUBBELL (Massachusetts): Our friend from Rhode Island has received some somewhat adverse criticism, and I would like to go to his rescue as it were, and say that on this work I have been very much impressed that this human element has a very important part in accidents, and it is something that really, it seems to me, has got to be faced. In addition to the recording of the physical element, the one thing that comes into our minds is this: that we are handing out licenses too freely; that the examination that most of us face now, that operators are put through before they receive their licenses, should be made more strict, in such a way as to eliminate so far as possible these undesirable human factors.

MISS ETHEL USHER (Connecticut Bureau of Motor Vehicles): I feel, as one of the states which is working as a close neighbor to Rhode Island, New York and Massachusetts, and has had statistical records on much the same basis over a period of several years, I ought to go on record as saying that in Connecticut we operate very much as Mr. Burnham does, on a theory and basis that after all the automobiles are operated by human beings; therefore, are under the direct control of the human being. Therefore, if any prevention work is done, it must be done and aimed at the human element, and if we are getting statistics we are getting them for the purpose of getting a definite basis for prevention work, otherwise why bother to get them; and if the human element is the one that is the chief cause of these accidents, then we must be told so, because it is the common belief and it is borne out in almost every act of life, that unless the human being is told he is responsible for some act, he is going to lay the responsibility on other shoulders and not do anything about it. Therefore, we in Connecticut follow much the same line as Mr. Burnham is doing in Rhode Island, trying to establish the fundamental cause as being in the hands of the operator, and it has been our experience over a period of five or six years of work with these accident reports, made out by the operators themselves, that in a large majority of the cases there is a definite act on the part of some one person involved that is evident, and is primarily the cause. There are cases, of course, where the situation is complex, as it must be with several human minds involved. In those cases it is much more of a problem to determine the primary cause, but we have found in far and away the majority of cases there is some one act that stands out as causing it.

CHAIRMAN DUBLIN: Is there any other discussion? If not, I would ask Mr. Burnham to summarize the discussion, and will he please keep in mind to answer this question: whether in his State he does not also employ the essential items in the record that we are considering as basic to the system of the committee, such as we employ in New York and other States; whether he places any reliance on those facts; whether he is able through the application of that information to interpret the human element that he obtains through the statement of fault, and also how reliable is the information that he obtains of this type: what checks he has on this reliability, and finally what use he puts that information to in the prevention of accidents. I may say that as for myself, I am entirely open minded on this issue. I can see very well the possible advantages of Mr. Burnham's system. I can see, also, why we, as a committee, did not venture into that field, because we were pioneering, and had in mind only a simple statement which could be widely disseminated, which did not require a large staff and an expensive piece of machinery. But I can see very well how if this system of Mr. Burnham's is successful and does actually do the trick, that it will be necessary to adopt it

generally and change our method to include those items of the human element which he has in mind. So I would ask Mr. Burnham to conclude this discussion and cover some of those points I have just raised, as well as raised by some of the other speakers.

Discussion by Mr. H. C. Burnham

MR. BURNHAM: To summarize briefly—the first thing that was brought out was the attempt to pin individual responsibility. That we do not do. If John Jones and Bill Smith have an accident, we do not attempt to say whether John Jones or Bill Smith was to blame. That is the function of the courts or the penal section of the Board.

What we are interested in is what general mistake in the entire accident led to the trouble. To cite an instance: Two drivers have a collision at an intersecting street. The course of the two motor vehicles is at right angles. John Jones writes in and states he slowed down to eight miles an hour and sounded his horn and he saw nothing coming. There was not any intimation of an accident and he got half way across the intersection when Bill Smith came down at 40 miles an hour and struck him. Bill Smith's report comes in. He states he slowed down to ten miles an hour, blew his horn, he looked around, he could not see any other automobile, and he got to about the middle of the intersection when John Jones came along at 40 miles an hour and hit him. Any trouble to find out what that accident was caused by? I don't think so. Simple reason, that they both had the desire to stop and they could not stop, and the accident occurred. When a man is going eight miles an hour he is only traveling at the rate of about somewhere in the neighborhood of about eight or nine feet a second, and at eight miles an hour he can stop his automobile if he has any kind of brakes at all, in about six or seven feet, and in the worst blind corner you have a sidewalk eight feet wide, and a man before he reaches the curb line of the intersecting street can see at least 90 feet up the street. So if he looked all around he could have seen the other automobile.

The whole point was that those men, both of them, like every other driver on the road, were driving along at their average rate of speed, in the neighborhood of 20 to 25 miles an hour, passing intersection after intersection, paying no attention to them, not slowing down, and two of them happened to meet and tried to occupy the same point at the same time, and the accident occurred.

The same way with pedestrians. We find a pedestrian comes from the left side of the street to the right side of the street—clear street—nothing to hide the driver's view; we find that the weather is clear; the road is straight. Daylight. No reason in the world to expect an accident. There is no other traffic to amount to anything, and the pedestrian is struck, and the driver writes in and says that he did not see the pedestrian and did not notice the accident was about to happen until he hit the pedestrian. Is it hard to find the human error that led to the accident? What was the driver doing? Where were the eyes that God gave him to see with? What was he doing with them? We do not know what he was doing, but we do know he was not paying attention to his driving of the automobile. He was not watching the ever changing panorama ahead of his car so he could take cognizance of any situation which might lead to an accident, and therefore we know he was not paying attention.

One of the gentlemen cited the case of the man that had a fuss with his wife. Well, I don't know as there is anything complicated about that. His mind was on nothing else except that fuss, and he was going around in a mental fog; his brain was on a vacation and anything was liable to happen. He was liable to go along and trip over a curbstone because he forgot to lift his foot. He might trip over a rug; he didn't see it. He might walk into the furniture; he didn't see it.

It is the same as the driver approaching the railroad crossing. We have a railroad crossing—the railroads have developed all kinds of warnings—STOP, LOOK AND LISTEN—big signs—bells ringing—lights flashing—crossing tender standing out with a "Stop" sign. All of those things are within the vision of the driver, and the law tells him he must be careful, and he runs into the side of a train. We don't have any difficulty in tracing that human error back to this—that that fellow was not thinking of the railroad crossing. He gave it no thought whatsoever, but he approached the railroad crossing at such a rate of speed that when he found an emergency facing him, he was unable to stop, and there is no question but he was driving too fast for the conditions of the highway at that point.

Do you want a law violation? He did not have his motor vehicle under control. There is not any state in the United States where the law in substance does not direct that every motor vehicle shall be under the full control of the driver when on the highway. It is a universal law, and when a man cannot stop his automobile when he wants to, his automobile is not under control.

The same way with skidding. Some people say skidding causes an accident. Skidding is an absolutely expectable result when a man drives too fast for the condition of the pavement. He says, "I have good brakes." We go back at him and say, "Well, Mr. Man, here is your point: your brakes are only just as good as the coefficient of friction between your tires and the surface of the road. If you were driving on grease you would have no brakes whatsoever, because the only thing you could do is put a band around the metal drum to try to stop the wheel from turning, but the real braking action takes place between the tire and the pavement. And in wet weather you may have your coefficient of friction drop to one-tenth what it would be in dry weather. Drivers do not understand it. They think they can go along in wet weather and put their brakes on. I notice today in this statement of the visit to the subway a most significant thing. Pick it up and I will read it to you. See how they have considered the human element.

"At the Interborough Subway shops at 147th Street, Manhattan, inspection systems and devices will be demonstrated; devices responsible, for example, for the fact that in twenty years' operation no wheel or axle has ever broken in service."

The same thing applies to steering gears on automobiles, and if you go out and look at automobiles and see the man who has allowed the bolts to wear almost through, so you get all kinds of road shocks, it is a sure thing that steering gear is going to break. We cannot blame it on the steering gear; it is the failure of the grey matter inside of the skull to function, because he did not know anything about it.

To get down to brass tacks as to accident prevention, there is one thing we must all remember, and that is that the accident frequency in the United States today is such that the average person rarely sees an automobile accident. All of us here—we hear nothing but accidents: it is our job. But Bill Jones goes on the streets of the city day after day, day after day, and does not see an accident. What does he know about accidents? Nothing. And when he meets an accident ready to happen, how is he going to recognize it? That is our job. We have got to tell him where it is going to occur, and therefore we have got to keep the most comprehensive statistics. We have got to tell Bill Jones that it doesn't happen generally on a wet day. It does not happen in heavy traffic. That it is at a time of clear weather, in the daytime, on a straight road or an intersection, that he has got to be careful. He has got to be careful in passing parked cars. He has got to be careful in passing anything that hides his view. And the only thing that we can do is to get our history of experiences. They are statistics.

Mind you, we are not getting dry figures here. Our statistics are living. Every one of the figures that represents a death or an injury to a human being is human. They are not mere figures. They represent coffins, broken bones, sorrow, every-

thing like that. We say 174 dead. Can we visualize 174 coffins—little children and sorrowing homes—the terrible loss that is inflicted? We must make those figures live. Can we make our list of injuries visualize the hospital beds, the suffering from broken bones? The suffering that extends for years, sometimes the crippling?

I have reference now to one man in Rhode Island who was struck by an automobile. His spine was broken. That man will never put his foot on the floor again. To me that figure represents that man, and that's what we have got to sell the public. They are not figures, but they are human experiences; things that the public must realize may at any moment happen to them. And that's why we have got to show them the human error; why we have got to compile the most comprehensive system of experiences on the highway.

In Rhode Island we are using a system practically comparable to that of the National Safety Council. There are many small details where we differ. We do supplement our system of statistics in the laboratory of the highway, where we go out and observe the human element at the wheel of an automobile and a foot. We have these observation posts, and we check what the people are doing to find out whether our statistics are a correct picture of highway conditions. We must do that. We must not lean back in our office chairs and point to a series of figures and say, "These are enough." We should check them up; check them up by actual experience.

And when we get through with that, we have only started on our job. We have got to go out and sell to every Tom, Dick, Harry, Lizzie, Ann and Mary on the highway just those experiences. The figures are nothing. We have got to get the information out in a form that the lowest intelligence can understand. We have got to get down to the truck driver; make him realize what he must do; what he must look out for on the highway. We must make these various statistics present a mental red flag to their intelligence, so when the conditions crop up again it will say, DANGER, USE THE BRAKE. We have got to get that reaction.

In Rhode Island we are releasing each week to the press a little story about our accident troubles. We are continually talking to organizations. Every Thursday night from the main radio station in Rhode Island we put on one of these stories. We are making a motion picture. We are re-staging the average accident.

Gentlemen, we have only two main types of accidents—motor vehicles and motor and pedestrian. Twenty-six per cent of the average accidents are motor collisions due to the intersecting streets. Fifty-five per cent of all the accidents occurring on the public highways involve a motor vehicle and a pedestrian, and 50 per cent of those accidents involve children under fifteen years of age. We go to our legislature, and the legislature states they are not mentally responsible, and in every other human endeavor the adult is responsible for the immature child. Can we pin any responsibility upon the child?

We find that the elderly people, the people who are not able to move quickly, who are not able to get out and indulge in physical acrobatics in front of an automobile, are struck. I saw one such accident myself. The highway was 45 feet wide—clear, straight stretch. The afternoon was bright; sun was brilliantly shining down, not in the operator's face. This lady, 78 years of age, came to the curbstone, looked down the street, looked this way, and then she started to walk across the street slowly. I stood there and watched her. Some 300 feet away was an automobile. The driver came along. The woman reached the center of the road and the driver thought he would go between her and the curbstone. He blew his horn. He forgot that perhaps the elderly lady might be deaf, as she was. Then he decided he could not make it between her and the curbstone; so he turned slowly to the left, and he decided he would not make it that way, and he put on his brakes, and the rear end of the car skidded and struck this elderly woman, threw her into the air

and deposited her on the curbstone. I ran over there. The first thing that driver said to the old lady, who was not seriously injured, thank goodness, was "Why, madam, why didn't you get out of the way; I blew my horn."

What kind of a mental attitude is that for a driver; but go out and find out how many drivers will tell you, "I blew my horn." Honestly, the automobile horn is the most remarkable thing we ever heard of. Every driver presumes that it is going to blow everything out of his path and assure him a clear highway and drives on that principle. It is purely mental. It is not physical by any stretch of the imagination. We have got to get that idea over to the driver: that he is not care free—that he has this responsibility. And if we look at the State laws we have a fine background for it, because universally the laws in substance state that no operator of a motor vehicle shall drive in such manner as to endanger the life, limb or property of any person. The right-of-way law is mentioned, but if we study the laws of the State we find this: that the right-of-way law never becomes operable until after the driver has complied with the previous section of the law, which requires him to slow down to a rate of speed at which he can control his motor vehicle. Only on through or boulevard types of highways does it permit him to go by an intersection without slowing down. Otherwise he must first slow down, have his car under control, and then he can think about the right of way, because he cannot proceed so as to endanger the life, limb or property of any person on the highway. That's an important point to remember in analyzing accidents, because our function, after we get our figures, is to sell this thing to the public and sell it so strongly and finally that they are going to get on to the fact that they have got to pay attention to their driving.

And we have got to get comprehensive figures so that when anybody questions our deductions or conclusions, we are able to put before them a vivid picture, which is so convincing that we do not have to argue about it, because argument is futile and defeats its own purpose. And that is the real necessity for statistics, so that we know where both feet are planted solidly, and we can stand behind fact and actual experiences and convince people.

ADJOURNMENT

October 2, 1928**Accident Facts—How to Use Them****W. W. MATTHEWS, Chairman****Chief of Safety, Motor Vehicle Bureau, Harrisburg, Pa.**

The session was called to order at two o'clock by the chairman, Mr. W. W. Matthews, Chief of Safety, Motor Vehicle Bureau, Harrisburg, Pa.

CHAIRMAN MATTHEWS: The Commonwealth of Pennsylvania feels honored in having one of its representatives preside at this important session of your Congress, not only because this afternoon's discussion, with that of this morning, represents the first time that two special sessions of an Annual Safety Congress have been devoted to the particular subject of Accident Statistics, but also because the invitation carries with it the implication that young as we are in the compilation of motor vehicle accident data, we perhaps are making progress.

Your chairman is doubly honored in being privileged to substitute for Commissioner Eynon, who, were it not for the fact that he is representing Governor Fisher at a conference in a remote state, would be here to participate in your deliberations, and assist in reflecting the rapid increase and activities of public departments along this line. He has asked me to express his very deep regret at his inability to preside over this session, as originally announced.

The general subject for the afternoon is "Accident Facts—How to Use Them," and I submit that were we able to solve that problem in all its phases motor vehicle accident prevention would take long strides forward.

Undoubtedly too much emphasis cannot be laid on the compilation of motor statistics, especially since traffic accidents are responsible for so staggering a toll of human lives, the injury of so many of our citizenry—to say nothing of the immense property and economic loss.

But the question remains as to what use to make of the facts, after we have expended time, money and effort to collect them. Are we collecting charts, treatises, summaries and exhibits for a library, or are we analyzing the statistics with a view of their use and value in safety education, highway policing, highway construction and legislative enactment?

Your average motorist is impatient of profound doctrinaire theses and impressive monographs, and the mere statement that a certain number of persons have been killed and injured within a certain period makes little or no lasting impression on him.

The picture must be so drawn that his attention and interest are aroused, and a comparative means must be found to register in his mind the fact that the accident hazard is a real, ever-present and constantly changing problem.

That should be the first function of safety education, and the lessons to be drawn from these accidents are of the greatest value in publicity in implanting the safety idea in the minds of the motoring and pedestrian public.

The statistics on motor violations causative of accidents enable highway patrols and traffic police to centralize their activities on motorists who are responsible for a majority of the accidents, and to lessen the number of preventable accidents by punishment of the irresponsible and reckless driver.

There are, of course, always certain persons who cannot be educated to obey laws enacted for their own safety and that of others, and these drivers must be removed from the streets and highways by the exercise of the license suspension power vested in the motor vehicle administrator.

Close analysis of each accident report, and the determination to follow through on all cases of reckless driving and disregard for the safety of others, should accomplish this result.

Granting that a certain number of accidents are unavoidable, there is no doubt that a much greater number are due to temporary inability of the driver to react satisfactorily to certain more or less unfamiliar situations quickly enough to prevent trouble.

When faulty road construction or conditions are responsible, highway engineers should be quick to analyze the defects and to remedy them, and if the accident reports show a lack of reasonable alertness or attention on the part of the driver, his fitness to enjoy the driving privilege is immediately in question.

Where a motoring practice, now legal, is a causative factor in a large number of accidents, the state authorities, through a study of these statistics, are able to arrive at a method of their prevention and to recommend appropriate legislation.

So many angles of importance are presented that they cannot be enumerated—they offer material for endless study, but the most reassuring feature of the whole situation is the evident widespread realization on the part of those engaged in alleviating the serious condition, of the necessity for their familiarity with such facts and the best means of using them.

Properly appraised and intelligently used, accident facts will help us to chart a smooth course over the avenues of safety, rather than a perilous passage on roads to destruction.

CHAIRMAN MATTHEWS: New York has given much attention to reporting and studying its traffic conditions and accidents, and this work is under the supervision of your first speaker, the Honorable Philip D. Hoyt, Deputy Police Commissioner of New York City, who has very kindly consented to address this session.

How We Use Statistics for Accident Prevention

By PHILIP D. HOYT

Deputy Police Commissioner, New York City

Dr. McClintock, who made an address yesterday, stressed the importance of using facts instead of guesses in solving the traffic problem. Those of us who are responsible for traffic control in this city have occasion to know of the importance of using facts in deciding upon our traffic program. Traffic counts, speed tests, and other factual data which we obtain, are used almost daily; but no set facts that we obtain are more important than the accident statistics which we use in our plans for traffic control here.

I assume that what you are interested in particularly is facts and not opinions. So it is my purpose to describe to you somewhat in detail just how we collect and use our accident records.

The traffic problem is one of many phases. City or regional planning, the study and initiation of engineering projects which will provide additional facilities, is one of them. Regulation or handling of traffic with existing facilities is another. Discussion of the traffic problem too frequently considers one purpose of regulation—the acceleration of traffic, and ignores or minimizes the more important function, the protection of human life. Speeding up traffic is of course an essential object of regulation, but public safety comes first. The primary duty of the police in handling traffic is no different indeed from its duty to protect society against the criminal element. That is why traffic regulation generally lies in the hands of the police.

The complexities of the traffic problem in New York City are increased not

merely in proportion to its population, but because of many other factors, some of them peculiar to this city. The geographical barriers which divide and surround the city; the density of population; the height of the buildings; the number of automobiles; the extent of the suburban district—all complicate the situation. Handling traffic safely under such conditions on the city's five thousand miles of streets, is a task calling for the utmost effort.

Our toll from street accidents is high; yet we feel we are making some progress in our attempt to serve human life by a thorough and systematic study of accidents. Last year, for the first time since the appearance of the automobile, the number of fatalities and injuries to both adults and children resulting from highway accidents in this city, decreased from the preceding year. The fatalities from motor vehicles in this city in 1927 were 17.8 per one hundred thousand of population. The figures of the National Safety Council show that the general rate for the entire country, urban and rural, was 19.6 per hundred thousand, while the urban rate was 22.4.

The most encouraging fact, however, is that since 1923 there has been a steady reduction year after year in fatalities to children of sixteen and under, due to highway accidents in New York City. In 1923 there were 453 children killed; in 1924, 432; in 1925, 422; in 1926, 413, and in 1927, 408. In the first eight months of this year 218 children were killed as compared with 266 during the corresponding period last year, a decrease of 18 per cent. It is not, however, my intention to burden you with figures. Those I have just referred to are sufficient to give you a picture of the accident situation in this city and to show the decided progress in the reduction of accidents. This is due in no small measure, in my opinion, to our use of accident records. It is my purpose in this discussion to tell you something about our system of collecting, classifying and using these records.

The information relating to each accident involving death or injury comes in the first instance from a report made out by the patrolman on post. A printed card used for this report calls for certain specific information. The principal causes of accidents are specified on this card, so that the patrolman who has occasion to make out the report knows exactly what information we require. On the back of the card is a blank space calling for the details, for purposes of further classification. Our total force of 17,500 policemen is at our service in investigating accidents and making out these reports. One copy of the report or printed card goes to the local police station, in the district where the accident occurred. Another goes to the Information Bureau at Police Headquarters for various uses which will be referred to, and a third goes to the Accident Record Bureau of the Traffic Division, also at Police Headquarters. The Captain of each of the local precincts keeps his own file of these cards and prepares from them a precinct spot map of accidents in the district of which he is in charge. Each Captain is thus able to keep in close touch with the situation in his locality. The cards returned to the Information Bureau are used for a variety of purposes, such, for example, as checking up persons who have been reported missing, and who the cards may show have been removed to a hospital following a highway accident. The cards returned to the Traffic Division are first classified by names alphabetically. Reports are received daily from the Medical Examiner, and these are carefully checked; so that when an accident victim reported as injured later dies, the report may be corrected.

Every accident is next listed as to the cause. Seventy different causes are included in this classification. The cause records are the basis of a monthly report. The next classification is according to location. This is made in three ways. First, by a file of streets and avenues; second, by police precincts, and third on spot maps which show the location of all accidents involving death or injury for each of the five boroughs of the city. Further classifications are made as to the hours of accidents and the ages of the victims, divided into several groups. In the case of

children sixteen years old or under, several special classifications are made. These are according to ages, hours, school districts and schools.

All these records being merely collected, classified and filed away would be of little value. To avail ourselves, therefore, of this store of information is our next task. It is one to which we have devoted considerable thought in an effort to develop a system that would be of material aid in reducing traffic hazard. The monthly summaries are carefully studied. Our first interest is in the total for the month and the comparative figures for the preceding month and preceding years. Are accidents increasing or decreasing? Are children or adults the victims? What are the principal causes? Are they on main avenues or side streets? What hour do they occur? The answers to these and similar questions are found in the summaries and they give us a general idea of the accident situation in the city.

Closer study is made of the localities of accidents. This street has a high record. Is it because of the lack of traffic control, or inadequate regulations? The locality classifications are of particular interest in our planning of traffic control light systems; in fact, they are the basis of our request for appropriations for that purpose. Traffic lights may be provided where policemen may not. By the end of this year some 3,500 intersections in this city will be controlled by traffic lights. It would take about seven thousand policemen to cover these crossings during the hours when the lights will be in operation, involving an annual cost of more than seventeen million dollars. That does not mean we save that amount by supplementing traffic officers with traffic control lights, but it does mean that traffic lights will provide control at nearly three thousand intersections where otherwise control would be impossible, not only from the standpoint of cost, but because of the difficulty of obtaining and training that number of additional men of the right calibre.

So in planning our traffic light programs, the reports showing just how many persons were killed and injured on each thoroughfare of the city are of the utmost importance. The assignment of the three thousand men detailed to traffic duty in this city and the sixteen hundred others who do special duty in the vicinity of schools, is another task calling for frequent reference to the locality record.

In addition to the general regulations which the Police Department makes for the control of traffic here, several hundred special regulations affecting particular localities are made each year. In our consideration of the necessity for such regulations, many of which are requested by residents or civic organizations in the various neighborhoods, the locality accident records are of great use. These records also aid us in the direction of the activities of the police in enforcement. They often tell us where more attention should be given to speeders, or that drivers are not observing strictly the regulations covering turns, right of way, or other rules.

In order to go more deeply into accidents involving deaths in this city, the Traffic Division has recently inaugurated a system providing for a more detailed investigation of such accidents. Every death now occurring in the city as the result of a highway accident is investigated by a special squad, operating from Police Headquarters. This squad is composed of experienced traffic men who work in uniform. The work is so distributed that the investigator can give a full day to each fatal accident. Although the information received from the patrolman on post is quite complete, there are frequently conditions at the points where accidents occur which the ordinary policeman does not feel the responsibility to investigate and make the basis of recommendations to his superior. The members of this special squad, being few in number, know exactly what information is required, and their business is to make recommendations to improve traffic conditions at that point. The investigator visits the scene of the accident at the same hour of the day when it occurred. This enables him to take into account all conditions at that particular time, such, for example, as the volume of traffic, street lighting, or

many other factors. The investigators are all draftsmen, and their report includes a diagram of the locality, showing all the physical conditions and the position of the vehicles or pedestrians figuring in the accident. Specific information covering several points is required in the report—whether there was a traffic post or a traffic light at the point involved; the street lighting condition; any special traffic regulation, such as one-way street; and the condition of the pavement. These reports are taken up in conference with the patrolman who wrote them, and there is a thorough discussion of conditions at each point, for each fatality, so that we may get an answer in each case to the question whether anything possible can be done to improve conditions.

Many of these recommendations naturally come within the jurisdiction of the Police Department. Attention may be called to a crossing where traffic lights or traffic policemen should be provided; warning lights indicating dead end street, for example, or various other traffic regulations of a cautionary nature may be necessary; regulations such as one-way streets may be advisable. The investigator's visit may result in the discovery that particular attention to enforcement should be given at this point. White lines to designate pedestrians' crossings may be needed. Many recommendations relate to other departments. Street lighting conditions may be in need of repair or improvement. Repairs to highways or bridges may be necessary. The highway facilities may be inadequate, requiring engineering measures for relief. In some cases the recommendations relate to individuals or private agencies, involving, for example, the routing of vehicles to less congested sections. The investigations frequently disclose facts of interest to the school authorities and their cooperation is sought.

This system of a detailed investigation of fatalities, although comparatively new, and by no means fully developed, has been found to be of the greatest assistance to us in improving traffic conditions.

So you see there is hardly a step in our traffic program, whether it relates to the assignment of personal investigators, the placing of traffic equipment, or the use of our broad regulatory powers, that is not based upon our accident experience.

In addition to the uses which the Police Department makes of our records, these records are also constantly being supplied to private agencies for use in accident prevention. They are supplied in detail to safety organizations. Organizations interested in the extension of the playgrounds throughout the city obtain them regularly to support their requests for additional recreational facilities.

One of the most important uses of these records is in connection with the safety education program which the Board of Education is carrying on in this city under the personal supervision of Dr. William J. O'Shea, Superintendent of Education, and also in the parochial schools in the five boroughs of Greater New York. Every month an analysis of accidents involving children of sixteen or under is sent to the school authorities. This analysis stresses the causes of accidents and shows how these accidents vary from month to month. By means of these analyses the school authorities are able to determine what careless practices lead to accidents, and to impress upon the children the need for personal carefulness in these respects. Each of the twenty-seven school district superintendents receives a report for his district. A separate report is prepared showing the number of accidents involving children attending each of the 994 schools in the city; so that each school principal may learn every month whether the accident toll for his school is decreasing or mounting. The value of educational methods in accident prevention cannot be too highly estimated. Our own experience shows that can be done, although thus far we have made only a beginning.

One of the most important uses that can be made of accident statistics, in my opinion, is in safety education. This can best be accomplished through the schools. Safety education in the schools has been greatly developed during the last few years, but its possibilities as a regular part of our school program are only begin-

ning to be realized. Teaching the children how to take care of themselves under present-day traffic conditions is a duty no less important than teaching them reading, writing or arithmetic. Safety instructions, furthermore, can be combined with those and other subjects of the regular curriculum without taking any additional time. Such instructions, in fact, can be so planned that it will stimulate interest in the subjects into which it is incorporated. Education is not my forte, but I feel so strongly on this subject that I cannot refrain from making this reference to it. Personal safety, in my opinion, should be an acknowledged subject of instruction in the schools throughout the country. The importance of such a program is recognized. It remains only for some countrywide educational organization, perhaps some great educational foundation, to get behind this movement, in which great strides have already been made, and develop a systematic, comprehensive plan of safety education, which will be generally accepted as an essential part of the training of our youth. There is no accomplishment that I can think of that would be more worth while.

CHAIRMAN MATTHEWS: Thank you, Commissioner. One of the purposes of meetings such as this is the interchanging of ideas and the opportunity for discussion, and it is hoped that you will feel free to make any comments that you might desire in connection with any of the papers presented, and I am sure that if any of you would like to ask Commissioner Hoyt some questions concerning this program developed by the City of New York, he would be very glad to answer them. One of the principal points which he has stressed is the necessity for education in the schools. One of the most tragic facts about this whole accident situation is that there are so many fatalities and injuries to children under fifteen years of age. A great many people stress the fact that these safety campaigns perhaps may cost a great deal of money—take a lot of time and effort and there are no definite, tangible results that you can get hold of; but consider for a minute the saving of children's lives. Who knows but what the life of one small child who is saved from an accident may be worth more to the State or Nation in the field of arts, science, literature, military genius, than the cost of all the safety campaigns ever waged.

HARRY RAINES (Director of the Washington Driving School, Brooklyn): I would like to ask Mr. Hoyt, is it important for the auto driver to be trained properly before being tested by the Motor Vehicle Inspector, and are auto driving schools necessary or not? Should we only caution the children in the public schools, and not have schools for auto drivers or learners? Why not schools for the learner who intends to become a driver, to be cautioned in traffic regulation, motor vehicle and automobile driving, and protected with a car with a double clutch and brake, so he understands his own mistakes and the importance and the power of the clutch which connects the motor.

E. B. LEFFERTS (Automobile Club of Southern California): I would like to ask Commissioner Hoyt the size of his special investigating squad that investigates all fatalities. How many men comprise that squad?

COMMISSIONER HOYT: We have three men regularly on it, and it is to a certain extent flexible, so we may increase it.

MR. LEFFERTS: Do I understand that three men are sufficient to investigate all traffic fatalities thoroughly in the City of New York?

COMMISSIONER HOYT: Yes sir. They are sufficient to devote about a day to each fatality. There were 1,042 motor vehicle fatalities last year, 1,138 highway fatalities including all classes of vehicles, street cars, bicycles, horsedrawn vehicles and riding horses. That would make an average of about three a day.

MR. LEFFERTS: They don't try to investigate accidents in which persons are injured but not fatally?

COMMISSIONER HOYT: Not as yet. We have made a beginning only with fatal accidents.

H. C. BURNHAM (Research Director, Motor Vehicle Department, State Board of Public Roads, Providence, R. I.): Mr. Chairman, it seems as if we are giving considerable attention to the school children. It seems as if we have placed the entire responsibility for the situation on the coming generation. It occurs to me, what are we doing at the present day? The gentleman over here suggests we establish automobile schools and teach the new drivers. What are we going to do to take care of the man who learned to drive a car fifteen years ago? What are the Police Departments and other interested organizations doing to teach the men who are behind the wheel of the motor vehicle today the essentials of safety in driving and, more important, thinking? I would like to know what New York is doing with their traffic police to educate the drivers to using their heads for better driving conditions.

COMMISSIONER HOYT: The average traffic cop who stands at a busy corner don't have a great deal of time to educate anybody. He has his hands pretty full. We have tried to bring our traffic men into two or three schools every year, so that we explain the regulations to them thoroughly. That's the first thing, to have them understand the rules, and then impress upon them the necessity of explaining these to the motorist who simply runs afoul of some regulation by force of circumstances because he does not quite understand it. There is not a great deal of time for those men on the crossing to do much in that respect. We have, however, done this: We are sending out in the case of comparatively trivial violations, a warning letter, explaining that at such a time and such a place this car, bearing such a number, which is registered in the name of the person to whom the letter is sent, has violated a certain regulation. The regulation is quoted. The necessity for the regulation is explained in the letter, and those are sent out on reports that we receive from patrolmen, who simply turn in the numbers when they see a violation of that character.

The results we have had from that plan have been very good. We have hundreds of letters. We close our letters with the plea that the person cooperate with us in trying to help us to see that the traffic laws are enforced. In nearly every case the person thanks us for calling it to his attention and in some cases we reach the owner of large fleets of trucks. We have had cases where men have called meetings of their drivers and asked our men to come and talk with them on the traffic regulations and explain them. Although we have by no means developed the full possibilities of that plan, I think that that has been most helpful in educating the driver as to the regulations of the city.

Of course the trouble is that any system of regulations is pretty hard to simplify. There are so many exceptions that it is pretty hard to explain them in words that almost everyone will understand, and very few people will take the trouble to study the regulations, although we print them and have them available at every police station, and have advertised that fact very extensively in all the papers of the city. Does that answer your question, Sir?

MR. ALLEN (New York City): I wanted to ask you, Mr. Commissioner, how the general police officer, whether he is assigned to traffic or anything else—who patrols the beat—whether he takes the opportunity to graciously or otherwise explain to a person who he sees violating or taking a chance, the dangers of that violation. In other words, Mr. Commissioner, is there any part of the curriculum of your police school in New York City here that is devoted to safety, and to specific instances of safety education?

COMMISSIONER HOYT: No, there is not. That is, it is not one of the duties of the patrolman to engage in any systematic educational work, although I think very often that is done, and we frequently have names and cases reported to us by the patrolman on the post to whom we send the warning letters which I have just described.

RICHARD A. LEARNED (Society for Instruction and First Aid to the Injured, New York City): I should like to ask Mr. Hoyt if he has any statistics or figures here on accidents in large cities abroad—accidents in London, for instance? I ask that because I have driven a good deal here and good deal there, and there the automobile driver is much more courteous than he is here, and he is taught to be courteous, the police officers are taught to be courteous. The police are courteous to him, and there is more looking out for the other fellow than there is here. I am an American and proud of it, but I think here it is every man for himself and the devil take the hindmost.

COMMISSIONER HOYT: I have not the figures for the cities abroad. I have the figures for the cities in this country. Of course we have the figures of the National Safety Council available.

CAPTAIN CASEY (New Orleans): I may be able to answer the gentleman's question. I was in Europe last year and I visited Paris. At first sight you would think that about one hundred people were being killed in the streets every day, because there is a lack of pedestrian regulation there. I was surprised to find that the fatalities were very low as compared to American cities, and in looking for the causes I found out that the big bulk of the motor traffic in Paris is taxicabs. Possibly 75 per cent of those are trained drivers. They operate small cars, under rigid mechanical inspection; so that while they come bearing down on you at 45 or 40 miles an hour, they do not run over you; they stop at a very short distance.

Furthermore, there is a great deal of what we call "courtesy of the road" in the European cities, as compared with American cities. You will find in driving in Paris, if you get into a tight corner—for instance, a driver wants to make a left-hand turn, he is in a bad spot—automatically the other drivers will step aside and permit him to turn. The reverse is unfortunately true in this country:—lack of courtesy and the inclination to get there regardless of the other fellow. In London the accident rate is rather high, but they have a splendid body of police there—the metropolitan police in London. Yet I was surprised to find that the accident rate in London compares somewhat with New York.

I would say that the lowest accident rate in European cities as compared with American cities is entirely due to the lack of courtesy of drivers in this country, and to the courtesy of drivers on the other side.

CHAIRMAN MATTHEWS: That is rather a sad commentary on the American driver, that he is perhaps less courteous than Europeans are, but nevertheless that's one of the conditions we have to deal with in this country.

Those of us who are working with public accident statistics should be able to learn from the experience of those who have been busy in a similar field in industrial accidents for a great number of years. Your next speaker is one of the earliest pioneers in this field and will tell us of some experiences of the accident statisticians and the lessons which we may learn from them. It is with pleasure that I present Dr. L. W. Chaney, of the Bureau of Labor Statistics, Washington.

Mistakes to Be Avoided

By DR. LUCIEN W. CHANEY

Bureau of Labor Statistics, U. S. Department of Labor, Washington, D. C.

The foundation of all statistical procedure is of course the facts as determined by careful inquiry. If these facts are accepted without due criticism it may easily happen that the whole following treatment is hopelessly obscured.

The making of reports is often entrusted to those who have no adequate idea of what is needed and who make almost ludicrous errors. This may be illustrated

by an occurrence in my own early contact with accident matters. I had found with one concern a considerable body of data which seemed to throw some light on the hazard of the beginner in industry. In the blank furnished by the insurance company for reporting the accidents was this question: "What instructions were given the operator before starting work?" Over a period of several years the answer entered opposite this query was "to finish the job." It is clear that the one responsible for making these reports had small notion of the meaning of the question which he was attempting to answer. The concern was one having a large number of stamping presses and the instruction "to finish the job" was followed by a distressing number of lost fingers and mutilated hands.

So conspicuous an instance of misunderstanding would be readily detected but when such errors are possible it is evident these basic facts must be closely scrutinized in order to give assurance of reliability.

For three years now the Bureau of Labor Statistics has been gathering the facts regarding a group of some 29 industries from the compensation commissions in the various states. It has been necessary to introduce an undesirable number of explanatory foot notes in the tables prepared from this data in order to guard against misunderstanding due to the fact that the states do not gather their material on a uniform basis.

It has long been the custom for insurance companies to require a report for "any bodily damage however trivial." This was unsatisfactory because of the difficulty incident to securing complete reports. One large steel company had been operating under the insurance rule for many years and supposed that they were securing complete reports. It was then decided to improve the medical service. A chief surgeon was appointed with subordinates stationed at the various plants. Immediately under pressure from this new service the number of cases greatly increased and at the end of the first year the records of the emergency rooms and hospitals showed almost exactly twice the number of cases as were recorded during the previous year.

Consideration of this and similar instances led to the conclusion that unless an injury led to a loss of time from work it was difficult almost to the point of impossibility to be sure that reasonably complete record had been made.

The effort to develop a definition of an accident which would serve satisfactorily in the study of accident experience in the iron and steel industry resulted finally in the following: "An accident is an accidental injury resulting in death, permanent disability, or temporary disability beyond the day of injury." This definition of a "lost time" accident insures that practically every case coming under the definition will be a matter of record. When a worker is absent from work it becomes immediately a matter of concern to the paymaster's office.

With accidents as above defined as a basis it would be possible to proceed with some confidence were it not for another feature of the situation. In establishing the compensation laws it has seemed necessary to have a "waiting period" before compensation payments begin. Unfortunately this period is not of the same length in the different states. The tendency now is to adopt seven days as the standard but this tendency has not yet brought about uniformity. It becomes necessary therefore to determine the length of this period in any state which may be under consideration and to ascertain whether, though not compensated, cases of less than seven days are reported to the compensation board.

The foregoing gives some idea of the care which should be exercised regarding the basic data. The chances of error are many and must be checked with the utmost care.

In the second place having assured ourselves of the trustworthiness of the reporting which it is proposed to use we may advance a step and consider the error of mistaking enumeration for statistical treatment.

For example it is very common to see a list of industries with the number of

accidents for a given period entered opposite each industry. Such a procedure affords some interesting information but fails entirely to shed light upon the serious problems of accident prevention.

The idea that such a process of counting the cases has statistical significance is quite generally entertained. It will therefore be quite pertinent to present a rather full discussion of the standard procedure.

The importance of accurate accident reports has already been stressed. To afford a way to use these reports so as to afford a correct idea of their meaning another factor is necessary, namely, the amount of exposure to hazard corresponding to accidents occurring. The inadequacy of accident reports without the corresponding exposure may be indicated by a simple illustration. Let us say that two concerns report 200 and 100 accidents in a given year. What are the possible interpretations of such a condition? It is possible that the concern having 200 accidents is twice the size of the one having 100. Or it may be that the plants are of the same size but that the processes of the plant having 200 cases are twice as dangerous. It is evident on a moment's notice that there are an infinite number of possibilities and that unless there is some way selecting some one of these no definite conclusions are justified. This selection may be accomplished by determining the factor of amount of hazard and establishing its relation to the accidents occurring. The ratio between exposure and accident occurrence is an accident rate and affords an index of conditions of great exactness.

Several methods of determining a suitable base for the calculation of accident rates have been proposed such as the average number of workers on the pay roll, the pay roll itself or the "man hours" worked. The workers on the pay roll and the amount of the pay roll are undesirable for similar reasons. Neither of them is constant in value. Labor turn-over varies from plant to plant and wage rates are by no means stable. The most satisfactory unit for expressing the amount of exposure to hazard is the "man hour." A worker who in a given year worked 250 days, 10 hours per day, would have 2,500 hours of exposure, while a fellow worker who labored 200 days in the year, 8 hours per day, would have 1,600 hours of exposure.

The advantage of the "man hour" is its uniform value. A day, a week, a month may have several meanings according to the custom of industry or the particular plant under consideration. An hour is a uniform period of duration wherever and whenever it is mentioned.

It is coming to be more and more common to make wage payments by the hour and this tendency renders it easier to maintain a record of "man hours" for statistical purposes.

It is not the intention at this time to go into the details of handling the factors of "man hours" and accident occurrence but to emphasize as strongly as possible the necessity for such a procedure. The mere enumeration of the cases is wasteful and of very little value.

It has been indicated above that the only entirely satisfactory method of making comparisons of accident experience is by developing ratios between amount of exposure, preferably expressed in "man hours," and accident occurrence.

This leads to consideration of a third error desirable to avoid namely the attempt to make comparisons between units of operation by means of percentages.

To illustrate, a given company has ten departments in each of which 10 accidents happened in a given year. That is each department had 10 per cent of the accidents. Now suppose a second year in which each department has again 10 accidents except department 10 which in the second year has 12 accidents.

If now we compute percentages it will be found that departments 1 to 9 have each 9.8 while department 10 has 11.8 per cent. Comparison of these two groups of percentages will certainly suggest that departments 1 to 9 have changed for the better while department 10 has changed for the worse. The fact is that no

change has occurred in departments 1 to 9 the change being confined to department 10. Such comparisons as that shown above are somewhat common and are always misleading.

A fourth error to be avoided is the supposition that the best statistics will directly indicate what steps in accident prevention should be taken. Proper accident statistics will indicate the need of accident prevention effort, they will indicate where such effort is needed, they will indicate whether the efforts are or are not succeeding. They will not in many cases determine just what steps should be taken. In other words the accident problem is both a statistical problem and an engineering problem and the neglect of either phase spells disaster.

CHAIRMAN MATTHEWS: Thank you, Doctor. Dr. Chaney has mentioned the differences in the method of reporting accidents. I have some little experience of that kind in my own work in connection with that of other States. Frequently we present summaries of various types of accidents and we get inquiries as to just what we mean by some figures, and we have the same inquiries to make about some of the other reports that we get, and in defining accidents if someone could develop a reasonable definition of what was an automobile accident, perhaps we might be able to make some further progress. Sometimes I think that if we only crashed up a couple of cars, perhaps destroyed a little property, the situation would not be so bad; but the fact still remains that in practically every automobile accident there is some personal injury even a fatality.

Dr. Chaney has also mentioned the exposure to hazards in industrial accidents. Now, in operating an automobile, the driver is almost continually exposed to hazards,—not so much these which he may create himself, as to these presented by the problem of other drivers; and this reverts back to the question raised by Mr. Burnham as to what can be done to educate people now driving cars. There are a number of angles to that situation which I won't attempt to discuss. Perhaps there is among the audience someone else interested in industrial statistics who might be able to draw some analogy between those and the automobile accident statistics and give us a little further light on how we might apply some of the same problems and reach the same result. The meeting is now open for discussion.

W. E. SANFORD (United Electric Light & Power Co., N. Y. C.): I have spent a good deal of time for the last six months in studying the records of our company and analyzing the accidents for a year, dividing them up into classes A, B and C, in which A was the important class. In other words, any accident in which the possibilities seemed to point towards a serious chance, we classified as an A accident. If there was a pedestrian involved, or any speed over ten miles an hour—by that I mean indicated, not reported—we call that an A accident, and we ride the drivers pretty hard on an A accident.

But I think the important thing goes back to what was stated in the last address; that we do not allow enough for exposure in the reports we have been getting out. We have been getting out reports—so many accidents between 14th and 59th Street—and so many from 59th to 125th Street—and nothing to show how many cars driven in each district. There might be one car below 125th Street, and twenty between 14th and 34th. The figures will not show this because they do not show exposure. I found in analyzing the thing, by checking up and getting the exposure we could really get something that would give some information.

And when you get down to an accident, "fatality" does not mean much in accident prevention, because the least little accident may result in a fatality. A case in point: Not long ago we had a case in a filling station. A woman was alighting from a car. A taxicab backed up and caught her between the top and the body of the car. He only backed up about two feet, but if he had gone another two or three feet he might just as well have taken off both her legs. Had he gone an inch less, he would not have touched her at all. It is just as important to check up

on every accident and find out what happened and what the possibilities were. Any automobile accident may result in death.

L. R. SCHUYLER (Lycoming Mfg. Co., Williamsport, Pa.): I am wholeheartedly in favor of the National Safety Council giving us some information so that we can cooperate in obtaining a general basic computation in the reporting of accidents. I think we should have some common footing so when we read over these statistics we may know the other fellow is not putting anything over, regardless of what State he is from.

MR. PARKER (Pennsylvania): There has been much talk here about educating the driver, but judging from what I have seen here in New York City, I think a better place to start would be in educating the jay walkers. I never saw such a display of what I would consider in my poor countryfied experience as jay walking as I have seen since I have come to this great city of New York. I stood on the corner this morning and I saw the traffic policeman hold out his hand for the cars to stop, and the cars stopped. I saw him trying to keep pedestrians from going through when the traffic was going through, and the pedestrians kept on going through the cars. As a motor car driver I rather resent the idea which is prevalent with most people that in all cases, or almost all cases, the driver is "the guy that done it," and you all know that's true. "Four out of five times it is the driver. He was driving too fast, or he did not put on his brakes quickly enough. It is the driver's fault." As a motor car driver I rather resent that. I have been driving a car about six years, and, like my friend there, I have never had an accident, and I never went to any auto school either.

CHAIRMAN MATTHEWS: The Chair is about to exercise its privilege to call on someone from the floor. I would like to ask Mr. F. W. Johnson of the Citizens Safety Committee of the Philadelphia Chamber of Commerce if he might not be able to make a few remarks relative to this particular situation.

MR. F. W. JOHNSON (Citizens Safety Committee, Philadelphia Chamber of Commerce): Respecting the jay walker, I quite agree with all the previous speaker has to say and I quite agree with all that is to be said and has been said with much force on the opposite side of the question. As a matter of fact, as our distinguished Chairman in his wide experience in these matters in the State of Pennsylvania knows quite as well as I, there is a great deal to be said on both sides. It is a highly controversial subject. Unquestionably, as disclosed by the figures of our National Safety Council for the year 1927, approximately 65 per cent, or substantially two out of each three people who met death in street accidents in this country last year were pedestrians. And so there we have summarized the high spot of the street accident death rate in this country.

I confess I do not agree and I never have taken the position that this jay walking problem can be approached and attacked most effectively by simply broadcasting an appeal or an admonition to pedestrians not to jay walk. I believe, in the first place, that the word "don't" has been entirely outlawed in the development of this great work in which we are all so deeply interested. There is no use in telling anyone not to do a thing—don't do this; don't do that. I had a very earnest volunteer worker in my office a few days ago—a wonderful fellow, who runs a locomotive throughout the day and then in his hours in the evening and holidays, he goes out and works among the poor children of our city—and he told me with great pride of a list of twenty-seven Don'ts that he had prepared for these little children. I asked him in each case what he wanted them to do, and he told me, and I said, "Then why don't you say to these little children 'What you *should* do is this?'" In presenting your Don'ts to people, you are presenting your argument upside down. So it seems to me in saying to jay walkers "Don't jay walk" we are not really doing anything constructive and we are not appealing to the great mass of American people along the lines that will make for responsiveness.

The first step, educationally speaking, is not to leap to the limit of our objective, because no educational process works out in that manner, but rather that we should explain and endeavor to influence the great mass of these people to exercise judgment in walking the streets. I maintain that there is nobody in this hall, and they are all safety workers, that does not jay walk. I had the pleasure of attending a meeting of my committee of the National Conference on Street and Highway Safety in Washington sponsored by our great Secretary, Mr. Hoover, and after that meeting of three hours' discussion of this problem of the jay walker, we crossed one of the principal streets of Washington to the Metropolitan Club for luncheon, and, Mr. Chairman, I give you my word that every one of those twenty-one members of that Committee jay walked across that street.

Jay walking, gentlemen, I would remind you, has certain economic factors to commend it, and that's what you are bucking today. Jay walking works an economy of time and distance, and if there is anything to which these high-powered Americans today are given, it is the saving of time and the saving of distance. So that when a gentleman walks out to go to his office, take a railroad train, keep an appointment, if he can take the shortest or most direct route, he gets there most quickly, and that's why we are traveling express train speed, why we are going in so strong for one hundred miles or more per hour in our air travel, and why we have air mail and the fastest steamships, and why we don't stop to call on a friend but telephone; we don't write, we telegraph; we haven't time to lunch properly, so we grab a sandwich; we haven't time to eat in the middle of the day, so we hold a business meeting while we are lunching. As a matter of fact, we are obsessed with saving time and shortening distance. So I am trying to educate our people in Philadelphia, not to the giving up of jay walking instantaneously and entirely, because I regard that as futile; but I do say to our people, "When you choose to jay walk, at least please use your head and your eyes, and if you will jay walk, jay walk safely; use judgment; look where you are going"—and I am hopeful that we are making progress.

COMMISSIONER PHILIP D. HOYT (Deputy Police Commissioner, New York City): May I also say a word on this jay walking situation? It seems to me the jay walking campaign can be successful only on two conditions. The first is that the people are ready for it; that they will accept it voluntarily; and the second is if you can put enough policemen on the street to enforce it, whether they like it or not.

If they do not want it and you adopt a law, you are simply having another law on the statute books which nobody wants, and to which you have to devote a lot of man power to enforce. We had experiments here in this city. Some years ago in attempting to stop jay walking we had at a number of our intersections as many as eight men stationed to hold back the crowd. The experiments were not very successful. I do think the people know a great deal more about jay walking and the dangers of jay walking than they did one or two years ago, and I think they are learning more about it all the time; and I think the time will come when jay walking regulations will be accepted voluntarily; but until they are, it seems to me it would be futile to enact any jay walking regulations unless we are prepared to appoint and train and send out on the streets a very large force to enforce the ordinance.

CHAIRMAN MATTHEWS: It seems to me perhaps we have jay walked around the subject a little bit. Probably your Chairman is as much responsible for it as anybody. However, these discussions are interesting and there is no doubt but what something of value can be taken from the suggestions.

Last Spring the Statistics Committee of the National Safety Council released its annual printed report containing a great deal of valuable data in connection with accident facts. The Chairman now has the honor and pleasure of presenting to you the Chairman of that Committee, Dr. Louis I. Dublin, who is also statistician for the Metropolitan Life Insurance Company, and he will now present the high

points of that report and developments since then. Dr. Dublin has chosen as his subject, *The Accident Problem as Revealed by Statistics*. Dr. Dublin.

DR. LOUIS I. DUBLIN (Chairman, Statistics Committee, National Safety Council): Mr. Chairman, I hope that you have all had an opportunity to examine carefully this document entitled "Accident Facts, 1928." This is the sixth report which my committee has issued. I can at best summarize the main points in this report.

The Accident Problem as Revealed by Statistics

By DR. LOUIS I. DUBLIN

Chairman, Statistics Committee, National Safety Council, and Statistician,
Metropolitan Life Insurance Company

Accidents caused the death of 95,500 people in the United States during 1927, according to the report of the National Safety Council's Committee on Statistics.

About one death in every six arises from accidental causes. Since 1911 the number of accidental deaths in the United States has increased twenty per cent. In 1927, the increase over 1926 was four per cent. If this figure maintains for 1928, there will have occurred this year nearly 100,000 deaths from accidents, almost as many as the death-toll from tuberculosis! The heavy and increasing accident mortality is due largely to automobile accidents. In 1927 there were eleven times as many automobile fatalities in this country as occurred in 1911.

To offset somewhat the rising death roll of the automobile there occurred during the past fifteen years a reduction of twenty per cent in deaths from accidental burns, a decline of thirty-three per cent in drownings, of seven per cent in falls, twenty-nine per cent in mine accidents, forty-nine per cent in railroad accidents and a decline of fifty-three per cent in street-car accidents.

The automobile has become the leading cause of accident fatalities; it now accounts for one out of every four accident deaths. In 1927 for the first time in the history of accident statistics, the accident death rate *per 100,000 cars* showed a decisive increase. Prior to 1927, the risk of death per 100,000 cars in operation had been decreasing. In 1918, 157 automobile fatalities occurred per 100,000 cars registered; this figure decreased gradually to 95.5 in 1926. During this period the number of automobiles increased from 4,900,000 to 22,000,000. But in 1927, the death rate per 100,000 cars rose to 100.5 with a registration of 23,000,000 cars at the end of 1927. What attitude should the country assume toward this new phenomenon,—the increase of deaths per automobile registered in 1927? Have we done all that can be accomplished the country over in promoting safety on our streets and highways? Have our facilities for checking automobile accidents been swamped by the recent tremendous increase in cars on our streets and highways? Have we enough facts about personal and operating factors in highway accidents to study our street and highway safety problems locally, intensively and effectively? Undoubtedly, the automobile accident rate can be reduced if our states adopt a uniform system of reporting, studying and controlling the accidents which occur on our streets. Facts come first; they provide the foundation for police and engineering methods in promoting public safety.

The facts gathered under the National Safety Council's uniform accident reporting system showed that sixty-five per cent of the 25,800 automobile fatalities in the United States were those of pedestrians, and that only thirteen per cent occurred in collisions between automobiles, four per cent in collisions between motor-cars and railroad trains and seven per cent were in non-collision automobile accidents. These facts again emphasize the urgent need for country-wide extension of facilities for reporting, studying and acting upon the hazards which confront the citizens using our streets.

We must study the 23,000 to 25,000 fatal accidents which arise in the home each year. Almost as many fatal accidents occurred each year in the American home as on our public thoroughfares. Home accident deaths exceed the number of industrial or occupational fatalities each year in the United States.

A thorough analysis of home accidents should be made in each community. Some thirty-five per cent of the domestic accident fatalities last year were due to falls, twenty-one per cent to asphyxiation and suffocation, nineteen per cent to scalds and burns, six per cent to poisons and the rest of the home fatalities to a variety of hazards, all reducible if reported and studied. The National Safety Council's Committee on Statistics is planning production inquiries into the domestic accident situation, because it believes the next forward step in life conservation should be the safeguarding of the home and the reduction of injuries to women and children. The task of making the American home the haven of shelter and security ascribed to it in the world's literature, is one of gigantic proportions. It calls for the united effort of the safety movement, allied with all the other community interests having contact with the home, the press, family social agencies, women's clubs, the official and private health agencies, and the schools.

DR. DUBLIN: That last sentence is the theme which I want to harp on—facts as a basis for the prevention campaign—and having that in mind our Committee has had several meetings, continues to meet three or four times a year, and analyzes the material which has been collected from the cities.

Let me tell you that this Committee of ours is developing what will ultimately prove to be a most important service—nothing less than a registration area for the reporting of fatal and non-fatal highway accidents, just as there is a registration area for the reporting of births, just as there is a registration area for the reporting of deaths, both under governmental auspices in the Census Bureau. We are developing on a voluntary basis, under these auspices, a registration area for the reporting of public accidents, and more particularly vehicular accidents. An area comprising fifty million people is now reporting monthly to the Chicago office, on standardized blanks, so that uniformity is obtained; and this material is tabulated and analyzed, and, as you see, every month a report made in the PUBLIC SAFETY magazine.

What the outcome of that is you can readily see. We hope that before very long, and with your cooperation, it may be possible to have all the States of the Union, and if not that at least all the large cities of the country, bound together by this endeavor of reporting these facts, first voluntarily and then later under governmental auspices. These facts will then be analyzed, and once analyzed made the basis of a local campaign for the prevention of accidents. That is our hope.

We do not believe that you can by any emotional appeal, by any call for conscience or for judgment, or for anything else but the facts of where accidents are occurring, stem the tide of this increase in accidents. This Committee deserves, we believe, your cooperation. We want you to take these facts as presented in our annual report, and make it your local gospel. Collect your material locally along the lines we have outlined in this report. Use the material locally through your press. That is the idea we have in mind. When you have done that, we believe you will succeed in stemming this tide.

Now, in addition to the question of public accidents, our Committee is gradually opening up a new line of work. We notice that there is an equally large number of accidents that occur annually in the home, causing as many deaths as caused by the automobile. About 25,000 fatal accidents arise in the home each year, and nothing is being done about it. We are trying to collect material with which we can analyze the causes that are basic to this large number of deaths. What is it that is happening to the homes that results in that large number of deaths and injuries? When we have those facts it will be possible to develop a campaign very similar to the

campaign in industry and the campaign on the streets, which will ultimately, we hope, help to reduce the number of those injuries and fatalities. Your cooperation is asked for that locally. Your local Safety Council should gather this material from the various agencies and the police; through the following up of clippings; through local investigation, and send the reports in to the National Safety Council.

I want to say a word to you about this National Safety Council Committee. A small group of devoted men are doing a splendid work with a very small budget indeed. They are accomplishing wonders. It seems very right that this work that is being accomplished by Mr. Forney, Mr. Williams and the members of the staff in Chicago, should receive fullest recognition and should be expanded, and with that thought in mind a number of us have suggested that possibly the time is ripe for the recognition that, under the auspices of the Safety Council, there should be a section whose business it is to concern itself with the problem of the facts in the accident situation. We have therefore proposed that there shall be organized a new section, a section for accidents statistics. At the beginning this section will concern itself primarily with public accidents and with home accidents, leaving out of consideration those industrial accidents for which there is already provision in the several committees in the various other sections.

This matter is brought to your attention for your action. It is hoped that the Chairman will present this matter of a new section on accident statistics and receive your response and let us hope, your approval. If this matter does receive your approval, we believe that this entire movement will be accelerated, and that much more good will be accomplished. I think that the office has distributed among you an outline of the By-Laws of this proposed new Statistics Section.

R. L. FORNEY (Statistician, National Safety Council, Chicago): Mr. Chairman, the proposed By-Laws have not been distributed as yet among this group. My feeling, however, is that Dr. Dublin has given you a very good idea of what we have in mind. Do you desire that these proposed By-Laws be distributed among you before you vote upon this proposition, or, in view of the review and the study which this matter has already received, will you give your approval or your disapproval to the idea of establishing a Sectional Committee of the Safety Council? I am at your disposal in that regard.

CHAIRMAN MATTHEWS: This is not a very long prospectus here. The Chair will read it.

Proposed By-Laws of the Statistics Section, Public Safety Division, National Safety Council

Article 1

NAME

The name of this organization shall be **STATISTICS SECTION, PUBLIC SAFETY DIVISION, NATIONAL SAFETY COUNCIL**. This Section will be a development of the **STATISTICS COMMITTEE, PUBLIC SAFETY DIVISION, NATIONAL SAFETY COUNCIL**, and upon completion of organization, the above mentioned Statistics Committee shall cease to exist.

Article 2

PURPOSES

The purposes of the Statistics Section shall be as follows:

1. To serve as a clearing house for statistical information on public and home accidents.

2. To publish this information and analyses of it at suitable intervals.
3. To encourage and promote the collection, tabulation, and analysis of such information by agencies not already doing so.
4. To work for uniformity of methods and results among such agencies.
5. To bring such agencies into the membership of the National Safety Council and the Statistics Section.

Article 3

MEMBERSHIP

All members of the National Safety Council who are engaged in statistical work relating to public or home accidents will automatically be made members of the Statistics Section. Other members of the National Safety Council may become members of the Section on request. The members shall meet annually during the Annual Safety Congress of the National Safety Council.

Article 4

OFFICERS

The officers of the Statistics Section shall be: Chairman, one or more Vice Chairmen, Secretary. The Chairman and the Vice Chairmen shall be elected by members of the Section at each Annual Meeting for a term of one year. The Secretary of the Section shall be the Statistician, Public Safety Division, National Safety Council.

Article 5

EXECUTIVE COMMITTEE

The Executive Committee of the Section shall consist of the Officers, the Chairmen of standing committees, and such other members of the Section as may be elected at each Annual Safety Congress. The Executive Committee shall meet on call of the Chairman or of any five members.

Article 6

STANDING COMMITTEES

There shall be standing committees as follows:

1. Committee on motor vehicle accidents.
2. Committee on other public accidents.
3. Committee on home accidents.
4. Committee on child accidents.
5. Program committee.
6. Membership committee.

The Executive Committee may provide for standing or special committees.

Article 7

AMENDMENTS

These By-Laws may be amended at any annual meeting of the Section by a majority vote of those present, or at any meeting of the Executive Committee by a majority vote of the entire Committee, subject to approval by the Executive Committee of the National Safety Council.

CHAIRMAN MATTHEWS: Those, I believe, are the salient points outlining the purpose of the new Statistics Section. If there are any of those particular articles which you would like read again, or which you would like Dr. Dublin or Mr. Forney to explain to you, I am sure they will be glad to do it. I understand that the purpose of presenting this question at this time is that the Executive Com-

mittee of the Council may have some expression from the members here present, possibly in the form of a resolution stating that it is the consensus of opinion that such a Section should be established.

(It was moved and seconded that a Section as proposed be established.)

CHAIRMAN MATTHEWS: Is there any discussion on the proposition? Any further information that anyone would like to have brought out or any further questions?

A. K. GAGE (Ass't Prosecuting Atty. for Wayne County, Detroit): My objection to separating statistics from the consideration of the Public Safety Division would be that you cannot be in two places at one time, and I think most people who come to the meetings of the Public Safety Section realize the importance of these statistics to a proper understanding of all the other questions that come before this Public Section, and without those facts I think we will lose a great deal of the interest in these meetings. If the two Sections can be coordinated so we can attend both Sections when we come here for enlightenment, very well; but if they have to be held at the same time, we cannot divide ourselves very well and be in two places at one time.

CHAIRMAN MATTHEWS: One of the features of congresses such as this is that it is almost necessary to run parallel sessions, but I believe that might very properly be worked out, and perhaps Mr. Williams, who is in direct charge of the Public Safety Division, might be able to give us some information as to what the plans are along that line.

SIDNEY J. WILLIAMS (National Safety Council): The formation of this Section would not, I hope, have the effect that Mr. Gage foresees; we would still try to do as we did this year—not have the Statistical Section meetings come at the same time as other Sections that the same people would be interested in, and I do not anticipate that a year from now the program would involve any more conflicts than this year. We cannot avoid some conflicts.

As we see it, the statistical work of the Council is growing so fast—not only that, but there is such an increase in the statistical work around the country—so many cities and States are taking the thing up, and people are specializing on it, that we feel that this step would be a proper development, would give a better chance to coordinate the work of the different State and City departments around the country, and coordinate that work with the work of other organizations.

CHAIRMAN MATTHEWS: Any further discussion or comments? Are you ready for the question?

The question is that it is the sense of this meeting that a Statistics Section be established in the Public Safety Division of the National Safety Council. Those in favor of the adoption of this resolution will signify by saying aye; those opposed? So ordered.

ADJOURNMENT

October 3, 1928

Motor Vehicle Legislation

HON. ROBBINS B. STOECKEL, Chairman
Commissioner of Motor Vehicles, Hartford, Conn.

The third session was called to order at ten-fifteen o'clock by the chairman, Hon. Robbins B. Stoeckel, Commissioner of Motor Vehicles, Hartford, Conn.

CHAIRMAN STOECKEL: I see by the program that the chairman is supposed to begin the meeting by a few remarks. They will be very few and very brief, unless we get into an argument over something. This program which we are going to discuss today has to do with motor vehicle legislation. Two or three very apparent facts with relation to legislation stare every person in the face, and I think they ought to be mentioned as a part of the background for this meeting.

The first fact is that most people think that when they make a law they have cured a condition. The second is that a law in order to be worth anything at all, has to have a great public sentiment behind it. That public sentiment must be militant enough to call it forth and to force it upon the class for which it is intended. Third, the law must be popular enough so that people will try to enforce it; that is, it must have a basis of common sense.

In connection with another talk on legislation I was thinking some time ago about a good illustration of the kind of a law which has failed because of the fact that it did not have those things, and I went back immediately in my history to the old Connecticut blue law which made it an offense for a man to kiss his wife on Sunday. You can see that the law did not have any of those factors behind it which made it enforceable, and it has long since died.

QUESTION: Mr. Chairman, does it say anything about the other fellow's wife?

CHAIRMAN STOECKEL: I was just going to refer to that. There was never any law against kissing another man's wife on Sunday.

Now, we are here to discuss the various and sundry applications and details of legislation, and we have with us this morning Mr. A. C. Godward, who is one of a growing group of traffic engineers, who knows the application of traffic ordinances, who is bringing efficient methods into the handling of this great problem in his city, and who was a member and probably is yet, of the Committee on the Model Traffic Ordinance. I would like to introduce Mr. Godward, who will speak to you on the subject of the Model Traffic Ordinance.

The Model Municipal Traffic Ordinance

By A. C. GODWARD
City Planning Engineer, Minneapolis, Minnesota

On August 20, 1926, there was presented to the people of these United States the Final Text of a Uniform Vehicle Code prepared and recommended by the National Conference on Street and Highway Safety.

Two years later, in August of 1928, there was presented through the Conference and by the Committee on Municipal Traffic Ordinances and Regulations, the Model Municipal Traffic Ordinance, a supplement to the Uniform Vehicle Code, an ordinance which was recommended for adoption by all American cities.

The Uniform Code consisted of four Legislative Acts entitled, respectively:

- (a) A Uniform Motor Vehicle Registration Act.
- (b) A Uniform Motor Vehicle Auto Theft Act.
- (c) A Uniform Motor Vehicle Operators and Chauffeurs License Act.
- (d) A Uniform Act Regulating the Operation of Vehicles on Highways.

The Model Ordinance submits:

- (a) A uniform and comprehensive traffic ordinance.
- (b) An ordinance to create a division of traffic engineering.
- (c) An ordinance to create an Official Traffic Commission.
- (d) An ordinance to control Roadway and Sidewalk Obstructions.

To elaborate upon the subject matter so well presented in these reports widely distributed by the Department of Commerce would be a futile repetition of facts with which you are already conversant. To present in the few minutes allotted even a resume of the more than four years of deliberation, research and deduction of the Conference and its Committees is an impossibility; so permit me to discuss this morning the genesis, the progress and the purpose of this gigantic effort—to the end that we may increase your interest and secure your continuing support.

The efforts of the Conference and all who have so gladly and whole-heartedly participated therein will result in reduction of hazard on the street and highway and increase in convenience to the users of such highways, in the same measure as we can secure the public cooperation in the promulgation of the educational features of the code and the ordinance, the promotion of their enactment and insistence on consistency in their enforcement.

Any national problem approaching the status of an emergency and affecting all of the people of our country, has of late been the peculiar concern of the Department of Commerce.

In 1924, and earlier, we recognized the traffic condition of America as an emergency. We viewed with alarm the toll—the price of convenience—mounting to 25,000 fatalities, a half million personal injuries and an economical loss of billions of dollars annually.

This record of traffic accidents on our streets and highways was such as to almost convince some of us that our progress was indeed a delusion, that new gifts intended as a benefit to humanity were bringing sorrows and losses that were not compensated by either convenience or pleasure.

The demand of the people of this nation was for Governmental assistance in remedial action, that they might retain their privileges and yet reduce the costs and that demand upon the Government was based upon the fundamental principle that the purpose of Government was the protection of its people and the promotion of public safety, safety of life, person and property.

In answer to the growing need and that national demand, the Secretary of Commerce, the Honorable Herbert Hoover, called the first Safety Conference, representative of all sections and all activities to unite in research, study and recommendations, culminating in the presentation of the Uniform Vehicle Act.

This work—comprehensive as it was by inclusion of all particulars pertinent to State traffic legislation, was yet not complete in its provisions for uniformity of traffic rules. There was needed a uniformity of municipal traffic ordinances and a new committee, appointed by Mr. Hoover and led by Chairman William E. Metzger of Detroit, was charged with the task of producing a model traffic ordinance for the guidance and assistance of traffic and legislative officials of municipalities.

In the deliberations of the National Conference and in those of many State Conferences, it was observed that the outstanding feature was the lack of uniformity in traffic regulations, ordinances and rules of the road and that this lack of uniformity was the greatest contributory cause to accidents which were occurring.

Again it was agreed that the price of traffic safety was courtesy, and courtesy on the highway was carefulness and unselfishness.

Then and now the great majority of our people are willing to pay the price of safety if through uniform legislation we educate them as to how to best exemplify the required courtesy.

The Conference believed that the small majority of our people to whom courtesy was but a word and the Golden Rule but a jingle; the reckless, the habitually careless and the incompetent; those who could not or would not drive their motor vehicles in a manner thoroughly consistent with safety of others must, in the interest of that same safety, be denied the privilege of the road and that this could best be done by uniform laws and uniform ordinances, which would permit of uniform enforcement that is impartial, unprejudiced, prompt and positive.

Safety, in the opinion of the National Conference, had the characteristics of all fundamental movements and success in its promotion must, therefore, be dependent upon education; education that is uniform and consistent.

In the interests of safety, it is their endeavor to correct physical conditions of the motor vehicle and the highway; secure uniformity in State and Municipal legislation; standardization of rules, regulations, road practice and traffic control, and impartiality in law enforcement.

To this end, through their efforts, they have produced, presented and recommended the Uniform Vehicle Code and the Model Traffic Ordinance which—combined—are a rule and guide to courteous and safe conduct on the streets and highways of America; a common textbook for the study and education of all good citizens and a penal code only for those few who do not have the proper consideration for the rights and safety of others.

This textbook and code has been formulated in this attitude by the many who have participated in the committee and conference work.

If it is accepted in this attitude by you and the public at large then we can hope to early establish habits of safety which, in the last analysis, will be more effective than penal enforcement.

Those of you who have endeavored to promote the passage of state legislation, inclusive of the Uniform Vehicle Code, will recognize that there is a distinct difference between this Code and the Model Ordinance—a difference predicated on the division between State authority and the rights of the Municipality.

State legislators represent rural communities and municipalities and are jealous of the rights of those Governmental subdivisions.

Wisely in the preparation of the Uniform Vehicle Code, legislation which properly belonged with the municipality was omitted. This has now been presented in the form of a Model Traffic Ordinance.

Based upon Model Ordinances of various States and active and effective Ordinances of many Municipalities, it contains:

ARTICLE I.—A definition of the terms included in the Ordinance.

ARTICLE II.—Designation and allocation of authority to the police, commissioners, Board and other authorities.

ARTICLE III.—Standardization of regulations pertaining to Traffic signs and signals, legends and police control and requirements of obedience.

ARTICLE IV.—Establishment of the rights and duties of pedestrians.

ARTICLE V.—Ordinances relating to reasonable operation of street cars, railroad trains and other common carriers, and the relation between such vehicles and other traffic.

ARTICLE VI.—Regulations as to standing, stopping and parking.

ARTICLE VII.—The Rules of the Road or the operation of vehicles within municipalities.

ARTICLE VIII.—Miscellaneous provision in the interest of safety convenience provisions, many of which could well have been included in the Vehicle Code.

ARTICLE IX.—Penalties and Procedure upon arrest.

These provisions, all of which can well be considered within the scope of Municipal rights and powers, have in the Model Ordinance, been augmented by addition of portions of the Vehicle Code. These additions are for the purpose of making a complete text for more comprehensive educational use and for permitting the enforcement of State law provisions by the police of a city in compliance with its ordinances. This, incidentally, in some municipalities will permit them to collect fines for violations of state laws and add materially to the revenues needed for traffic ordinance enforcement.

In Article IX, Section 56, it will be noted that Procedure Under Arrest is not stipulated. Experience of cities did not appear to justify a definite recommendation.

The Engineering Committee of the National Safety Council are now occupied in research and study of this matter and hope to submit a report in the near future.

The Supplementary Ordinances, relating to an Official Traffic Commission, a Division of Traffic Engineering, and Controlling Roadway and Sidewalk Obstructions are self-explanatory and are obviously desirable for the effective enforcement of the Ordinance.

If any so desire, it will be a pleasure for your speaker—or other members of the Committee here present—to elaborate on specific provisions of the Ordinance itself.

In conclusion, let us remember that the Code and the Ordinances are an effort to give adequate and uniform rules and regulations to those who wish to obey such rules and the courtesies of the road; and a means whereby we may penalize those who cannot or will not drive in a manner consistent with safety, to the extent we hope that we will reduce the hazard of the Street and Highway.

The Code and the Ordinance, when enacted and enforced by our Government—which is ourselves—when studied and obeyed as a matter of habit by the public—which is ourselves—should result in safety—safety of the person and property—the guarding of which is the purpose of the Government.

CHAIRMAN STOECKEL: Mr. Gorward will be glad to answer questions, if there are any, and the meeting is now open for discussion on his paper. It seems to the chairman that the desirability of uniform traffic ordinance regulation is absolutely admitted; that the presence of a good model, as has been presented to you, is conceded to be a tremendous step in advance towards handling the most difficult portion of the traffic situation.

As there seems to be no questions, no discussion, on this paper, we will pass on to the next subject—that is, bringing the traffic laws up to date, and was assigned to Mr. Charles C. Janes of Ohio. Mr. Janes has telegraphed that he is unable to be here but his paper will be included in the transactions at this point.

Bringing Our Traffic Laws Up to Date

By CHARLES C. JANES

Secretary, Ohio State Automobile Association, Columbus, O.

I am glad to be a part of this very important meeting, which is being conducted for the express purpose of contributing, if possible, to the cause of safety, and to make an analysis of the problem which confronts us everywhere today—the saving of lives and property. I am sure that is why we are all here, and to the best of our ability will do all we possibly can in this direction.

In addressing you on this matter of Bringing Our Traffic Laws Up to Date,

I do not wish to criticize or discredit anyone for the laws or regulations that we have today. On the other hand, I desire to compliment all those who have from time to time attempted to solve the complexing problem which has faced us since the advent of the motor vehicle. I am unwilling to concede that there ever has been a master mind in working out the traffic laws for the various states and cities. To my way of thinking it has been everybody's problem—Legislators, Safety Councils, Automobile Clubs, Chambers of Commerce, individuals of all rank and file have in a measure contributed to the good that has been done and are responsible for the laws we now have.

It is my privilege at this time to pay particular respect to the Committee on Municipal Traffic Ordinances and Regulations, appointed by Mr. Hoover, which met in Washington last July. Although, but forty of the committee of one hundred contributed, in my judgment they have given us one of the finest and most constructive pieces of proposed legislation that has ever been produced—A Model Traffic Ordinance.

I was not a member of this committee, but I followed their work very closely, and I believe I am sufficiently informed to say that the proposed law which they have so kindly drafted for us deserves our support.

I am personally acquainted with many members of this committee and especially the chairman, Wm. Metzger of Detroit, whom I greatly admire for his sincerity and for the valuable time given to this proposed law. His ability to complete such a job can not be over-estimated.

No doubt, all or the majority of those present have been privileged to familiarize themselves with this model ordinance. As an owner and driver of an automobile for over twenty-seven years, I wish to contribute my thanks particularly for the new phases which deal with up-to-date traffic hazards and the causes for many accidents, which have been embodied in the proposed ordinance.

Section 3 provides for a Board of Police Commissioners or other traffic authorities authorized to adopt emergency regulations.

Section 7 compels persons propelling push carts or riding bicycles or animals to obey traffic regulations.

Section 10 provides that the traffic control legend shall be red, yellow and green.

I believe the use of the yellow or caution signal is absolutely necessary. It provides a definite time interval between the red and the green, which allows both the pedestrian and motorist a few seconds to concentrate and move with more confidence and safety. I am a convert from the "red to green" to the three color signal. My observation has been to the effect that where there are but two colors used it has caused much confusion, jerking of cars, abrupt application of brakes and wild scrambling of pedestrians.

The timing or intervals between signals should be carefully studied by competent officials in order that traffic may be moved at the highest possible speed that safety will permit. Long unnecessary delays are tiresome and annoying to all concerned. I am also in accord with the progressive or alternating system of traffic control.

Section 15 gives the pedestrian the right of way. No one will question the propriety of this. However, provision is made in paragraph C that when crossing a roadway at any point other than within a marked or unmarked crosswalk, they shall yield the right of way to vehicles. At the same time the driver is never relieved of the duty of exercising due care for the safety of pedestrians.

Some authorities claim that pedestrians should give the same respect to traffic lights, as motorists do. They further suggest stiff penalties for "jay-walking." It is claimed that this will lower the accident rate and speed up traffic. A number of Western cities, also here in New York, for that matter—especially on Fifth

Avenue—I have observed that pedestrians are being held at the curb until signals clear the way for them. This has made a very noticeable improvement in traffic.

Section 18 makes it unlawful for any person to stand in a roadway for the purpose of soliciting a ride from any private vehicle. "Thumbing" has become a menace, particularly in Ohio, at least, my home State. These rides are usually solicited on main thoroughfares where traffic is heavy. Thoughtless stopping by over-sympathetic motorists has been the cause of many serious accidents.

Section 24 provides that railway trains and street cars shall not block the streets for more than five minutes. This is a very welcome section to both motorists and pedestrians. It also deals liberally with the railway companies in exempting trains in motion, other than those engaged in switching.

Section 27 authorizes traffic authorities to designate bus stops and taxicab stands. This will tend to eliminate taxi cruising in the cities—another menace to traffic and safety that should be stopped.

Section 39. Limitations on turning around. Tourists are the principal violators of this section. They are not familiar with the local regulations and invariably make turns at the wrong place, hampering traffic and impairing safety. I am in favor of prohibiting all so called "U" turns in downtown business districts. In my travels over the United States, I can not recall an intersection in any city street or boulevard where "U" turns can be made safely.

The Model Ordinance would, of course, be a step forward, but we need more than that. We need a uniform traffic law for the entire United States—a state motor vehicle code, which would automatically bring uniformity between states as well as cities. When this is accomplished, I believe, we will have solved the traffic problem.

We hope to have a state-wide uniform traffic law enacted by our Ohio General Assembly, which convenes in January. Our proposed code follows very closely the recommendations of the Hoover Conference. A similar bill was introduced two years ago, but was defeated. Since then, however, we have conducted a publicity campaign on the need of such a law, and we feel confident that the proposition will be approved this time.

The need for a uniform traffic code in the United States is seen daily with the increased tourist travel everywhere. Every state has different rules and regulations for motor vehicles, which makes it very confusing to the motorist. A uniform speed law is needed. In the District of Columbia, for example, an automobile is not permitted by law to travel more than thirty miles an hour, while in Massachusetts the limit is twenty-two miles. In other states the limits range from twenty-five to forty-five miles an hour. In Michigan the speed limit has been entirely removed, and, I am glad to say, it seems to be working out very well. They, however, compel every motor vehicle to undergo brake and other mechanical inspections at regular intervals and reckless and drunken drivers are prosecuted to the limit. Twenty-three other states have wiped out obsolete speeds laws and have changed the emphasis from mere speed to carefulness.

Traffic authorities in many cities seem to have reached the conclusion that it is better to move traffic as rapidly as possible. Cautious drivers are frequently greeted—"Step on the gas" or "Do you think you're in a funeral procession?" Some states have minimum as well as maximum speed limits. The proposition has merit that cannot be denied. Slow driving often "jams" up traffic on the main highways. The driver who wants to drift along at fifteen or twenty miles per hour should stay off the main thoroughfares. There are numerous roads he may select, where he may drive as slow as he likes, causing little or no inconvenience to others. I do not believe it advisable to encourage speeding and my remarks are not intended in that direction.

With the uniform traffic law, we should have the standardization of all street and highway markers, traffic lights and equipment. I honestly believe we are "over regulated" on signs. Signs and traffic lights are placed where they really are not needed and where officials know they will not be obeyed. This practice tends to make motorists disrespect signs at dangerous intersections. That uniformity in signs and regulations can be carried out has been demonstrated by the State of Massachusetts. Since June 5th motorists have been guided by a uniform system of signals, marks and lights throughout the borders of the commonwealth. What a pleasure it must be for the Massachusetts resident to motor through his state! There are no local variations to confuse him and he runs no risk of arrest because he misunderstood the meaning of signs, marks and signals.

Massachusetts has set an excellent example. There is no reason why the country which has the greatest number of automobiles should also have the greatest number and variety of traffic laws, marks and signals. Today one can drive from the Atlantic to the Pacific and never know when he has passed from one state to another unless he takes the pains to find out. There is nobody to interfere with him at state borders and he is as free in one state as in any other. Yet drivers of cars are continually bewildered by the differences in driving regulations and the posted means of proclaiming them. What is valid and legal at one place is against the law a few miles farther on, and a custom esteemed to be the "best word" in safety in one jurisdiction, means the opposite in another.

Speaking of misunderstanding signals reminds me of the "left arm" signals of today. When the driver in a car ahead sticks out his arm, you know perfectly well that it means:

1. He is going to turn to the left.
2. He is knocking the ashes off his cigar.
3. He is going to turn to the right.
4. He is waving at a friend.
5. He is going to pass the car ahead.
6. He is feeling for raindrops.
7. He is going to slow down.
8. He is pointing out something interesting.
9. He is going to stop.
10. He is arguing with the wife or the kids.

Along with the uniform traffic laws, I think we should have a concentrated courtesy campaign. This is the day of speed, and common courtesy has been forgotten. "Courtesy prevents accidents" is a mighty good slogan and very true. Many accidents have been caused by one motorist trying to "beat the other fellow" to the intersection. Out on the open highway you also find the discourteous motorist shoving others off the road, glaring his bright lights in your eyes at night, etc. I might say, however, that in states like New York, New Jersey, Pennsylvania, Michigan, etc, where there is a state traffic police, the rules of the road and the rights of others are more carefully observed.

Before closing I wish to make another observation:

Harley Wiley Corbett, president of the Architectural League, here in New York, believes the traffic problem of the future city will be solved by the abolition of all automobile traffic. He says "Autos will pass because of inability to traverse streets." He was speaking, however, of the future city "fifty miles across and with a dense population of 50,000,000."

In Corbett's city of the future there will be pneumatic tubes for human beings, elevators the size of present-day ballrooms, underground freight distribution and aeroplane stations on skyscrapers. Other modes of urban travel will replace the "slow" taxicabs, subways and elevated.

But this does not solve the existing traffic problem of the modern city. If automobile traffic could be abolished on the city streets—and it cannot—that would not solve the traffic problem. Street car systems and suburban railroads in the average city could not absorb the increased traffic that would be thrown upon them by the abolition of motor traffic on city streets. The automobile is not the sole cause of prevalent traffic conditions. On the contrary, the automobile is rendering indispensable assistance to urban transportation.

Not so long ago, it was predicted that eventually the pedestrian traffic would disappear because everyone would be riding in motor vehicles. We all know how absurd that is. As the population increased, motor vehicles increased and as the motor vehicle registration increased, pedestrian traffic increased. Motorists are pedestrians, and pedestrians are motorists.

The final solution seems to be this—bring the traffic laws up-to-date, both state and municipal. The adoption of the uniform traffic law would, I believe, accomplish this. When motorists and pedestrians are thoroughly familiar with the law by which they are to abide, they will be in better position to take care of themselves. As it is now, a few minutes' drive takes a motorist from one jurisdiction where he understands the regulations to another where lack of knowledge of the local rules makes him an innocent menace. All this would be changed by uniform laws, and, in closing, I heartily recommend the adoption of the uniform traffic laws, as I am convinced it is the proper move.

CHAIRMAN STOECKEL: In Mr. Janes' absence I will call on Mr. Frank Ballantyne to discuss the subject.

FRANK E. BALLANTYNE (Maine Automobile Assn., Portland): This job of pinch hitting usually has its disadvantages. I share with you rather keen regret that Charlie Janes is not able to be here and I am going to emphasize the words up to date, because in some circumstances it seems to me it might be well to consider bringing them back to date. I have in mind particularly the habit which has grown upon some of our Eastern seaboard cities, that of erecting their present-day traffic signals with a view to some time in the future having them regulate airplane traffic at the same time they regulate street traffic. Sometimes it seems to me that in our planning of traffic signals and our planning of traffic regulations, our municipal officers and municipal authorities have attempted to take in a bit too large a scope.

When the Model Municipal Traffic Ordinance was issued in its final draft, I had the pleasure of presenting a copy of it to the chairman of the City Council in one of our Eastern seaboard cities, and he passed it back to me with the remark: "Oh, that won't fit our case." I said, "Bill, have you read it?" "No; haven't seen it before." "Well, how do you know it won't fit your case?" "I know; we have gone all over that problem and we are licked on it. We have just done the best we could." Well, fortunately, I knew Bill, and I anticipated Bill's reply, and I handed Bill a little clipping taken from that morning's newspaper, showing an accident that occurred in one of the principal thoroughfares of that city, and I said, Bill, did you see this report in the morning paper?" "Yes, I saw it." "Did you think maybe it might have been prevented?" "No; I don't know any way to prevent that accident." Well, anticipating an opportunity to have another dig at Bill because of his narrow-minded selfish interest in his attitude toward a municipal code, I said, "Bill, there is a certain paragraph on such-and-such a page of that particular code which if this city had had in effect, that accident would not have happened." "Is that so?" "Sure, it is so." "Well, let's see that." We did that; turned to that particular paragraph, and we proved very conclusively to the chairman of that City Council that if that particular paragraph had been in effect in that city, that one accident at least would not have happened. That was my opening wedge and I jumped into it with both feet and tomorrow noon I think

that particular council will adopt the Uniform Municipal Code, just because we took advantage of that opportunity.

The human relation side of the Motor Vehicle Code, as referred to by Mr. Godward, is the stumbling block in the advance of uniform traffic laws. There is another stumbling block. The committee, which has worked hard, and to which I certainly want to pay a sincere note of tribute, have not been able to take care of minute details such as obtained in our city, for instance, but they have offered a near solution, and if those of us who are engaged in the business of finding a way to prevent accidents will view this code with a bit of unselfishness, with a purpose bigger than our own individual selves, and accept an opportunity to be educated, and learn something as a result of it, I think we will get further.

I have in mind an instance which appeared recently in Maine, when Dick Armstrong from the Motor Vehicle Conference Committee, who was here this morning, spoke before our Council. Dick elaborated quite a bit upon the uniform code for States and a uniform code for municipalities, and a lady in his audience, a lady who happens to be a leader in women's club work in the city, approached me after the meeting and said: "That particular thought that Mr. Armstrong brought out about having all of our traffic laws the same all over the State is the most interesting part of the whole conference to me." She said, "I am interested in good roads; I am interested in safety; I am interested in all the various fundamental elements of this problem, but the privilege of having our tourists, upon whom we depend so much in the State of Maine, the privilege of having them come into our State and know when they come into Portland a green light means something and when they get to some other place that green light means the same thing, it seems to me that's one of our biggest opportunities today, and if I in my work can help, because of the contacts I have with some forty-eight or forty-nine organizations throughout the State, I want you to count on me."

There was a big, broad-minded attitude to the traffic code. This job is not by any means your job or my job. It is everyone's job. I think you will find in every case that the man who is willing to submerge his own personality for the good of the community is the man you need and I need to put across any form of uniform traffic regulations.

CHAIRMAN STOECKEL: It occurs to the chairman that there does not seem to be any great difference in principles or fundamentals in the adoption of a traffic code over anything else in human experience which involves many people. The principle of self-sacrifice is involved; the willingness to consider the problem of the other man is probably, as I look at it, the entire solution of many of the most difficult problems which we have to meet.

The meeting is open for discussion on Mr. Ballantyne's remarks.

H. C. BURNHAM (Research Director, Motor Vehicle Department, State Board of Public Roads, Providence, R. I.): It recently became part of my duties in studying the matter of accident causation, to take over two thousand operators, and under actual conditions obtaining on the highways, attempt to find out why they did a certain thing which was contrary to the regulations. We have laws, plenty of them. We all believe that our ordinances and laws are more or less designed to meet the conditions. The missing link seemed to be the fact that the drivers, or the users of the street, seem to have a colossal ignorance of the ordinances and laws designed to produce safe use of such highways.

Ask a man why he committed a certain violation. Search him and study him and you finally arrive at this conclusion: He did not intend to violate the law, but he forgot all about it, or did not even know about it. It seems if we work out model or uniform codes that that should be one of the things we should consider the most;—to sell that code to the average user of the highways, so that he knows what it is all about, and knowing thereof he can conform with the least inconvenience to himself and to the general public.

ALEXANDER GAGE (Detroit): Speaking directly on the point of this second address, it seems to me that one of the things that we have to take into consideration in relation to bringing our traffic laws up to date is the proper coordination of the various activities in our larger cities at least. We have a large number of departments that have something to say on most of the questions involved in proper traffic regulations; and because of the fact that most of the men that are at the head of our great municipalities frequently are chiefly distinguished because of political ability and not because they have made a particular study of traffic regulations and traffic necessities, we have very little realization oftentimes of the necessity of getting these various departments coordinated.

I have in mind, of course, my own city, where we have a situation of a number of very excellent men who are at the head of the various city departments, but up to date, so far as I know, there has been no effort to coordinate the different departments with the idea of getting together on the question of uniform traffic regulations. Each one of these men, without any particular training or information, has his own ideas and they get together when they have some particular proposition that they want to put over, but they do not get together with the idea of reconciling their various views; and perhaps the Safety Council, the National Safety Council, could do no finer work than a missionary work among leaders, the political leaders of our great cities, to get them into the frame of mind where they would seek to coordinate the heads of the departments on this great topic of safety.

W. A. CORBETT (New Jersey Bell Telephone Co., Newark, N. J.): I would like to ask Mr. Godward what the Committee found for the three-system light in preference to the two.

A. C. GODWARD (City Planning Engineer, Minneapolis): I do not know that it is quite fair to discuss that; it will be brought up by Mr. Powell, Mr. Goodrich and others at Thursday's session. There was a lot of discussion on the two systems, the two-color as compared with the three. The general consensus of opinion of the Committee, after full discussion, was that the yellow or amber cautional colors were necessary and desirable for safety.

MR. BALLANTYNE: We are told that the State of New Jersey is about to enact a State law. If there is anybody present who can tell us something about that, I personally will be grateful to hear about it.

FRED J. BLACKSHAW (Chief of Police, Ridgewood, N. J.): We have the Wise Act, which was passed in the session of the New Jersey legislature last year and became operative on September 1st of this year, covering the three-color lights. In part of our State we have the flare light or beacon. We have had the intersection light. We have the light in the center of the street. From now on there will be no lights placed in the streets at any intersection, but they must be on the curb on either side. Those that are in now will remain there until September, 1929. The lights all through the State of New Jersey are red, orange and green, and traffic moves on green only.

We have tried to educate our people to cooperate with the Police Department, and we have met with wonderful success. I, as Chief of Police of Ridgewood, have had cards printed—a warning, and giving a number of the ordinances of our town. We do not serve them with a summons until the second offense. We have given out since September about 1,500 of these red tickets, but I have yet from September 1st until this morning had a second offense come to the office.

MR. BALLANTYNE: The Chief has answered part of my question, and if I am taking too much time say so, and we will pass on to the next; but what I am interested in finding out is how far has the State of New Jersey gone to make it mandatory upon its various communities to adopt the various features of the municipal code. He spoke only about the traffic lights. I am interested in knowing

whether they attempt to say that Ridgewood must have a speed of twenty miles an hour—alike in all communities.

FRED J. BLACKSHAW: I will answer that. Our new limits are, 40 mile speed in open country, 20 in a municipality, and 10 mile in a school district.

MR. GODWARD: Just a word in regard to that distinction between State rights and the municipality, brought out by the Chairman. The success of the Model Code will depend upon the people themselves; their lives, their movements, their convenience. There is abroad in the United States,—maybe not so much on the Eastern coast, but there is in other parts, a feeling among the municipalities that the State has taken away too many of their rights as it is. Personally I think the States should go very slow in enforcing as a State law things that are primarily and fundamentally local and municipal in their effect, and that we will make greater progress towards uniformity, uniformity of not only legislation, but of enforcement if we will let the municipality continue to keep some of its rights and be responsible for the enforcement of its own ordinances. The States can never enforce in every municipality of America all the things necessary to the safety of the municipality. The municipality has its ordinances and their laws, and feels it is its privilege to give service. I think we should go rather slow in giving the States all rights that the people themselves would like to retain.

MR. BALLANTYNE: It seems to me, not to show any disrespect to Mr. Godward, that the State of New Jersey in enacting such a law, rather than having taken away any rights of the people, has given us rights. They have given us the right to know how to drive anywhere in New Jersey, and if there is any State on the Eastern seaboard—with due respect to you, Chief—that has been a chief offender with respect to the various forms of traffic lights, it has been New Jersey. You can drive from Cape May up to Ridgewood and you will have passed a dozen different kinds of ordinances, and you will have to have a Bible with you and an encyclopedia to know how to drive. If New Jersey has taken that step, I think it is a decided step forward, and I am interested in getting all the information I can on it.

F. W. JOHNSON (Citizens Safety Committee, Philadelphia Chamber of Commerce): We are close to Jersey and are experiencing some of the difficulties of the gentleman from Maine in the past, and I think that is now completely wiped out. The present New Jersey law, combining as it does the major points of the Hoover code and in addition to that, many of the desirable points of the Model Traffic Ordinance, all in the one code, does tend to produce greater uniformity through the State. One point I want to bring out is this: that in the New Jersey law, there is a diagram that definitely shows how and where and from what position the turn shall be made, particularly with reference to the turn to the left. It includes as well numerous standard signs. There is just one thing—this may raise a little discussion, but in the matter of penalties the New Jersey law places in the hands of the minor judiciary the right to fine and imprison. That we from Pennsylvania most seriously feel is unwise.

J. H. WYSE (Canadian National Safety League): This auto traffic code is one of the best things that has ever been conceived. I come here to sit at the feet of the Model Traffic Ordinance and not inflict you with our troubles north of the United States, but some time ago I got one copy of this code and it appealed to me so much that I asked for eight more copies, and I distributed them in Canada in some of our largest municipalities there. The replies were so gracious and so much interest was shown in that code that I wrote to Washington for one hundred more copies. Now I am going to distribute them to one hundred of our largest cities in Canada with the view of obtaining as far as possible uniform

traffic regulations; that is, so we will have over the entire continent a uniform traffic code, and I think it will not only be of great benefit to us touring in the United States, but of benefit to United States citizens touring in Canada. For that reason I think this almost ought to be regarded as an international code, and the Canadian National Safety League is going to do everything possible to make it so far as the United States and Canada are concerned.

W. GRAHAM COLE (Metropolitan Life Insurance Co.): The New Jersey Act we have been discussing here is putting across coordinated municipal regulation. New York State undertook that a number of years ago in its Highway Traffic Act, which, although not consistent with the New Jersey law in respect to individual clauses, does the same general thing. There is a movement on foot at the present time to revise that Act and make it consistent with the accepted Model Municipal Traffic Code. We will have New York and New Jersey, the two States very closely allied with each other, working on practically the same State law, which takes into account the Hoover Municipal Traffic Code.

A Copy of the Traffic Regulations with Each License

MR. LYON: I should like to ask the Chief whether there is any provision in the Jersey law for making the automobile drivers familiar with the law, and whether that provision is carried out. I ask that because in this State the Commissioner of Motor Vehicles is supposed to give a copy of the traffic regulations to each new licensee; but it is not done. The licensee gets it if he asks for it, and the result, as I know from personal experience, is that there is a most appalling ignorance of traffic regulations. If they were better known by the drivers in the State, there might be fewer accidents.

One of my boys recently came from England, where he lived for many years. He is an auto engineer, and in order to become familiar with American makes of cars, he went into a big service garage and tried to find from somebody in that garage something about traffic regulations; there was nobody there who could tell him, and he had to go to the Commissioner of Motor Vehicles to get a copy. There was absolutely nobody in that garage could tell him a single thing he wanted to know about traffic regulations. While we are busying ourselves with getting a model traffic law and bringing it up to date, wouldn't it be well also to busy ourselves with making the motor drivers familiar with such laws as there are?

BURTON W. MARSH (City Traffic Engineer, Pittsburgh): My work in Pittsburgh as Traffic Engineer of that city has brought me in contact with a problem which I believe many persons in this room may encounter if they are sincerely interested in seeing this uniform legislation adopted in the State with which they are mainly associated. I think it will be well to have the gentlemen present understand, if they do not already, that during the discussions of this Model Ordinance Committee, in Washington, there were in a number of cases certain ideas which different people from certain States had which we were willing to adopt, with the idea of going along on something which would be uniform. There were points of view which some of us had—I think I would say probably everybody had—which they were willing to give up in order to go along on something which would be a standard.

Now, when I went back to Pittsburgh and started to work on getting this adopted there, and it is now before our Law Department, I encountered just these same local ideas. I would like to suggest that if you want to help secure this legislation and have it really amount to something as standard, you ought

to try to help in your city to sell the idea of going along if there is some slight difference; in other words, paying a little price of your own idea in order to secure a standard practice.

I do not believe the last speaker has answered the question of the previous speaker,—What is being done towards educating the motorist as to what is expected of him? I believe the Chairman is too modest to get up and tell us what is being done in Connecticut, but coming from that State I do know this: That the Motor Vehicle Department under his control is doing more than is being done in any State I know of to teach the motorist what is expected of him. I should like to ask him if he will outline briefly the policy of the Connecticut Motor Vehicle Department concerning the dissemination of the proper information. I believe his policy is not only sound but practical, and I know it is deeply appreciated by thousands of motorists in that State.

A Public Jealous of "Paternalism"

CHAIRMAN STOECKEL: If it seems to be the wish of the meeting that the Chairman close the discussion, there is one observation which I would like to make. It comes out of an experience of some years as a State official. That is, that members of the public are increasingly jealous of what they call in letters to me "paternalism," meaning that, in my opinion, so far as Connecticut at least is concerned, it may not be possible to proceed to put a traffic ordinance into the State law, because the people are desirous of governing themselves through the ordinance method. I don't say we shall not try it. You can't always weigh up the material that comes to a Commissioner that way. Some of it is pretty bad; some of it is moderate; but there's enough of it in volume to make it certain in my mind that in Connecticut and possibly in New England, there is enough of a feeling that what we ought to present is a model, just-as these gentlemen are presenting their model ordinance, and let the public decide.

Now, as to the dissemination of information in Connecticut, it is a pleasure to tell you very briefly about it. The Department of Motor Vehicles has had, ever since I have been in there, a first rate publicity bureau, and that bureau has had the statistics and has given them out without fear or favor. We have tried to keep the condition before the public at large through newspaper releases; and then I have written a monthly bulletin, started writing it six years ago, and have covered in that topics which occurred to me and which seem to have aroused interest enough to keep people talking about the motor vehicle problem, which is the main thing. If they will talk about it enough, they will come to a point where something can be done. We are now engaged in an unceasing newspaper campaign, which is bringing the situation before the public at large continuously, and trying to suggest remedies where they can be used.

Now, to turn to the next subject: There are in my opinion a good many bad laws on the books of almost every State; not meaning that they are bad in the sense they are vicious, but probably they are unenforcable because they have not got the elements required to make them popular behind it. On the other hand, there are a great many good ideas which are drafted into the laws and presented to each legislature which do not ever succeed in getting any further than possibly before a committee, and it is necessary, as everyone who has had experience with the legislative committee and legislation in general knows, to have an understanding of the problems of the making of laws. We are fortunate in having with us today Honorable Seth T. Cole, who is counsel to the Commissioner of Motor Vehicles, in New York, and who will speak to you on the subject of "Practical Pointers on Legislative Promotion."

Practical Pointers on Legislative Promotion.

By HON. SETH T. COLE

Counsel to the Commissioner of Motor Vehicles of the State of New York

The subject of legislative promotion is vital to every effort to procure sound safety laws. It often happens that meritorious proposals fail to obtain legislative approval because their promotion is handled in a haphazard manner, while sometimes measures which are unsound from the safety standpoint find their way onto the statute books because the opposition is inept and ineffective to combat the organized movement in their favor. Opposition to safety legislation usually comes from business interests which feel that they may be adversely affected and I do not put it too strongly when I say that such opposition is usually well organized and represented by trained and capable legislative agents, whereas the proponents of safety measures are too often unorganized and inadequately represented in the legislative halls.

From what I have said, you will gather that organization is a prerequisite to effective promotion of legislative proposals and my efforts shall be devoted to outline what, in my judgment, are the steps which should be taken in order effectively to prepare and present a legislative program of safety measures to the end that favorable consideration and action may follow. My remarks will apply with equal force to the promotion of any safety program although they will be directed primarily to the subject of motor vehicle legislation and will be based upon an experience of several years as legislative representative of the Department of Taxation and Finance and Commissioner of Motor Vehicles of the State of New York.

The first step to be taken, and perhaps the most important, is the determination of the subjects to be included in the safety program. This can best be done by the organization of a small committee of arrangements composed of persons most interested in the subject. This committee should get into touch with organizations, public officials and others concerned with safety problems and procure from them such suggestions as they may have to offer in the way of proposed new laws or changes in existing laws. When these proposals are received, they should be carefully considered and classified, and should then be incorporated into an agenda for a conference to which should be invited all persons and organizations to whom the safety movement carries an appeal. This conference should be held from two to three months before the legislature convenes. At it the several proposals should be carefully analyzed and discussed from the standpoints of those in attendance at the meeting and the interests which they represent. It is of importance that there should be submitted to the legislature only such proposals as, in the judgment of those qualified to consider them, are of sufficient importance to call for legislative action and well suited to accomplish the purpose sought to be served. The measures selected and agreed upon should constitute the legislative safety program and might well be set forth in a pamphlet describing each proposal with a brief statement of the reasons for its being advocated. Such a pamphlet would prove to be of great value in the campaign for legislative endorsement.

In any given jurisdiction the question of the composition of the conference to formulate the safety program will, of course, be determined by the local situation. I may suggest, however, that where motor vehicle legislation is being considered, the conference should include the state officer charged with the administration of motor vehicle laws, the head of the state police, outstanding safety engineers, representatives of the state safety council, state and local organization of motorists, the state organization of chiefs of police, the state grange, the state farm bureau, the state federation of labor, the state insurance organizations, the state motor vehicle dealers' organizations, the state taxicab association, the American Auto-

mobile Association, the Motor Truck Association of America, and the American Motorists Association. This list is merely suggestive and is not intended to be all inclusive. It is probable that other organizations to be represented will occur to those charged with the duty of calling a conference. My purpose is to indicate in a general way the various interests which should have representation.

The campaign in favor of the safety program should be one of education. Each organization represented at the meeting should lay the program before its membership and urge that each member bring it to the attention of his local representatives in the legislature and enlist their support. The importance of reaching the individual legislator through his constituents can not be over-emphasized as this is one of the most effective ways of insuring the success of the program. The cooperation of the newspapers should be sought as well as that of the motor vehicle magazines and other interested publications. A trained publicity agent to prepare articles for publication and supervise the publicity campaign will be found to be of great value.

The bills to be introduced in the legislature for the purpose of carrying the program into effect should be carefully prepared. A subcommittee of the conference to have charge of this feature will prove helpful. The assistance of those familiar with the drafting of legislative bills should be sought, including the advice of the state bill drafting commission, if there be such a body. Too often have measures of much merit gone to pieces on the rocks of legislative procedure because the bills in which they were embodied have been hastily and loosely drawn. Bill drafting is a science by itself and should be undertaken only under the direction or with the approval of those skilled in the subject.

After bills have been prepared, the members of the legislature who are to introduce them in the respective houses should be carefully selected as the fate of a bill frequently is affected by the standing and connections of the legislators by whom it is sponsored. If possible, it is usually desirable that legislation be introduced by the chairmen of the committees to which it will be referred. Bills should be gone over in detail with the introducers to the end that they may be thoroughly familiar with them and in a position to discuss them intelligently in committee and on the floor of the legislature. Every effort should be made to convince the introducers of the desirability of the legislation and to make them earnest advocates thereof. A piece of proposed legislation should have a father who really understands and believes in his child.

Bills should be introduced early in the legislative session in order that there may be ample time for their consideration and, if the necessity develops, for their adjustment or amendment. To a large degree, all legislation is a matter of compromise and there should never be a stubborn attitude or unwillingness to make reasonable concessions, provided the essential principle at stake is not placed in jeopardy. As soon as a bill is introduced, a conference should be arranged with the leaders in the respective houses of the legislature and the purpose and effect of the bill should be carefully explained to them. In addition, the introducers and leaders should be furnished with a written statement showing the purport of the bill and the reasons for its advocacy. After the bill has been referred to committees, each member of the committees should be interviewed, apprised of the purpose of the legislation and furnished with explanatory data.

After a bill has been introduced and printed, copies of it should be distributed freely among the active members of the legislature with suitable markings and annotations to readily explain its purpose, but not in such detail as to require a great amount of time to absorb. In the hurry of legislative work the average legislator, who is not a member of the committee to which a bill is referred, will gain more from a copy of the bill so prepared than from a more detailed explanation. Many will not find sufficient time to analyze the more detailed data but will examine the synopsis and obtain an understanding of the legislation.

It is of importance that safety bills should be referred to the proper committees. While ordinarily this will follow as a matter of course, it should be given some attention. An improper reference may tend to interfere with prompt and careful consideration.

The progress of bills through the various legislative channels should be carefully watched to see that they do not suffer from neglect. Committee chairmen should be urged to report the bills to the respective houses of the legislature as soon as they have been given adequate consideration by the committees or, if public hearings are necessary or desirable, these should be held without delay and thereafter the bills should be promptly reported. When they find their way to the calendars of the houses, attention should be paid to their progress to see that they are regularly read and advanced toward final passage. When finally passed in one house, bills should be pressed for action in the other house to the end that they may be passed there and sent to the executive for his consideration. If a bill does not move satisfactorily the source of the obstruction should be sought out and removed. Many times a slight and unimportant amendment will remove an objectionable feature which has delayed progress. A careful follow up system will bring such objections to light but in the absence of such system a trivial objection may be sufficient to defeat the proposal. Always bear in mind that legislative committees and houses are busy institutions during the session and that that which is everybody's business is nobody's business. Diligence in following the course of legislation is essential.

It is desirable, where possible, to secure the services of trained legislative agents who understand the legislative machinery and are therefor better equipped to promote legislation than those who have not had the necessary training even though they may not lack in enthusiasm. A legislative agent should fully understand the bills which he is promoting and be convinced of their merits, for unless the advocate has faith in his cause, he is not so likely to impart faith to others. A lukewarm representative who has never really grasped or felt the importance of a measure will often produce fatal results. In selecting legislative agents, only those should be chosen who have the confidence of officers and members of the legislature.

As soon as a bill reaches the executive, his counsel should be furnished with full information in writing concerning the bill and the reasons why it should be approved. A conference should be arranged with counsel and, if necessary, a public hearing by the executive should be called for. When a public hearing is held, it should be arranged sufficiently far in advance so that the proponents of the bill may be notified and given an opportunity to appear. It is not essential that a great many speakers be heard at such a hearing but they should be carefully selected to make the best possible presentation of the case for the bill. As many as possible in addition to the speakers should be encouraged to attend the hearing. A large number of people appearing in favor of a measure make a strong impression upon the mind of the executive.

Thus far I have discussed the ordinary legislative procedure but I do not feel that my subject would be fully covered without a reference to the excellent results which may be obtained where an important legislative program is involved through the means and aid of a joint legislative committee representing both houses of the legislature and, if thought desirable, including representative nonlegislative members. Where extensive and novel changes in the law are to be undertaken, it may be well to start a year in advance by the appointment of such a committee. This will enable the committee to hold hearings and conduct its investigation during the summer months and prepare its recommendations for the legislature before it again convenes. In states holding biennial sessions of the legislature, it may be necessary to have a committee appointed two years in advance or possibly machinery may exist for the appointment of such a committee during the interim between sessions. Experience has shown that the legislature is prone to look with

favor upon the result of an inquiry conducted through the medium of its own members and the recommendation of a joint legislative committee are usually enacted into law without delay and with little of the ordinary mass of red tape to be cut through.

In conclusion, let me say that legislative promotion is not a matter of accident or chance. It calls for the most careful preparation and for a thorough follow up system. It often involves the expenditure of funds for legitimate publicity and to pay for legitimate services. These funds are usually obtained from individuals and organizations who are interested in procuring better safety laws and in greater protection to life, health and property. Eternal vigilance and hard work are most essential to success in this line of endeavor. I believe that adherence to the methods which I have outlined will aid in the presentation of any legislative safety program and in the great majority of instances result in the production of better and more adequate safety laws.

CHAIRMAN STOECKEL: The program now passes to a demonstration of methods of examination for drivers' licenses given by the New York Motor Vehicle Department. In the absence of Commissioner Harnett, I will ask Mr. Leon Aronowitz to explain, if explanation is necessary, how this will be conducted so we may all follow it.

LEON ARONOWITZ (Statistician, Bureau of Motor Vehicles, Albany, N. Y.): Mr. Chairman, in Commissioner Harnett's absence I want to express his regret at his inability to be here, and he wished me to extend his greetings to this meeting. Lieutenant John E. Mahoney and Inspector Arthur Putz of our Bureau will give a demonstration of how a road test is conducted. At the conclusion of this road test, if there are any questions the members care to ask, they will be present here and will be pleased to answer. There is just one thought I wish to leave with the conference—at the present time in New York State we have one hundred and four inspectors, and we are conducting approximately 450,000 examinations every year for new drivers. In addition to the new drivers, anyone who has had his license suspended or revoked as the result of an accident, is required to come in and pass a special test before his license is restored. If the Chair is ready, I think Lieutenant Mahoney is ready to begin.

Demonstration of Examination for Driver's License

By LIEUTENANT MAHONEY

State Bureau of Motor Vehicles, Brooklyn, N. Y.

The State of New York through its Motor Vehicle Bureau wishes to present to your body the mechanics of road testing. The Bureau has a duty to perform to the public of this State and to those who visit our State. With the thought always in mind that the Bureau's creation and existence depend upon the service that it gives to the people of this State, we take into consideration what is necessary for a driver, and we divide it into three parts; that is, he must be physically competent; he must be mentally competent; he must be morally competent, besides being able to operate an automobile. Consider that in the year 1927 in this State alone approximately one person every four hours in every day of that year went to meet his Maker through the agency of an automobile—every day during the year 1927 there were 235 people injured.

This work is conducted by a group of inspectors. These inspectors are selected after a competitive Civil Service examination. They are given a course of training which includes attendance at the New York State Police School. Before they

are turned loose, they are put on probation, and then the Commissioner takes that inspector—does not delegate this power to anybody else—and paints for that inspector a very vivid word picture of his responsibility. He brings home to him the fact that some member of his family may be killed or injured—the little voice that he is listening to and brings joy to his life, may be stilled by a careless or incompetent driver; and he tries to bring home to the inspector the fact that he must be ever careful and ever watchful in everybody that he passes after a road test, so that he may not be morally guilty of murder or of the charge of somebody being injured or property damaged.

Now, we have three classes of applications. We have the chauffeur's application, an operator's application and a junior operator's application. The chauffeur's application covers a person who drives for hire. The operator covers a person who does not drive for hire, that is, the ordinary pleasure driver, and the age limit is eighteen years. The junior operator's license takes care of the boys and girls in the rural section primarily; those who work on the farm and would take produce to the nearby market or point of transportation, or take milk to the creamery. It has since been extended to cover boys and girls who are helping their father and mother. No junior license, however, is issued in any cities, and the junior cannot drive in a city. It is only issued in the rural districts, and then only as an aid to the father and mother; and after nightfall there are certain limitations on the junior operator; that he must be accompanied by some member of his family, an adult.

Now, I am going to ask the Inspector to fill in one of these applications to show you what we try to cover. In this application, the first thing we must do is to establish the person's identity—that is, his name, where he lives; if he is employed, where he is employed, his employer's name and his employer's address. If he has a business of his own, we want his business address. Then to further identify him, we get when he was born; the day, the year and the month; how tall is he; how much does he weigh; is he white or black, male or female; what is the color of the eyes; what is the color of his hair. The next thing is to find out does he speak, read and understand English. You can readily see that if we turn a man loose on the road who could not read a sign, who would not know when to stop, would not know what streets were right hand streets or left hand streets, one-way or two-way streets, it would be a very bad thing. Another very bad thing is if he came to a bridge in some rural district in which the capacity of the bridge was printed on the sign—if the capacity was four tons and that man was driving a vehicle carrying eight tons and went over the bridge, the natural result would be that he would go through the bridge.

We ask him if he is familiar with the Motor Vehicle Law and the State Highway Traffic Law. If he says no, we cannot accept him. We tell him to go and study it. The average man when he sees that question, will try and get some pamphlets, some books. As a matter of fact, on the tables where the applicants make out the applications in the Brooklyn and New York offices, it is one of the functions of the janitor in the morning when he opens up to see that those tables have a supply of the Motor Vehicle Law and the State Highway Traffic Law on them, and to replenish that supply when it is exhausted.

They ask him then if he has ever been convicted of a felony. "Were you ever convicted of any violation of the Motor Vehicle Law or any ordinance or code relating thereto?"—and if he was guilty of a felony he must tell the details of it. If he was guilty of any violation of any Motor Vehicle Law or law relating to the operation of motor vehicles, he must give the details. "Tell when you were convicted, where and what the crime was." And we next ask if he suffers from any physical disability. Now, the man with one arm, one leg, one eye, a man who is suffering from the result of infantile paralysis, something that would tend to make his extremities useless, we want to see that man; we want to know all

about him; we want to pass on him before the license is issued to him. We ask him if he has ever suffered from fainting spells, vertigo, epilepsy. We want to know more about that man if he has. We ask him if he uses narcotics and to what extent he uses them. We are interested in that man to find out if he abuses it, and abusing it thereby is an unfit person to receive a license from the State of New York. And in every way we try to set up a safeguard so that the persons driving on our highways or traveling on our streets are protected so far as the mental, physical and moral condition of the man is concerned.

Now, on this application there is a form of affidavit. The applicant when he passes in his application is handled by clerks known as examiners. These examiners, through training and experience, are very competent in picking out the little missing links in these applications. For instance, if they find that the man has been convicted of a felony, they tell him he must take his application and present it to what is known as the Complaint Section; and after an investigation and examination in the Complaint Section, if they think that he is a safe man morally to issue a license to, they stamp it with a rubber stamp and he returns to the issuing office and files his application. If his license has been suspended or revoked by this State for any reason, the issuing office must send him to the Complaint Section where he is inspected and examined and the same stamp placed if they O. K. it. If he is a habitual law breaker—that is, if he has five or more misdemeanors to his credit in this or any other State, the examiner refuses to accept the application and refers him again to the Complaint Section. If he is convicted of leaving the scene of an accident, driving while intoxicated, several other points of law breaking, we refuse to accept his application and refer him to the Complaint Section.

In this acknowledgment he swears that every statement made in his application is true. If he has answered all the questions and meets all the requirements, a road test permit is issued to him. Now, these road test permits—the white is for the chauffeur and the yellow is for the operator. On the application for the chauffeur, pictures must be attached, and one picture then is placed on this road test permit. This road test permit carries a description of the person; that is, his height, weight, color, male or female, color of his eyes, color of his hair. You can readily see why we insist upon that. For instance, I might file an application and my friend over here would take the test for me. So that we want to try and pin it right down to the fellow who is going to take the test. He files his application and this permit is issued to him, and on the face of it tells him where and when he will take his examination. Throughout the greater City of New York and in every small village where we think it is necessary, there is what we call a road test post. In the City of New York we have 38 of those posts during the busy season, and those will get down to probably 15, 18 or 20 during the non-rush season. We try and lay out those posts to develop the driving capabilities in the man. The ideal post takes in two right turns, two left turns, four or five intersections, through traffic and a hill; to stop and start your candidate on your hill or to turn him around on the hill. In any event, he must be turned around at the end of his test; that is, complete turn. Now, due to the population density and the geographical condition of the city, this is not always possible. We must go where we can give to the people the greatest accommodations of certain areas, but unfortunately we cannot always find a hill on every road test post. So to make up for that, we add a few more blocks of traffic, or take him through more congested areas. In other words, we try to make it fair and square for every applicant who goes along.

The applicant, after the time has been placed on this slip, presents himself at the road test point. He must have a licensed chauffeur or operator to accompany him. On this application there is a question: "Do you desire a learner's permit?" A learner's permit is a provision made by the legislature that those wishing to

learn how to drive might do so and be identified. If any man came in, physically incompetent or morally incompetent, the State would not be protecting the rights of its citizens if it said to that man, "Here's a 60 day permit; you can go out and drive as long as you are accompanied by someone who will see you don't kill somebody else." That man may have both legs off; he may be blind; he may be in the common expression, a "hophead"; that is, one who is addicted to the use of drugs—and it would not be fair to the citizens to do that. So we say you must make out an application, show your qualifications, and if they meet with the requirements of the Bureau, we will issue to you a learner's permit.

This learner's permit permits him to drive while accompanied by a licensed chauffeur or operator. He cannot drive alone, and there is a little joker in that that many people do not know; that is, among operators and chauffeurs—that they are responsible for any crime, any infraction of the rules and regulations, that the 60-day permit holder makes. In other words, if he passes a red light, the officer is entitled to give both the beginner and the operator a summons.

Now they come to the road test point and present themselves to the inspector, and the inspector has an appointment card on which the number of this permit appears, and he checks that. If the number is not on it, then he refuses to take the man, and sends him to the office. There's another way we try and safeguard and make things fair, and square.

Before the inspector gets to the point, I want to describe to you what happens. When the inspectors report to the office tomorrow morning, they do not know where they are going and neither do I. I have a bowl, hollow, with numbered pills in it. Those pills are shaken up and each man is given a pill. That pill is numbered, and that represents the post he is assigned to for that day. He does not go to the same post twice in any week, and the men are changed from the Brooklyn office, where I work out of—a new contingent of men is sent to me every week; so that no friend knows where an inspector is going, so he can go and have his test prepared to go to that particular point; and no inspector can work up a little clientele of his own favorites. What we want to do is to put the thing on a level, shoot straight and keep it straight.

The inspector takes up this permit and after checking it, on the stub here there is a notice—"IMPORTANT"—and it says "No road test will be given unless you comply with the following:" the certificate of registration must be in the possession of the man who is to take the test, or the driver of the car who brings him there, and the headlights must be equipped with legal lenses and properly adjusted, and the license plates must not be obstructed, and the horn must be in working order and the steering device must be in working order, and on commercial vehicles there must be a mirror. Now, you can readily grasp the idea of that. As Mr. Aronowitz said, last year we gave over 450,000 examinations. That means that somewhere in the neighborhood of 450,000 cars were examined. The brakes were tried out; the lights were looked at; the horns were looked at; the steering mechanism was examined.

The first step in the road test is to ascertain whether the man has vision. That's very necessary, and to do that he is given an eye test at the road test station. This is the eye test chart (displaying chart) and the rule is that the man must read this line with both eyes uncovered at a distance of 20 feet. Now, I am going to demonstrate this to you. The inspector for this purpose is a candidate taking a road test. Now, I ask him to sign his name on the reverse side, and at the same time I ask him how long he has been driving. I will explain why I ask him that question later. This also has on it an acknowledgment in which he swears that he is the man who presents himself to take this test. Now, I start to give him the test. We cover the right eye and ask him to start from the top and call the letters off. (Inspector reads letters on test chart with right eye covered.)

Now, of course, the space up here does not permit us to mark off the exact 20 feet, but assuming that this is 20 feet, the man has a vision at 20. That's marked in a space provided for the purpose. In his right eye he has a vision of 20.

Now we try his left eye. Now, read the third line from the top. Now skip the next one and read the next. Read the next line backwards. We get the same result in that eye. The same result in the left eye and the same result with both eyes.

The idea of jumping around is simply this: That a man of average intelligence could stand on the road test line and memorize that chart. It has been done. It is done every day in the week, and we try to overcome that by jumping around from line to line, so that he does not memorize it. We ask him to read one line backwards, another line forwards, and skip two lines; pick out individual letters and ask him.

The eye tests are scheduled every hour and the time devoted to each candidate is about 7 minutes. Each class is made up of seven or eight candidates.

Let us assume that this man failed in his eye test; that he had a vision with both eyes uncovered of less than 40. The inspector marks it on this permit, and each inspector has a punch. Each punch has a designated symbol on it (mine happens to be a key, like St. Peter) and he takes and punches the first result, so that there cannot be any change in it, and the applicant is advised to see an eye doctor; and one very particular thing in force is that he must not tell him what eye doctor to go and see.

Now, assume that the man has vision in only one eye; that is, one eye has no vision. The inspector marks on that in the space allotted to him, "No vision." That candidate must pass two tests, whereas the ordinary man must only pass one. If a candidate only has one leg, one arm, one hand, or suffers some physical disability, the inspector marks that in the space provided, and that man must also be passed by two inspectors. He must pass two tests successfully.

Now the time is ripe for this man to take his actual road test, assuming that his car meets with all the requirements; that he is physically fit so far as the inspector can see; and he is taken for a ride—not the kind of a ride that you read about in the papers. He is given two right turns; two left turns; turn round on a hill or on the level; four or five intersections through traffic. The party who came with him to the road test point is permitted to ride in the car with him.

On the reverse side of this permit are twenty reasons why you cannot have a license, and I am going to go over them in the time allotted to me, always bearing in mind this: The average man when he comes to make a complaint, complains that some right has been denied him by the State; that is, that he cannot drive; whereas it is not a right—he was not born with it. It is a privilege that the State gives him after he qualifies that he is a driver. In other words, it is our job, as I said before, to stop the careless and incompetent driver from starting out on the road, and I want to say this: In 1927 less than one per cent of the people who were given road tests had an accident in that year—less than one per cent. It was the fellow who was driving more than one year that did most of the damage. But when a man comes to complain, he always loses sight of the fact that the reason he was kept off the road is not because the Bureau took a negative attitude and said, no you can't do it; but because they took a positive attitude and said, you can't drive because you are not a competent or a careful driver; and most of the cases are that they are not careful.

The first reason for failure is inexperience. That does not need any explanation. The fellow that gets into the car and jerks the head off the inspector before he pulls away from the curb, grinds the gears out of the car, you don't have to take him any further—he is inexperienced; he is guilty before he starts.

The next is poor shifting. That's No. 2. Now, poor shifting means the fellow that starts off in first and goes a little distance and slips into reverse—starts back

again—you give him another chance. He starts off in first, goes along, gets on famously, goes into second. He comes to a street intersection, and he throws on his foot brake—forgets all about his clutch. He stalls. You have congested traffic. That man if he continues to do that kind of thing is not going to get very far. He is going to jam up traffic and cause a number of accidents. The inspector encourages him a little more and he starts him off again. He gets on well again until somebody about half a block away passes him. He jams on his brake and forgets again he has a clutch. Now, that man cannot drive; he does not know how to drive. He does not know how to shift. He is a menace. He is a liability on the highway.

No. 3 is repeated stalling. Same thing. The fellow forgets that he ever had a clutch in the car. The only thing he knows about is the stopper. Some fellow who was teaching him told him "never forget you have a brake," and he didn't. He simply jams that on at every opportunity.

Now, the next one comes in the class of what we term the potential killer—the fellow who speeds on corners and throws traffic regulations up in the air and forgets all about them. The fifth count is "swing wide on turn." Here he is right here. The inspector tells him half way down the block he will take a right turn at the next corner and he goes up and swings out wide.

The next one is swinging on your left turns. The inspector tells him to make a left turn. But this fellow shoots across: He says, "I don't care about this other fellow; this fellow makes no difference to me"—and the inspector says "You are not a fit driver." The inspector is right, because the inspector is trying to save human lives.

The next count is speed in turning. Assuming that he does make a proper turn, which he usually does not when he speeds on a crossing—we say your speed on crossings ought to be around eight miles an hour, and that's the proper speed for crossings, eight miles an hour, and those of you who have paper and pencil can figure it out. The man going faster than that, I believe for each mile per hour he increases his speed a foot and a half for every second. Now, the persons traveling across here, once they set their foot off this curb, have a right to be there, they have the right of way, being a pedestrian. If the pedestrian happens to be a good broadjumper with this fellow coming around here at $17\frac{1}{2}$ feet a second, he has got to jump to get out of his way; and the fellow that argues with you that he ought to go around that turn at 15 to 20 miles an hour, he is crazy, because another thing is, as he increases his speed he also increases the distance in which he can bring his car to a standstill, two or four-wheel brakes notwithstanding.

Rolling back on a hill—that's another point. Now, the proper way to start on a hill, probably most of you know it—is to overcome the law of gravity. The idea is to let your clutch in slowly, release your brake, feed her enough gas so she will overcome that gravity, and go up the hill. Here's what happens—a man comes to a stop on a hill; the inspector says, "All right, we will go up here a few feet and turn around." He goes into first; puts his foot on the gas; feeds her the gas, and then lets in his clutch; but he forgets his brake—he stalls the car. Or he will start, put his clutch pedal down, go into first speed, let his emergency brake off, and he starts to roll down the hill, and then he is panic stricken. Now, you can visualize what will happen when a man starts rolling down a hill who loses his head if there is nothing there to stop him. Of course there may be another vehicle there he is going to wreck. Or there may be a pedestrian who is going between his car and the car in back. There may be a jam there, or somebody killed or sent to the hospital. A man operating an engine of that kind, with so many horsepower, ought to know how to start it on a hill, and the State takes the stand that it is protecting its citizens when it insists he must know how to start that car up and control it on a hill.

Delayed braking. Those of you who have driven cars have probably met this person. He is the fellow that will travel behind you and keep bumping you all

the time. He is the fellow that will shoot out of a side street and jam his brakes on screeching, and then grin at you and say, "Everything is O. K." But the time is going to come when the brakes won't hold and everything will not be O. K. That fellow is a careless driver. He is going to go through a water hole some day and his brakes are going to be wet, and he is going to come up to a crossing and see how close he can come to hit a man; but he won't only hit him; he will kill him. He is a careless driver. He is an incompetent driver. He is a liability.

Of course, the next one is "accident"—where a man has an accident. That automatically lets him out from getting a license. The same way with the near accident. It may be that he does not really have an accident, but through the alertness and the quickness of the inspector, or the good driving of the fellow who is coming in the opposite direction, he only has a near accident and not a true accident.

Reckless driving—This is what we find in a great many cases in the driver of some experience. Any act or omission that makes the road unsafe for others is reckless driving—mainly speeding. That constitutes reckless driving, but any act and any omission that makes the road unsafe for others is reckless driving.

Operating the machine too slow to be safe. Many times well meaning friends will tell him, "Take it easy with the inspector and show him you are careful and you will get by." He will go along at ten miles an hour, assuming he is making a wonderful hit. The ideal conditions would be if we could put him in a machine and see how the brain responds under certain conditions. That would be the ideal way to give a road test; but, as it is, we can only see what a man does that the inspector can observe. That man going too slow ties up traffic, as I pointed out before.

Failure to signal on turning. Now, the man who will go along and turn where he pleases, without notifying the other man of his intention, and does that repeatedly, he is not a safe driver. He is not carrying out the ideas that your body represents. He is not carrying out the ideas of the Commissioner, or the State of New York. We say the man traveling behind you has a perfect right to know what you intend to do, and the only way he knows what you are going to do is for you to put your hand out and tell him. Otherwise he does not know what is in your mind. It is safe for him to assume you are going to go in a straight line.

Next one is "assisted or coached." We all have well-meaning friends that sit in the back seat. They tell the candidate to do this or that; but somebody asked a friend of mine not long ago, "Do you drive a car?" He said, "No, I steer it and my wife drives it from the back seat," and that's pretty much like the person who coaches or assists a candidate.

Poor judgment in traffic. A man comes up in two lanes of traffic. He pulls out, comes around here, cuts these two fellows off; or he makes this turn here, cutting this man off, instead of making the proper turn, which is this, and getting on the inside lane here, and coming up this way. Another indication of that type is that he will come half way up to a crossing, and some vehicle happens to cross it; he stops right then and lets it go by. That man holds up traffic, with the resulting traffic conditions.

The next point is nervousness. That's open to debate in this respect: That a man or a woman is naturally nervous when they present themselves to take a road test. It is natural they would be nervous; and the inspector tries to discount that nervousness in summing up the result of the test. If a person is too nervous, and he thinks they are a risk on the road, then he fails them on that account, but ordinarily a man is nervous when he appears for his test.

And the next one is the last one—failure to follow instructions. Now, there's an idea prevalent in some quarters that the inspectors try to trap a man; that they want him to do things he should not do, and they tell him to do this or that. It is not anything of the kind. A man gets his license on his merits, a fair and square deal. The inspector may tell that man to stop over here, "I want to get out," and

there is a pump there and the fellow says: "Oh, no, I won't stop there; it is against the law." That is not against the law to stop at a pump to discharge a passenger. It is against the law to park your car at a pump. He may tell him to pull over to a No Parking sign; that he wants to alight, and he tells him, "No, there is a No Parking sign there; I can't park." The inspector did not ask him to park. He refuses to follow instructions and at the same time shows an ignorance of the laws. He may ask him to turn around in the middle of the street that is not heavy in traffic. He refuses and says it is against the law. It is not against the law. There is no law which says you cannot turn around in the middle of the street to make a complete turn. It is against the laws of commonsense if you make that turn in a street with very heavy traffic.

After he has successfully passed his examination, the inspector turns this into the office, and he is mailed his license. If he fails, he is mailed the sad news and he is told why he failed, and he is expected to polish up and do better the next time.

I spoke a little while ago about a man having to take two tests where he had one arm or one leg or any physical disability. We have restriction stamps. For a deaf man or a man that is dumb, cannot speak, there are certain restrictions. If the inspector in giving the eye test notices that the man wears glasses, he so notes it on the road test permit, and when the license is issued, it is stamped with a red stamp, something like this, which shows that the car can only be operated when the bearer of this license is wearing glasses. It may be that he has special equipment that is due to the loss of an arm or leg. He has certain equipment in his car. If he has one leg, we might perhaps prescribe the tying up of the brake clutch; one arm, we might prescribe the shifting of the shift lever or the bringing over of the emergency brake to a certain position. When a man has one arm we may prescribe a hook in the arm he has to get hold of the hook in the steering wheel. In that case we stamp on the license "Restricted to operate with special equipment." A man who is hard of hearing or deaf, we prescribe a full length mirror for him, or, if his hearing is not so bad that he can use an acousticon, we prescribe the acousticon.

I have covered as much as I thought of in the time that has been given to me, and want at this time to express my thanks for your courtesy in listening to me, and if there is any question that you would like to have me answer that is in line with this particular subject, I will be very glad to do so.

D. A. DREW (Director of the Traffic School of R. H. Macy Co., New York): I would like to ask the Lieutenant why it is, when you are giving a license in the State of New York, why a man who passes his test on a passenger car is not allowed to drive a truck on the streets of New York.

LIEUTENANT MAHONEY: That particular question you ask me is often brought up. We will assume that a man presents himself to take a test with a Chevrolet roadster or Chevrolet touring car. It is a light car and he takes his test on that. He passes his test successfully as a chauffeur, and he goes to work for any concern. Now, he holds a chauffeur's license. He can drive for hire, but it would not be fair to turn around and put that man, who is in the habit of driving a little toy, on a great big ten or twelve ton truck, would it?

MR. DREW: The reason I brought up that question is this: We have the largest fleet in the department store field today; we have over 345 trucks, and to my knowledge we are the only organization in the department store field that has at the present time a traffic school. Only recently in our Long Island City Works when we advertised for chauffeurs, we had quite a few young, likely looking chaps that we hoped might make drivers. When we failed them, their first argument was they passed the motor vehicle test given by the State. That's why I asked the question. The other question I would like to ask is this: When the applicant is with the inspector, how far must he be from the car in front?

LIEUTENANT MAHONEY: The only thing is that he must be far enough away from the car that at the speed he is going he can stop his car without striking the car ahead. We call that flirting with the car ahead. It is not a very nice sensation to have a candidate that you are driving with pulling in behind a great big Mack truck, and every so often come up and graze off, and sometimes hanging from the Mack truck will take the head off the inspector.

Every applicant is entitled to two tests; that is, he is entitled to fail twice on his eyes and he is entitled to fail twice on his road condition. Then the application is cancelled. He must file another application.

CHAIRMAN STOECKEL: For one fee? He gets two chances for five dollars?

LIEUTENANT MAHONEY: He gets two chances for one dollar. With this chauffeur's application there is a fee of five dollars. If he does fail two of his tests, a refund is made of four dollars to him. The State holds that other dollar as wear and tear and charges to overhead.

CHAIRMAN STOECKEL: The Chair desires to thank you all for your kind attention, for your participation, and to express to you its gratitude.

ADJOURNMENT

October 3, 1928

Traffic Law Enforcement

HON. WILLIAM McADOO, Chairman
Chief City Magistrate, New York City

The fifth session of the Public Safety Division was called to order at two-fifteen o'clock, by the chairman, Hon. William McAdoo, Chief Magistrate, New York City.

CHAIRMAN McADOO: Gentlemen, it gives me great pleasure indeed to have the privilege of presiding over your gathering. Some years ago I met many of you, I think, at Washington at the convention somewhat similar to this.

Since I came into the room, I have been asked many questions about what we do in New York, so far as the law is concerned and the police, in regulating vehicular traffic.

You know, New York is divided into five boroughs, and each borough has to some extent a government of its own. The City of New York contains over 6,000,000. London has a population of 7,000,000 people. But in reality, taking the Metropolitan District, as it is, we have a population of about 9,000,000, not to speak of the immense number of visitors that pour into the city.

The magistrate courts were reorganized in 1910 and we have 37 courts and 57 magistrates. And the courts are divided again into specialties. We have three traffic courts in the borough of Manhattan, which is this borough, three traffic courts in the borough of Brooklyn, two traffic courts in the borough of the Bronx, and we are about to establish another traffic court in the borough of Queens. No cases excepting those relating to traffic go into the traffic courts, and the traffic courts are in session every day in the week, except Saturdays and Sundays.

Yesterday, in the Manhattan Court, I disposed of 700 cases which is infrequent. We are governed by the State Law in the disposition of these cases, by the city ordinances, enacted by aldermen and approved by the Mayor and by police legislation. Under the charter the police commissioner has a very extensive law-making power, and the regulations made by the police commissioner are enforceable with the state law and the city ordinance.

We regulate as to speeds. We have minimum and maximum speeds which must not be exceeded. There was a very bitter controversy as to whether a man should be charged with reckless driving that imperiled the public safety or whether he should be arraigned for exceeding the minimum of miles within the law. Practically all our cases in the traffic court are for exceeding the speed limit as fixed by the ordinance.

We have the fixed mileage per hour, and then we have as to the penalty a fixed minimum below which we cannot go. We must fine the speeder \$25 for the first offense, and if he is a second offender, and is so charged, we cannot fine him less than \$50.

Under the police regulations under the charter, we cannot fine a parker for less than \$5 and we can carry the penalty up to a great deal higher. So if I am sitting in the traffic court and there are 150 people brought in for parking, I can do only two things with them. I can acquit them if they plead not guilty. If they plead guilty and are convicted, I can suspend sentence. But I cannot go below the \$5 limit. I am strongly in favor of the minimum fine, and I would like to see it standardized throughout the country. It not only is more definite than to leave a wide discretion with us as to the payment, but it relieves the magistrate of being allowed to say, "This man will only be fined \$2. He is a poor man."

We have also to state the number of days imprisonment there will be if there is failure to pay. I have had a wounded veteran before me, with a glorious record overseas. He was guilty, of course. He said, "I can't pay that \$5. I haven't got it."

I don't feel justified in suspending the sentence, because in the first place, it is always suspicious, and I am very chary about doing a thing like that. He says, "I will go down to the city prison," and God knows, I don't want to send a veteran down to the city prison, a man who is wearing a medal for carrying our flag in France. But I can suspend sentence.

A Money Fine Often the Worse Punishment

In some cases, a man comes in and says he has a mother and twelve children. He says, "I would rather spend three days in the city prison than to pay \$50." Of course, I can minimize the prison sentence. We have no minimum of days or months in the prison.

Our serious offenses of course are driving while intoxicated, and there the license is lost.

We have here in New York, and I think it ought to be general throughout the country, a very wide and sweeping discretion as to the suspension and revocation of the license, and I am convinced from long years of experience that taking away the license is the most determined thing you can do as against a reckless, a drunken or a careless driver.

I was up in Maine last year spending my vacation, and reading the local paper. In the City of Bangor I was told, and I saw it was true, that for driving while intoxicated in every case there was six months imprisonment, \$200 fine and costs.

Before proceeding with the afternoon's program, I am going to trespass on your patience by saying a few words about an evil which I believe is prevalent all over the country.

Traffic Law Enforcement

By HON. WILLIAM McADOO
Chief City Magistrate, New York City

If, as a Judge or a Magistrate I have before me a person who is on trial for an equally serious offense, or a felony, no one would think of calling me up on the telephone to influence my judgment and it is a serious offense under the law for anyone to interfere beyond certain lines with the Court in arriving at a determination as to the penalty.

Legitimate information from probation officers and others, of course, is sought. We have here in New York as in all great cities a large number of ordinances and regulations made under the Charter by the legislative authorities of the city and the Police Commissioner and very rarely is the Magistrate approached in these cases asking for suspended sentences or acquittals; but all over the country from the village to the metropolis there seems to be a general public opinion that it is perfectly legitimate to lobby the Magistrates, Police Justices, Recorders and Justices of the Peace in the matter of violating laws regulating vehicular traffic. There are otherwise respectable men, who consider themselves good citizens who would ring me up at two o'clock in the morning to ask me to intercede for them or a friend in the Traffic Court where the whole fine would not amount at most to five dollars and where the plea, in keeping with the facts, must of necessity be guilty.

In going with a car this summer through certain states and cities, friends in

those places advised me in advance that if I got in trouble on the road with police officers or constables to let them know and they would take care of me in their locality, meaning that their influence would protect me from any serious consequences. Now, these men really consider themselves good citizens, and I am not going to dispute it and I know it would be useless for me to argue with the people who attempt to lobby us in the matter of defendants brought in by the police for violating the law in the rules of the road.

Now, here is a plain citizen who has not violated any law and who is highly esteemed by his neighbors and the members of his club. He has a ticket for parking or some violation, serious or otherwise. His first impulse is to go to some person either in or out of office, who is a man of influence, and to have him intercede with the Judge to either have the case kissed out of court or the penalty made as light as possible. If he succeeds he is the proudest man in the neighborhood. He lets it be known among his friends and at the club that he is in touch with the powers of government; that he is a recognized person of influence and lives in a sphere entirely different from those whom he meets in business or socially and lets it also be known that if any one of the rest of them gets into trouble to let him know and thereby a sort of endless chain is started to interfere with Recorders, Justices of the Peace, Police Justices and Magistrates all over this broad land.

Correction Is a Serious Problem

How are we going to correct this? By public opinion? Well, who will make the public opinion? It is a very serious matter because it is an undue interference with the conscience of the Judge. It is putting an unfair pressure upon him.

Here is a man who is a real close friend, whom he otherwise highly esteems and he reaches the crossroad in the case between his plain duty to the public and the atmospheric pressure of friendship. Then too, the serious evil in it is this, here are two hundred people crowded in the Traffic Courtroom charged with the same offense, under very nearly the same circumstances. They include all classes of people, men and women of social prominence, obscure people, rich people, poor people, high and low; now, here comes a man well known in the community, socially, commercially or politically, and I let him off; or, here is a woman of great wealth and social prominence and I suspend sentence in her case.

What am I going to say to the other one hundred and ninety-nine people? Haven't I given a public demonstration that the law is not equitably courageously and impartially enforced? Won't this poor woman going down the stairs, who has paid \$25, think to herself, if she does not say it aloud, that if she was a rich and prominent woman she need not pay anything, whereas the \$25 meant a whole lot to her?

Of course, if all Magistrates, Recorders, Police Justices and Justices of the Peace, or whatever our titles may be, throughout the whole country should form into a sort of secret organization and take blood-curdling oaths that we would not listen to appeals of this kind and then carry out our pledges, we might get some results. But, if all the friends or alleged friends, whose requests were refused, organized against this they would beat us against an unorganized and uninformed public thousands to one and our tenure of office would be much endangered. Brethren, these are serious thoughts!

We have a very important and constructive paper to be delivered by Mr. Brown, Attorney for the Detroit Automobile Club, Detroit.

How Detroit Cut Accidents Through Law Enforcement

By HOWARD D. BROWN

Attorney, Detroit Automobile Club, Detroit, Mich.

It is my particular pleasure to be here to tell you a story of how Detroit cut its death rate in automobile accidents. I shall attempt to point out as nearly as possible the procedure that was followed in that great city to reduce the number of fatalities.

I want to impress upon you that Detroit is the fourth city in this country in size and that here was a battle so to speak between an organized police force, thousands of pedestrians, and practically 400,000 automobiles. The police department, under its good commissioner, William P. Rutledge, was faced with this problem.

In order to give you some of the background, it will be necessary to take up a few statistics. In 1927 there were 421 people killed in traffic accidents. In the last two months of that year, the situation became so bad that it was necessary to consider ways and means to reduce this great hazard.

As a matter of fact, on November 18, 1927, there were five people killed, and on the 10th of the same month, there were four people killed. During the whole month of November there were forty-eight people killed. And in December, up until the 28th, there were 38 people killed. The citizens were being aroused. What were they going to do to cut down their accident rate? Commissioner Rutledge was faced with the problem of working out a solution, and I will tell you somewhat how he went at it.

As a matter of fact, he had tried safety education in the schools, having organized a Public Safety Bureau. This bureau had enlisted the cooperation of men, women and children. They had given in the course of a year 1,260 shows of motion pictures in which the safety problem was well worked out. These meetings were attended by approximately one million people.

In addition, 500,000 safety posters had been circulated all over the city. Everything had been done that the police commissioner and his officers could think of to stimulate the people into recognizing that there was a serious problem and that they must drive in such a way as to cut down accidents.

A Violation Bureau was organized in which the people could admit their own guilt and pay their own fines. But that apparently wasn't sufficient to reduce the number of accidents. The Commissioner realized that all these educational facilities had to be supplemented. There must be something else done, because the death rate was still soaring. Evidently education in itself wasn't sufficient.

So he started to analyze the problem, and in analyzing the accident rate he discovered that a great many of these accidents resulted from violation of the law. But when he went out on the street and observed traffic, he was impressed that there were a great many minor violations that people were not checked up on. The motorist was running by the red and yellow lights. He was turning the corner against the red light without coming to a stop, which is against the ordinance of the City of Detroit. They were doing all sorts of things and "getting away with it" in common parlance.

How could this be changed? The Commissioner decided all these old methods had been insufficient and that somehow the people had to be shocked into realization of the importance of the traffic laws. There must be some change in the psychological setup in order that people would recognize that these traffic laws were to be obeyed.

In other words, the Commissioner made up his mind that he would have to exact obedience from a public that was not willing to give obedience voluntarily. So this is the way he proceeded.

He called the commanding officers of the Detroit Police Department together into his office. He told them in substance that the traffic laws had to be enforced to the letter. He told them that they would have to get sufficient man-power to see that those regulations were enforced. He told them that there would be no publicity. He didn't even publish a general order on the subject. He simply conveyed these orders verbally to the men assembled in his office. He didn't want the public to realize that they were going to be checked up until the officers had already started to do it. In other words, he decided he was going to give many of them a little practical education in traffic enforcement.

Well, to change the scene a bit, on December 28, the next day after the Commissioner called his officers together, I was driving down to my office. When I arrived at the boulevard which is approximately three miles from the downtown district, I noticed there were two officers at a signal-controlled intersection. I thought that was rather strange. I had never seen two traffic officers posted at an intersection where there was an automatic signal.

I continued on, and at every intersection, I discovered two more officers. I began to wonder what had happened. I had never seen so many patrolmen in my life on the way to the office in the morning. I thought there must be a riot somewhere.

Then I began to observe the driving public was rather beginning to take it seriously, and when they came to these intersections they were slowing down. You could hear the brakes squeak and they would come to a stop, and they would not cross the limit lines, because if they did, they knew they were going to get a ticket.

Afterward, when I sat in the Commissioner's office and heard his side of the story, here is what he told me: On the morning of December 28, 1927, he threw 600 officers into the three-mile circle. You can imagine that that would have considerable effect when the public had no anticipation whatever that there were going to be so many officers there.

In addition to the 600 patrolmen on foot, he had a flying squadron of 40 motorcycle officers and he put those officers on one main artery for two hours. They would go up and down and up and down, and then switch over to another main artery, until the motorists in Detroit began to think there must be 10,000 motorcycle men in that city, because they had seen them in one street and then they had switched over and seen them on another street.

The Commissioner was proceeding with his policy of an eye for an eye and a tooth for a tooth, and during that day the officers gave out 4,115 violation certificates. The department gave out 8,493 tickets from December 27 to 31. Previously the average number of tickets served was 300 a day. So you can see there was considerable increase. In other words, the public was getting some first-hand information on practical law-enforcement.

Well, what happened? Did it have any effect as to the public? I can answer and say that on December 27, 28, 30 and 31 there was not a single automobile fatality in the City of Detroit.

Here was something new—the police had made a showing. They were as surprised as anybody else. They were encouraged. The idea here was a revelation. Lives could be saved through traffic enforcement. The public had never heard of such a thing evidently in our part of the country. The idea that people could drive automobiles on the street without killing people was rather a revelation to a lot of them.

And then the idea began to take hold. The police were encouraged that they had shown some results and as a result of that enforcement, which was continuing there was only one fatality in Detroit between February 23 and March 8.

Of course, there was some reaction from stringer enforcement. The Commissioner's orders had been that no tickets given to violators were to be cancelled

or killed. Of course, some of the politicians who couldn't serve their constituents in the ordinary way, as Judge McAdoo mentioned, rather took exception to the fact that tickets couldn't be killed, and so they demanded a showdown in the matter.

But what happened? The newspapers of Detroit ridiculed the politicians. The Public Safety Committee appeared before the hearing to a man and stood by the Commissioner. The better citizens of Detroit demanded that enforcement continue and Commissioner Rutledge be given a free hand to carry out his program. The work continued.

But all these 600 officers who were patrolmen were not accustomed to enforcing the traffic regulations, and so you would expect that in cases there were violation tickets given out where only a warning should have been given. To overcome that, the Commissioner organized what he called a Board of Review, and that Board of Review consisted of the deputy chief of detectives, the head of the Violation Bureau, and the patrolman making the arrest, and if the citizen who had received a ticket thought he had been aggrieved, he could appear before this Board of Review and state the facts as he saw them, and if the Board of Review thought that he had been illegally arrested, the ticket was ordered cancelled.

I want to impress upon you the importance of this Board of Review. Mind you, orders had been issued that no tickets should be killed. Consequently if you did not correct that by creating the Board of Review, there would be bad feeling on the part of the public. But when this Board of Review was created, that sounded the death knell of the ticket pulling system, because the Commissioner could say, "Very well, if you think you have a kick, go and appear before the Board of Review, and if they feel your kick is justified, then your ticket will be cancelled." And that is one way that probably the Commissioner got to sleep nights too.

What was the result? What was the final result of all this hullabaloo and enforcement? In 1927, for the first eight months, there were 243 people killed in Detroit. During the same time, in 1928, there were only 173 fatalities. In other words, through stringent enforcement, 70 lives were saved over the same period in 1928 above that of 1927. Reducing these figures to a percentage, it shows that 28.8 per cent lives were saved in the first eight months of 1928.

Enforcement is still proceeding. Of course, it is impossible to keep 600 officers in the three-mile circle and to check up on every violation. But on Saturday, when the schools are not in session and on holidays and at such other times when the inspectors can be released from their precincts, they have been on the corners and are checking up on every minor violation.

A man runs across a limit line. He is warned or given a ticket. In other words, he knows he has to live up to the law.

The Commissioner had hoped, when he started this campaign, to reduce fatal accidents 50 per cent. It is true that he has not arrived at that goal. But he has saved 28.8 per cent of lives during this year.

Sometimes you hear it said that safety work is devoid of interest. I want to say that one great city's heart goes out to its Police Commissioner and to its police officers for saving 70 lives, and we in Detroit feel that all this work and effort on the part of the Police Department has been a very commendable thing and that we are very much gratified and interested and hope that it can continue.

I believe this story I am telling you would not be complete if I would not tell you something that we have learned from this situation in Detroit. Every story should have a moral. In the first place, we have learned this—and I want to emphasize this with every bit of energy that I have—The minute you take off enforcement, the minute you release stringent enforcement, your death rate goes up.

Therefore, I feel that we cannot say that educational and other methods that we are using to reduce accidents are sufficient in themselves. We must in one way or another secure an adequate stringent and forceful means of cutting down these accidents, and that can only be in my opinion through holding the people respon-

sible for their actions. I do not believe the public is willing, up to the present time, to give voluntary obedience. Therefore, the police have to exact obedience from the public in order that they may drive properly.

I am very glad to say to you, that our own Commissioner, Mr. Rutledge, who did not expect to be here, has been able to attend this meeting, and I know that you will all be glad to hear a word from him.

CHAIRMAN McADOO: Mr. Rutledge, we would be glad to hear from you.

WILLIAM P. RUTLEDGE (Police Commissioner, Detroit): I haven't a speech of such length, Mr. Chairman, to warrant my getting up on the platform. I have listened to Mr. Brown's talk, and it sounded to me as though he were nominating the Commissioner of Detroit for a candidate for the Hall of Fame.

I have been a policeman for 33 years. I have been in the traffic-enforcement branch of the police department for a number of years. I was director of traffic thirteen years.

You heard Mr. Brown say that we had—although he didn't use those words—tired of the effort of bringing about a better condition by educational methods, and decided that some more practical lesson should be given. The result is very gratifying indeed to the Police Department of Detroit. We read in the pamphlets of the National Safety Council that throughout the country there has been an increase of approximately nine per cent in automobile fatalities while we had a decrease of 30 per cent in the first eight months of this year.

I said at the beginning of the year that unless the people were awakened to the seriousness of the situation, there would be upwards of 500 people killed in Detroit during this year. I based that upon the fact that last year there were 396,000 automobiles registered and 396 automobile fatalities. When Mr. Brown spoke of 421 he included other fatalities, other than automobile fatalities.

Last year there was one death for every thousand automobiles. This year there are 475,000 automobiles registered in Detroit, and so it goes without saying that had we continued at the same ratio of one per thousand, we would have killed 475, this year.

Mr. Brown stated that we aimed to cut the death rate in half, 50 per cent, but we attained the mark of 28 per cent. We are still encouraged that we may reach the mark of reduction of 50 per cent for the reason that the last three months of last year, as he told you, on some days we had four and on other days we had five killed. There were 48 people killed in November last year. There were 34 in October, 38 in December, and 120 in the last quarter of last year.

We started a campaign yesterday by which we believe we can cut that death rate in half for the last quarter of the year, which will mean a saving of nearly 200 lives in Detroit this year, based on the automobile registrations.

If I can be of any service to those who are interested in the saving of lives and traffic accidents, I would say that Detroit is particularly fortunate in having a police department that is absolutely separated from any political influence. The police commissioner is free, as Mr. Brown said. He has a free hand. If there is any police commissioner or chief who has not a free hand, the only way I know to obtain it, is that the mayor or the director of public safety, or the Common Council shall let the police department operate without any hindrance of political or other improper influence.

The stopping of the killing of tickets was a rather difficult problem. I guess you will agree with me that it is a common custom. It is similar to what His Honor the Chairman said about the problem or about lobbyism.

I was told by newspaper men that I couldn't get away with it. And it was rather difficult to convince certain politicians that a ticket couldn't be fixed. You understand what I mean. An officer hands a violator a ticket and he is to report to a Violation Bureau and adjust it. If he doesn't he goes to court and adjusts it there. Between 10,000 and 15,000 of those tickets were adjusted improperly last

year. Not one has been adjusted improperly this year. I mean by improperly, it has not been adjusted outside the Violation Bureau.

The Judge referred to these people as alleged friends. I had many alleged friends who were frequent callers at my office, but they are not so frequent any more. It seemed for a while as though I were ostracized to quite an extent. The men with whom I had visited at their summer homes over week-ends were not my friends any more, because they couldn't unload a pocket full of tickets on me or anyone else in the department. The Common Council had their friends, and when they learned they couldn't fix the tickets for their constituents, I was attacked not only by the Common Council but from other directions.

I am a retired policeman. I retired two years ago to accept the position of Commissioner, and it was publicly stated in the press, by a politician, that if I were old enough to retire I was too old to be police commissioner. I am, of course, drawing a retirement pay together with my salary, and that was attacked. It was rather discouraging.

I am just telling you this so that if you are going to stop fixing tickets, you want to look forward to a rather disagreeable time. But you have to stop fixing the tickets.

I was in a town in the South last winter, and the traffic officer told me how discouraging it was there, how 75 per cent of the tickets were cancelled by the people with influence in that town, a town of a little over a hundred thousand.

One man from whom I received a ticket and whom I met in one of the meeting clubs at lunch time, the Detroit Athletic Club, after I had returned the ticket to him with a polite letter that that sort of thing was a thing of the past, and whom I was avoiding because I thought he would look upon me the same as some of my other alleged friends had, proved to be a real friend. He hailed me, as I was avoiding him, trying to get out of the door without meeting him, and he said, "Hey, Bill! When I got that little note from you, returning that ticket to me, your stock went up 100 per cent with me, and I am with you. Stick to it!" Then I commenced to receive encouragement.

I have nothing else to say except a repeat that it is a matter of life and death, whether a police department can be allowed to function without interference and hindrance from politicians and to get along without political interference of any kind whatever.

CHAIRMAN McADOO: We have an open discussion on all these talks, and if anyone else wants to speak on the matter, I would be glad to hear from him.

I was immensely encouraged by this talk from Detroit. In the first place, I find that human nature hasn't changed at all in Detroit from New York City. Even Henry Ford is not able to change human nature. The same thing occurs all over the country.

We may gather from that, I take it, this: that after all, we lean upon the integrity and the intelligence of the individual police officer. He acts by himself. They don't go in couples or dozens like companies in the army. There is no one present but the police officer, and he gives out the tickets or the summons. Therefore, his character for integrity should be thoroughly established.

I am glad to tell you that in this great city, with 16,000 policemen, it is the rarest thing that any charge is made against the fairness or honesty in the giving out of summons. That is a great tribute.

MR. SPAYD (Secretary, Brooklyn Safety Council): You folks perhaps don't know Judge McAdoo as we do in New York. I would like to say that he is

largely responsible for the remarkable record that was made in New York in the safety line.

I also want to ask the gentleman from Detroit to what he attributes that great number of fatalities in Detroit. It seems to me that 400-and-some is a tremendous lot of people to kill in a city the size of Detroit. In Brooklyn, we have 2,250,000 people, and in 1927 there were 158 people killed.

MR. RUTLEDGE: The Police Department will have to confess there has been some laxity in the enforcement of the so-called minor trivial violations, the ones we mentioned about turning without stopping and starting up before the green light came on, and that sort of thing. But I don't know why there were more. I don't know whether there were, as I haven't any figures on other cities of the same population. We have a population of about 1,400,000. We have a very large number of cars in Detroit—375,000 cars—and there are a great number of owner drivers in Detroit. There are 500 or 600 new applications for drivers' licenses every day.

Just what the loss of life is attributed to, I don't know. Mr. Brown is an expert in the Automobile Club, and I would like to have him tell you about that.

MR. BROWN: No, I can't answer that question. An analysis has been made every week of our fatalities by one of the members of the National Safety Council, and we find—I can't give the exact percentage—but a great many of these deaths are children and aged people.

I do think that in Detroit we drive much faster than it is possible to drive in a city like New York, of course. Our thoroughfares permit fast driving.

The Pedestrian Often at Fault

The Commissioner just whispered in my ear that a great many of those cases through analysis have been shown to be the fault of the pedestrian and not the motorist. It ranges about 48 or 50 per cent the fault on the part of the pedestrian and probably 50 to 52 per cent the fault of the motorist. So when you are discussing the pedestrian control you are speaking of something that is very dear to our hearts in Detroit. I rather feel that in controlled intersections there must be pedestrian control. Either there must be sufficient time for them to cross the street or they must be held back in one way or another.

CHAIRMAN McADOO: What is your total police force in Detroit?

MR. RUTLEDGE: 3,300.

CHAIRMAN McADOO: Do you have a special traffic squad?

MR. BROWN: Yes, there is a traffic director that has charge of the traffic division. It is a special squad that looks after traffic. That is very well backed up by the Safety Committee that meets once a week, in which all the representatives of the various sections of the city, the Department of Public Works, the Department of Street Railways, the Recreation Department, and the Board of Education are represented. You have a cross-section of the community—the big industries, the public service companies. They all meet and at that meeting the director of traffic division attends or one of his lieutenants and they discuss many matters that come up in the regulation of traffic.

CHAIRMAN McADOO: How many men are engaged in the regulation of traffic?

MR. BROWN: About 275.

CHAIRMAN McADOO: Do you train the men for traffic work?

MR. RUTLEDGE: They receive a training in traffic regulation, yes. They have a special course in the training school, pertaining to traffic regulation.

CHAIRMAN McADOO: The next subject on the program will be handled by Mr. Joseph T. Davis, President of the St. Louis Safety Council, St. Louis.

Getting Public Support for Law Enforcement

By JOSEPH T. DAVIS

President, St. Louis Safety Council, St. Louis, Mo.

If we could deal with every individual personally by appealing to his better instincts through the power of reason, the subject of crime would not be such a problem. We would not be here for the purpose of discussing traffic law enforcement as a matter of public safety nor would we be solicitous of "Getting Public Support for Law Enforcement."

Unfortunately, however, in all ages we have had to consider individuals collectively, as parts of classes, groups or the masses. In this populous country the individual becomes a part of the whole community or political subdivision, and as such his individual thought, action and sentiment conforms to those of his class or group. The sentiment of responsibility which always controls him as an individual disappears entirely unless the moral sentiment of the group is aroused to action.

As a member of the class or community he is subjected to the sentiment and acts of others and becomes an imitator. His sentiment of responsibility to others is again under the contagious influences of the class.

Consider for a moment the inclination of the motorist: As the stream of traffic, in which he is moving, increases the speed, he unconsciously increases the speed of his car. The fast driving habit forms and he becomes a speed maniac unless restricted. He observes that most drivers disregard boulevard stops with impunity and he imitates them.

The pedestrian fails to observe the traffic signal and "jaywalks" across the street because others have established precedents for him to imitate.

This condition is true from childhood. Parents admonish their children to be careful of their associations and place restrictive means upon them to prevent the acquiring of bad habits. The child grows into manhood and becomes one of a community.

The individual is no longer under the restraining influence of his parents. The State now steps in and places its restrictive influence upon all of the individuals who comprise the group.

The State or City enacts traffic laws and ordinances to preserve order in the community and to force upon the individual that sense of responsibility to others which he lost by being absorbed into the group.

These laws are merely rules of action and conduct, restrictive in character, and are in-operative and unenforceable within themselves. They must be enforced by a group of individuals, the police, prosecuting officials, and courts, which we designate as the Law Enforcement branch of our government.

Here, again, the human element enters. Too often a member of the group of the law enforcing body will lose his sense of responsibility to the community and allow himself to be controlled by selfish motives and impulses especially if public sentiment is not aroused.

The great majority of the law enforcement officials are honest and are desirous of serving the community. On the other hand, however, the official is human and is possessed of all the human frailties, some of which are selfishness, ambition and indifference.

While the State restrains the individual, the public, composing the State, must in turn restrain the law enforcement officials through aroused public opinion. No public official can stand the searchlight of public opinion playing upon the selfish, ambitious or indifferent conduct of his official duties. Public support must be had to create public opinion so as to impress all members of the group and law enforcement officials that law enforcement is applicable to each whether he is a

willful or unconscious violator. In all crusades some innocent victims must suffer for the good of the whole.

The crystallization of public sentiment to keep public opinion aroused is a matter of some effort. Once more we find the individual absorbed in his selfishness and self-satisfaction. Too many times his selfishness in business causes a well meaning law abiding citizen who believes in law enforcement to take an indifferent attitude because of fear. He feels that an active interest for law enforcement will injure his business. He may resent, as an individual, the conduct of the officer, but he takes no action, due to indifference, fear and other reasons, or possibly because as an individual citizen he would be ineffective. As soon as he joins with others under proper leadership his influence becomes manifest and he realizes that there is no cause for fear. In other words this public sentiment crystallized into public opinion must be the result of organized and fearless leadership. This leadership in safety movements is dependent upon the Safety Councils in various communities.

The public is willing to follow unselfish and constructive leadership in most moral and humanitarian moves, which tend to the betterment and protection of themselves and their neighbors. Such sentiment can be aroused and the support maintained for law enforcement by a well organized and active Safety Council acting as the leader in the safety movement of the community. Leadership once established, public support may be secured for proper law enforcement by means of cooperation with the legislative and law enforcement branches of the community. The public press and other organizations will follow this leadership with the result that a constructive public sentiment for strict law enforcement is aroused.

I may be pardoned if I refer to the leadership of the St. Louis Safety Council in the City of St. Louis—merely to aid as an illustration of what has been and can be done in a community.

Since prestige and public confidence is necessary to establish leadership, the St. Louis Council was and is organized along strictly non-political and non-commercial lines, and is composed of outstanding public spirited business and professional men.

Our Council first interested itself in the subject of traffic law enforcement about six years ago. Up to that time the Council had not seen fit to consider it a special duty to get into the field of law enforcement as applicable to the community as a whole. It had contented itself with carrying on an educational program outlined for the purpose of reaching the individual through process of reasoning and by appealing to his personal sense of responsibility. It was found, however, that this plan was ineffective because the average citizen had lost that sense of responsibility after he became part of the group.

By the end of 1922 we found that deaths due to traffic accidents were constantly increasing. Our Executive Committee which meets every week, decided some affirmative and constructive action must be taken. A Law Enforcement Committee, with Mr. Arthur Morey of the Commonwealth Steel Company as Chairman, was appointed. This Committee in due time found and reported that the increase in fatalities was due primarily to a failure of proper law enforcement and that, in part at least, such failure to enforce was due to antiquated and improper laws and regulations.

An analysis of the disposition of traffic cases in the City Courts indicated a policy of lax enforcement by the Police Judges with a result that the violators who were brought into Court were let off with small money fines and in many instances by merely paying the costs. The traffic laws did not provide for punishment whereby the offender could be sentenced to the workhouse.

The press gave wide publicity to this report and this was the beginning of arousing public sentiment and opinion.

Following this, the Council decided an effort be made to see that the traffic laws be made as practicable as possible and see that public support be had so the laws would be enforced and the guilty severely punished.

In the early part of 1923 the Council formulated a plan of cooperation with all of the law enforcement officials and agencies. It was felt that a change was necessary in the policy of the City Courts. On three different occasions during 1923, committees appointed by the Safety Council called upon the Mayor, who appoints the City Judges, and called to his attention the failure of the City Court Judges to assess heavy fines under the then existing laws.

While we were now having some public support, still so little had been done prior to Public Safety work being started on law enforcement that the officials had not yet realized the importance of rigidly enforcing the laws as one great step to reducing traffic accidents, consequently these committees met with only a small degree of success with the Mayor. After each session with the Mayor the Judges would assess a little heavier fine, but would soon fall back to the old system of small fines and Court costs.

During the early part of 1923 the Council began an active campaign for changes in the traffic laws which its Law Enforcement Committee had found to be inadequate and impractical of proper enforcement. The Council called upon the Mayor for support. The Mayor then appointed a special committee consisting of the Presidents of the Safety Council and the Automobile Club of Missouri and the City Counselor to make a study of the traffic laws of other cities and to prepare a new traffic code for the City of St. Louis. This Committee accomplished a splendid piece of constructive work and in April of 1924 the City's Board of Aldermen was induced, through public opinion, to pass the new code. This was a great step in the right direction for the improvement of traffic regulations, but we still had to educate the law enforcement officials, which was even more difficult than that of securing the new code. Among other excuses given by the City Court Judges was that they insisted the provision for punishment by sentencing the violator to the workhouse was invalid as being against the provisions of the City Charter. The Council promptly arranged for a test case with one of its members as the defendant. The Safety Council entered its appearance and filed briefs as a friend of the Court. The Supreme Court upheld the ordinance as being valid.

Again we realized that we were not getting proper support from the local law enforcement officials.

Our statistics showed that in 1923 our fatalities numbered 156 as against 131 in 1922 and in 1924 they increased to 187 even in the face of the activities of the Safety Council. We began to realize the relationship between increasing fatalities and laxity in law enforcement.

We were receiving splendid support from the press and the public, but we realized that something out of the ordinary would have to be done to crystallize public opinion upon the law enforcement officials.

The Council then decided to appoint another law enforcement committee of outstanding members of the Bar of St. Louis, irrespective of their political affiliations. This committee worked conscientiously for several months and finally gave a report which gave the press and public an opportunity to concentrate public opinion upon the question of law enforcement. By the time our Municipal Election in the spring of 1925 came on, public opinion was so well crystallized that the successful candidate for Mayor adopted the Law Enforcement subject as one of his major planks. He promised the public and the Safety Council publicly that, if elected, he would appoint men to office who would enforce the traffic laws.

When elected, the Mayor appointed two new City Court Judges and gave strict instructions that they were to enforce the traffic laws without fear or favor.

The press of St. Louis took notice and carried first-page news items of this change and gave warning to motorists. The newly appointed Judges gave warnings

through the press and from the bench as soon as they assumed their duties as City Court Judges. They gave warnings that reckless and careless drivers, speeders and other flagrant violators of traffic laws need expect no leniency in their courts. Promptly they began assessing the maximum money fines of \$500.00 in many cases and in others they assessed 10 to 90 days' workhouse sentences.

While the Safety Council believes that public officials should be openly criticized if they persist in failing to perform their duty, the Council also believes that it is equally as beneficial to publicly commend officers for performing their duty. As these new judges enforced the laws, press notices were released by the Council commending the judges. The press gave the news of the fines and punishments being meted out to the violators.

It was not long until the fatality rate began to decrease.

During the first four months of 1925, before the new judges assumed their duties, motor vehicle deaths showed an increase of nearly 50 per cent of the first four months of 1925. After the new judges assumed their duties, during the last eight months of 1925, there was a flat reduction of 14 deaths over the same period of 1924.

In 1926, this policy of law enforcement was continued and motor vehicle deaths showed a further drop of 18, with a total of 174 for that year. In 1927 under a continuation of the law enforcement policy the number of deaths was reduced to 147—a decrease of 25 per cent, as compared with the year 1925.

The strict enforcement of traffic regulations and the assessment of severe penalties has produced results in St. Louis. Records of the Safety Council show that approximately 90 per cent of the automobile drivers in St. Louis during the year 1927 had no accident record inside of the limits of the City of St. Louis. It is logical to assume that at least two or three per cent of the 10 per cent who had accidents could charge contributory negligence to the party injured. It would appear, then, that in 1927 there were about 7 per cent or 8 per cent of willful or grossly careless drivers.

We believe that these figures will bear out the contention that most individual drivers try to observe the traffic laws providing the group to which they belong is made to realize that traffic laws are made to be observed and not to be violated. The large percentage of individuals of the group can be made to respect traffic laws and the rights of others through proper enforcement and through public opinion. A larger proportion of the 7 per cent, however, are the type who are willfully reckless and they think that they have a prior right on the streets. They will not listen to the Safety Council and its educational program. These are the drivers who are causing most of the trouble and the only way this class of drivers can be reached is through the Police Department and the Courts. If the laws are enforced and the guilty prosecuted without fear or favor it doesn't take long for this message to sink into the consciousness of the reckless. When you threaten a driver with heavy fines or with workhouse sentences you appeal to his selfish instinct in a way that creates his respect and attention.

Careless drivers on the streets of a community are a great deal like bad apples in a barrel of good ones; if the bad apples are allowed to remain undisturbed any length of time they spoil the other apples in the barrel, and so it is with careless drivers. If they are allowed to run rampant on the streets their bad influence and their recklessness affects other drivers through contagion.

In order to maintain proper law enforcement the Safety Council, as the leader, must follow up the work.

We have a concrete example of how political ambition to be Circuit Judge has caused one of our model City Court Judges to become as bad or even worse than his predecessors. Since he opened his campaign for the nomination for Judge of our Circuit Court, he has failed to enforce the traffic laws with the result that

many motorists who were before him for violations carried his campaign banners on their cars.

The Safety Council immediately became active with the result that public opinion has caused him to resign his position until after the campaign.

In the meantime the Safety Council has appointed another Law Enforcement Committee which is now about to report.

The Provisional Judge appointed to fill the vacancy of the Police Judge who resigned began to follow the policy of his predecessor and delivered a speech from the bench to twelve guilty violators a few days ago in which he accused the newspapers and the Safety Council of destructive criticism and was promptly answered through the press. The editorial of September 28, 1928 of the St. Louis Post Dispatch, if I may be pardoned for reading, will show the newspaper support law enforcement is receiving:

"Traffic Paroles"

"If proof the pudding is the eating, then the policy of paroling speeders in Judge Rosecan's court causes the death toll to mount.

"Joseph T. Davis, president of the St. Louis Safety Council, points out that there were only seven fatalities from September 5 to 26, the period in which the policy was abandoned by Judge Blocher, who is sitting for Judge Rosecan while the latter is campaigning for the Circuit Court, whereas there were eight fatalities in the first four days of September, when the policy was in operation, 14 from July 5 to 26 and 16 from August 5 to 26.

"Nevertheless, Judge Blocher characterizes as destructive criticism protests of the Safety Council, the press, and Chief of Police Gerk, against the parole policy, and he has again put it in force. It involves only a verbal promise to the Court not to drive for 30 days, a promise which the Chief of Police says the speeder seldom keeps. Judge Blocher's defense of the policy, as stated in his remarks to 12 speeders arraigned before him, is that since most of the speeders are youths 'it is unfair to put the stigma of the workhouse upon them.'

"The Post-Dispatch protests against such sentimentalism where human life is at stake. We assume, of course, that the dispute pertains to flagrant carelessness. Mr. Davis has proved that the workhouse is a deterrent. Chief Gerk has complained that the parole system sets at naught the work of the police. The death toll this year is more than 40 in excess of that at the same time last year. At the rate we are going, or 131 people killed in the city by automobiles up to this morning, as against 88 for the same period last year, there will be a toll of approximately 200 by the end of the year.

"If it is unfair to put the stigma of the workhouse upon youth, how fair is it to kill these 200 men, women and children? And how fair is it to the people of St. Louis when other cities are licensing drivers and depriving them of their licenses when they prove themselves a hazard to society, to continue practicing such loose traffic methods as we persist in here?"

Our experiences in the matter of keeping public opinion concentrated all the time, which seems to be necessary, has caused the St. Louis Safety Council this year to appoint a permanent Law Enforcement Committee.

We are convinced that through proper leadership public support can be had and maintained for Law Enforcement providing a group of public spirited citizens are willing to take sufficient interest to promote the cause of public safety.

CHAIRMAN MCADOO: We shall now have the pleasure of listening to Mr. E. B. Lefferts, Manager of the Public Safety Department, Automobile Club of Southern California, Los Angeles.

A New Procedure in Traffic Law Enforcement

By E. B. LEFFERTS

Manager, Public Safety Department, Automobile Club of Southern California,
Los Angeles

"A New Procedure in Traffic Law Enforcement" is what we know on the Pacific coast as the San Diego Plan.

Traffic law enforcement is a difficult problem in Southern California, as it is in every community. If enforcement is too strict, the community is apt to become antagonistic to the regulations and those charged with their enforcement; but, on the other hand, if enforcement is lax and sentences are light, the law becomes more or less of a joke and the enforcement officers and court lose the respect of the community. The latter condition is usually attended with an upward trend of the accident curve.

In the southern half of California, which is the territory served by the Automobile Club of Southern California, we have had both severe and lax enforcement in different sections at the same time. From our membership of in excess of 129,000, we have been able to get a very good cross-section of the general motoring public's reaction to these different types of law enforcement, while the close contact which we have with the law enforcement officers and courts has given us their viewpoint and has enabled us to understand the difficulties with which they are confronted.

Hearing both sides of this question would give the impression that the motorists and the enforcement units were like two armies in daily combat; or possibly a better simile would be the attitude of the naughty boy who is trying to do everything he can without being caught by his teacher. I really believe this to be the truer simile, because so many men and women seem to have such a juvenile reaction toward the traffic regulations, in spite of the fact that their other attitudes show the maturity you would expect from a person of their age and position in the community.

In their enthusiasm of playing the game of trying to out-wit one another, both motorists and officers seem to have lost sight entirely of the safety motive that underlies our rules of the road. This is one of the contributing factors to our increasing accident and death toll resulting from the use of vehicles propelled by an internal combustion engine.

The seriousness of the annual loss from accidents has led to a demand from many quarters for more stringent laws to cope with the situation. I grant that this is typical of our national attitude, but in my opinion, the solution for our traffic problem does not lie in the enacting of more regulations; we have sufficient laws today with which we can effectively undertake the solution of this perplexing question, but we are not making the most effective use of them. As an example, in analysing 89,320 accidents I find that 23,101, or 25.9 per cent, were attributed to a violation of the right of way rule. This, I appreciate, is a very difficult regulation to enforce, yet we have generally throughout the nation a law specifying who has the right of way when two vehicles approach each other at an intersection, and still a failure to observe this law in the foregoing analysis was the largest single accident cause.

Studying facts of this nature led me to come to the conclusion that we were not approaching our traffic problem from the proper angle. In searching for an answer to this disconcerting problem I talked with judges hearing traffic cases, enforcement offices and with professors of psychology at our universities and found that they were in general agreement that fear is the basis of most human behavior. Accepting this fact, why should we not focus our attention upon accidents rather than upon technical violations of our Motor Vehicle Act, thereby developing in

the minds of the motorists a definite *fear* of being involved in an accident, instead of fear of being observed by a traffic officer, as is in most cases the situation today.

In discussing this situation with many police executives, most of them were willing to agree to the soundness of these arguments, but the idea of concentrating their officers' attention upon accidents was too radical a departure from an established procedure for any to undertake until in June, 1927, I had the pleasure of meeting Mr. J. V. Doran, who had just been appointed Chief of Police of the city of San Diego. While going over with him the traffic situation, I suggested that he break away from the old established method of traffic law enforcement and have his men concentrate their attention upon accidents, pointing out to him that the California Vehicle Act compels the reporting to the authorities of every traffic accident in which a person is injured. His department would therefore be notified of all mishaps of this character, which would enable his men to start their activity with this type of accident.

This appealed to Chief Doran, who then called for Captain Arthur R. Hill,

Model of a street intersection with traffic.

in charge of traffic, with whom we discussed the matter more at length. The result was the issuance, on July 1, 1927, of the following order over Chief Doran's signature:

"Effective this date, all auto accidents, whether involving personal injury or not, coming to the attention of any police officer, will be carefully investigated, measurements made and names of all witnesses secured. If the person responsible can be determined beyond question, he is to be given a summons to court; if there is a question as to who is responsible, summons both parties and all witnesses to court."

This practically amounted to the San Diego Police Department serving notice to the motorists that they were not going to lie in wait for them and pounce out and make an arrest whenever a technical violation of the Motor Vehicle Act was witnessed. They were in reality putting the motorists on their own responsibility to drive safely, which I repeat is a basis of the rules of the road, and admitting that it is impossible to patrol thoroughly and completely every side road and back street in the city. In other words, they were recognizing what is generally known, namely, that it is not possible to have an officer watching every motorist all the time. They put the responsibility on the driver to so operate his car that even though an officer is not present, no violation will be committed which might result in the injury of any person or property.

The traffic officers, since the promulgation of this order, are not overlooking

high speeds that in reality constitute reckless driving, or other violations which come to their attention; however, these are not their main objective.

Judge Claude Chambers, who has charge of the Traffic Court, has provided himself with a small model of a street intersection, on which traffic signals, warning signs and other traffic markers are shown. These are not fastened down, but may be moved around to show the exact conditions that existed at the location where the alleged law violation occurred. This model includes miniature automobiles and street cars.

When those charged with violating some provision of the Motor Vehicle Act, and thereby causing an accident, appear before the judge they are requested to

Demonstrating how the accident was caused.

show on the model, with the help of the traffic officer, the exact conditions which pertained at the time the collision occurred. From this demonstration the court is able to determine which driver committed the violation that was responsible for the accident and makes the procedure more simple than attempting to describe intelligently without this aid, just what happened. In many instances the court has found that both drivers contributed to the collision by each ignoring some of the provisions set forth in the law, which, if observed, would have prevented the accident. In such cases the judge has based the penalty upon the seriousness of their respective offenses.

One of the interesting effects of this program is the attitude of those motorists who are given citations to appear in court; the traffic officer is no longer considered as their sworn enemy; nor do they waste so much time in volubly describ-

ing their years of experience in driving during which time they have never received a traffic citation or been involved in an accident, in an endeavor to persuade the officer that he should put his citation book back in his pocket. Neither do these protestations have much weight with the court or with juries, since there is irrefutable evidence that careless driving has been practiced.

When we consider this question of enforcement of our traffic laws or in fact any other law, we must recognize that it is not necessarily the apprehension of every violator, but the swift and sure punishment meted out to all those who are apprehended which serve as a deterrent. We have found that this same effect has occurred in San Diego, in that the swift and sure punishment of those who have caused accidents has served as a remarkable deterrent to other drivers who might under other conditions have been less attentive to the business of driving or less scrupulous in their observance of the rules of the road.

One question probably is in your minds as it was in ours: Does this procedure increase the number of hit and run drivers? The answer based upon one year's experience is, no! On the contrary the motorists have developed the habit of calling for a police officer whenever a collision occurs even if no personal injuries have resulted as they want the benefit of his expert judgment as to responsibility; which shows that in San Diego a traffic officer is coming to be recognized by the motoring public as an individual who is endeavoring to increase the safety on the highway, and therefore entitled to their cooperation, rather than feeling that he is in the nature of a tax collector who is put out there to serve as a medium of collecting toll to help fill the city coffers.

While developing better attitudes upon the part of motorists and officers toward one another, it has also been developing the police personnel into trained investigators. Upon arriving at the scene of an accident they note all facts and essential details and are able to present better cases in court. This is resulting in the loss of very few cases due to the type of evidence presented.

I am not going to bore you with a mass of statistics, but when we are studying this traffic problem they must be considered if we are to show whether or not results have been obtained, and results are the thing in which we are most interested.

I am glad to say that this program has justified our hopes and has effected a reduction in accidents. This plan has been in force for a little over a year, and during the first twelve months the accidents were reduced from 961 to 703, showing a decrease of 26.8 per cent; while the number of personal injuries has dropped from 1,206 to 877, a decline of 27.1 per cent. These reductions took place in face of an increase of 2.08 per cent in population, an increase of 7.03 per cent in motor vehicle registration, and an increase of 9.8 per cent in this type of accidents in other communities similarly situated.

We all observe certain laws of health because we realize that failure to do so will result in punishment of some kind. The laws of nature, when violated, exact their punishment of a personal nature, which is what has been done in San Diego with this new procedure in traffic law enforcement.

Today this program, which has proved so successful, is spreading to other parts of Southern California and is helping to develop an appreciation of the seriousness of accidents and creating a desire to keep from being involved in such happenings. It is developing a realization upon the part of the public that the traffic regulations have been enacted for the purpose of making motoring safe and not to serve only as a means of annoyance and a medium of increasing the revenue of the community. This is resulting in a better knowledge of our traffic laws and, of course, a closer observance of them. The drivers are legion who, month in and month out, so operate their vehicles that they have no accidents. Looking from effect to cause, we are justified in reaching the conclusion that these drivers of necessity must have a fair knowledge of the municipal and state traffic regulations

of their community, coupled with a sense of the mechanical capabilities of their vehicle as to stopping, pick-up, maneuvering, etc., under various conditions, with last but not least the judgment not to attempt the impossible. With this legion of drivers, the safety engineers, enforcement officers, and courts need have no concern. Under the plan I have been describing to you this type of driver is off of everyone's mind as they deserve to be, thus allowing the necessary time to concentrate upon those who through ignorance or indifference do not operate their vehicles so as to have a clear accident record.

I submit to you in closing that were this plan of focusing attention on the accident phase of the problem, rather than upon the technical aspect of traffic violations, followed throughout the nation, I feel safe in predicting that the next few years would show a decrease rather than the increase in traffic accidents with which we are today confronted.

CHAIRMAN McADOO: I would like to say a word myself on that.

I take it that the Los Angeles program, or system, is to concentrate on the accidents and not to insist upon a general and wide-ranging enforcement. In New York, we punish a man for allowing his car to smoke. First of all, it imperils the public health. Secondly, if they all smoked, we would be running the cars like ships navigating in the fog.

As I said in the beginning, we don't consider anything trivial. We punish a man for exceeding the speed limit in this locality, as I told you in the beginning, fifteen miles being the maximum. But we try a large number of cases for reckless driving, and most of our reckless driving cases involve an accident. So the accident cases come to us just the same as they do in San Diego, and our punishment for reckless driving can be very severe.

I have said, and I will say it again, because I hope you will all take it into consideration in other cities. We believe that the suspension and revocation of licenses is as much a deterrent as imprisonment.

JOSEPH T. DAVIS (President, St. Louis Safety Council, St. Louis): I want to commend Mr. Lefferts on his paper, and particularly with reference to the manner of the investigation of accidents by a police officer at the time the accident occurs. I think that is one of the faults which we find in most of our cities. I know it was one of our troubles in St. Louis.

We had this very subject up before our Safety Council a few months ago. We didn't know the policy had been adopted out on the Pacific Coast. But it occurred in this manner. A serious accident happened in the neighborhood of one of the representatives of our staff, one Sunday evening. There was no police officer around at the time the accident happened, and when this staff officer of the Safety Council heard of the accident, he immediately rushed to the point of the accident and began taking measurements of the places where the two machines were after the accident was over. He observed the skidding of the cars on the street, and he made plats showing all of these details with measurements.

Then he followed that case. By the time the police officer got there all the police officer did was merely to take the names of the two parties who were driving the cars and ask a few questions and ask the names of the witnesses.

When the matter came up before the police court, our staff representative, following the case because of his interest, went to the police court, and none of the witnesses appeared. There is one of the great difficulties that we encounter in all our police courts with reference to traffic accidents. Where a collision or accident occurs the party who is guilty usually gets to the party who is injured or who has been damaged and says to him, "Let's settle this question of financial loss, and if we settle that, we won't have to appear in police court."

That was the case here. But no witnesses were present. The police officer was there. He merely had the names of the witnesses and the names of the parties, that some right has been denied him by the State; that is, that he cannot drive;

Our staff representative stepped up with the details and measurements, and from the details and the measurements which he presented to that court, the offender or the man guilty of causing that accident was severely fined. If it hadn't been for him, the guilty party would have gone without punishment.

That is what I see in this plan. We took that up with our police department in St. Louis, and our police department, I may say, has been cooperating with us to the fullest extent. But we found there are not a sufficient number of policemen in the city of St. Louis. We only have about 1,600 or 1,800 police officers in the city, as compared with the number in Detroit and New York. So we are inadequately policed from the traffic standpoint. But we have the cooperation of the police force, if we can increase the police force, to put in a group of technical men whose duty it shall be to immediately go to the place of accident, as soon as the accident occurs, take pictures and take measurements and get all the physical facts surrounding the accident, and then we will carry out that policy.

PERCY C. ABELL (Manager, British Columbia Safety League, Vancouver, British Columbia): I think I can tell you, with some justifiable sense of pride, that I come from a country where the law is enforced, and therefore, it is respected.

Our Superintendent of Police in British Columbia, has the power and is using the power to suspend and cancel a driver's license without the culprit going into the courts at all.

For instance, our Safety League in Vancouver encounters in our records or through our members, an individual whom we know to be a menace. We don't issue summons or go to any police department about him at all. We go up to the Superintendent of Provincial Police, who deputizes one of his officers to take that individual and submit him to what is apparently a test as to his fitness to drive a car. The culprit doesn't know he is there for another purpose. Depending on the circumstances, he may be told to be a good boy or he may have his license cancelled or suspended.

MR. LEFFERTS: I would like to inform the gentleman from British Columbia that we have pretty much the same thing in our state through the Division of Motor Vehicles. Any certificated report of a habitually careless driver is forwarded to the Division of Motor Vehicles, and calls for an investigation of capabilities of that individual, with the end in view of suspending his license or revoking it, if conditions warrant.

CHAIRMAN McADOO: If you will look at our newspapers, you will see long lists of the licenses revoked. It is a common punishment in the State of New York.

ADJOURNMENT

October 4, 1928

Traffic Engineering

W. B. POWELL, Chairman

Chairman, American Engineering Council's Committee on Signs, Signals and Markings, Buffalo, N. Y.

The sixth session was called to order at ten o'clock by the chairman, Mr. W. B. Powell of Buffalo, Chairman, American Engineering Council's Committee on Street Traffic Signs, Signals and Markings.

CHAIRMAN POWELL: At the second National Conference on Street and Highway Safety, the American Engineering Council offered to make a study leading to a standard code for city practice, and was given the job to build up a committee which was to function as a sectional committee of the American Engineering Standards Committee, so that the code when published would be a standard. We then secured our material by sending out questionnaires to selected committees in each of the communities, and having returns from something over one hundred cities, that material was very carefully compiled and analyzed. Then we started to work on the drafting of the code. That work has been in progress for two years, and the committee has been actively at work on the material for something over a year. We have held a number of meetings and we have done a tremendous lot of work by correspondence, and the last meeting of the committee was held on Monday and Tuesday of this week under the auspices of this organization, who very kindly loaned us one of their committee rooms for the purpose, and I am happy to say that today we are just ready to go to press.

How well the report will be received and how generally it will be adopted is a matter for the future to decide. We have done the very best we could with a situation that was extremely difficult, because as we got to work on it we found there were very wide divergences of opinion on certain matters, and in some cases we had to compromise, so that we are not entirely set even as yet; but at least we have something that will point the way, and I hope it is generally adopted and used. After a year or so we may find by actual experience just where it can be modified, so that we will eventually get a standard that we can all accept and adopt without any reservations whatsoever.

Now, in order to discuss the details of the report for your benefit, we have had three gentlemen scheduled for this morning's session, who have been closely related to the work. I take great pleasure now in introducing Mr. G. C. Kelcey, of the American Gas Accumulator Co., who will tell you about the A. E. C. Report on Signals.

The American Engineering Council's Report on Signals

By GUY KELCEY

**Manager, Traffic Engineering Division, American Gas Accumulator Company,
Elizabeth, New Jersey**

In the invitation which was extended to me to speak at this meeting, it was requested that I offer appropriate comments on the American Engineering Council's Report on Traffic Signals.

I find myself in the very difficult position of discussing this report before it has been presented and without having had an opportunity to ascertain clearly just what changes have been made in the tentative draft upon which my discussion is based. I shall, therefore, proceed on the assumption that the tentative report has been adopted in the final draft, except for such modifications as have been called to my attention during the past few days.

The Committee has organized and clarified much that has been confusing to traffic officials. Within the range of present traffic experience and knowledge, this committee has done most excellent work and their effort will be of great value to the traffic official and to the manufacturers of traffic devices, who, by the way, are distracted by the great variety of demands for special equipment which does not fit in a quantity production program.

The time for this discussion is limited, so, while much should be said in praise of the conclusions of the Report, it would seem more constructive to confine my remarks to those aspects of the Report which may possibly be confusing to traffic officials or which may later be subject to modification.

The United States has gone in for standardization to a greater extent than other nations. Our urge to standardize arises principally out of several motives. There is the standardization of intolerance and of the fixed idea. There is the standardization of habit, to which we all conform to avoid being unconventional. Again, standardization of production which permits the manufacture of many identical articles with the advantage of low cost, ease and economy of repair, maintenance and replacement. Finally, there is the uniformity expressed by the standardization of road signs which, like the alphabet, enables us all to read the same message at a glance, just as we all read the same language.

Before proceeding to the details of the report, it is proper at this point to mention that standardization has opportunities for both good and evil. If standardization is overdone, or if it be premature, it can easily close the door on improvement and on invention. Again, it is easy to standardize without taking into consideration all conditions, because the scope of any one man's experience in traffic work cannot comprehend all conditions. This may be illustrated by the many attempts at standardization of traffic practice during the past eight years. A highway official with mountains to contend with has an entirely different idea of a curve, turn or grade than a highway official in a prairie state. The narrow, winding streets of New England towns present an entirely different problem than the wide, straight streets of some western cities. No one who has not had to take the responsibility for the solution of multiple intersection problems such as are to be found in the six point intersections of Indianapolis and Chicago, can have a very sound judgment of what may or may not be used in their treatment. The driving habits and abilities of motorists in South Carolina, Wisconsin and New Jersey are surprisingly different. So condition after condition varies from one jurisdiction to the next, and so, likewise, does the point of view of what is the proper treatment and the proper standard. As a result, we have had a great number of standardizing bodies or groups in different parts of the country, whose conclusions are sound within the range of their limited experience. We have also had a tremendous pressure to standardize on pet ideas from a considerable group of persons who make traffic an avocation and not a business, and whose real experience is in question.

It seems proper to say, therefore, that standardization will be attained in actual practice only when the combined experience of men with a great variety of local traffic problems is added to the experience and ability of highway officials who drive thousands of miles a year over every conceivable kind of road, whether it be the shell roads of Louisiana, the gravel roads in Wisconsin, the mud roads of other states; the long, high speed stretches of concrete, or narrow, winding, moun-

tainous highways of our eastern and western states. Until these conditions are reconciled, national standardization is not possible because any standard adopted, which does not fit, will not be used in practice.

The American Engineering Council, in its present effort, has probably gone as far as it is possible at present to combine in the personnel of its committee as wide an experience as possible, but their effort will have permanent value only insofar as the investigations and study of this Committee are expanded and continued and the standards code, which is here presented, modified and improved in terms of changing conditions and experience.

For a number of years the American Association of State Highway Officials and the Bureau of Public Roads have combined their best experience to formulate and produce a set of standard signs. This standard suits the highway problem; whether in mountainous or flat country, or on mud or concrete roads. The American Engineering Council Committee in its report, recognizes and adopts this standard with some modification. Under the standard referred to, a sign twenty-four inches on a side, and used as a square or diamond, constitutes the backbone of the system of signs. Used as a square, the horizontal dimension is twenty-four inches, and as a diamond the horizontal dimension becomes thirty-four inches. There are many towns and cities where the streets are so narrow and where there is so little sidewalk space that, if this diamond sign is installed, it will absorb much, and in some cases all of the usable sidewalk width. In addition, the points of this sign are dangerous to pedestrians, and particularly to running children. This standard is perfectly adapted to highway practice but, unless the same type of sign can be used in cities and towns, the system can hardly become a national standard. In this instance, highway officials, thinking only of highway problems, adopted a most excellent standard for their use. Many municipalities cannot use it effectively, and it cannot, therefore, become a universal standard without modification. This modification the Committee of the American Engineering Council has seen fit to make, by reducing the dimension to eighteen inches instead of twenty-four inches. This modification is still probably not enough. It should be required that the points of the sign used as a diamond be rounded off to safeguard pedestrians and children. Since town signs must present as little horizontal width as possible, it is desirable that the diamond shaped sign, which presents a maximum horizontal dimension, be used as little as possible or not at all, and, if the shape standard could be changed, it is highly desirable that the diamond sign be eliminated where narrow streets are involved. The problem could be met by installing all such signs at an elevation of eight feet.

Under Section 1 on "Street Traffic Signs," appears a list of eight traffic requirements, which are designated by various shapes and dimensions. All these requirements reduce to three—prohibition, limitation or information. A diamond shaped sign, which indicates a condition inherent in the roadway itself, is specified for "SLOW," and a square sign, which warns of a condition not inherent in the road, is to be used for "CAUTION." One wonders if the average traffic official will know where to use a "SLOW" sign and where to use a "CAUTION" sign, and if, after he has made his decision, the public will know the difference. For practical purposes, are now "slow" and "caution" the same thing to the average driver? If so, a driver will react the same to either one, and why should one be designated by a diamond and the other by a square sign? This illustration is used to suggest that distinctions can be too finely drawn for the average driver's comprehension and that efforts at standardization should aim to simplify. It is hoped that your Committee has in mind the ultimate simplification of the various designations, which, in the end, can express no more than "Stop" or prohibition, "Caution" or limitation, and finally, information.

The committee's report urges the adoption of a stop sign with a red lettering "STOP," and points to the advantage of being able to eliminate the red lettering.

It is urged that the committee reconsider this action, since much, if not most, of the stop sign work of the future will be done with reflecting material, which, under the influence of automobile headlights, will cause the word "STOP" on the sign to stand out brilliantly to the driver at night. To produce a color with light, it is necessary to screen out or take away part of the light, and that which is left is the color required. To produce red, 60 per cent of the light is lost and 40 per cent is used. Under actual road test, one make of reflector stop sign with red letters was just readable at night under driving conditions at 121 feet, and with white reflecting letters of the same material at 215 feet. To produce, therefore, red lettering, it is necessary to sacrifice so much visibility at night that the standard which requires the luminous part red is of questionable benefit. The committee's decision to use a yellow background and a red lettering for a stop sign would appear to be sound since, in the proper interpretation of colors red indicates "Stop" and yellow "Caution." It is suggested for the committee's consideration that so much is to be gained by having luminous or illuminated lettering on a stop sign white; that this should be permitted, and that the reflector lettering "Stop" be bordered with red, thus satisfying the requirement that red be used.

Attention is called to requirement No. 2, entitled, "Height and Location of Movable Posts on Roadway," in which it is suggested that the center of the sign be four feet above the pavement. Immediately following this recommendation, it is suggested that if reflecting signs are used, they shall be three feet above the pavement. This would appear to be reversed, since an ordinary non-luminous sign must be down in the range of headlights to be seen, and, therefore, centered at three feet above the pavement, while a reflecting sign collects enough stray light anywhere up to eight feet above the pavement to render the reflecting units brilliantly luminous under the headlights. A non-luminous sign should never be placed above the headlight range; while a reflecting sign is effective even though above the headlight range, and, therefore, may be so placed.

The section of the Report on Stop Signs invites several further comments.

In Paragraph 4 under Rule 10, it is indicated that "A Stop sign shall be placed at a point where the message is to be obeyed. At intersecting streets, this point is on the property line of the side protected street." This recommendation is open to some question. The property line in some instances is so far back from the curb line of the Through Street that vision is obscured by foliage, street light, telegraph and other poles. From such position, traffic on the Through Street cannot readily be seen. If this rule should be adopted the careful driver would stop at the property line where the law requires, and would stop again when near the curb line where he can see the traffic he has to cross. Under this rule, if he is not a careful driver, he will cause accidents. It is suggested for consideration, that this rule be revised, and that traffic be required to stop where the best visibility of the intersected street can be obtained, and that a stop line be painted on the pavement at this point.

The Committee is to be recommended upon its adoption of the sign wording "Stop Through Traffic." There are approximately sixteen different variations of the wording "Through Traffic Stop," such as "Boulevard Stop," "Through Highway Stop," and more recently Massachusetts' proposal of "Through Way Stop." After all, whether it is a way, a highway, a boulevard, or an avenue, the reason for stopping is "Through Traffic." The expression "Stop Through Traffic" fits every case, and combines the sixteen variations into one which is universal.

Under Rule 16—"Slow Signs," it is recommended that the word "Slow" be in two-inch letters when used with "HILL" and other similar designations. A two-inch letter, to a person with normal eyesight, is readable at 125 feet in daylight; and at 10 feet under headlights at night. Restated in terms of time, this means four seconds at 20 miles per hour during daylight. At night it is of no value. It

is a question if the word "SLOW" has any value on a sign if it is put in two-inch letters. The question also arises if the words "HILL," "CROSS STREET," etc., need to be supplemented by an insignificant word "SLOW" when it helps to confuse the main message and when the main message tells the whole story.

Under "Street Traffic Control Signals"—Section 2, it is suggested that Stop and Go signals should not be operated at times when the volume of traffic is reduced. A Stop and Go signal is usually placed at a difficult corner. As the volume of traffic decreases, the speed increases. Many traffic officials have found it expedient and of great benefit when the normal operation of the signal is discontinued, to operate the amber as a flashing light. This is suggested for consideration by the Committee.

The use of two or three colors for Stop and Go signals is a question of controversy, a limited number of cities and towns having adopted the two-color. The great predominance of opinion seems to favor the three-color. Under the circumstances, the advisability of mentioning the two-color at all in a standard of this kind is doubtful. If, in the investigations made by the Committee, the subject is so obviously in doubt and not definitely clear, all reference in the standard to the use of either two or three colors might well be left out, for the reason that the publication of it in the standard will cause much confusion. In my own experience, the use of amber after green is not only finding increasing favor, but perfectly fits the traffic need. On the contrary, the use of the two-color signal or the amber after both green and red leaves much to be desired.

Under "Signal Specifications"—Rule 60, Item 2, a 60-watt capacity lamp has been specified as standard. Sixty-watt lamps in some signals which have been installed give an indication that is so poor that the signal is a hazard rather than a safeguard. In other signals, the indication is good. Any standard set up around the matter of lamps or optics used in a signal should be in terms of the intensity and distribution of the signal indication. As a matter of fact, it is the signal indication to the driver with which we are actually concerned. Properly used, a 25-watt lamp can be made to give a far better indication to the driver than a 60 or 100 watt lamp improperly used. This leads to the point that a highly desirable standard which should be adopted as early as possible, should concern itself not with the kind or size of lamp, but should establish a minimum requirement for light distribution and intensity of signal indication to the driver and to the pedestrian.

It is very gratifying to know that the Committee has seen fit to re-comment against words on signal lenses. One is always reminded of the milk wagon horse in Stamford that shied at a cat one morning at 4:30 and ran away. Two blocks down the street he came to a Stop and Go signal that switched from green to red, and the horse stopped. They vouch for this story in Stamford, and, if it is true, it indicates that horses know what red, yellow and green mean, and humans ought to. This has been a troublesome point for years.

The committee expresses the thought that only one type of signal installation should be used in each city. I should like to register my opinion that, to attain such standardization, sacrifices efficiency of treatment of many locations. If the signal is a good signal and properly designed, it will find traffic and compel attention and drivers will not have to hunt for it. In my opinion a good signal may be placed in a variety of positions on a corner to advantage. It is suggested that the requirements for standardization of location should be that the signal or signals shall be visible to the traffic approaching from any direction.

Under the "Height of Signal," the Report states that experience indicates that the bottom of the housing should be four feet to eight feet above the pavement if the signal is inside the curb line. This conclusion is open to question, because at any height under eight feet the signal is likely to be obscured by parked, stopped or moving vehicles.

The report leaves one with the strong impression that obstructions, such as va-

rious types of signals and mushroom buttons in the street, are not considered with favor. I offer as my own opinion that one of the greatest difficulties with traffic arises out of irregular movements of vehicles at intersections. These irregular movements can be prevented without interfering with the proper operation of vehicles, expediting the movement of traffic and reducing accidents. Safety zones and refuges in the throats of streets are in many cases very valuable for such work.

Rule 79—"Railroad Crossing Gates." There is a considerable problem here since railroad crossing gates are usually lighted by a small red light or lantern that appears to be so much like a tail light that drivers pass around it to the left. For this reason, most gates are broken to the left of the light. Some standard night marking and illumination should be provided for railroad crossing gates which will eliminate this difficulty.

On the subject of railroads, there are many railroad, track circuit operated, train approach signals in the roadway on streets and highways, that give an indication only when a train is approaching and constitute a real menace to vehicles at night. It is urged that a standard be adopted requiring that all such signals located in the used portion of the roadway should be equipped with a flashing amber light to operate at all times when the train approaching signal is not being given.

We hear a great deal from railroad men about vehicles running into the side of trains. Those of us who drive 20,000 to 30,000 miles a year are well aware of this situation. Again and again one pulls up just in time to avoid running into a freight train standing or moving across the road, which so blends into the background landscape, that it is not visible to the driver, and this is particularly true on rainy nights. Something should be required to render freight cars, particularly on long trains, visible at night.

In the Report, the expression "wide" as distinguished from "narrow" streets is used in a number of places without exact definition. A street which would be considered wide and suitably straight in Marblehead, Massachusetts, would be called narrow and winding in Atlanta, and a wide street in Atlanta would be called narrow by the City Engineer of Minneapolis. Narrow and wide streets should, therefore, be exactly defined.

In Rule 84, under the subject "Protection of Safety Zones," several suggestions are offered for the consideration of the Committee. The traffic approach ends of safety zones should be parabolic in shape. When this shape is used, a vehicle striking the zone is deflected. When any other shape is used the vehicle is stopped abruptly.

In connection with safety zones, the Report suggests that posts be used to safeguard the zone. This, in my judgment, is a dangerous practice, because a vehicle colliding with such a safety zone will usually strike a post with the left side of the machine, and the force of the movement of the vehicle will swing it into the safety area, and not deflect it away from the zone. Again a red signal is recommended for the traffic approach end of the safety zone. One wonders if this is not a misprint, since, under all standardization actions of recent years, including that of the present Report, red is recommended only where a stop is required. The use of a red signal on a safety zone would be, in my judgment, a most serious error.

While the subject has never been brought up for serious discussion, I wish to question one of our most fundamental traffic rules, namely, the requirement that "The man on the right has the right of way." This matter first came to my attention in an article written by E. B. Lefferts, now of the Automobile Club of Southern California, and justifies serious consideration. The history of this regulation seems to be that in Europe, where traffic drives to the left and not to the right, the regulation was and still remains that the man on the right has the right of way. We changed this rule from driving to the left to driving to the right, but we did

not change the regulation that the man on the right has the right of way. Actually, when traffic drives to the right, the man on the left should have the right of way and most drivers agree that, in their own experience, they give right of way to the driver on the left naturally, and that to give right of way to the driver on the right is unnatural. Under the regulation of "The man on the right has the right of way," a driver approaching an intersection must keep his eye on the man who is approaching from his left, because he is the man most apt to hit him. At the same time, he must look away over to his right, to see if he must give right of way to someone approaching from that direction. A driver must, therefore, look in two exactly opposite directions at one time, and it cannot be done. If, in the exact meaning of the regulation, a driver gives right of way to a driver on his right, he stops in the intersection to do it, a position which is not only dangerous but which blocks other traffic. We may never change this rule but, after thinking about it and observing its operation for some years, I have come to the conclusion that it ought to be changed and urge the Committee to consider the matter.

My endeavor in these comments has been to present constructive criticism of the Report. They are presented with the utmost respect for the difficult work the Committee has had to do and for the most excellent job they have made of it. No one who has not sat on such a committee knows the difficulties of formulating exact standards from a mass of complicated opinions, practice and ideas, nor the difficulty of reconciling the opinions of the members of the committee.

The American Engineering Council's Report is as a whole most excellently done. It is a foundation on which our future traffic standards are now stated or upon which they will be built. Contrary opinions which have been expressed relate to points which, in my judgment, must ultimately be modified; if the standard is to be fully accepted and adopted by the traffic officials, who, after all, take the responsibility for the expenditure of public funds and whose reputations depend on the results obtained. The judges in this case are the drivers, few of whom can say what is right, but who are quick to know and to say so when a traffic treatment is wrong.

In conclusion, it is important to point out that these or any other standards are subject to modification in order that they may fit new conditions or as new experience may require. In their use, there will be many questions as to the meaning and interpretation of the provisions of the standard. For these reasons, the committee's work has only just begun. It is of the utmost importance that the American Engineering Council or the Hoover Conference arrange to have a committee of, say, three men who are actively engaged in traffic work and who can be referred to, to interpret the provisions, settle questions which are certain to arise, and who will keep abreast with developments so that provisions of the standard may be promptly modified when necessary. If this is not done, this will be just one more set of standards, accepted by some and misused or ignored by others.

CHAIRMAN POWELL: Gentlemen, I think we have heard a most excellent paper, and as chairman of the committee that has been responsible for this work, I am very happy to say that quite a number of suggestions that have been proposed in the paper by Mr. Kelcey have either been incorporated in the latest revision of the report, or in some substantial manner the point has been taken care of.

The last matter that Mr. Kelcey discussed with regard to the right of way at intersections is not within the scope of our committee, and is rather within the scope of the Committee on Model Ordinance, which, as you know, has just very recently submitted its report for general consideration. Our committee can only handle the mechanical devices that are used for traffic control and does not go outside of that field.

Now we have the lantern arranged so we can go on with Mr. Cole's talk which was really scheduled for the first talk on the program. Mr. Cole, I may say, has

been one of the most active members of our committee and has been practically the chairman of a sub-committee on the drafting of the official signs which are recommended in the report. No one, therefore, is better qualified to speak on that particular feature of the report than Mr. Cole, and I take great pleasure at this time in presenting Mr. W. Graham Cole, Metropolitan Life Insurance Co., who has had that matter particularly under his personal supervision.

The A. E. C. Report on Signs and Markings

By W. GRAHAM COLE

Manager, Safety Division, Policy Holders Service Bureau, Metropolitan Life Insurance Co., New York City

The Program Committee, in arranging for the program today, has taken apart the committee report on signals, signs and markings, and had understood that your former speaker, Mr. Kelcey, was going to discuss the signal end of it and assigned to me the signs and marking end of it. However, I think we ought to feel gratified that Mr. Kelcey covered the sign part as he did from the standpoint of one not on the committee and brought out those points which come to the minds of the hundreds and thousands who will see the report from a different angle from those who had their nose more or less close to the grindstone in working on the report. However, I find it necessary to ask your indulgence to repeat in a way a portion of Mr. Kelcey's remarks, from the standpoint of a committee member presenting to you the report itself.

In the first place, as a member of the committee, and not a member of the staff of the American Engineering Council, I wish to take this opportunity to assure everyone that the American Engineering Council left no stone unturned to secure from the Nation as a whole a report of what was being done in this field. We are all bothered with numerous questionnaires; we have them come to our desks frequently. Some of them are small, fragmentary; some of them are rather inclusive; but right on top of one comes another. The American Engineering Council in undertaking this study, prepared a very inclusive report, and through its local organizations scattered throughout the country was able to collect information on this subject that has never been collected before. I do not think there is a question that the supporting material, which will be bound in the rear of the report itself, will present to you gentlemen and to the traffic engineering field of the country, the first authentic broadside presentation of existing conditions in the country in the matter of traffic control signals, signs and markings. The Council, through its member organizations, not only collected this information, but was able through engineering minds in these communities throughout the country, to bring together comments on those matters of traffic control that reflect the actual opinion of the engineers in these communities. And so I think that you have a report based on the most authentic information that can be obtained.

The committee did not feel bound in every case to make recommendations consistent entirely with the condition as found. It felt that many conditions were changing, had changed frequently and that new practices were coming into play, and the fact that a particular practice was utilized by a predominating number of cities did not necessarily indicate that it was the best practice. And so although they used as far as possible the predominating practice, they also gave expression to improvements that had been perfected and had not been installed in all of the cities.

It is the purpose, therefore, of this talk this morning to present to you the findings or the recommendations of this Committee on Signals, Signs and Markings, or that portion of the report dealing with signs and markings.

There is no question of the value of signs to the motorist. There is no question as to the value of having them standardized. I recall an instance of a motorist who was driving over a bridge in Harrisburg, Pa., and who made a turn at the crossroad as he came off the bridge, with a green light shining in his face. There was a traffic policeman of Holland extraction on the beat who hailed the man and sent him to the curb. He came over and the fellow said, "Officer, what did I do now?" "You turned on the green light." "Well," said the motorist, "Where I come from it is a rule that we must turn on the green light." "Well," said the policeman, "here it is different—when the light shows *go* you stop; when the light shows *stop* you go."

If it is true that we need a standard on signals, we certainly need a standard on signs. We all believe in signs to a certain extent, and if we could look forward just a moment and see ourselves driving around the United States, realizing that in every community in which we went we saw a particular sign, and it had the identical meaning, and it looked just like the sign we had seen in the other places, and we were to do the same thing when we saw that sign there as we did a thousand miles away when we started our trip, what a convenience it would be to drivers. What a saving of lost motion and time in finding out what to do, and furthermore what a great advantage it would be for human safety, because when a driver spends his time finding what to do instead of doing it properly, accidents are unavoidable. I think there is no need of expatiating on the desirability of standardization throughout the country so far as we can get it.

Now, as has been mentioned by your Chairman and by Mr. Kelcey, the report proper is put out as a tentative practice, as a suggested traffic practice. It is impossible at this stage to get a standard that is going to be suitable for time immemorial and will be adaptable to every condition and suit everybody's whims. Here is the first step, however, to bring out something that is as near standard as you Committee has been able to secure at the present time, and which, if used, will bring out its own inefficiency and greatly help to develop a standard which will ultimately, we hope, be utilized throughout the country.

The Committee in its considerations felt that it should give attention to several phases of signs. It should have effective signs. It should have signs that were standardized, and, because of the need of standardizing signs, it felt it was necessary to group those signs, because of various meanings, into certain classifications, which classifications could therefore be standardized.

An effective sign must have a clear meaning, be easily read, be in understandable English, and be something that will attract attention and tell the message quickly. If it is going to take time to read a sign, decipher it and understand it, you are going to delay traffic, and you are going to do a lot of things you ought not to do. A sign should attract attention immediately. If it is a sign that requires immediate obedience, it should be placed where that obedience is to be given. If it is a sign that requires caution at some future place, it should be so located to give proper warning to the motorist that he is coming to that particular place where caution is demanded. A sign should of course be visible—not only visible in the day time, but equally visible at night, particularly those signs that are giving definite local instructions on what to do, and those signs which are giving information as to how to do it and where to go.

For a day sign the color combination had to be given consideration. A sign had to be produced that would give a good visibility under average daylight conditions. So the coloring of the signs had to be given considerable thought, not only to get a combination that would be contrasting between groups, but would also give a good visibility under varying conditions. And then in order to have it illuminated properly at night, the Committee has made several recommendations in the order named: (1) That the sign have an attached light close to it that will illuminate the face of the sign itself; (2) That it have self-luminous letters to make

the sign stand out; (3) That it be placed so it can be illuminated by existing street illumination—in our modern broad highways and well lit streets, it is frequently possible to place signs so that the existing light of the street will illuminate the signs adequately. (4) By the use of reflected letters so placed on the sign and the sign so placed that the reflecting element of the sign will catch the head-light ray and reflect it back to the motorist, and the sign will then be illuminated every time the headlight strikes it. Beacon lights were considered, and it is suggested that when they are used they be used in conformity with the color meanings utilized for the signs in other places.

In order to have a good sign it must be well maintained. The Committee has just inserted a little clause calling attention to the need of maintenance. In my industrial safety work, I feel that one of the things that has gone against the reduction of accidents in industrial plants perhaps as much as any one element, is the lack of attention frequently given to signs in the plant. I was in a plant not long ago and saw a sign on a paint wagon that they were passing around between machines which said something about not smoking around that wagon, but you could not see the letters on the sign. Absolutely useless. When you have a sign you put it there for a definite purpose. If you let the sign go to pieces, you immediately indicate to the general public that somebody believed that was a good message years ago, but they forgot all about it and don't care about it today. If you are going to have a sign that means anything worth meaning, that sign should be maintained in the very best condition and kept up to date, for the psychological reason, not simply for the visibility—the psychology of impressing upon the people that the city still believes in that sign.

The sign should be properly constructed, of proper material. The Committee feels that in the construction of the sign first consideration should be given to durability, for the obvious reason I have just mentioned, and second to economy, but stressing the fact that durability is of first consideration and frequently covers economy in the long run, although it may produce the highest price for the initial cost.

The materials recommended by the Committee for signs in the order of preference are: cast metal, sheet metal or wood. They refer you to the specifications of the Joint Board of Interstate Highways of the United States Bureau of Public Roads, the American Association of State Highways Officials, and the United States Bureau of Standards for specifications as to materials and finish, including paint.

Now, in arranging for a standard sign there are several items that must be taken into account. First, the shape. If we could get a sign throughout the country that just by its shape means something to everybody, we will have a very excellent driving condition. If you could go through a town and, seeing a sign of a designated shape, you don't have to stop and read it, just think how that will help us; what an advantage that would be.

The matter of dimension is to be standardized to a certain extent. The shape is the predominant thing, but if we can have a standard on dimension, we will not have a heterogeneous supply of signs all over the country, and furthermore we will adhere to an economic principle, because mass production will be possible where the dimensions are standardized.

Coloring is very essential, just as essential as shape. If we have a combination of shape and color which means a definite thing, we certainly have gone a long way toward standardization.

For those who read we want a lettering that is more or less consistent with the use in other cities. The lettering is of importance, that is may have the same meaning here that it has somewhere else. But I said that thoughtfully—"for those who read"—it is the hope and the desire of the Committee, I think, that eventually the

shape and color will have a designation to the motorist that will have a definite meaning, regardless of whether he desires to read, can read or does read.

The height of the sign is something that affects standards, and something that should be given consideration, because if the proper height can be determined in a community, why not use that height pretty generally around the country, so the motorist will know that signs are at a given point and he will not be looking to the house tops nor down on the street bed for information. He will know just about where to obtain that information. In traveling around I have seen one-way street arrows painted on the surface of the street; I have seen them on a small post about eight feet above the ground; I have seen them on the side of a house where the name of the street is supposed to go. From the street surface to the second story of the house is the range I have seen these signs; so why blame the poor motorist who goes the wrong way on a one-way street if he is a stranger in the town.

For signs on movable posts in the roadway, the Committee recommends they be not over four feet high to the center and in requiring signs placed to catch the rays of the light, that they be not over three feet high at the center.

In the railroad signs we have adopted the specifications and wording of the A. R. A. The railroad crossing sign is the ordinary crossbar used by the A. R. A., black on white—location to be not more than 15 feet from the crossing. The A. R. A., I understand allows that sign to be placed at the side of the road or the center of the road. The Committee recommends that the center of the road is a dangerous location and should not be used. Railroad grade crossing approach, size 24 inches in diameter, with 2 lines drawn to form quadrates, with the letters R R in the upper quadrant, to be located 100 feet or less from the crossing. Where there is a street intersection between that 100 foot position and the crossing, your Committee recommends a second sign be used, calling the attention of the motorist coming from the side street that he is about to come to a crossing. The sign should be illuminated and the colors should be in accordance with the law, preferably yellow, or white if required.

If we may have the first slide: the STOP group as selected by your Committee:

(Here the signs recommended by the Committee were thrown upon the screen and described by Mr. Cole as follows:)

This sign is to be placed at the point where it is to be obeyed—namely, right at the property line. In the matter of colors we found that there were two more or less standard color designations for the STOP sign; one proposed by the Joint Board of Interstate Highways—black on yellow; and one proposed by the Traffic Signal Code Committee—white on red. The two were very divergent, and the Committee endeavored to obtain a sign they thought would meet the requirements. Our outstanding feeling was that red should designate STOP. We wanted to have the red apparent not only in the day time, but in the night time. We felt the red letters on the yellow background would be consistent with the Highway Department regulations, which is black on yellow background, in that the background would be the same. As the Highway official signs became illuminated, it would be necessary for them to get away from the black lettering and put in a black strip with red or white lettering. The Committee felt that the red lettering, although cutting down somewhat, as Mr. Kelcey said, on the visibility, would at the same time show to the motorist day or night a red designation; and we feel that it is very important to keep red as a definite commanding order to stop. So the red on yellow was selected for that purpose.

The diagram accompanying the report will have (as this slide has) dimensions concerning the size of the letters and the size of the sign.

The next set of slides is the SLOW group. They shall be diamond shaped signs; an 18 inch square placed as a diamond—the color black on yellow background—the design, the word SLOW at the top in small letters, the message in the center, and the direction at the bottom in the form of a symbol.

This particular one for Safety Zone has an arrow at the bottom, pointing to the right, and with provision that in those cities permitting automobiles to pass to the left of the Safety Zone, the arrow shall be double pointed. The same sign could be used at a street car crossing where the word CAR LINE would take the place of Safety Zone.

At the cross street, as shown by the next slide, the Committee feels in the matter of wording that the word SLOW, and later on the word CAUTION, are useful to place on the upper part of the sign for the purpose of designating and gradually educating the public to the meaning of the shapes and colors. In some of the signs, however, it is felt, because of the wording, that it would be perfectly permissible to leave the word SLOW or CAUTION out, this being one of them.

The next is the hill sign, to be placed on grades of six per cent or more.

The next sign, the curve sign, is to be placed on curves having a radius of not more than 600 feet. For turns having a radius of less than 200 feet, the turn sign with the arrow pointing in either direction.

The next group of signs, for which, unfortunately, we have no slides at the present time, is the CAUTION group, that the Committee recommends be the same color design as the SLOW group, but square in placement rather than diamond in placement. They shall be the same size, namely 18 inches; color black on yellow. Those signs will be the school zone signs, which would have the words SCHOOL ZONE in the middle, or the playground sign, having the word PLAYGROUND on it, and then the report provides for the use of that particular sign for any other condition that may be required for caution, such as "narrow bridge," "men working," "dangerous road," etc.

The next group of signs are the one-way and detour signs. The Committee recommends an arrow 30 inches long by 6 inches wide with the words ONE WAY or DETOUR, as the case may be, in black letters on a white background. It also realizes that some communities prefer to place that arrow on a rectangular background and provides in that case instead of using simply a cut out arrow, it may be painted on a black background 8 by 37 in dimensions.

The sign to be used for one-way streets and to designate that a detour is existing, will not contain information as to the direction the detour takes or the route, which will be taken care of by other signs, as is done on the highway.

The next group is the informational group, which are black letters on white background, the size depending somewhat on the wording to be placed on it, but generally to be multiples of six inches both ways, and to have the vertical dimension greater than the horizontal dimension unless otherwise specified. Those signs may be KEEP TO THE RIGHT, NO TURN, DEAD END STREET and the like.

The next slide shows the speed limit sign, which comes under the informational group; is rectangular; of same color; size, multiples of six inches. They recommend two sizes—the highest size used a 24 by 36. It is thought in many places in the city an 18 by 24 sign will be perfectly satisfactory; so we have allowed for both sizes, specifying, however, that the larger size shall be placed at roads on the entrance to a city, and that the smaller sign be used at such places as necessary throughout the city. The Committee also recommends a sign, not shown here, to designate the end of a speed limit. In the majority of cases, where one speed limit ends, another local speed limit begins, in which case the new sign designates the speed has changed. But to provide for those places where the community has a speed limit and there is no legal speed limit immediately following, the Committee has provided a sign which will show end of designated speed limit provided at that place.

The next group are the so-called restriction signs. The shape of these signs to be rectangular, to be size 18 by 12, 18 inches high. They are to be grouped according to the meaning they are to designate. The NO PARKING signs are to be red on white carrying out the idea of red meaning definitely to stop, or prohibition.

Those signs may be the one shown here, to be used near a street intersection, or one used near a fire house, in which the words FIRE HOUSE would appear; near a crossing; at a loading zone, and at a passenger zone, where a vehicle is allowed to stop to load and unload passengers, where the sign will change to NO STANDING—PASSENGER ZONE; near a fire house the word PARKING would be replaced by the word STOPPING.

The limited parking sign uses green instead of red, to be used where parking is limited, giving the time designation on the sign.

All other restriction signs are recommended black on white, with the exception of those pertaining to the pedestrian. The Committee does not feel that the cities should place signs against such practices as jay walking, which can more readily be taken care of by posters in the public safety campaign, but if there are places at intersections where it is absolutely hazardous for pedestrians to cross in a given direction, in those places small signs may be erected, rectangular, stating NO CROSSING, and we recommend for this purpose that blue letters be used on a black background.

That completes the signs themselves. The other part deals with the markings.

It was felt that markings on the streets are essential, particularly on obstructions in the bed of the highway, in order to attract attention to the obstruction that the motorist is meeting; that markings are valuable on curbs to designate certain loading requirements, and that they are valuable on streets for a number of purposes which will be mentioned; but the report calls attention to the fact that markings of any kind on street surface or curbs are subject to conditions of weather and are useless in snowfall. It recommends the use of markings as lines on pavement; colors on curbs; words on pavements or curbs, and cross-cut or checkerboard designs on obstructions.

Where the words are marked on the streets they should be very clear and concise; should be used just as sparingly as possible. There may be an advantage for a certain location to have a word or a message on the street, but the Committee feels that that usage should be very sparing and only where absolutely necessary.

There are several methods of marking. Round inserts, the committee recommends, should be of aluminum, non-rusting; steel, monel metal, brass or some other metal that will have a contrasting and bright surface to contrast with that of the other street surfaces. That this be not less than four inches in diameter, be securely attached by bolts, protrude not over one-half inch above the surface and have round edges. The report also provides for rectangular inserts which should be of a prominent color contrasting with the pavement; to be of brick, stone, rubber or metal, set preferably in line either continuous or broken, and placed so as to be flush with the pavement. Where paint is used it is recommended that the line be not less than four inches wide; that it be white or yellow if placed on bituminous pavement, and white or black if placed on concrete pavement.

In the matter of canvas markings, which have been utilized in some cities, it is recommended that white or yellow be used, and that the specifications for the canvas call for the placing of it on the pavement surface by someone and in a way that will hold up under any and all conditions. We feel that some canvas that has been used has moved around the street surface and has thus become practically useless.

In the matter of mushroom buttons, the Committee feels that those that project several inches above the sidewalk are detrimental to traffic and has recommended against their use. It has acceded to the use of them, however, at places that are barred to traffic, such as the center of a street, where rotary posts may be used, or something else to designate a no traffic space.

The Committee has taken cognizance of the flexible marker which can be made

of rubber or some other flexible material, which drops down to the street surface when struck by a car. Where they are used it is suggested they have yellow letters on black background, to be not more than 8 inches high or 30 inches long, and that they be so placed in the street as to be readily removed for replacement and in case of stormy weather, so they will not be destroyed by snow plows or other things.

In the matter of marking for railroad crossing the report adheres to the standard of the American Railway Association, that they be alternate strips, black and white, 9 inches wide on an angle of 30 degrees to the horizontal. Prominent obstructions in the roadway should be marked alternate black and white, 3 to 6 inches wide, at an angle of 45 degrees to the horizontal, or a checkerboard with squares 6 to 12 inches wide.

That, ladies and gentlemen, is a brief summary of the outstanding phases of the report dealing with signs and markings. It is the earnest hope of the Committee and of the American Engineering Council, to whom the Committee submitted the report, that traffic engineers throughout the country will consider this in the form of a hand book on best practices and will at least give it the most reasonable try out, hoping that experience will indicate the need for certain modifications and that ultimately we shall have a standard throughout the Nation.

CHAIRMAN POWELL: Should there be anyone who has any questions to ask, or any discussion with regard to this paper, we shall be glad to hear it.

FRANK L. GILLMOR (Columbia Casualty Co.): In showing those rectangular signs with the height longer than the width, the restriction signs, the diagram showed a sign with square corners. Those square corners to my mind present a slight hazard to pedestrians, in the way of tearing clothes and personal injury to children striking their heads against it, and it might be well, I would say, to incorporate some standard practice to round those corners to a two or three inch radius.

MR. COLE: That is included in the recommendations. The drawings from which these slides were made were preliminary drawings sent out for the Committee and the finished drawings have not been completed.

FRANK MATSON (Minnesota Railroad Commission): I am particularly interested in grade crossing protection. I understood Mr. Cole to say his Committee recommend that the proper distance for an approach warning sign at a railroad crossing to be 100 feet. Is that correct?

MR. COLE: Yes.

MR. MATSON: I would like to ask what consideration influenced the Committee to recommend that the approach warning sign be placed so close? In our State we find that about 400 feet is the proper distance. An automobile traveling at 40 miles an hour, which is the average road speed in our State, will go 100 feet in two or three seconds. I have not figured it.

MR. COLE: The report called for 100 feet or more, leaving it more or less to the State law. Please remember that this report covers signs in cities where speeds are lower.

MR. MATSON: Did the Committee consider any marking on a railroad crossing sign indicating more than one track? That's a problem we are working on now.

MR. COLE: That matter was given consideration and my impression of the reason in Committee was that we thought the main consideration was to call the motorist's attention to the fact that he was approaching a railroad crossing, and that he should govern himself accordingly; he should find out what was the condition at the crossing, and that if we tried to show too many designations, we would get into a multiplicity of signs.

CHAIRMAN POWELL: In cities you frequently find crossings that run to a great many tracks. If we tried to show by the number of lines on the sign the number of tracks, it would be more confusing than anything else. Whereas in the country

you have generally not to exceed four, generally only two, in the city you might run into a condition where you have eight or twelve. I know one crossing that has thirteen, and to put that number of bars on the sign would tend to obliterate it and make it confusing instead of helpful. So we discarded the whole idea, as Mr. Cole said.

BURTON W. MARSH (Pittsburgh): I believe it would be very helpful to some persons present if the Chairman, being Chairman of both the meeting and the Committee, might announce at this time when these reports would be available, as the budget making time in some communities is approaching, and I know a number of communities are waiting for this report to determine their sign program for the coming year.

CHAIRMAN POWELL: In response to that, before Mr. Marsh came in, at the introduction of the meeting I did announce we expected to put this report in press during the current month, and while I cannot answer for the printer's schedule exactly, I feel pretty sure this will be available for distribution about the 1st of November.

MR. MILLS: I should like to ask the Committee if any recommendation has been made for cities and towns for marking the names of streets. It seems to be a cause of considerable slowing up for the motorist in looking for street signs, which a great many cities have entirely omitted. Is that a function of this Committee?

CHAIRMAN POWELL: We did not feel that that came specifically within the scope of this report, because those are not traffic controlling devices, and we were confining ourselves to those devices used specifically for traffic control. I think, however, that the speaker is entirely correct that some effort at standardization in that respect would be most helpful, and it is quite possible if there was a demand made of that sort, that the Committee might supplement its present report with material on that subject later on.

A. P. VAN GELDER (Delaware Safety Council): I understood you to say that there was criticism of mushroom signs for certain places. I did not quite catch that. I would like you to make it a little more clear. We have in our city of Wilmington quite a number of mushroom signs that have been recently installed. They have a self-reflecting glass in them, and they are used at the unloading and loading stations of trolley cars. They seem to be very good in Summer. We have never tried them in Winter. I don't know how they would interfere with the snow cleaning.

MR. COLE: The Committee felt that where a mushroom button which protrudes above the pavement surface has a fairly good diameter, it was an obstruction to moving traffic if placed in the line of moving traffic. If placed on the side where automobiles would not go over it, it would have use; but where placed in the middle of the street, the Committee recommended against the practice.

MR. VAN GELDER: What would you substitute for a trolley alighting station?

MR. COLE: There is another part of the report which deals with the proper marking for alighting places of trolley cars.

CHAIRMAN POWELL: We followed explicitly the recommendations contained in the report of the Model Ordinance Committee, which has just been published. They recognize two classes of alighting zones for street cars: one with the raised platform, and the other one without a raised platform but still equally well protected. They then mentioned there are two other types used which are not recommended. One is the type which has simply a pavement area that is protected by movable signs to be taken away at times of the day when not needed, and the other is the type of pavement simply outlined with a mark and possibly with mushroom buttons as well. Neither one of those are recommended by the Ordinance Committee or by our Committee. We feel they are hazardous rather than advantageous.

MR. VAN GELDER: Our case comes in the second classification, but I do not get yet what you do recommend.

CHAIRMAN POWELL: We recommend either the raised platform or the alighting zone without a raised platform that is adequately protected by a massive obstruction at the approach end for traffic and that is properly lighted and marked, and having a sign on it marked SAFETY ZONE, such as you saw here, and then protected along the side of the zone facing traffic by adequate posts not more than 8 feet apart.

MR. VAN GELDER: We had posts. Our community did not like them as well as the mushroom button. They were all the time getting out of place.

CHAIRMAN POWELL: Permanent posts; not movable.

How the Signs Fit In

MR. MORRIS (University of Massachusetts): If I understand Mr. Cole correctly, he mentioned that they had a NO STANDING and a NO STOPPING sign in addition to NO PARKING. As parking is usually defined as stopping longer than necessary to load or unload, I was wondering just where the NO STANDING sign fitted in. What's the difference between NO STANDING and NO PARKING?

MR. COLES: NO PARKING permits you to stop a vehicle long enough to load or unload, where the driver may be off the vehicle and the vehicle left for some time. NO STANDING permits a car to be halted momentarily to let off a passenger with the driver still at the wheel. Stopping is to stop for any purpose at all. There are these three grades. In front of a fire hydrant, for instance, it is absolutely wrong to leave a car parked. It would be no danger, however, to have a car temporarily stand there, and let a passenger off, if the driver is right at the wheel. Nor would there be any hazard in having him stop there for a moment.

MR. GILLMOR: It has occurred to me that in a good many cities the trolley passengers board the car at the near corner. In many cases the bus stop is also on the near corner, making quite a congestion of traffic, and especially at the busy times of the day, around five or six o'clock in the evening. Often just a short distance away, a matter of a hundred feet, there will be a fire hydrant. It has occurred to me in lots of cases that the transportation companies would not work any hardship on their passengers to make the fire hydrant zone an alighting station for bus passengers. Probably the average fire hydrant is not used more than once or twice a year. There is always ample warning for a vehicle to get out of the way, if they hear the fire gongs coming, and in a congested location like that there is usually police protection in addition; and it strikes me that it would increase the efficiency of the street to a large extent, if the fire hydrant zone were located within 100 or 150 feet of the crossing, to use it as an alighting zone for passengers for busses, instead of loading at the corner and possibly holding the general traffic after the lights change, due to the loading of the bus.

ERNEST P. GOODRICH (Chairman Engineering Committee, National Safety Council): Here in New York the street cars stop on the near side and the busses on the far side.

CHAIRMAN POWELL: I find our time is rapidly passing and we still have one more speaker. Mr. Ernest P. Goodrich, Consulting Engineer, New York, and who has perhaps had as wide an experience in traffic matters as anyone in this country, and he is going to tell us something about when traffic signals are justified.

When Are Traffic Control Signals Justified?

By ERNEST P. GOODRICH
Consulting Engineer, New York City

At one of the early meetings of this Congress an eminent traffic expert described some of his observations with reference to traffic signals. In one case he had discovered that the installation of a signal had produced more accidents than had occurred in its absence. That is a direct challenge to the general theory that the installation of a signal will prevent accidents. Another case was mentioned of a community where an appropriation of one hundred thousand dollars was being made for the coming year's traffic installation work, but it was on the understanding that one-thirteenth of the appropriation should be used in each of the thirteen wards of the city, whether the traffic required that particular distribution or not. The Committee on Signs, Signals and Markings, of the American Engineering Council points out that the improper location of signals, or their installation if they be too numerous, is apt to breed disrespect on the part of many a motorist. If he is required to stop too often when there is no traffic interference involved, he will try to jump the signal—move on the red, and otherwise disobey the law.

In many cities the installation of lines of signals on certain streets is pushing the motorists onto other streets where the delays which are always incident to every traffic installation do not occur, but thereby creating extra hazards on those streets, particularly to children. Not long ago the writer took occasion to invite one of the traffic officials of New York City to lunch, with the object expressly in mind of asking him not to install traffic signals on all the north and south traffic lanes so that one could travel on at least one street without having to stop every two minutes to wait for the signal. Another reason for the lunch was to submit the suggestion that a different type of signal be installed in New York than is now so universal. If the progressive system were used instead of the stop-and-go, there would not be the objection which the writer had raised to the installation of the traffic signals on all the avenues.

In other words, there should be a balance between the profit and loss at any intersection or any group of intersections, if a truly engineering or scientific or economic determination is to be made as to the adequacy or justification of any signal. Judgment must enter to a certain extent; but not to the extent which occurs under the usual method of today, when the traffic official, or the mayor, or the Commissioner of Public Works or somebody else, goes out through the city and says "We ought to have a traffic signal here and there and over there;" or for an alderman when an accident takes place perhaps due to an improper crossing condition or to the location of an intersection at the bottom of a hill, to go to the next meeting of the Council and say, "I want a traffic signal installed at my corner within the next month." It may be that no accident is liable to happen at that intersection again for the next ten years; still he wants a signal at that point.

In New York, for example, the first signals that were installed on Fifth Ave. at 23rd and 42nd Streets were shown to have increased the accidents at those intersections because they were placed in the center of the streets on islands. In another city a traffic signal was installed about half way up a long hill where an intersecting street entered, and the signal had to be replaced once every three months on the average. Inevitably, wherever a traffic signal is installed, there is a loss of time to vehicles which pass that intersection, because part of the time as it is normally operated today, the signal is set against traffic and it has to wait. In a group of signals on the progressive system, the two ends of that group have the same sort of traffic loss involved. If the signals are entirely independent, each one of the signals has the same effect in slowing traffic.

Now, the value of vehicle time has been studied to a considerable extent by various engineers. Some place it at five cents a minute; some say four cents a minute; some as high as ten cents. If you have been involved in the loss of a train caused by a traffic delay, you will place your time considerably higher than five cents a minute. Many arguments have been put forward to show that in the long run a motor truck going over a road can adjust its time so as not to involve a loss due to a traffic signal. By and large, throughout the year, taking the cost of taxicabs and the cost of motor trucks by the hour, five cents a minute is a pretty good figure to assume as the cost of vehicle time including the passengers; with one cent a minute for pedestrians. But, on the other hand, by and large, all the vehicles in a community are slowed down and it costs someone money to do that. It costs in the gasoline which is burned while the motor is running; it costs in extra wear and tear on the brakes and on the tires because of the stopping and the starting, and there are other actual material costs which are involved. On the basis of sound engineering economics a traffic signal should be installed only when or where the annual costs for interest, depreciation, maintenance, operation, and evaluation of delay created, will be less than the benefit which its operation would produce in reducing and/or preventing delays and/or accidents at any installation point.

The possibility of reducing traffic delays will depend largely upon traffic density. The possibility of reducing or preventing accidents will depend upon their causes. In general, two major accident causes exist; the first is traffic density, and the second is some local physical condition such as a blind corner or a steep grade. Physical conditions must be treated independently of traffic density requirements, and are not here considered.

The capital investment of a signal installation must be estimated for each separate intersection because conditions differ widely. A study must be made of the type and design of fixtures which are required under existing and probable future traffic flows. Whether a single centrally suspended fixture should be used, or whether four, two-way, corner, three-light, post, fixtures should be employed under local or central control would make a vast difference in the first cost. Often the control of a single intersection would be useless, whereas the installation of signals at a group of related intersections would be well justified. In addition to fixture costs, estimates must be made of power lines, whether on poles or in ducts, and of the costs, if any, of cutting and restoring pavements.

The annual charges include the usual economic ones of interest, depreciation, cost of power, maintenance, and replacement (every signal is run into at some time or other) together with the estimated value of the delay-time caused by the signal, and possible increases in accidents. The total value of delay-time per year created by the signal will depend upon the distribution of traffic throughout the twenty-four hours, throughout the days of the weeks, the months of the year, the hours during which the signal is operated, and to some extent upon the cycle employed. Diagrams of typical hourly, daily, and yearly distribution have been published from time to time in the technical magazines and are also to be found in Volume III of the Regional Survey of New York and Its Environs, "Highway Traffic" (pages 76, 78, and 79). It may possibly be advisable in some instances to operate a signal only a few hours a day during only the summer touring season.

The credit items which relate to intersections where signals are to be considered include the salary of a policeman if then employed, and if the signal installation will eliminate the need of such officer. The proportional part of the time of the officer is to be computed where a reduction can be made in his previous duties. The report of the Cleveland Automobile Club with reference to a proposed traffic system for that city gives a review of the savings in police time, estimated by various Chiefs of Police in other cities, and is the best résumé with which the writer is acquainted in that particular item.

At points where accidents have occurred which could not be eliminated by other local means, it is good practice to evaluate the cost of such accidents over a period of not less than five years and take an average per year. The tentative report of the Committee on a Standard Code for Street Traffic Signs, Signals and Markings of the American Engineering Council states that 77 cities out of 85 report that the installation of signals has reduced vehicle collisions, the percentage of reduction ranging from 10 to 95. In 68 cities out of 79, signals have reduced pedestrian accidents, the reduction reported being from 15 to 100 per cent. The statistics committee of the first Hoover Conference on Street and Highway Safety gives an estimate of \$5,000 for each fatality and \$175 for each personal injury involving damage other than fatality, with \$50 for the average property damage.

There is in addition, the time loss which is experienced by traffic passing through any uncontrolled intersection, due to the entangling, the confusion and congestion which occurs when vehicles try to use such an one with fairly heavy traffic. Some years ago an experiment was made for about a week on Fifth Avenue in New York City when the police officers were taken out of the street and put on to the curb and told not to suggest to drivers how they were to proceed, to leave them to their own devices. Naturally the writer spent many hours watching the scheme. It was not uncommon to find four vehicles interlocked not alone for seconds but minutes, at the intersection of Fifth Avenue and 43rd or 44th Street, for example; a vehicle would come up behind on each one of the traffic lines, so that it would be almost impossible for that unlocking to work itself out. The policeman on the curb would then go out and make one back up when he did not want to do so and finally get things straightened out. What might be called helter-skelter traffic involves losses to the community through delays of this kind and must be evaluated. The report of the Engineering Council Committee stated that in 70 cities out of 88 the installation of signals has expedited vehicular traffic while in 46 cities out of 78 there has been an increase of street car movement.

The valuation of this benefit is intricate and time will not permit its discussion in this presentation. It may be stated, however, that where it is believed that traffic can be expedited, a valuation can be placed upon this feature by multiplying the total number of vehicles per year by the number of minutes which the traffic can save between the limits of the signal installation, and multiplying this quantity by the value of vehicle time at five cents per minute. An accurate determination of such a figure involves careful traffic tallies and their analysis, at rather heavy cost. It should be stated, moreover, that rough estimates based on inadequate information are practically useless.

An example will be illuminating. Assume \$2,000 for the first cost of installation. Assume interest at 5 per cent, depreciation at 10 per cent, maintenance at 20 per cent and cost of power at \$200 per year which is equivalent to 10 per cent. These total 45 per cent making an annual financial cost of \$900. Assume further an intersection with an average main line traffic of 10,000 vehicles per day and a cross traffic of 5,000 vehicles, during the hours when the signal will be in operation. This ratio of traffic would indicate a two to one ratio of the parts of the cycle ignoring the gaps between changes. One-third of the main line vehicles would be halted on the average during one-half of the corresponding "stop" period; while two-thirds of the cross traffic would be halted one-half of its "stop" period. Assuming that this traffic moves during 300 days per year on a 90 second total cycle, it is easily computed that the delay will amount to 750,000 minutes. At five cents per minute this aggregates \$37,500 per year. The total cost per annum is thus \$38,400.

Against this figure are to be set up the annual salary of a policeman, for example; or, if a fatal accident has happened during a five year period then an offsetting amount of \$1,000 can be applied. Again, a total traffic of 4,500,000 vehicles per year might be demonstrated to have experienced an average delay of 12 seconds at that intersection. It is easy to compute that the value of such total

would aggregate \$45,000 per year. Attention should be called to the large computed monetary cost of delay inevitably produced by the operation of a signal.

Another method of approaching this problem is by an analysis of the traffic at any intersection in the light of the reasons which have been advanced why signals should be installed. As to this matter the tentative report of the Committee on Standard Code for Street Traffic Signs, Signals and Markings of the American Engineering Council, issued under date of August 1st, 1928, in the section which introduces the subject of street traffic control signals reads as follows:

"The most generally effective mechanical device employed to increase safety and to facilitate traffic at intersections on city streets is the automatic traffic control signal. The principal reasons why signals should be installed are:

- (a) To increase the safety of pedestrians and vehicles at congested intersections;
- (b) To facilitate the movement of traffic with a minimum of delay at congested intersections;
- (c) To provide for the continuous movement of traffic throughout the length of a heavy traffic route;
- (d) To interrupt a heavy traffic stream at intervals so as to afford opportunity for cross traffic to move.

There is a tendency to use traffic control signals unnecessarily. At times they are installed indiscriminately and without a proper analysis of the conditions and probable effects. They are frequently operated at times when there is no justification. As a consequence of ill-advised use, serious abuses arise, for example:

- (a) Impatient and reckless drivers disregard the signal "Stop." This habit threatens the usefulness of traffic control signals, for their value depends upon the confidence inspired by their observance;
- (b) There is a general dispersion of traffic from main thoroughfares to unsignaled side streets, where the volume of traffic and the accident hazard, especially to children, is greatly increased."

Some discussion has already been devoted to reasons (a) and (b) and computations with reference to (b), the facilitating of traffic with a minimum of delay will be given later. The need for (c), developing continuity of movement throughout the length of a heavy traffic route was disclosed more than fifteen years ago when an extensive diagram was constructed to show simultaneously for all of the intersections on Fifth Avenue in New York City between 14th and 59th Streets, the actual time for beginning and the length of each "stop" period created by the police officers on duty. At that time each officer was entirely independent. Some moved traffic with short stop periods and others with long ones.

It was an examination of this diagram which led to the invention, by the writer, of the Progressive System, but as far as the police were concerned the diagram resulted only in the first efforts toward coordinated control by hand semaphores. Studies with reference to the economic advisability of installing a large system are fundamentally the same as in the case of a single intersection, traffic conditions at all of the intersections included within the zone of influence of the complete system being studied and the total costs estimated for the several items already listed. In this connection it should be pointed out that a group of progressive signals will generally not produce any greater numerical inevitable delay than will be the case at a single intersection which carries the same total traffic.

With reference to reason (d) given in the Committee's report, the following mathematical treatment may be of interest. In order to make a comparison between the time loss before and after a signal is installed to handle a given traffic flow either existing or as may be estimated for some future date, certain formulae have been developed.

The first problem resolves itself into finding the time taken for a crossing vehicle to negotiate an intersection (including clearances) and the time spacing (taking account of clearance) between the main line vehicles.

Let V = Velocity in miles per hour of main line vehicles.

$$\frac{5280V}{3600} = \text{velocity in feet per sec. of main line vehicles.}$$

Let n = number per hour (average) of main line vehicles.

$$\frac{5280V}{n} = \text{spacing in feet (average) of main line vehicles, center to center.}$$

Let L = Length of vehicle

$$\frac{n}{5280V} - L = \text{clearance (average) between main line vehicles.}$$

$$\frac{n}{5280V} - L$$

$$\frac{n}{5280V} = \text{time (average) between vehicles (which in practice, however, actually move in groups with gaps)}$$

If $L=15$ this becomes

$$\frac{3600}{5280} - 10.2$$

(Note): For $n=750$ and $V=20$ this time spacing = 4.3 sec. and the clearance = 126 feet.

(Note): A vehicle will "nose in" with a spacing of about 75 feet at $V=20$.

At W miles per hour = $\left\{ \frac{5280W}{3600} \right\}$ feet per sec. } a vehicle will require

$\frac{10+b+L}{5280W}$ sec. to cross a lane of width = b plus 10 feet clearance (5 on each side) + length of car. This reduces to

$$\frac{3600}{5280} \frac{10+b+L}{W} = 0.682 \frac{25+b}{W} \quad (\text{with length of car} = 15)$$

(Note): it can generally be assumed that $b=10$, so this equals $\frac{23.87}{W}$ = the crossing time

(Note): If the boulevard stop is required of all crossing vehicles, as may be considered applicable in this case, so that $W=5$ miles per hour average, this = 4.8 sec.

There will be no delays under average uniform conditions if this equals the main line time spacing, or

$$\frac{3600}{n} - 10.2 = 23.9$$

This can be solved for n .

$$\frac{n}{3600} = \frac{W}{3600} + \frac{V}{10.2}$$

$$n = \frac{23.9}{W} + \frac{10.2}{V}$$

If $W=5$ and $V=20$, this becomes $\frac{3600}{4.8+0.51} = \frac{3600}{5.3} = 680$

Under such conditions, up to 680 vehicles per hour can cross without delaying a single main line vehicle. This gives a total of 1,360 per intersection, per pair of intersecting lanes.

A different approach can be made by using the maximum capacity of a lane as developed theoretically by the Regional Plan of New York and Its Environs, given by the formula.

$$C = \frac{5280V}{L + 0.733V + 0.072V^2}$$

Where V =velocity in miles per hour
and L =length of vehicle.

In this formula if $L=15$ and $V=20$
 $C=1820$

With this number per hour the average time, center to center of vehicles, is 1.978 seconds, and the gap between vehicles allowing for clearances is 1.125 seconds.

Assuming a crossing time of 4.8 seconds, it is seen that each crossing vehicle will reduce the possible number of main line vehicles by $(4.8-1.125) \div 1.978 = 1.857$.

In other words the maximum traffic per pair of intersecting lanes at an uncontrolled intersection can be found for the numerical conditions set, from the formula,
Main line traffic $\div 1.857 \times$ cross traffic $= 1820$.

Vehicles crossing in groups will decrease the number 1.857 to some extent because the clearance required by a single car is slightly more than that required between cars moving even at a low starting speed and because the average velocity W is considerably increased when vehicles move in groups.

Ten separate vehicles would delay full capacity main line traffic by $10 \times (4.8-1.125) = 37$ seconds, but a group of ten moving at 15 miles per hour at the minimum safe spacing and averaging 15 feet in length would require 19.2 seconds.

In other words ten separate crossing vehicles would reduce the main line capacity by 24.3 vehicles, while if grouped, the reduction would be only 9.7 vehicles. This shows one reason how and why a signal installation may be justified.

On the other hand, delays due to acceleration loss, congestion caused by slow cars, turning cars, over-cautious drivers, pedestrians on the roadway, etc., will increase the coefficient 1.857, while for other main line speeds, the figure 1820 will change. For a traffic density less than the maximum above studied, other considerations enter the problem.

Imagine a single vehicle on the cross street.

If the time spacing of the main line travel is greater than the maximum possible delay, two types of movement are possible.

(a) There may be no delay over a period t —a seconds, where t is the total average time spacing center to center of main line vehicles and a is the time taken by the main line vehicle to cover the cross lane including vehicle length and clearances.

(b) There may be some delay which can vary from 0 seconds to a maximum of W , where W is the crossing time of the cross street vehicle.

I.e. t =average time spacing (c.t.c.)

c =capacity time spacing (c.t.c.) at velocity assumed

w =delay=crossing time (with clearances) for cross traffic vehicle or group.

W may start at beginning or at end of t . The average delay will be the average of these two extremes within close values or $\frac{1}{2}t$.

First main line vehicle will be delayed $w - \frac{1}{2}t$

Second main line vehicle will be delayed $w - \frac{1}{2}t + c - t$

Third main line vehicle will be delayed $w - \frac{1}{2}t + 2c - 2t$

Mth main line vehicle will be delayed $w - \frac{1}{2}t + (m-1)c - (m-1)t$
 Where m is the largest integer in $\frac{t-c}{w-\frac{1}{2}t}$

the total delay D will be $mw - \frac{1}{2}mt + \frac{t-c}{0+m-1} \frac{mc}{2} - \frac{0+m-1}{2} mt$

$$D = m \left(w - \frac{1}{2}t + \frac{mc}{2} - \frac{C}{2} - \frac{mt}{2} + \frac{1}{2}t \right)$$

Hence $D = \frac{m}{2} (2w + mc - c - mt) + d$, where d is a factor which must be

added for the lost time caused by decelerating and accelerating. (A)

This ignores the possibility that the last delayed vehicle may experience no delay for a part of the time interval, unless the fractional value of m is used as a closer approximation.

If $w+c$ is less than t, the above formula will not apply.

In that case, the maximum delay may be w

the minimum delay will be 0

the average delay will be $\frac{w}{2}$

approximately

But for a period $t-w$ there will be no possible delay.

Therefore the average delay will be only $\frac{w}{t} \times \frac{W}{2} = \frac{W^2}{2t} = D'$ (B)

If $w=t$ and $m=1$

the long formula (A) becomes $\frac{1}{2} (2t + c - c - t) = \frac{t}{2}$

and the second formula becomes $\frac{t}{2}$ which is the same, as

should be the case (ignoring the part time delay of one vehicle as was stated above).

These figures for delay apply for each crossing vehicle so that the total delay caused in an hour to the main line vehicles will be the average delay multiplied by the number of vehicles crossing per hour. The crossing vehicles also will be delayed because they must come to a full stop and because they will often or usually have to wait for a main line vehicle to move out of the way. The time loss due to decelerating and accelerating may be taken at $0.3V$ seconds where V is in miles per hour. This is to be added to the delay found from one of the two above formulae, usually the short one with a different value of w. t will still be the time spacing on the main thoroughfare.

To find the delay to main line traffic at an uncontrolled intersection, per lane;

Let N = vehicles on main thoroughfare per hour.

X = vehicles on cross thoroughfare per hour.

$\frac{3600}{N}$ = time spacing of vehicles on main thoroughfare in seconds =

Let V = velocity on main thoroughfare in mi. per hour.

$\frac{5280V}{3600}$ = velocity on main thoroughfare in ft. per second.

Let $L+C$ = average vehicle length plus clearance.

$L+C = 25$ ft.

$$\frac{L+C}{5280V} = \frac{25 \times 3600}{5280V} = \text{time increment to allow for length of vehicle and clearance} = \frac{17}{V} \text{ seconds.}$$

Minimum spacing at velocity $V = L + aV \times KV^2$
 $= L + 0.733V + 0.072V^2$ according to assumptions of Regional Plan
 $= 15 + 0.7V + 0.07V^2$ for ease of application when $L=15$.

$$\text{Minimum time spacing } c = \frac{15 + 0.7V + 0.07V^2}{5280V} = \frac{15 + 0.7V + 0.07V^2}{1.47V}$$

$$= \frac{10.23 + 0.5V + 0.0477V^2}{V} = \frac{10.23}{V} + 0.5 + 0.05V$$

The long formula (A) then becomes

$$\frac{m}{2} \left\{ 2w + (m-1) \left\{ \frac{10.2}{V} + 0.5 + 0.05V \right\} - \frac{3600m}{N} \right\}$$

If all cross vehicles have to come to a stop before crossing then w can be assumed as
 $\text{lane width} + \text{vehicle length} + \text{clearance}$

$$w = \frac{10 + 15 + 10}{5280V^2} = \frac{35}{1.47V^2} = \frac{23.8}{V^2}$$

with $V^2 = \text{about } 6$, $w = 4$. This is also shown by observation to be correct.

$$\text{Then the long formula (A) becomes } \frac{m}{2} \left\{ 8 + (m-1) \left\{ \frac{10.2}{V} + 0.5 + 0.05V \right\} - \frac{3600m}{N} \right\}$$

$$\text{Let } V=20, \text{ then } c = \frac{10.2}{20} + 0.5 + 0.05 \times 20 = 0.51 + 0.5 + 1.0 = 2.01$$

which may be called 2

The safe capacity at 20 mi. per hour is $3600 \div 2 = 1800$ vehicles

It is next necessary to find m in terms of N . With $w=4$

$$m = \frac{w - \frac{1}{2}t}{t - c} = \frac{4 - \frac{3600}{2N}}{\frac{3600}{N} - 2}$$

$$= \frac{4N - 1800}{3600 - 2N} = \frac{N - 450}{900 - 0.5N}$$

$$\text{For example, let } N=1800, \text{ then } m = \frac{1800 - 450}{900 - 900} = \infty \text{ and the long formula is also } \infty$$

In other words every vehicle is delayed when the main line is running to capacity and is interrupted by one crossing vehicle.

$$\text{Let } N=1000, \text{ then } m = \frac{1000 - 450}{900 - 500} = \frac{550}{400} = 1 + \frac{150}{400}, \text{ hence } m=1$$

The main line delay will then be

$$D = \frac{1}{2} \left\{ 8 + 0.3c - \frac{3600}{1000} \right\} = \frac{1}{2} (8 - 3.6) = \frac{1}{2} \times 4.4 = 2.2 \text{ seconds}$$

plus loss due to decelerating and accelerating which may be taken at 6.

$$D \text{ therefore} = 2.2 + 6 = 8.2$$

If $X=500$, the total delay per hour to main line traffic will be 4100 seconds, which is 500×8.2

The delay per lane of cross traffic is to be computed as follows:

Let y = time occupied by main line vehicle to traverse (with clearance) the cross traffic lane. The crossing vehicle may arrive at any time from the start of y to its end. The average delay to a crossing vehicle is then $\frac{1}{2}y$ as far as the passage of the main line vehicle is concerned. If $y < t$ there will be some periods when the crossing vehicle would not be delayed. The length of such period

would be $t - (t - y)$ and the average delay would be reduced in the ratio of $\frac{y}{t}$,

so that the average delay would be $\frac{1}{2}y^2$. If $y = t$, the average delay becomes $\frac{1}{2}y$

as above. In addition to these delays, if the crossing vehicle is assumed to be required to come to a full stop, there is added delay caused by deceleration and

acceleration. The total average delay to cross traffic is then $\frac{1}{2}y^2$ + d . This is

seen to be the same as for the main line traffic with a change of variable from w to y .

There will be a cumulative delay exactly as in the case of the main traffic if y is greater than the t for the cross traffic. This is never the case under the assumptions here made that the cross traffic never exceeds that of the main line and that main line traffic has the right of way so that all cross traffic must come to a full stop before crossing.

The total cross traffic delay D^1 will then be $X \left(\frac{1}{2}y^2 + d \right)$

$$\text{But } t = \frac{3600}{X}, d \text{ may be taken as } 0.3V, \text{ and } y \text{ as } \frac{17}{V^2}$$

$$\begin{aligned} \text{Then } D^1 &= X \left(\frac{1}{2} \frac{17^2}{V^2} \frac{x}{3600} + 0.3V \right) \\ &= \frac{0.04X^2}{V^2} + 0.3VX \end{aligned}$$

If $V=20$ and $X=500$

$$D^1 = \frac{0.04}{400} \times 500 \times 500 + 6 \times 500 = 25 + 3000 = 3025$$

$D + D^1$ then equals $4100 + 3025 = 7125$ seconds per hour, when $N=1000$ and $X=500$ with $V=20$

The long main line formula (A) can be expanded as follows:

$$\begin{aligned} D &= \frac{X}{2} \left\{ \frac{49.6}{V^2} + (m-1)c - mt \right\} + dmX \\ &= \frac{X}{4} \frac{2w-t}{t-c} \left\{ \frac{49.6}{V^2} + \frac{c}{2} \left\{ \frac{2w-t}{t-c} - 1 \right\} - \frac{t}{2} \frac{2w-t}{t-c} \right\} + \frac{dX}{2} \frac{2w-t}{t-c} \\ &= \frac{X}{4} \frac{2wN-3600}{3600-cN} \left\{ \frac{49.6}{V^2} + \frac{c}{2} \left\{ \frac{2wN-3600}{3600-cN} - 1 \right\} - \frac{1800}{N} \frac{2wN-3600}{3600-cN} \right\} + 0.6V \end{aligned}$$

The cross traffic formula is:

$$D' = \frac{0.04}{V^2} X^2 + 0.3 V X$$

Then the total delay = $QX + \frac{0.04}{V^2} X^2$, where Q is a constant.

It is seen that the coefficient of X^2 is very small and that quantity can be ignored without material loss of accuracy.

Since practically every intersection at which a traffic signal is worthy of consideration, will have a line of traffic in each direction on each street, it is evident, under uncontrolled conditions, that each of the four intersections of traffic lanes will involve possible delays. Since the formula for the delay experienced by cross traffic is seen to give appreciable results only for the factor of deceleration and acceleration, a closely approximate method of computing the time lost to cross travel is to figure only that one element of delay for every crossing signal. Since it is very rare that the traffic on the main thoroughfares is the same in the two opposite directions, it is necessary to compute the lost time for each traffic lane separately. Furthermore, such computation must be made for each crossing lane with reference to each main line lane. Such a computation will not take account of possible simultaneity of arrival of vehicles in the two cross lanes and in the two main line lanes; a formula for which is not difficult of deduction, but the use of which is found to give such small results as not to warrant its use. Furthermore, the ignoring of the element of simultaneity practically counterbalances the element ignored in the cross traffic formula.

The above formulae are to be used in estimating the hour by hour delays at any intersection under uncontrolled traffic conditions. After a signal has been installed the following formulae apply:

Let q = total length of cycle

$\frac{q}{f}$ = be the length of the stop period for traffic N

Then $q = \frac{q}{f} + q \left\{ 1 - \frac{1}{f} \right\}$ = the length of the stop period for traffic X

Let $N + X = T$

$\left\{ \frac{q}{f} + q \right\} N$ = portion of traffic N which is stopped

$\frac{1}{2} \frac{q}{f}$ = average delay

$\frac{1}{2} \frac{q}{f} \left\{ \frac{q}{f} + q \right\} N$ = total delay of N traffic

$\frac{1}{2} \frac{q}{f} \left\{ 1 - \frac{1}{f} \right\} (T - N) q \left\{ 1 - \frac{1}{f} \right\}$ = delay of X traffic

Total delay = $\frac{q}{2} \left\{ \frac{N}{f^2} + (T - N) \left(1 - \frac{1}{f} \right)^2 \right\} = D$

To find the condition which will give the minimum delay, differentiate this with respect to X and equate to zero. Ignoring constants

$$\frac{dD}{df} = \frac{2Nf}{f^4} + (T - N) \left\{ -\frac{2}{f^2} + \frac{-2f}{f} \right\} = 0$$

$$-N-(T-N)(-f+1)=0$$

$$-N-T+N+f(T-N)=0.$$

$$f(T-N)=T$$

In words, this formula means that for minimum delay the stop periods must have a ratio which is the inverse of the traffic in the larger of the lanes in each of the two cross roads. The total delay can be computed from the following formula, using the total traffic in all directions in any application to a specific case.

$$\frac{T-N}{T} = \frac{1}{f} = \frac{X}{T}, \quad f = \frac{T}{X}, \quad f^2 = \frac{T^2}{X^2}$$

$$1 - \frac{1}{f} = 1 - \frac{T-N}{T} = \frac{T-T+N}{T} = \frac{N}{T}$$

$$D = \frac{q}{2} \left\{ \frac{NX^2}{T^2} + X \frac{N^2}{T^2} \right\} = \frac{NX}{T^2} \frac{q}{2} (X+N) = \frac{NXq}{2T}$$

$$D = \frac{q}{2} \frac{NX}{N+X}$$

As an example,

If $N=2000$, $X=1000$, $q=60$

$$D \text{ per hour} = 30 \frac{2000000}{3000} = 20,000 \text{ seconds per hr.}$$

$$20,000 \div 3000 = 6 \frac{2}{3} \text{ seconds average per vehicle.}$$

This computed loss of time is seen to be less than the loss found in the last example for uncontrolled conditions if the figures in that example are multiplied by four to take account of the four points of lane intersection and if it is assumed that the traffic is equally dense in both directions on each street.

The fact pointed out earlier, that groups of vehicles cause less delay than the same number of vehicles crossing individually because of the higher average speed of crossing, points to the advantage of holding crossing vehicles so as to force them to cross in groups whenever a main line of traffic is running at nearly its maximum capacity. Obviously this is accomplished by a signal and is the justification for its installation.

The general formula for the amount of traffic at which a signal becomes advantageous may be stated as that at which (the number of vehicles per hour on the main thoroughfare) plus (the number of vehicles on the cross thoroughfare multiplied by the difference between the crossing time of a cross thoroughfare vehicle and the time spacing between main line vehicles divided by the center to center time spacing of the maximum capacity traffic on the main thoroughfare) equals (the maximum capacity traffic in vehicles per hour at the assumed uninterrupted speed on the main thoroughfare.)

At 20 miles per hour this has been shown to be $N+1.857X=1820$ for a lane on each highway. Because of the presence of two lanes each way under ordinary circumstances, and for ease of use, this formula may be taken approximately as $N+2X=1500$.

The economic justification in any given case can be determined from the formulae for the delay under controlled and uncontrolled conditions by applying proper

monetary values to the difference in annual time loss and including the other economic factors listed.

Finally, some light may be thrown on the question of signal installation by observations made by the writer in Paris a few months ago. Several hours was spent every day watching the operation of the traffic system. Two years ago very careful counts were made in London and Paris, and also in New York, to see which of those cities had the densest traffic. Two years ago New York had denser traffic than either London or Paris at the points which are supposed to be densest. This year Paris had denser traffic than any point in New York, and it was therefore interesting to see how it was handled. In the first place, the traffic policeman now takes care of the pedestrian in exactly the same way he does of the motorist. All have heard of the old idea that the pedestrian in Paris had to look out for himself. Generally speaking, he does today, because he goes anywhere he pleases. Men and women were seen to start across the Paris boulevards in the densest kind of traffic. They deserve to be killed, because it would be of less damage to the community as a whole to have them out of the way than to have them there. (In Madrid a traffic policeman on horseback was seen trying to stop men crossing traffic.) In Paris the traffic policemen come on duty about nine o'clock. One has to hunt to find them. They are somewhere in a portico or by the curb, because traffic at that time does not need their assistance. It is only when traffic gets denser or perhaps a group of pedestrians comes along in a bunch, or there is a group of taxicabs interfering with things, that the police comes out and holds up his baton and lets the people get through and then goes back to the sidewalk. When the time arrives that the majority of his time is actually in the roadway, he stays there, and he manages traffic on the individual control basis until it gets still denser. Then, up the line a little way (two or three blocks) a gong sounds and from that time on a single red light system is employed which coordinates the traffic controlled by the individual policemen up and down the avenue for several blocks. The light is one red light only. It means STOP when it is on. Otherwise one can go, and it is the most effective traffic arrangement that the writer has ever seen. It beats infinitely that of the United States, with all our light systems. It is less costly. It applies when the traffic requirements demand, and it stops when they are through.

As a final suggestion—don't trust to individual opinion as to the need of a traffic signal on any one intersection or another. Study it out on a scientific basis, on a sound economic basis, and then you can go to your Councilmen and say, "We want a traffic signal here because it is worth while here; you are wasting money if you put it somewhere else." Then you have accomplished something, it is believed, to the benefit of the traffic control of the United States.

CHAIRMAN POWELL: I am sure that I can on behalf of the meeting thank Mr. Goodrich for this very interesting discussion of a topic which up to the present time, so far as I know, has never had any reasonable scientific approach. I think that Mr. Goodrich is a pioneer in this particular field, and while some of us have been exploring in a practical way somewhat along the same line, I am quite certain that he has opened out to us the really correct engineering approach to the problem.

While I am on my feet I just want to say this about his experience in Paris. I have not been there this year since the red light system was put in effect. I was there last year while they were installing it, and there is this to be said about the Paris traffic and its regulation, signal and otherwise. It is wonderfully handled, and for this reason: They have a most effective corps of policemen and plenty of them. At the Place de la Opera I counted thirteen on duty on an eight-way intersection into a large square. We would be lucky in this country if we had three in such territory. Those men every one of them are experts, just as our Fifth Avenue policemen are here, and that's why the traffic is satisfactorily handled.

I think that in part explains the satisfactory arrangement of traffic in Paris, not entirely due to the traffic system itself.

Are there any questions you would like to ask Mr. Goodrich, or any discussion you would like to indulge in, suggested by what he has given us?

FRED C. MILLS (Boy Scouts of America): Do the overhead installations, suspended signals, cut down the cost of replacement, and have they proved satisfactory?

MR. GOODRICH: They reduce the replacement cost but there are other disadvantages which in the view of this Committee have put the overhead suspension system down about fourth in the order of preference.

MR. MILLS: May I ask this: with the traffic lights at the intersection, just about how much has it slowed down traffic as compared with policemen at that intersection, one-half would you say, or a third?

MR. GOODRICH: That varies from city to city very materially. The information which was secured by this Committee with reference to these matters is to this effect: In 79 cities signals have expedited vehicle traffic; in 9 they have not. They got no data as to the amount except in a few cases. In 46 cities there has been an increase in street car movement; in 36 there has not. In 14 cities there has been an increase in traffic on streets equipped with signals, in 15 a decrease, in 15 no change. In 42 cities there has been an increase of traffic on adjacent streets; in 16 a decrease, and in 10 no changes.

One of the reasons for not installing signals when not needed is this: In 60 cities drivers tend to anticipate a change of signals; in 23 they do not. In 77 cities signals have reduced vehicle collisions; in 8 they have not. The percentage of reduction has been from 10 to 45 per cent. In 68 cities signals have reduced pedestrian accidents; in 11 they have not, the percentage of reduction being from 15 to 100. I might say, in amplification of what I did say before, that some engineers and statisticians figure one per cent per minute as the pedestrian time value, or 60 cents per hour. Sometimes it is worth more. Again if you are going to get killed it is worth less.

FRANK MATSON (Minnesota Safety Council): I would like to ask Mr. Goodrich what he thinks of the substitution of a caution sign, such as SLOW—CAUTION in place of a stop and go signal.

MR. GOODRICH: It depends on the amount of traffic. I would use all the other devices up to their limit, before I would install a traffic signal at any intersection.

MR. MATSON: What I meant was taking down the stop and go and putting up a caution sign.

MR. GOODRICH: That would depend on the amount of traffic. If it is above the figure disclosed by that formula, leave the signal in; otherwise shut it off and put up your sign.

ALEXANDER GAGE (Assistant Prosecuting Attorney, Wayne County, Detroit): I think in discussing these very technical papers we must not lose track of the law enforcement value of an officer as compared with an inanimate signal light. That is a consideration which is not perhaps in order in this discussion, but I think it might be well to remind the members of the fact that a traffic signal cannot assist in any way to enforce the traffic laws, and a policeman if he knows his job, can.

CHAIRMAN POWELL: Last Spring we had some studies made of actual traffic on some of the intersections in our city (Buffalo) that we felt were signaled when they should not be; that is to say, the volume of traffic was not sufficient to justify the utilization of the signal. We took a period of five hours observation on different days and at different intersections, but in the middle of day, when the traffic was supposedly flowing at about its normal rate, not during the peak hours, and during those five hours of observation we undertook to determine the traffic delay to the vehicles that were crossing the intersection from both directions. We

had, for instance, on the main street a total delay of 198 vehicles for a time of 40,590 seconds, while on the cross street 82 vehicles were allowed to pass; and a careful analysis of the time records that we got from the intersection indicated that those same 82 vehicles could have filtered through the other traffic with no greater delay than one or two seconds to each vehicle. The summation of the whole matter was this: For a period of 2½ hours a total of 602 vehicles on the main streets were delayed 13,420 seconds to permit without delay the cross passage of 308 vehicles. You can easily see how figures run up in totals when you come to aggregate them; and on the basis of those studies we worked out a final analysis which indicated that Mr. Goodrich's formula was very nearly correct, except that in our opinion we could easily put that constant up to 2,000 without doing any serious damage to the average traffic intersection; but we verified his figures very closely from actual practice.

ADJOURNMENT

October 4, 1928

Traffic Engineering

ERNEST P. GOODRICH, Chairman
Chairman, Engineering Committee, National Safety Council

The seventh session was called to order at two-thirty o'clock by the Chairman, Ernest P. Goodrich.

Practical Means of Building Safety Into Streets and Highways

By **ROGER L. MORRISON**
Professor of Highway Engineering and Highway Transport,
University of Michigan, Ann Arbor, Mich.

Whether any given means of building safety into a street or highway is practical, or not, depends, of course, upon various factors, and the most important factor is usually the relation between the cost and the available funds. Some safety provisions are so inexpensive that they are of almost universal application, while others are so elaborate that they are practical only on the most heavily traveled highways, and their use, to date, has been largely confined to toll roads. Still others seem practical only for the most important streets of the largest cities. In a general discussion of the various construction features for the promotion of safety it is necessary therefore, to use a rather elastic definition of the word "practical."

A few years ago a safe road ordinarily meant one over which a vehicle might proceed without being wrecked, provided it was driven slowly enough at bad places, but now a road is not usually considered safe unless it is reasonably so for high speed traffic. Many requirements for this kind of safety are more or less well known by the majority of people, but they are so often neglected that mention of them appears to be justified in any discussion of the subject.

Ordinary Safety Provisions

Surely nothing is better understood than the inherent danger in certain surface conditions, and yet loose gravel, for instance, is allowed to take its yearly, and even daily, toll of life, limb, and property. Clouds of dust on untreated gravel and macadam roads are often serious hazards, and wood block pavements on comparatively steep grades continue to claim their victims with every rain. Unnecessarily high crowns on many roads and streets cause drivers to hug the middle and add to the dangers of passing vehicles. Obviously they increase the hazard of skidding. Pot holes and ruts are all too common sources of danger.

According to *Public Roads* for March, 1927, about half of the Federal-aid projects completed in the latter half of 1926 had a surface width of 18 feet, and nearly 23 per cent were less than 18 feet wide. Doubtless there are many situations in which 18-foot surfaces are justified from the standpoint of economy but, with ever increasing speed, it would seem as if 20 feet should be the minimum width for main roads. Almost equally important is the width of the shoulders, which should be ample to accommodate parked cars and to safeguard those which acci-

dently run off the pavement at high speed. An eight-foot firm shoulder is none too wide and side slopes on embankments should be about four to one, unless protected by guard rails, to minimize the chances of overturning if cars run off. Where guard rails are used they should be of a type such as cable or mesh, rather than wooden rails which may splinter and cause death or serious injury if forced into a car. Deep ditches should be far from the pavement.

Comparatively few highways conform to the above widths, and still fewer do so for their entire length. The majority of bridges and culverts are little wider than the pavement and are frequent causes of accident. The ideal situation would be to have all such structures as wide as the pavement plus the shoulders and the present tendency is toward this ideal.

While considering the cross-section of the highway, another safety provision should be mentioned and that is a foot-path, or sidewalk. This is not a simple matter because, to be entirely safe, walk-ways should be located beyond the shoulders and side ditches, and if they are to be used, their grades must be practically as uniform as that of the roadway. Even if built upon the shoulders they would take pedestrians off from the pavement, and that is especially important when one considers the large number of children walking to and from school.

A minimum radius of 1,000 feet for curves is highly desirable and there should be a minimum sight distance of 500 feet at all points, including hill-tops and intersections with highways and railways. There are hundreds, and probably thousands, of dangerous intersections which could be made safer at comparatively small expense, by removing obstructions to sight. It may be mentioned in passing that many railroads conduct rather elaborate poster campaigns to minimize crossing accidents and then habitually spot box cars so close to crossings that it is impossible for a motorist to see an approaching train until he is practically upon the track.

The danger of long steep grades and of curves without proper superelevation and widening, where needed, is generally recognized and these hazards appear to have been eliminated to a much greater extent than most of the others which have been mentioned. The use of standard warning signs is also becoming very general.

Super-Highways

There is a great deal of question, from a safety standpoint, as to the best arrangements of multiple lane highways, meaning highways with more than two traffic lanes, and in the absence of a large volume of accident data, very dogmatic statements are hardly justified.

On highways where, at times of greatest traffic density, the travel is largely in one direction, a three lane highway, with the three lanes clearly marked, may relieve congestion without being any more dangerous than, if as dangerous as, a two lane highway, because overtaking vehicles in the direction of lighter traffic can enter the middle line gradually and dodge back if a vehicle traveling in the opposite direction starts to enter the middle lane at the same time. There appear to be a few comparative accident records which support such an opinion. On the other hand, with congested traffic in both directions at the same time, the danger of head-on collisions seems obvious, as there is no way to regulate traffic in the middle lane, and it is hard to see how a three lane road could be used safely under such conditions.

Whether or not pavements carrying four or more traffic lanes should be divided in the middle, to increase safety, also depends largely upon traffic conditions. Certainly if the volume of traffic is usually about equal in both directions, a divided pavement will be safer, with no danger of head-on collisions, but if traffic is predominantly in one direction in the morning and in the opposite direction in the evening, then both congestion and accidents may be less on an undivided pavement. In the case of a four lane highway there

may be more congestion on a divided than on an undivided pavement unless passing is permitted on the right, as well as on the left, side of overtaken vehicles.

It is to be hoped that, before long, definite data as to traffic flow and accidents upon multiple lane highways, under various conditions, can take the place of speculation and opinions based upon limited observations. The cost of such studies is insignificant compared with the large sums involved in construction.

Intersections

When considering safety, the short distances included in intersections become as important as the long distances between them, and in many cases this is also true of economic losses due to congestion.

The importance of adequate sight distance has already been mentioned, and intersections of trunk lines with secondary roads should be protected with "stop" signs on the latter. The proper and improper use of automatic signals is too complicated a problem for discussion within the limits of this paper, even though they may be considered as construction items.

At important intersections curved pavements are often built connecting the intersecting highways so that turns can be made safely at comparatively high speeds and the situation at the main crossing will not be complicated by turning movements. In some instances rotary intersections can be used to advantage, but here again we are handicapped by a lack of adequate data upon which to base the most efficient design.

The safest intersection is, of course, a grade separation. These have been built in Detroit, Chicago and a few other cities, and the famous toll roads of Italy have no crossings at grade. Usually the only real objection to a grade separation is the cost so that, theoretically, one should be built whenever the annual cost of the installation is less than the annual cost of getting along without it. The solution of this problem would be one of simple arithmetic except that the actual value of practically all the factors is unknown and must be estimated.

Looking at the matter as a purely economic one we have on one side the annual interest, depreciation and maintenance costs of the structure, and on the other side the annual costs due to delays and accidents. To put a reasonable value upon each of these items would take careful study of each individual case and then an estimate as to future developments.

For instance, taking purely arbitrary figures, it may be assumed that the cost of a certain grade separation is \$300,000, that it will be in use for 50 years, that the average interest during that period will be \$7,500, and that annual maintenance and contingencies will be \$1,500. The total annual cost, upon that basis, would be \$15,000. If the value of time for each vehicle is estimated at the very modest sum of one dollar per hour, and the average delay to each vehicle is 10 seconds, the annual cost of delays alone will be approximately equal to the annual cost of the structure if the combined traffic upon the intersecting highways is 15,000 vehicles per day. A study of the actual nature of the traffic, the delays, and the accidents, in any given case, might show that a much smaller, or much larger, volume of traffic would be required to justify an outlay of \$15,000 per year, and of course this sum also might be much smaller, or much greater, in different locations.

There is no hesitation about spending thousands of dollars in attempts to save a few individuals lost at sea, or in a mine accident, or other disaster which is more or less spectacular, and immense outlays are made by the railroads, often under legal pressure, to place added safeguards around the lives of passengers, where accidents are few, so that it seems hardly logical to place

the installation of a grade separation purely upon a basis of economic justification. However, the availability of funds is such an important factor that there seems little chance that such structure will be installed any faster than is warranted by economics alone.

As a safety measure, the elimination of railway grade crossings is, generally speaking, more important than the elimination of highway grade crossings, and we have discouraging reports that, in spite of the many separations being built, the number of grade crossings is growing larger instead of smaller. The situation would doubtless look much brighter, however, if it were measured in terms of some unit of hazard. It is not a highway crossing a railway which makes trouble, but a highway vehicle crossing the path of a train, so that the elimination of a crossing involving 50 trains and 5,000 vehicles a day may be as important as the elimination of a hundred country lane crossings of branch line railroads. The relation is not a direct mathematical one of trains times motor vehicles, because the heavily traveled crossings are better protected, but certainly one trunk line crossing eliminated and one wood-road crossing added does not leave the general situation unchanged, even though it may appear so upon official records.

Wide, smooth, level highways adjacent to railway crossings are extremely desirable and, as previously stated, everything possible should be done to remove obstructions to a clean view of approaching trains.

Closely related to grade separations is the matter of pedestrian subways in cities. When they are used then there is no question as to their value both in promoting safety and in relieving congestion, but if they are not used they represent merely a waste of money. Indications are that some subways are very successful and that others are almost complete failures, and sometimes there is a popular demand for more subways when those already built are not used. Careful observation of such installations should develop some valuable information as to the various condition under which pedestrians will, and will not, use subways.

There are two main phases to the problem of building safety into streets and highways. The first concerns ordinary thoroughfares and here the problem is primarily one of putting into effect the principles which are already well known to most highway engineers but which are often neglected, usually through lack of funds or the absence of enlightened public opinion to support the spending of money for increased safety instead of for other purposes.

The second phase involves the so-called superhighways, and especially those intended to accommodate very high speed traffic. Here we are confronted with a new set of problems to be solved, and mistakes in their solution will be tremendously expensive, not only in money, but probably in lives, personal injuries and property damage. Judging by what has already been done, notably in Italy, and by the plans which are being made by such cities as New York and Chicago, the day is rather fast approaching when motor speedways will be built right to the hearts of the largest cities, and much painstaking research will be needed to determine how to get the vehicles quickly and safely to their destinations, and what to do with them when they get there.

CHAIRMAN GOODRICH: As to passenger subways, I made a special trip in London a few years ago over to the subway intersection called the Elephant and Castle, where they have a multiple point intersection with very heavy traffic. It was so dangerous to pedestrians and they had had so many accidents, that they spent considerable money in making a passenger subway arrangement underneath the intersection.

All of the different entrances go to one space, perhaps as large as this room.

and I was very much interested to see how many people were down there. I counted three children on roller skates and myself as the total.

As an example nearer home, there is one over here on the intersection of Thirty-fourth Street and Sixth and Broadway. The railroad company has an underground passenger station which some of you might be interested in examining.

It is so arranged with reference to turnstiles that you can go down the stairs under Thirty-fourth Street and up the other side parallel with either Broadway or Sixth Avenue. You can also go down on this side of Broadway and Sixth and cross and up on the other side, and I have occasionally told my assistants to go down there and see if they could see anybody making use of that subway for other than station purposes and I never have found anybody who makes use of that particular facility to keep off of the street. There is more excitement in crossing the street the other way.

BURTON W. MARSH (City Traffic Engineer, Pittsburgh, Pa.): I would like to supplement the two cases cited by the Chairman, just to show how the present day pedestrian point of view is against the use of pedestrian subways.

In Pittsburgh we have a railroad station, the Pittsburgh and Lake Erie, which is a lower level than Smithfield Street. There is a very excellent, well lighted subway leading from the point where you must leave the station to the side of Smithfield Street which goes into the city over the bridge. You must go to that side in order to get to the street car, but the fact is that a very small proportion of the people will use this well lighted passenger subway, which requires that they climb no more stairs.

They will leave it entirely undisturbed and go up the roadway and just take their chances of going across which is very dangerous.

We also have another case in Pittsburgh on one of our heavy, fast-moving arteries, a boulevard. This was provided for an important intersection where there are a good many children crossing to go to school and also quite a number of people draining a certain district. It is almost never used. Part of the trouble there, however, is the conditions. It is not as good as it should be, but those cases do further supplement the Chairman's statement that in the present temper of the public mind the pedestrian subway, to my mind, has a very limited application.

MR. MILLER MCCLINTOCK (Harvard University, Cambridge, Mass.): I should dislike to see this discussion of separate grades for pedestrian traffic left in quite so pessimistic a condition. I agree in general that where you have erected a structure which requires expenditure of a considerable amount of additional effort as against the mere opportunity to take a chance, you usually take the chance rather than spend the effort.

Therefore, structures designed to make pedestrians use separate grades, must be designed in such a manner as to make it appear easy.

There are under Michigan Boulevard in Chicago two pedestrian subways, both of which are well constructed, policed and lighted. The one at Monroe Street connects with the suburban station of the I. C. Lines. It used to be necessary for persons who were going from the west side of Michigan Boulevard to this station, as they do in large numbers, if they wished to use this subway, to go down the steps, walk under the Boulevard, climb and then go across and then down again to the depressed platform of the railway station. Only 5,000 persons per day used this subway, a considerable number however.

Sometime after it was constructed the Illinois Central made a connection between the eastern end of this subway and the same grade down and without any steps, to a platform of the station. The last check we made showed a use of about 25,000 persons a day, showing how the greater ease resulted in very much greater use.

I have been in rather close contact with the pedestrian tunnels in Los Angeles in connection with their schools. They are called School Tunnels. They are used only at those places where there is heavy traffic and fast traffic in the immediate vicinity of schools and where it is not necessary to erect stop and go signals. These are widely used by school children. The school authorities do report (this is substantiated by actual experience) that a very considerable number of children who are crossing those streets do use the tunnels. There you have a child mind and opportunity to discipline.

W. B. POWELL (Buffalo): My experience in London, and I was a resident there twenty years, was that at least the times I used the subway it was very largely used.

Of course, it is a very bad intersection, and the reason why it is used so largely may be because the underground has entrance in the passageway also. You can go out underground and get out into any street you want, but certainly that subway is used very extensively.

CHAIRMAN GOODRICH: I want to explain, perhaps, that my various remarks after Professor Morrison's very interesting paper were to give the pessimistic side of those various things and I hoped that you would kick. There are other subways in London which are perhaps better used than the one at Elephant and Castle.

I should like to add not alone in reference to tunnels which are sometimes suggested for pedestrian travel but bridges also, that I have a photograph of a bridge which once existed on Broadway down the intersection of Fulton Street, a very congested intersection at one time and even more so than today. The picture shows one man leaning over that bridge and looking down on the people on what is called Death Avenue in Manhattan. The bridge was maintained for a long time over the railroad tracks.

I have stood there myself by the hour and have stationed assistants there to count the people who went over that bridge rather than cross this railroad trackage and truck delivery space, and have counted as many as three persons an hour using that bridge with 300 crossing on the surface.

At Forty-second Street and Fifth Avenue where there is a very large amount of traffic, ramps would be better than stairways, and in order to get people to go downstairs it would be wise to provide in the open space under that intersection all kinds of free advertising devices. Somebody who wants to introduce a new breakfast food could go down there and give away samples, and somebody else has something else for free distribution. Put them down there which is a good place to concentrate them for other reasons and at the same time attract people to go down there.

At the Forty-second and Fifth Avenue intersection the suggestion was made of carrying underground sidewalks from Fifth Avenue clear down to the Grand Central Station. That would probably be an inducement although a rather short subway from Twenty-third Street on Fourth Avenue, which was originally designed by the builder of the building as spaces where people could walk and could see displays and show windows which are placed down there, has proved absolutely useless.

MR. POWELL: The subway from Thirty-third Street and Sixth Avenue over to the Pennsylvania Station is very freely used, and you will recall the Stark case many years ago when they first put the bridges over West Street. Immediately they were very generously used and have had constant service ever since.

HENRY J. MINEUR (J. M. Horton Ice Cream Co., Inc., New York City): I can verify what the last speaker just said because I come by way of the Central Railroad of New Jersey and every morning and evening go across the river on the upper part of the ferry boat, and the upper parts of ferry boats are very much used and very few of the passengers go downstairs. In other words it is the main entrance and everyone takes advantage of it.

CHAIRMAN GOODRICH: We are concentrating this discussion on only one of the minor items in Professor Morrison's very interesting paper.

NORMAN ANDERSON (Ohio Bell Telephone Co., East Cleveland, Ohio): Is any stress being laid on the junction between the pavement and the shoulder?

I was reading in one paper about a man in Hagerstown, I believe; in passing a truck and trying to get back to the road the machine was overturned and he was killed.

PROFESSOR MORRISON: There is a good deal of difficulty there. I remember when they first started to build concrete pavements to any extent, fifteen or more years ago, there were all kinds of schemes of fluting the edge, etc., and trying to get away from the rut there.

I don't know of any remedy except constant attention to keep it so that they can run off and on without danger.

CHAIRMAN GOODRICH: We will have to interrupt this discussion now to take up the third paper on the program this afternoon.

Mr. Straus, of Macy Co., has suggested, as far as New York is concerned, a very interesting partial solution of one of our problems of trucking, and we will be more than happy to hear what he has to say along that particular line.

Off Street Loading and Night Deliveries

By PERCY STRAUS

Macy & Company, New York City

I have taken the privilege of enlarging my subject so as to include night deliveries with off-street loading. Both plans are the outgrowth of traffic congestion. Each plays into the hands of the other. Off-street loading will involve considerable cost. Night deliveries can be accomplished with little or no extra cost.

Off-street loading is the loading and unloading of trucks on private property instead of at the curb. It has three purposes: convenience, safety and reduction of congestion; incidentally, it has also a safety factor. It has been practiced for a number of years and in varying degrees by some express companies, some department stores, wholesale houses and manufacturers. Its purpose is to overcome the inconvenience of loading across a sidewalk with the attendant risk of pilferage and injury to passer-by, the delay involved in interference by sidewalk traffic and the congestion resulting to vehicular traffic of the parking of vehicles while loading at the curb.

To indicate how off-street loading is operated I am going to tell you what the corporation with which I am associated has done to accomplish it. When we were located at 13th to 14th streets and 6th avenue our method of receiving was to have the trucks that brought us merchandise back up against the curb, then to carry packages and cases to the receiving elevators. Our delivery wagons also backed against the curb, the drivers would bring packages from the basement in hand trucks, assort the packages on the sidewalk and then place them in the wagons in the order in which they were to be delivered. Furniture deliveries were similarly handled, with the additional risk of damage by rolling and carrying heavy pieces across the sidewalk. The trucks that were used for transporting packages to outlying delivery depots, for delivery next day in the suburbs, were also backed against the curb. These trucks often remained for hours at the curb while the loads were being assembled, as they could not leave until the last package of the day's sales had been packed, entered and loaded. This system is still used by a large number if not most of the large stores of the city. Variation is the change from horse-drawn to motor vehicles.

Today, our own method is radically different. For receiving, a platform approximately a hundred feet long has been built on 35th street at the west end of the building, far enough back from the building line to permit the largest truck to back up to it without obstructing the sidewalk. In addition there are two large elevators capable of raising the largest trucks to the floors on which merchandise is received, thus saving in the case of full truck loads, the expense of unloading first onto the platform, then into the elevators. Thus the receiving of merchandise can be carried on without blocking the sidewalk, except for the time necessary to back across it and at considerable saving of time to the truckman.

At present for package delivery purposes two basements of a building 125x200 are used. Motors are taken down to them by two short-run elevators. The saving of time, wear and tear on packages and protection from rain and snow, cold and heat has justified the cost. Packages are carried by moving belts with only one rehandling from the sales floor to the platform on which they are separated into loads for each wagon. The drivers can assort their loads protected from the elements and with the assistance of labor saving devices that speed up the process.

In addition, the removable bodies of large trucks that transfer the packages to delivery depots for suburban customers are loaded in one of these basements. Similar methods differing only in detail are employed in those depots and at the warehouse from which furniture and bulk merchandise are delivered. At none of these are the sidewalks or streets used except for vehicles while in motion. That this method is a distinct contribution to the relief of traffic congestion will be realized when it is known that the number of motors loaded daily for delivery of packages, bulk goods and furniture varies from 188 to 290 (for store and warehouse totals, including all depots, are 271 and 453) per day and the number of trucks that come to the main building to deliver merchandise vary from 200 to 500 per day. If this number of vehicles could be accommodated at the curb it would result in a congested condition of the streets near our main building even worse than it is today, and that would appear to be an impossibility.

Department stores in Chicago have solved their problem by transporting all packages in bulk from their stores to remote delivery stations as we do with our suburban packages.

It may be contended that such methods, while adaptable to large institutions, could not be applied to small merchants and manufacturers, particularly in cases of multiple occupancy of buildings. This no doubt is true, but adaptations suitable to varying conditions can be achieved.

If the transportation engineers of the country were asked for a solution of the problem I have no doubt it would be solved for the small shipper as it has been for the large one.

In addition to the question of *method* of off-street loading, there is the additional one of expense. Where there is congestion of traffic sufficient to justify it, the rental values are so high as to make the cost of the necessary space a deterrent factor. Then, also, an emergency exists which justifies the city to interfere and insist that every step be taken to relieve the danger and cost of congested traffic. The limiting of the heights of buildings restricts the rights of owners of real estate no more than would the requirement to provide space for off-street loading. We will soon awaken to the fact that the need for the latter is as great as that for the former, and when that time arrives the necessary ordinance will be passed.

Although the apparent cost would be great there is an entry on the credit side of the balance sheet that is far from negligible, if not actually large enough to overcome the debit entry of first cost. This is explained by Mr. B. F. Fitch an authority on transportation in a letter which he has permitted me to see in which he wrote:

(A) "Dealing with heavy duty trucks, which are universally in service for wholesale loads, and as the missing link in transportation between premises of shipper and carrier, I can state with authority that the fixed expense of a commissioned vehicle, under single shift operation, is not less than \$5,000 per annum. In addition there is the variable wheelage cost, dependent upon mileage, which covers such items as parts replacement, shop labor, gasoline, oil, tires, etc. That can be estimated at a minimum of 25 cents per mile, and a maximum of 45 cents, the established records between being in ratio with administrative experience.

"These heavy duty trucks, built to the limits of legal restrictions, viz., 28 feet overall length, eight feet overall width and 12 feet, six inches, overall height, make possible, on conventional chassis, body dimensions 18 feet long and eight feet wide, or 144 square feet of platform area. If you divide this 144 square feet into the fixed expense, viz., \$5,000, of each commissioned heavy duty truck, it is evident that the annual cost per square foot of commissioned motor truck platform is approximately \$35. When you compare this with realty rates of from 60 cents warehouse to six dollars maximum office rates per square foot of floor area, it is evident the expense of motor truck platforms for rehandling and short-term storage purposes is prohibitive, but, under prevailing conventions, essential at New York, hence, the high cost of trucking.

"This fixed overhead of \$35 per nine hour day for each commissioned truck reduces itself to a minimum cost of three cents per minute, whether the vehicle is running or idle. When running only, there is an additional cost to be added to this three cents per minute of 25 cents per mile.

"My clocked observations in innumerable cases lead me to believe the average heavy duty truck is delayed at least one hour for hand unloading and reloading of contents, and this delay occurs at both ends of the route. Hence, there is an average of one hour idle time per trip, which, multiplied by a minimum of three cents, pyramids into a transportation cost of \$1.80 per load before you start to move it. If moved one mile at the prevailing average of truck performance, six miles per hour on Manhattan, the actual time consumed in transportation is ten minutes, which multiplied by three cents, plus the wheelage expense of 25 cents, produces an actual transportation cost of but 55 cents per load, burdened with the non-productive termini item of \$1.80 per load.

"Mathematically, if termini time of trucks can be reduced to five minutes, one truck can be made to do the work of three, but actually, with proper provisions, the reduction in number of licensed heavy duty trucks on the streets will make possible the maintenance of ten miles per hour speed, so that in reality one truck can be made to do the work of four, and when that transpires, there will be no traffic congestion of commercial vehicles."

Mr. Fitch continues:

(B) "At present every individual, firm and corporation, appears to think they are getting something for nothing if they utilize public thoroughfares for spasmodic short-time vehicle storage, up to the limits established by traffic regulations. In reality, if the larger institutions had recessed loading platforms, it would be possible to load and unload interchangeable automobile bodies as we do at Cincinnati while the truck is enroute,—thus, increasing the potentialities of all vehicles approximately 400 per cent, with resulting decrease in trucking expense.

"The investment covering rental cost of ground area so appropriated to loading and unloading docks, plus frozen capital in demountable bodies and mechanical devices for interchanging same, is but a small percentage of investment and maintenance expense of the larger plurality of vehicles, made necessary to accomplish the same results by present practice.

"When trucking activities are so recessed from the streets, the increase in curbstore frontage will prove the best possible attraction for automobile patronage.

That argument each merchant can best figure out for himself, but a consistently followed campaign to educate the public at large on this subject will accomplish much in the absence of our ability to autocratically impose recessed loading docks in all buildings.

"After the benefits are demonstrated by progressives, public sentiment will change, and the change will make possible mandatory ordinances. When that develops you will find marked relief to traffic problems, because thoroughfares will be open for continuous movement of automobiles, with a smaller number of slower acceleration trucks to retard the traffic flow."

Permit me now to turn to the question of night deliveries. That is the suggestion that all wholesale deliveries within the congested traffic zone, say below 57th street, be made during the hours when those streets are not otherwise busy, say between 8 P. M. and 8 A. M., the exact period depending on the varying conditions. Its purpose is to remove from the streets that part of the traffic which can without hardship be carried on at night, so as to release the streets to that extent for the use of that traffic which must be in motion during the day. To a certain extent that method is being followed today, but only in those cases in which the point of origin and the point of destination are both in control of the same interests. Instances of this, are the American Railway Express which transports its packages at night from one of its distributing depots to another and department stores which send their suburban packages at night to their suburban depots for distribution to their customers next day.

To increase the use of this method the following suggestion has been made: That all wholesale deliveries to business houses, including hotels, from docks, freight stations, and other business houses within the district specified should be made at night. It requires no great financing and it can be introduced rapidly with the co-operation of the common carriers, trucking companies, business houses and trade unions. It has two distinct parts, 1. The inter-city plan which covers the moving of commodities into the city from points beyond its limits, by railways and steamships or carried directly from point of origin to destination in motor trucks. 2. The intra-city plan which covers the moving of commodities whose transportation originates and—or finishes within the restricted area of the city.

As I have just said: The night delivery plan requires no financing nor much time in which to introduce it, it needs merely leadership which would bring about the cooperation of all factors concerned, the railroads, the steamships, truckmen, business houses and trade unions. It would reduce the day-time traffic of the streets by spreading the street load over the twenty-four hours, thus making more efficient the use of, by far that greatest percentage of the municipally owned part of the city. It would save time to all concerned by speeding traffic through avoiding congestion. Today traffic is slowed down and congested by slow-moving heavy trucks, not only when in motion, but even more when drawn up at the curb or when maneuvering to back up or when actually backed up against curbs. Whenever I have traced the congested street conditions on avenues or side streets I have invariably been able to trace it to those same causes.

(C) This plan should be welcomed by railroads and steamship terminals. The flexibility of hours of work under this plan makes it possible for the terminals to increase their capacity for the handling of commodities without the necessity of structural changes. It might even be workable to schedule the loading and unloading of freight at the terminals at different hours during the night and morning for different sections of the city. In any case, the increase in hours during which work might be done should make it possible to handle freight in a more methodical way. The minimizing of confusion which now exists at times at many freight terminals because they are forced to handle a larger tonnage than their facilities are equipped to accommodate, would speed up truck loading, and thus enable terminals to dispose of stored freight in order to make room for other

incoming shipments. This would redound to the advantages of the terminals and the truckman, and finally to business houses which would get their expected shipments more promptly.

The intra-city part of night loading, prescribes that commodities which are to be trucked from any point within the city into the congested district, shall be brought together at a dump or dumps during the day and sent to their destinations in the congested district during other than the usual business hours.

This lends itself to economical handling. All shipments going to one place of business or to a section may be loaded into a trailer or skid. This plan would make it possible for a few good loads at night to take the place of many single or small shipments during the day time. The successful installation of this plan would go a great way toward solving traffic problems by reducing the number of trucks going over the same routes.

Only those commodities should be collected at dumps which can be transported that way without adverse results to business. Many cotton and linen merchants of the city have expressed a willingness to have their shipments handled in this way provided the expense permits.

Preliminary cartage figures show a saving can be effected by handling yard goods by the dump system. Transportation charges, under this system, including assembling at a central point, are cheaper than sending small shipments into busy districts during the day time.

Rates paid by converters range from \$.65 to \$1.50 per case and \$.25 to \$.30 per package.

A straight rate of \$.23 per hundred has been quoted for handling merchandise from converters' establishments to dump and then to stores at night. (Cases do not average over 300 pounds.)

A survey made by the Port of New York authority shows that many trucking concerns and nearly all the railroad and steamship companies are willing to give the inter-city plan a fair trial. Of course, there must be sufficiently large tonnage shifted to night loading and unloading to make it worth while for the terminals to keep open. Considerable work has been done to make known to all just what the plans are, and how they will affect each one concerned. Many letters have been received from manufacturers and wholesalers indicating their willingness to cooperate. The majority of the large department stores have been interested in the plans and have expressed their willingness to do whatever is necessary to help the traffic situation.

In our organization we have found it of great advantage to keep our receiving platform open from 7 a. m. to 7 p. m. during the normal seasons, and from 7 a. m. to 10 p. m. during the rush periods. We are ready to shift our receiving hours as soon as enough business houses, terminals, and truckmen come to the realization that the time has come to take the step.

To quote Mr. Fitch again,—he says:

"The following three simple procedures will accomplish the desired results, less capital expense demands:

"(1) Night trucking of commodity and railroad freight. (Proviso: Large lots or bulk loads, not shipments of smaller consigners.)

"(2) An almost universal development of recessed loading platforms, at the plants of all large receivers and dispatchers of truck lots of freight.

"(3) Inland railroad terminal stations served by motor trucks, in lieu of railroad pier stations served by car floats, scientifically located with reference to traffic densities, instead of the present inflexible locations which impose upon shippers long expensive longitudinal truck hauls on Manhattan, which are the result of industrial extensions further and further removed from pier locations."

This last suggestion I will not take time to discuss. In conclusion I am going to

draw on that same authority Mr. B. F. Fitch again. In one of the series of letters previously referred to, he writes:

"I will ask you kindly to bear in mind that spasmodically our present problem, which is considered impossible of solution except at huge capital expense, has previously from time to time recurred in history and has solved itself less any capital expense. Thirty years ago there was more congestion on Summer Street in Boston than there is today, and also more congestion in the Boston Hay Market district than there is today. Sixty years ago there was more congestion at Fulton and Broadway than there is today—even a pedestrian overpass was necessary.

"Public cooperation and newer implements or devices for individual service have progressively solved all such problems. Group transportation opportunities of the horse bus eliminated a larger plurality of the vehicles of individuals, and in sequence, street cars of increased passenger capacity extended that. This history, with marked effect on surface transportation, has extended through and has been realized by elevated, subway and other developments, up to the present motor bus era.

"The bus and the truck as flexible units, not involving right-of-way investment and capable of greater passenger carrying capacity and freight tonnage capacity than automobiles and horse drays, are automatically decreasing the number of vehicles on the street. Hence, it is evident, after a careful historical review of the traffic problems of all cities, that newer developments, easy of individual adoption, have from time to time in operation adequately solved problems which until the advent of these newer devices were considered of an engineering and construction nature.

"Scientific increased usage of motor buses and heavy duty motor trucks will alleviate this situation even under a single shift operation. Hence, needless to say, under a double shift operation there is still a side factor of safety in the traffic flow capacity of our thoroughfares."

Of the two plans night delivery is the easier to introduce. It calls for no investment except that of initiative and leadership. It would relieve traffic congestion by removing from the most congested streets in the busiest time of day, the type of vehicle that occupies most space and travels slowest. It would release curb space for necessary parking. It would reduce the cost of heavy trucking by increasing speed and thus reducing expense and the result would be safer and pleasanter streets by day and useful instead of fallow streets by night.

CHAIRMAN GOODRICH: This is a very interesting discussion of a problem which is here in New York and extends to other cities as well.

I want to ask for only one discussion of this before Mr. Straus goes as he has another engagement, and I would suggest that the figure of eleven per cent as the total relative area of the city is very small and must include the outlying districts like Queens and Richmond because in Manhattan there are thirty-two per cent.

I would like to ask Mr. Simpson if it is in Detroit that a man has developed a night distributing scheme with keys to the warehouses of his patrons.

HAWLEY S. SIMPSON (Traffic Engineer, Newark, N. J.): There is no such organization there unless it has been established in the last two years.

CHAIRMAN GOODRICH: I am misinformed about Detroit. I have been told of this arrangement. A truckman developed a night distribution scheme, and he arranged with the freight houses which are normally open at night on the one side to give him delivery, and he arranged with his clients to take a key to their warehouses, which were rebuilt to a certain extent, so he could unlock the door, slip into a compartment of that warehouse the material which was destined for that particular plant, lock it up, and go on to the next company. They could unlock

the door from the inside and take out the merchandise that was delivered at night.

I was told that it was satisfactorily worked out for something like a year. I am sorry I cannot give you the exact location, but it is in exact line with what Mr. Straus suggested.

One thing more. There is good precedent for this night trucking. Way back in Rome in the time of Julius Caesar an order was issued that fuel could be distributed only at night. Then done by slaves on their backs normally; and they wanted the daytime use of the streets for chariots and people who were walking, but there is an indication of something which has had long precedent.

MR. STRAUS: All we need is Julius Caesar.

V. T. BOUGHTON (Engineering News-Record, New York): To what extent would you plan to carry out that night delivery, that is to these little shops on Thirty-fourth Street? You wouldn't consider them in the night delivery?

MR. STRAUS: For receiving of their merchandise I would.

MR. BOUGHTON: How would it be arranged? Would they have to keep somebody on duty at night?

MR. STRAUS: I think it would have to be arranged so that certain districts would receive their merchandise at certain times of the night. If you have been through here after six o'clock in the evening, you know that it is pretty dead. Almost all the side streets up to Forty-Second Street and possibly beyond that are practically deserted at night, and it would be easily arranged that their receiving clerk, or whoever they have do that work would come later in the morning and continue on later in the evening. Of course it would have to be arranged in multiple occupations that one individual receive the merchandise for the entire group.

I believe that shipment of these small stores, just like shipments of the large stores, by express or freight, should also take place at night.

Of course, it is out of the question to make deliveries to the householders at night. If that were possible it would solve department store difficulties tremendously. If we could get our wagons through the streets when they were not congested we would do away with large numbers of them.

MR. SIMPSON: I wonder if Mr. Straus has any figures on the relative risk of theft of merchandise from trucks engaged in night delivery and those engaged in day delivery.

MR. STRAUS: When this proposition was first suggested I wrote to a good many different organizations which are mentioned, and it was brought out by one of the members of the trucking association in a discussion of this suggestion that this was a possible difficulty. It was then taken up with the police department and they said they had no hesitation in saying that they could safeguard the streets at night just as well as in the daytime.

MR. SIMPSON: The reason why I asked that question is that when this proposition was brought up in Detroit the railroad terminal men said they would arrange to accommodate night delivery, and even expand their terminals as the introduction of night delivery would double or triple their business.

The truckmen said they would gladly carry on their work both day and night if the retailer and wholesaler would demand it, but they didn't see where they were going to obtain any saving because there would be so much thieving.

MR. STRAUS: There was a time not so many years ago when drivers were held up on the streets but with the increasing efficiency on the part of the police we don't hear of that.

MR. SIMPSON: I should like to ask Mr. Straus also if he can give me some information on the question of off-street parking for customers' cars within the period of time that they are shopping in the stores.

MR. STRAUS: That is a matter that has been very much discussed. I think

Franklin Simons is the only store in the city that is doing it, although it is done quite extensively in other cities.

We have discussed it and have made up our minds that we had no more right to pay for parking of customers' cars who come to us in cars than we had to pay transportation costs of people who come to us on trolleys or taxis. It would immediately create a privileged class of people if we paid for the parking of their cars, and we made up our minds it wasn't within our sphere. That, however, is just our point of view. Incidentally an extremely difficult one.

I doubt very much if it is so much a problem in New York as in smaller cities where they use their automobiles more for shopping.

CHAIRMAN GOODRICH: We want to thank you, Mr. Straus, for bringing this to our attention and explaining it as you have. It was a very illuminating discussion.

MR. STRAUS: I hope if there is anybody from New York who has an opportunity to press for that solution of night delivery, they will do it, as it is one way to give us some traffic relief in a hurry.

CHAIRMAN GOODRICH: We have a man here with us this afternoon who is very much interested in saving life. He is Mr. J. J. Hall of the Automotive Equipment Association. He has a scheme for a campaign and it will be well worth while to hear what he has to say.

J. J. HALL (Automotive Equipment Association): The Save A Life Campaign came out of Hoover's conference in 1925. Our Association had two men who attended that conference and when they returned a Committee on Safety was appointed.

The gentlemen on this Committee have done an outstanding job. First, they found out that you can group all causes of accidents under two heads: the human element which covers the greater number, and the faulty mechanism of the automobiles. So they tried to concentrate on these two real causes of accidents. They also found that the burden of highway safety has been resting upon the shoulders of the motor vehicle departments and it is impossible for them to cope with the problem today with too inadequate an organization. The state of New York has nearly 800,000 automobiles and only 75 inspectors.

Through experience in Grand Rapids, Michigan, our plan was brought up to what it is today. First the inspection as to faulty mechanism of automobiles was put under police supervision only, and it was proved that they could cover only 2,000 automobiles. The next year by enlisting the automobile dealers under police supervision they covered something like 30,000 automobiles in the same length of time. It also was brought out that in our safety work we must be spectacular and must use circus tactics if we want to attract the attention of the multitude of motorists and pedestrians.

A little over a year ago this plan was taken into the state of New York and Governor Smith issued the first proclamation setting aside the entire month of August, I believe, or July, asking all motorists to submit to a free inspection of their vehicles.

Then came the problem of building within a month's time a physical organization under the Department of Motor Vehicles. With the assistance of garages, service stations, etc., we provided something like 6,000 stations located in every town and hamlet through the state of New York. That made it possible for motorists to get inspection promptly. If a car was absolutely safe, the owner was given a sticker similar to this one which is now being used. That is part of the circus tactics. You must let them know that you have a campaign on. We check for seven things: brakes, horns, steering mechanism, mirrors according to the law of the states, etc., and at the end of the campaign it was found that over 40 per cent of the motor vehicles checked were found defective in one way or another.

We enlist the following agencies for support: First the automobile clubs, and in Pennsylvania the Keystone Club did an outstanding job for us in Philadelphia. Then we get the radio and the moving picture industry; we get them to send their cameramen to the state house and take a picture of the Governor signing the proclamation and the motor vehicle men inspecting the first car. In Pennsylvania it was estimated that the safety reel was shown to five million people in Pathe and Paramount weeklies. Then the press gave us something like 50,000 square inches of free publicity in Pennsylvania.

In New York we checked 1,250,000 automobiles and in Pennsylvania while the figures don't show this because it was hard to get back these reports from the dealers, anybody down there will know we did even better than in New York. It is estimated that we covered one million cars.

Here are some of the startling figures that were found. These are from the reports the inspection stations must give back to the state:

Brakes needing adjustment were found in 214,183 cars. Brake relining, 67,637. Lights needing adjustment, 450,912. Lights replaced, 33,118. Horns adjusted, 22,000. Horns repaired, 7,890. And here's a thing that is overlooked in safety work and is of vital importance—steering mechanism adjusted, 49,000. And steering parts replaced—many of the drivers didn't know that their steering mechanism was being held together by the last thread of the worm—22,545 new steering mechanisms replaced in those cars. Mirrors adjusted, 16,000, and those driving without mirrors contrary to the Pennsylvania law, 50,727. Windshield wipers adjusted were 29,000, and those driving contrary to the law 36,000. License tags corrected—tags down behind bumpers which in case of an accident could not be seen, 45,582.

Another thing we are checking for now is operator's licenses and this is putting a lot of money back in the state treasuries. You would be surprised how many are operating without an operator's license.

The deaths in Pennsylvania were 155 in April 1927, and with the cooperation of every agency possible and 7,292 inspection stations, that dropped down to 65 in 1928.

I talked to Commissioner Dill of New Jersey just before coming over here, and he told me that their deaths were 102 the month of September last year, and about 68 this month. Twelve states have adopted this policy and every state we have been in has asked us to come back again.

WM. S. CANNING (Keystone Auto Club, Philadelphia, Pa.): Mr. Hall stated that he was unable to give the number of vehicles in Pennsylvania inspected under this campaign. I cannot give it myself but in the last week of the campaign in driving 100 to 250 miles a day in various sections of the eastern half of the state, I counted every vehicle as I went by, those parked, some in the garages and some on the road, and between 85 and 90 per cent of these vehicles bore stickers showing that their cars had been inspected.

MR. HALL: We must adopt spectacular methods to attract the attention of every one, and when those stickers start to appear on the cars, as Mr. Canning just told you, it has a psychological effect upon everybody in the state, because it is staring the man behind the wheel in the face and is a constant reminder to him to be more courteous, more careful and more considerate. That psychological effect has had more to do with the success of these campaigns than any one thing.

W. B. POWELL (Buffalo, New York): I should like to ask if it is not a fact that having had the car inspected and gotten one of these stickers, which is in a sense a certificate of merit, many drivers are then prepared to go ahead and drive indefinitely thinking that their brakes are going to continue to be in order. A month after that sticker has been put on, they may be out of adjustment.

MR. HALL: The motor patrols of Pennsylvania recognized the stickers for two months after the campaign had closed.

While 75 per cent of the people react voluntarily, the other 25 per cent cause a great deal of trouble. The big problem is the "junk" that is on the road. This is the element that goes down to the junk shop and buys a car for ten, fifteen or twenty dollars without a top or windshield, and then crash into good cars and abandon the car and leave it. If there was a law requiring inspection every six months, it would bring that element right up to the surface and they would have to get off the highways. I don't know of any other plan that will remove the junk from the highways.

A. K. GAGE (Assistant Prosecuting Attorney, Wayne County, Detroit, Mich.): In reference to this paper that wasn't presented this afternoon, "The Value of a City Traffic Engineer to the Legislative Body," I think one of the things that the Safety Council can do and you gentlemen who represent the best thought in your various communities is to make a concerted attempt, well organized, to bring the legislative bodies of your cities and states to a proper realization of the value of a city traffic engineer to that community.

I mentioned this to several of my friends who are responsible for meetings, and they said, "Well, that is rather an embarrassing proposition, to ask professional men and business men to try to put across with the political body, the legislative body, a plan for further development of their professional activities."

I don't want to be disloyal to the wonderful city in which I live, but we had a very distressing example, it seems to me, in Detroit of the lack of appreciation on the part of our city council of the fine work that was done by Hawley Simpson and by his successor Harold Gould in the preparation of a comprehensive traffic survey.

At one of the opening sessions of this Congress the other day I made bold to remark that I thought Professor McClintock had overlooked the point that a traffic survey was somewhat analogous to an inventory, and consequently was more or less temporary, and I suggested to him that the best practice in many industrial plants today is to aim toward a perpetual inventory and keep constant check of outgoing and incoming merchandise and material.

If that is true in industrial plants, it certainly might be applied to the analogous situation of a survey of traffic conditions in a city. Of course, you have changing conditions throughout the length and breadth of your municipalities and states, but those changing conditions can be noted and provided for in your perpetual inventory.

We had a situation which I personally regretted when our good friend, Hawley Simpson, was permitted to get away from us. He went down to Newark, where I understand his efforts are being properly appreciated. And then we had that work continued by another good friend of mine, Harold Gould, who carried it on to a definite conclusion and produced a very fine piece of work from an engineering standpoint as well as from a practical side. It seemed to me a regrettable fact that the city council members seemed to lack appreciation of the material they had at hand. They would refer to it and yet they didn't seem to realize that it was worth while.

I would like to see some effort put forth to present this thing to the legislative bodies in our municipalities and in our states, to have them realize that we must have these facts and that a proper expenditure for this purpose is one of the most economical things that can be done at this time to get these facts and to keep them up to date. I think that is one of the things that the Public Safety Division of the National Safety Council ought to give their efforts to accomplishing in the next twelve months, if possible.

ADJOURNMENT

October 5, 1928

Open Meeting of the Committee on Personality and Public Accidents

SIDNEY J. WILLIAMS, Chairman

Director, Public Safety Division, National Safety Council

The eighth session was called to order at nine-thirty o'clock by Sidney J. Williams, Director, Public Safety Division, National Safety Council.

CHAIRMAN WILLIAMS: Inasmuch as the Chairman of this Committee has not yet been appointed by the President of the National Safety Council, I am calling this meeting to order and will state briefly how we came to have a meeting of this sort.

We, all of us, have been interested for a long time in learning more about the personal phases and the personal causes of accidents. All have agreed that it is a very important subject and that the personal element in causing or preventing accidents is greater even than the mechanical element. But that is about as far as we go. We talk about carelessness and inattention, but we do not know what they are, how they operate and how they are to be prevented, except through the mass education that we use in safety work.

A few months ago through action of our Public Safety Advisory Committee it was decided to set up a special committee which was given the name of the "Committee on Personality and Public Accidents." Our staff was asked to undertake some preliminary study of the subject, at least to find out what was known on the subject in this country or anywhere else and if possible to outline a plan for finding out something further.

We realized then and now that this would be difficult, and one reason why nothing more has been done on it so far is that the subject is very vague. Where are you going to start and how are you going to get at this question of personality and personal characteristics?

A Question to Be Newly Discussed

Without going any further into the subject matter of the discussion this morning, this committee was set up. This is the first time that the committee or any group has been called together to consider the question, but in the meantime our staff has carried on some preliminary work which has been in the hands of Mr. Baker who is here this morning and who is a member of the Engineering Bureau of our Public Safety Division at Chicago. Later on Mr. Baker will make a short report of what the staff has done so far, the plans that the staff has in mind, and we then want to have a general discussion. We want to have comments not only from the committee members who are here, but any of the rest of you who have anything to contribute, so that we can come out of the meeting at the end of the morning with a little more definite idea than we have now on the practicability of our going forward with certain investigations which we have in mind.

We have asked Dr. W. V. Bingham, of New York, to open this meeting with a paper which will be the only formal address on the program, and which will deal with some of his very interesting experiences in connection with work along this line which he has been doing for some of the public utilities corporations.

So I will introduce Dr. W. V. Bingham, who is Director of the Personnel Research Federation, New York City, and who, as many of you know, has been doing work in applied psychology in relation to industries and other enterprises, for a number of years.

Personality and Public Accidents—A Study of Accident-Prone Drivers

By W. V. BINGHAM

Personnel Research Federation, New York, N. Y.

Personality and Public Accidents is a challenging topic. It focuses attention on the people who are most apt to have accidents,—the "accident carriers," to borrow a medical term. These men are usually the ones who spoil our no-accident records. They injure themselves and their fellow workmen.

The Accident-prone Driver

These prone-to-accident men, when employed as street-car motormen or bus drivers have a large share of collisions. When operating automobiles or trucks or taxicabs, they fail to avoid some of the many hazards of the streets, or do the wrong thing in a sudden emergency, with appalling results in personal injuries, deaths, and property damage.

For many years the world has been exasperated with these persons, has blamed and berated them, warned or cautioned them; but the statistics of public accidents keep right on going high and higher. What should be done about it?

First we must pause, as we are doing today, to ask whether we have gone at the problem of reducing highway accidents in the best possible way. We shall find, I think, that we have not yet got to the root of the matter. We have not made full use of what is now known about individual differences between people in their tendencies to have accidents. We shall also find that we need a great deal more information than is now available about these prone-to-accident persons, and how or whether they can be changed into safe operators.

The Chronic Repeater

Perhaps the most neglected causes of highway accidents are to be found today in the physical and mental makeup of men who repeatedly have accidents.

Psychologists, physicians and safety engineers who have examined the facts about individual differences in relation to safe operation, are in agreement that many of these unsafe drivers can be made over into safe, competent operators through use of the right incentives and right methods of re-training and supervision. At the same time it must be recognized that a small but dangerous proportion of the accident-prone drivers are so constituted that no amount of special effort can fully compensate for their constitutional handicaps. Should such men be permitted to drive automobiles?

The subject is intensely practical. It bears directly on the whole question of state policies and procedures in the examination and licensing of drivers, and affects the practice of the courts in dealing with traffic offenders. Many managers of street railways and owners of fleets of trucks recognize how closely it touches upon their methods and standards of hiring, of training, of discipline and of supervision. They want, if possible, to detect the prone-to-accident person in advance, and then either cure him or put him where there are no hazards.

The subject is of deep concern to casualty underwriters as well as to employers and public who have in the long run to foot the bills. It concerns parents who are anxious about the lives of their children, and indeed all of us who either walk or ride in the streets. Everyone wants to put a stop to the rising tide of accidents. One neglected but necessary step to this end requires thorough researches into human personality in relation to the causes of accidents. Only so can our efforts to prevent accidents be planned in the light of full knowledge.

Two main questions to be raised are, first, what are the differences between people who frequently have accidents and those who go through the same hazards without accidents? Second, what can be done to cut down accidents among these prone-to-accident persons?

The second question can surely be answered better after we have found the answer to the first. And yet, strange to say, the vast literature of the safety movement contains to date only a relatively few pages devoted to reports of researches on accidents of individuals known to belong to the prone-to-accident group. The next few years will surely see a substantial addition to this fund of literature. We cannot afford to be without it.

Personality of the Driver

Fortunately the psychologists, physiologists, physicians and safety engineers have not left us entirely in the dark as to the constitution of the accident-prone personality—the “accident carrier.” Indeed it is commonly recognized that some people seem to be temperamentally unfitted to face the complications involved in driving a vehicle safely through crowded traffic. Others are hampered by poor muscular coordination, or else have unusual difficulty in driving safely because of bad eyesight or hearing. Some whose eyes are good, nevertheless do not readily notice and interpret the really significant items in the constantly changing picture about them. A good operator needs to be able to perceive accurately and also to distribute his attention; he must not become too concentrated on one line of thought or action, incapable of spreading out his awareness to include all the little apparently irrelevant features of traffic situations. He will promptly notice the parked car is about to start out from the curb as he is approaching, or the pedestrian who is making the slightest gesture in the direction of stepping off the sidewalk into the gutter, and so on.

A good operator needs to have a grip on his emotions, in order not to get excited or panicky when the unexpected happens. His reaction-time must not be excessively slow; although the researches of M. Lahy, in Paris, have shown that irregularity of reaction-time is a more serious symptom than mere slowness.

And he needs a certain minimum of intelligence. This minimum is quite low. An intelligence level sufficient to enable a man to learn the correct responses and size up the situations through which he drives, has been found to be that of the so-called moron, the high grade feeble-minded. Above this level there is little relationship between intelligence and freedom from accident, but below it the possibility of training a man to be a safe chauffeur is slight.

These and other kinds of defects are conveniently classified into two groups. First, those defects which are temporary in nature, or remediable, like lack of the skill which comes through practice. Second, those defects which are constitutional or permanent.

Within this second group we should recognize that some permanent disabilities can nevertheless be compensated for. There are drivers who are deaf or one-armed or color-blind, but who, through development of exceptional skill and caution, can operate more safely than the average person.

There are certain illnesses, both temporary and chronic, which seriously affect the capacity to avoid accidents. For example, one of the most dangerous prone-to-accident drivers is the person who suffers from a mild form of epilepsy called psychic epilepsy. He is himself often quite unaware of his defect, for it does not show itself in convulsions like the better known form of the disease. Indeed its insidious symptom is nothing more than a brief lapse of consciousness, like a moment of sleep with the eyes open, which usually passes among friends or family for mere inattention or occasional absent-mindedness. The late Dr. Thomas W. Salmon called particular attention to the apparently unsuspected prevalence of this

form of disorder of the nervous system, and to its grave importance as related to highway accidents.

A motorman once drove his street-car through an open draw-bridge. He escaped alive but does not know how the accident happened. One wonders whether he and many others who have been hastily labeled as criminally negligent may not be sufferers from this insidious form of epilepsy.

As a matter of fact, it is not known how rare or how prevalent this disease is, throughout the population. Among 181 high-accident men, mentioned below, not one seemed classifiable under that heading.

Physicians and psychiatrists should have ample opportunity and ample funds to examine a large and representative sampling of accident repeaters, in order to determine the frequency of this and other mental and nervous disorders and their relation to highway accidents.

And while medical men are learning all they can about illnesses, high blood pressure, constitutional predispositions and other physical conditions in relation to accidents, the psychologists, too, should be called upon to examine these same accident-prone individuals, to measure their keenness of eye-sight and hearing, their ability to judge speed and distance of moving objects, their scope of attention and susceptibility to distractions, their quickness and accuracy in motor reaction, and their resistance to fatigue. Susceptibility to surprise should also be tested, for the prone-to-accident driver is sometimes entirely skillful and competent except when he is placed under the emotional strain of sudden emergency; then he loses his head.

These are some of the characteristics regarding which too little is known, and which should be investigated in the course of a thorough research into the personality of accident-prone drivers.

A Practical Study of High-Accident Motormen

A study of prone-to-accident men has recently been made under the writer's supervision on behalf of the Boston Elevated Railway, one of the members of the Personnel Research Federation. This investigation illustrates the practical value as well as the scientific interest of such studies.

The investigation was begun more than a year and a half ago at the suggestion of Mr. Edward Dana, general manager; Russell H. Sears, attorney; and James Smith, superintendent of transportation. Shortly after it was started we were fortunate in securing the help of Dr. C. S. Slocombe, who has been largely instrumental in carrying it forward and in putting the results to practical use in accident reduction. Dr. Slocombe is a New Zealander. He studied in London under Professor Charles Spearman, the distinguished British psychologist, and came to this country about three years ago. This is his second year as a member of the staff of Personnel Research Federation.

The industry in which the study has been made is a metropolitan street railway employing 8,000 men, including 2,900 motormen and bus operators. Its purpose in asking the Personnel Research Federation to undertake the inquiry was to see whether accidents could be reduced through individual study and treatment of accident offenders.

This railway has a large accident bill, in spite of the fact that its accident record is low in comparison with the records of other great metropolitan street railway systems. In other words, it was not because of an exceptionally bad accident situation that its management decided to undertake this investigation. Using the best methods that have been in current use for safety education, training, supervision, group rivalry, etc., they had been able to reduce their accident rate to what would ordinarily be considered a low level; but the bill for damages and claims on so large a system still amounts to a very large total sum. The question was whether this bill could be reduced by adding yet another approach to the program of accident reduction.

A preliminary statistical study was made of the complete and detailed personnel records of 200 employees. This was published in the *Personnel Journal* for December, 1927, under the title, "Men Who Have Accidents." Differences in ability to operate street-car or motor bus with safety were found to correspond with differences not only in training and in length of experience, but also in physical condition as indicated by blood pressure, and in skill in saving electric power as measured by automatic coasting recorders attached to the street-cars.

It was found that these results tended to confirm Miss Newbold's, in England, to which Mr. De Blois referred Wednesday in his address. She had found that industrial accidents do not distribute themselves impartially, by the law of chance. They happen to some people more often than chance would indicate. Moreover the men who are found in the high accident group in one year tend to be there in succeeding years.

Significance of Minor Mishaps

Fortunately for our study of prone-to-accident men, the street railways keep full and detailed records of minor accidents as well as of those which result in personal injury or serious property damage. This fact made it possible to ascertain still another point which is very important for safety engineering: It is the man who has more than his share of mishaps or trivial accidents who tends in the long run to have a bad accident.

In plants where an accident is defined as a lost-time accident and no full detailed records are kept of minor injuries or trivial accidents, the information is lacking to enable the safety engineer to identify, follow up and cure the prone-to-accident man before he has a lost-time accident. That situation, fortunately, did not prevail in this street railway where records are kept of every incident, even though it is merely scratching the paint off the fender of an automobile, or a person falling in the car because of jerky operation. If the more than ordinarily prone-to-accident employee is to be discovered in season, before anything really serious has happened to him, it is useful to keep records of minor accidents and of non-chargeable accidents also. The more information, the better.

Studying "Non-Chargeable" Accidents

A bus operator had a number of non-chargeable accidents. In each instance he had been exonerated, because, when the circumstances were looked into, it was found that his bus had been struck in the rear. It seemed clear that it was not his fault. It was the fault of some truck driver or automobilist. Each accident had been reviewed immediately after its occurrence, and recorded as a non-chargeable accident.

But, when all these records were brought together it was found that always the bus was hit in the *left* rear, never in the right rear or directly in the rear. Instantly this fact pointed to some fault of operation. This man had the habit of driving close to the curb, as is proper. But when he sees a car parked ahead of him, he drives up close to it and then suddenly turns left to go around it instead of beginning earlier to ease out into traffic.

The driver was not aware of that habit and no one would have been aware of it or realized that this particular defect of operation needed to be called to his attention, if records of these "non-chargeable" accidents had not been accumulated and studied systematically.

Preparing for Accident Reduction

Such preliminary studies as these led to a fresh attack on the accident situation in one of five main divisions of the street railway system. In this division the records of about 500 men were canvassed, and 181 high-accident men were selected for individual study, diagnosis and treatment.

In the meantime we had been making a comprehensive job analysis. We took the motorman's training and learned at first hand how it feels to face the need of making schedule through exasperating traffic conditions. I take off my hat to the motorman, having tried his job.

Mr. S. S. Brooks, recently of our staff but now dean of men at the University of Montana, worked for two months as a motorman in order to get a detailed description of duties, which runs to more than 40 closely typewritten pages. The motorman's job is not as simple as it looks. The description starts from the time when the operator has to begin to inspect his equipment, five minutes before he takes a car out, and carries him right through all the details of starting and stopping, making change, issuing transfers, opening and closing doors, watching for greasy pieces of rail, so as to apply the sand before the car skids, bringing the car to the end of the run, changing ends, putting down various records, coming back on schedule time and handling various emergencies along the way. By the time one describes in detail all the things that a motorman has to know and do, it runs into quite a pamphlet.

Diagnosis and Treatment

A check list of twenty five points of operation was made, as an aid in noting the more important details regarding a motorman's skill and manner of operating; and forms were devised as aids in recording and analyzing accidents in relation to the rest of the man's record—his illnesses, lateness, complaints, errors in reporting, disciplinary actions, commendations, etc. Arrangements were made for special medical examinations whenever they were indicated.

No inflexible program of examination and treatment was adopted, but every high-accident man was handled as an individual. Dr. Slocombe puts it picturesquely when he states that there were 181 cases and 181 methods of examination and treatment.

The motorman was ordinarily observed in operation. A special instructor rode the car with him a couple of hours a day for at least two days. Meanwhile his entire list of accidents was classified according to type, and studied in detail for clues as to what was wrong and why he was having more than his share. A conference or clinical interview with Dr. Slocombe and one or more of the instructional or supervisory officers then led to a tentative diagnosis and a prescription for treatment.

No two of the high accident cases were exactly alike. One man needed special re-training and close follow-up on certain details of operating his brake. The next needed a new pair of glasses. The third was developing cataract. A fourth was lax in the matter of closing the door before starting the car, and had a proclivity for running ahead of time. The division superintendent dealt with him and an inspector helped to effect a cure.

One man, over-fatigued, under-nourished, irritable and distraught, a widower with several children, was found to be in an unfit condition to operate a car because he was trying to be mother and cook as well as breadwinner. He was helped to make a temporary adjustment at home to relieve the situation until his eldest daughter, a senior in high school, graduated and picked up more of the burden.

Results

Many of these high-accident men became better than average operators and have remained so. A very few among the older men were pensioned, transferred to other work or dropped.

In general, the older man is the safer operator. This holds for all age groups including the group of those who have been with the company for more than thirty years. Some of the men with the finest records during the past year are about seventy years of age. It is not until the effects of senility really begin to show

that the question of pension needs to be raised; but it should then be raised promptly, no matter whether the man is seventy or seventy-five or fifty-five.

The ten months which have elapsed since this effort began is much too brief a time to give an indication of the permanency of the effects. It seems safe to say, however, that more than one-half of the group selected as high-accident men have been definitely cured of their accident proneness as shown by their record since last December. All but 10 per cent have shown definite improvement.

At the same time the effect of this close attention to high-accident men on the part of the Safety Advisor and the instructional and supervisory force had had its favorable effect on the other men and in the other divisions of the railway; so much so, indeed, that accidents during this year on the entire system of surface and bus lines are 17 per cent fewer than during the previous twelve months.

The particular division in which these efforts have been concentrated has steadily maintained each month since last December a safety record at least 25 per cent better than the other divisions.

On September first these operations were extended to the high-accident men in a second division and the management is watching developments here with the keenest interest.

Causes of Proneness to Accident

Dr. Slocombe has made a classification of the principal causes of accident proneness among 160 of the high-accident men, as follows:

Physiological defects were the principal characteristics of sixteen of these. This is exactly ten per cent. Of these, four were cases of senility, actual deterioration that comes with extreme age. The other twelve were various defects of a medical sort, including particularly the kinds of disorder of which high blood pressure is an indication, such as nephritis and arteriosclerosis.

Of the other ninety per cent of the high accident men, it is interesting to note that in thirty cases, or nineteen per cent of the total, the principal cause seems to be lack of understanding of factors constituting accident hazards of the highway. They had not learned to recognize, for instance, the significance of smoke coming from the tail of an automobile that is parked along the curb ahead, indicating that the driver is warming up his engine and is apt to shoot out into traffic at any instant. Little items of that sort these men had not learned. Such a lack of understanding of factors constituting accident hazards seemed to be the outstanding defect, as has been said, in nineteen per cent of these 160 cases.

The chief defect in fifteen of the men seemed to be poor judgment of speed—their own speed and the relative speed of other vehicles.

In nineteen cases it was faulty judgment of distance, evidenced by repetition of some such type of accident as that which happens as the motorman's street-car is rounding a corner and does not clear an automobile parked nearby.

Taken together, poor judgment of speed and distances accounts for a total of twenty-one per cent of the entire group.

The three classifications mentioned include a half of the cases. The other half distribute themselves among a number of psychological defects other than defects of judgment of speed and distance and lack of understanding of accident hazards.

Wrong attitude towards work, management or supervisor, accounted for three cases. Poor sensori-motor coordination, for nine cases. Excessive perseveration, seven cases.

Inability to distribute attention, seven cases. Oscillation of attention, seven cases.

Slowness of reaction, five cases. Excessive susceptibility to fatigue, five cases. Insufficient experience, fourteen cases.

Nervousness and fear, five cases. Excitement and worry, two cases. Impulsiveness, a tendency to act too quickly in a situation, three cases. Irresponsibility, four cases. Chronic hurry, six cases. This leaves three miscellaneous cases unclassifiable.

One Cause of Collisions

Perseveration is a formidable term but its meaning can be easily illustrated.

A motorman had a good accident record until a year ago last Spring when he began to have collisions. He had five of these collisions about a month apart. This automatically brought him into the high-accident group so that his case was brought up for special consideration.

An instructor rode the car with him, checked him on twenty five points of operation, and returned to say that he was entirely skillful and capable, and that there was nothing to indicate need for re-training or further instruction or follow-up. Nevertheless this man had had five collisions in as many months.

Dr. Slocombe had been studying those collisions to see what elements, if any, they had in common. They belonged to one type, namely, straight front-end collisions. This man somehow avoided all the other kinds of accidents, but he repeatedly ran into something directly in front of him. There was another characteristic common to all five of his accidents, namely, they all happened Sunday afternoons.

This seemed easy. What was the man doing on Saturday nights? He was at home with his family. He was not the sort of man who goes on a weekly carouse; so that was the wrong lead.

It finally occurred to Dr. Slocombe to check that man's record to see exactly what his work was hour by hour throughout the week. A motorman has to take out all sorts of cars. Different types of cars are sometimes used during rush hours, during the middle of the day, etc. On each of these different types of car the man has been trained, has had ample practice under supervision and has passed an examination for competence.

This man's schedule called for him to operate various sorts of cars, but it turned out that all of them were *medium weight* cars except on his Sunday afternoon run, when he had one of the enormous heavy cars. The minute that point emerged, the answer was clear. One can readily appreciate what is involved. It is like changing from a Ford to a Cadillac. To be sure, there are many motormen who have similar schedules and who do not have these collisions. What is the difference between this man and men with similar duties who are able to carry over their skill and to change their habits quickly to fit a new situation, like the attendants in the public garages who handle so many different makes of cars with various sorts of controls, and who bump so few fenders in the process?

This motorman has the type of nervous system that is characterized by excessive perseveration—a tendency to keep on acting in a given way, once started in that way.

This is sometimes a constitutional characteristic. For example, if one looks at a rotating disc which is half white and half black, it will flicker until the rate of rotation is increased to the point where the black and white merge to a smooth gray. The disc has to speed up to a certain rate before the response of the retinal nerve-endings to one white stimulation carries over and is still active when the next white flash comes along.

A man who has an excessive tendency to perseveration will see this flickering disc change to a smooth gray at a slower rate of rotation than you or I would. His nervous system has the tendency to continue active in a way once begun, longer than the ordinary nervous system does.

In a case of that kind, it is too expensive to undertake to train the operator to compensate for this constitutional peculiarity. It is better to change his schedule. That is what was done in this particular case. To be sure, even that step is somewhat expensive of time. It required a conference with the division superintendent to convince him it was worth doing. There had to be some argument with the schedule maker, and finally a long conference with the head of the local trade union in order to reassure him that this was not setting a vicious precedent in viola-

sort of thing that has been done for the Boston Elevated in the study that Dr. Bingham described. If we are to make any progress in this field it will require more of that sort of work by and for individual large companies, as well as any sort of research that may possibly be set up directly through the National Safety Council or through any research organizations not directly connected with large companies.

The next item on our informal program this morning is a brief report by Mr. J. S. Baker, of the National Safety Council staff, of the plans that have been formulated thus far. I hope you will listen to this critically and later in the discussion advise us as to the value and practicability of these plans.

J. S. BAKER (National Safety Council): I have been asked to make this brief report of the work of the Staff in connection with the study on personality and public accidents in the absence of any chairman, as yet, of the Committee which is directing our work in that line.

Dr. Bingham has very well described the importance of such work. He has pointed out how the classification of causes of accidents can be reduced largely, especially with respect to those individuals who repeat accidents, to a matter of personality rather than to a description of the circumstances.

Our aims in conducting any study into this are several. First we want to know whether certain individuals have more than their share of accidents. Second, what we can do with the present accident statistics gathered by state and municipal motor vehicle departments in segregating the accidents into various groups according to their personal causes. Third, what we can do to investigate scientifically and more accurately accidents that actually occur.

The first part of our work has been to enlist the support of the State Motor Vehicle Departments in Connecticut, Massachusetts, and New York, to keep tab or prepare for us a report on accidents that have already occurred to individuals having more than one accident.

We are not in a position at the present time to follow this intensively, but New York State's form for reporting accidents is to include in the near future a question regarding the number of accidents the individual has previously reported. This will be tabulated on punch cards and in a year or so we shall obtain some excellent data on exactly how many accidents certain individuals have had.

We expect that the State Motor Vehicle Department of Connecticut will be able to furnish us some similar information of a higher character because of the completeness of their records and the possibility there of not only checking what the individual says and tabulating on punched cards, but by actual examination of group and individual records of those who have had more than one accident to see if they have had the same type of accident.

The only thing that we can gain from this, considering the many deficiencies of present accident-reporting systems from the standpoint of analyzing them with respect to personal causes is the fact that certain people are prone to accidents. Dr. Bingham has pointed that out in his talk this morning in connection with railroad operators. If we can show that that is also true of motor vehicle operators, and I think we can probably show that it is more true, we shall have a strong argument for the passage of motor vehicle driver's license laws.

The second phase of our work has been to make up a list of personal causes of accidents. Disregarding the causes of accidents as classified from existing statistics we looked at it merely from the standpoint of the person involved. If you like to, you can consider any accident as having a personal cause. Even such accidents as are attributed to brakes being defective or steering gear being defective, you can pass back and say that the individual who is responsible for the condition of the car was also responsible for that accident, and personal negligence on the part of some one was therefore the cause of the accident.

In this classification, which is entirely tentative and subject to correction, we

tion of the trade-union agreement which provides that every man shall have the privilege of choosing his own route in order of seniority. But all this expenditure of time was worth-while; for it put a stop to these front-end collisions on Sunday afternoons.

It is better in such a case to go to some pains to rearrange a schedule rather than to undertake to train the man to be able to shift readily from one type of car to another.

There were, all told, seven out of 160 cases of prone-to-accident men in which this tendency to excessive perseveration seemed to be the most distinctive factor of their accident proneness.

The Psychological Approach to Safety

The classification we have used for grouping together the various causes of accident-proneness is not presented as complete or as highly reliable. But it indicates clearly the wide range of personality differences and defects for which one needs to be on the watch.

Only major factors in a man's proneness to accidents have here been considered. In saying that nineteen cases are due principally to faulty judgment of speed or distance, it is not implied that this was the one and only defect in those nineteen cases. For the purpose of this presentation, Dr. Slocombe in each instance, indicated what was in his judgment the outstanding or most important single consideration. But actually each individual high-accident man is a case by itself. It refuses to be pigeon-holed with other cases because so many special considerations arise that make it different from any other. So, both in the matter of diagnosis and of treatment, what may be called the psychological approach is required.

The psychological approach to safety is the approach which places special emphasis on the individual. It recognizes the great variety of individual differences. In dealing with each motorman or each truck driver or each automobilist, he is recognized, not as one of a mass, but as a distinct personality, unique.

When this psychological approach to the problem of the high-accident man is taken, there is no need to abandon the mass approach to the whole group of employees. It is unnecessary to sacrifice any of the values that come from using all of the educational appeals and other important aids to safety which the experience of the safety movement in America has evolved. Rather, this is one additional line of approach, which seems to attack the present safety problem at its most vulnerable point, at the point where there is the greatest hope of making an impression on the accident situation, because it tends to concentrate effort and attention on those particular employees who are responsible for the larger proportion of the accidents.

This psychological approach to the accident problem through study of the individual is not unique in the public safety field. The Milwaukee Electric Railway has followed it for years, and other transportation companies, both here and abroad, have found it a fruitful approach.

For those who read French readily or who can put a librarian to reading French, attention is drawn to the recent volume by J. M. Lahy, Professor at the Sorbonne and Director of the Technopsychological Laboratory of the Paris Tramways. The book is entitled, "Psychophysiological Selection of Workers: Motormen and Bus Operators."* In Germany the publications of Karl Marbe of Würzburg and Otto Lipmann of Berlin are outstanding in this field.

The articles by M. S. Viteles in the *Personnel Journal* for August and October, 1925, Vol. IV, pp. 100 and 173, admirably summarize the work done up to that time.

The ingenious work of Dr. Snow a few years ago in the Yellow Cab Co. of Chicago, is well known.

*J. M. Lahy: *La sélection psychophysique des travailleurs: conducteurs de tramways et d'autobus.* Paris. Dunod, 1927.

One of the most recent and significant of these investigations is being carried forward at the present time under the direction of V. V. Anderson, M. D., consulting physician and psychiatrist in the R. H. Macy & Company Store, here in New York. For a year and a half Dr. Anderson has been studying their delivery men in this individual clinical way—this combination of psychology, psychiatry and common-sense human interest—with the result that here also a substantial reduction in labor turnover has been effected, better morale has been introduced into the delivery force, and a good many difficulties of supervision are removed.

Before this session is over, others will describe their experience in using the psychological approach to the accident problem. Among the more important experiments are, one in Detroit in cooperation with the traffic court; a study being planned at the University of Ohio under the auspices of the National Research Council; and one in Pittsburgh, the plans for which this Committee has been called to consider today.

Long ago the quaint superstition was abandoned that a man is prone to accidents merely because he is unlucky. No one today will admit that he really believes in luck. As one gets to close grips with this problem of personality and accidents, he finds some other familiar concepts going into the discard, too.

One of these is *carelessness*. As our Chairman indicated at the beginning of the session, carelessness is a broad, vague term that cloaks a large variety of accidents. No supervisor should ever be satisfied with merely blaming a man for being careless. Let him ask instead, "Why was he careless?" And when that question has been fully answered, a much more informing and helpful explanation of the accident will be at hand, with a definite way of preventing its recurrence. The closer one gets to the real facts about men and accidents, the less use he finds for broad general terms like carelessness, recklessness, pure cussedness or bad luck.

Still another concept, indispensable to the claims attorney and the casualty company, has little value for the analyst of causes of accidents, and that is the concept of *blame* or fault. To raise the question as to who was to blame for an accident, is usually beside the point for our purposes and only stirs up an emotional cloud instead of helping to locate the real causes.

It is better to follow the question, "Just how did the accident happen?" not with the question, "Whose fault was it?" but with the question, "How could it have been prevented?" or, "What must we do to see that this doesn't happen again?"

The time is ripe enough for a thorough, scientific investigation to bring to light many much-needed facts about prone-to-accident individuals. Two years ago, as Chairman of the Committee on Causes of Accidents of Mr. Hoover's Second National Conference on Street and Highway Safety, I strongly urged the necessity for such researches. I am delighted that the National Safety Council has now taken definite steps to interest safety engineers and men of science in undertaking these basic studies of personal constitution in relation to accident proneness. In my judgment this marks a turning point in the whole safety movement in America.

My congratulations go to Mr. Sidney J. Williams, Director of the Public Safety Division of the Council, to Mr. J. S. Baker, his assistant, and their colleagues of the staff.

CHAIRMAN WILLIAMS: Dr. Bingham has brought out a number of very important points, which I think impress all of us with the fact that in this study which has been made in Boston the practical point of view was kept in mind at all times, along with that of the scientific investigator. I cannot help feeling that there is a very decided suggestion there for all of the large corporations that are in the membership of the National Safety Council, and which, like the company he referred to, have a heavy accident cost in terms of dollars, even though their rate may be lower than other companies that have done less of the standard type of safety work: namely, that any such large corporation can well afford to do the same

have divided accidents into three major groups according to the method which may be applied in treating them.

The first of these is handicaps. Handicaps which the individual cannot be expected to overcome. These are physical and mental deficiencies. Among them are deficiencies of eye-sight which cannot be corrected by glasses; general lack of strength; mental disability.

The Doctor has already spoken of certain of these, as he said the mental disability may be in the form of disease or of a low degree of intelligence. And in all cases any individual so handicapped should be refused the privilege of driving on the highways, because he will unquestionably endanger his own life and probably that of others.

The second group are causes which may be treated by educational methods. The persons in this group are sufficiently normal physically and mentally to drive properly but have not had proper training or the proper instructions in the hazards of driving. Under those come such items as general education. There are a few accidents caused every year by the fact that a man cannot read. There are signs directing him to stop or go slow or not to turn left. He doesn't know what they mean and gets into accidents.

A great many accidents, I believe, are caused by improper training as motor vehicle operator. We all know that there are no set standards for the general public to meet in learning to drive automobiles. Many individuals are instructed by relatives, by automobile salesmen, by garage mechanics, and their instructors themselves are not expert drivers. The result is that relatively few people ever have had impressed upon them the mechanical habits that must be formed to make good drivers. Few people have had repeated drilled instruction in manipulating a motor car accurately so that when an emergency arises they do instinctively the correct thing.

Many people are ignorant of motor vehicle laws. If you take almost any good motor vehicle law, such as those represented by the Model Traffic Code or the Model Municipal Traffic Ordinance, and read through the provisions of that law and then follow to the letter those instructions, you would be a fairly good driver. In other words those motor vehicle laws have been well planned and are just about the best driver's manual that could be put out. People who are unfamiliar with them are subjecting themselves to accidents. Education in the motor vehicle laws will prevent accidents.

Then there is another class of education which is more technical and which also has an effect on accidents. I mean the mechanical aspects of a moving vehicle. When you consider that an automobile has possibly sixty horse power tucked away under the hood, the individual controlling it doesn't realize what fifty or sixty horse power means in energy and you can see that he is likely to have an accident. If you were to give a man fifty horses to drive simultaneously he would be much more careful than he is with considerably more power in an automobile.

Few people realize that the stopping distance of an automobile is increased as the square of the speed. That is, an automobile going twenty miles an hour takes four times as far to stop as one going ten miles an hour. The same thing is true of collision damage. The energy stored in a vehicle moving at twenty miles an hour is four times that moving at ten miles an hour. The damage done to an automobile in a collision is proportional to the energy stored.

If those things were clearly known by automobile drivers—how much sooner they must start to stop when they are driving sixty miles an hour than thirty, how much more damage is likely to be done—they would take much more care in their driving.

The third classification, and in this classification is the great majority of accidents, is called the lack of will to prevent accidents. In it are the mental causes which are generally classified as inattention or carelessness. Individuals who have

accidents due to these causes are normal physically and mentally, have had adequate training as motor vehicle drivers, understand the motor vehicle laws, but for some reason they don't drive properly and in a short period of time become involved in an accident.

Among these is failure to allow for the fallibility of others, which means that a driver is good himself and he unconsciously assumes that other people are equally good.

He may have an over-grown idea of his rights. That is, he feels that it is his right to drive across an intersection on a green light without looking. He feels that having the right of way as established by law, he does not need to take care.

Then there are certain predispositions. Among these are intoxication, over-fatigue, properly better expressed as monotony. A man may fall asleep from such conditions.

Then there is preoccupation. A man is day dreaming.

Hurry is a great cause of accidents. We don't know how great.

Then there are a great many causes of distractions. A man is conversing with somebody in the automobile, and his mind is not on driving. It is on what he is talking about. He is trying to light his cigar, or trying to pass around the cigarettes. He may be distracted by back seat driving. He may be adjusting his clothing or has lost something, or something is the matter with his machine. He may be watching something on the street, people on the sidewalk. He may have to stop at a certain place and is watching street numbers, or other automobiles.

This entire list, as I said before, is entirely tentative. It is merely an indication of the kind of information we want to get in analyzing accidents from the personal cause. We shall be glad to have any suggestions or modification of it.

The next question, naturally, is what methods can be employed to get such information. Obviously the methods of reporting accidents of the various state motor vehicle departments fall short when it comes to analyzing accurately these things. The very methods that are used by these systems in gathering the data depend upon the police and individuals themselves. You must go further.

In order to do that we have set up in Pittsburgh machinery to do that. I say we have set up because it is practically assured that it will soon be in operation. This is a bureau for examining individual drivers who become involved in accidents. We will there take motor vehicle drivers who become involved in accidents, especially commercial drivers, and examine them by means of psychology and psychiatry. The psychiatrist will be furnished by the department of public welfare of that city, the psychologist by the university.

These men will first be examined psychologically. Their reaction time will be studied, eye-sight, hearing, and so on, and then they will be passed on to the psychiatrist who will examine them further. The reports will be tabulated in terms of one primary cause, or possibly two, and a number of secondary causes. The primary cause will be that one thing which had it not existed would have prevented the accident. The secondary causes will be those which contributed to the accident.

Also will be tabulated the type of mental or physical difficulties that the individual has experienced which have no immediate connection with the accident but which may possibly cause it indirectly.

This is all new work and in starting an investigation of personality of automobile accidents we feel that we have a big task to undertake. It is like starting to build the Panama Canal with a spade. We want all of the help we can get from all of the organizations. We don't want to duplicate the efforts of anyone else. We want all the suggestions that you here are able to give.

CHAIRMAN WILLIAMS: This meeting is advertised as an open committee meeting, and that is what it is. The Committee is small and some of the members who were promised that they would not be asked to make long distance journeys are not here. We have a telegram from one of them in Chicago regretting his

inability to be here, but all of you who are here and have shown your interest by attending, we desire you and anyone else to contribute anything you can do this discussion.

The subject is before you now. Has anyone a question he would like to ask Dr. Bingham or Mr. Baker, or any experiences to contribute bearing on this subject? Have you any advice or suggestion to give the National Safety Council and this Committee and this Staff in carrying out any work of this sort?

C. B. SCOTT (Bureau of Safety, Chicago): I am a member of the Committee and unfortunately I have another appointment. I am sorry to have to leave the meeting, but I have something on my mind I want to say before I leave.

I am intensely interested in this phase of accident prevention work, and I feel that it is strange that we haven't gone further into it during the years of effort along accident prevention lines.

As I sat there and listened to Dr. Bingham and Mr. Baker, it didn't seem impossible to me for some kind of concerted action to be taken by which industries could get a great many of these facts. There is a wide field of possibility for the average safety engineer if he directs his research work in that direction, and while I appreciate the value of such a study of the public safety problem I predict that the day is not far distant when we will do much more of it in connection with our industrial safety problem also.

The experiences of some twenty years of accident prevention work have convinced me that we have overlooked the possibilities along these lines. It is not the fault of the National Safety Council or anybody else. It is just that natural tendency of ours to get things that are somewhat easier done, to select the line of least resistance in our work.

CHAIRMAN WILLIAMS: I hope by the time of our Congress next year we shall put this subject on one of the general industrial programs.

I have felt, as Mr. Scott does, that there has been a prejudice on the part of a good many practical minded fellows, and so far as I have had anything to do with preparing this program, my thought was that we should start modestly.

As Mr. Scott said, there is certainly a good deal that can be done, and I would take the liberty of adding this: The results in Boston as described by Dr. Bingham sound simple. They arrived at practical findings, but the work had a very definite scientific foundation and was done by a man with years of scientific training, and while I feel that safety engineers in industries can do a lot by just turning their minds in this direction and thinking in these terms a little more than they have in the past, I hope that this thought won't be carried to the extreme of thinking that any safety engineer in any industry can do as good a job as Dr. Slocombe did in Boston.

I just want to add as the other side of Mr. Scott's thought, that we do need these jobs set up by men with the scientific background as well as the practical turn of mind that produces concrete results, and may I say again that I hope some of the larger companies will follow the lead of the Boston Elevated and set the work up in that way as a part of their regular safety appropriation and with the confident expectation that they will get their money back.

Is that a fair statement? That the Boston Elevated has gotten its money back through the reduction of accident costs?

DR. BINGHAM: A man from the Boston Elevated force is here and possibly he should answer that question.

JOSEPH L. TROY (Boston Elevated Railway Co., Boston, Mass.): It has paid the Boston Elevated Railway Co. Dr. Bingham is a little bit too modest in his talk in showing results. This year they expect possibly 4,000 collisions reduction, and considering the fact that all other street railway accident problems are increasing on account of the increased traffic congestion, I think had Dr. Bingham gone a little deeper he could have shown you much more satisfactorily the results obtained.

CHAIRMAN WILLIAMS: No psychologist or scientist or anybody else needs to apologize for a job that will bring returns as quickly and obviously as that. Advertising men and sales managers have been using the technical advice of psychologists for years and it really is about time that we safety people wake up on it.

J. A. DICKINSON (Milwaukee Electric Railway & Light Co., Milwaukee, Wis.): Dr. Bingham has mentioned the fact that psychological and psychiatric tests and studies have been carried on in the Milwaukee Electric Railway & Light Co. for some years.

I believe you will be interested to know that a worth while test is now being carried on in the industrial division in connection with station operation. The station operation men, are men who operate and control the machinery and lines from the power plant and sub-stations.

A selection test has been set up, following which as a criterion a group of about twenty men were selected among our station operators. These men were rated by two of the supervisory staff. They were then given psychological tests and it was found in all except two instances that they checked up with the supervisory staff's opinion. In these two cases the men were comparatively new. They had been in the employ of the company only a few months and the supervisory staff rated them slightly below the results of the psychological test. Because they had not been with us long enough, they did not rate them high enough.

CHAIRMAN WILLIAMS: Is there anyone here connected with the National Research Council or with the study at Ohio State University? If not I would like to put into the record the fact that the National Research Council through a committee is setting up a research study to be conducted through some of the people of Ohio State University at Columbus. They are in conference with us on the subject, and they have the same objective, namely to make some sort of a study of drivers who are involved in accidents.

They probably will use in some respects methods quite different from ours, which is a good thing because nobody can expect to hit the nail right on the head the first time.

At this time I must apologize for leaving the meeting myself for a little while on account of another engagement. I am going to ask Dr. Bingham to take the chair and you go right on with this discussion.

(Dr. W. V. Bingham assumed the chair.)

L. A. DEBLOIS (New York City): If I had known that Dr. Bingham had any such contribution as he made today I should have done my best to have brought him over to the big industrial meeting Wednesday afternoon, because I am impressed with the fact that we must bring this phase of accident prevention work much more forcibly before safety engineers than we have done heretofore, to get serious consideration from them.

We need more information on the distribution of proneness, if I may use that expression, under different hazardous conditions. We want to know whether this proneness exists with the automatic driver, with the train operator, with the quarrymen, and so on. Is it persistent in human experience? If so we have increased our argument tremendously.

I think we want also to know very much more about the corrective measures to be given—the possibility of doing what Dr. Bingham has told us the Boston Elevated has done. Is that possible in another industry that has its own special hazard? If so, we then have our course laid out for us.

But we want to know also more about the methods whereby that proneness may be reduced. We are dependent to a great extent on mass education. That is what we are doing in the safety movement. How much can we do through mass effort, and how much must we go into the more expensive field of individual correction?

MR. GORDON (Bureau of Safety, Chicago, Ill.): Dr. Bingham has referred in his paper to concentration and lack of concentration. You probably have heard

of the professor who, while sitting at his desk deeply absorbed in some problem, took his cigarette from his mouth and pitched it in the waste basket, causing a \$75,000 fire, failing to take into consideration all his surroundings. Too concentrated upon one particular thing.

We had a motorman standing at the front end of the interurban car at ten o'clock in the morning on a bright sunny day looking straight ahead, slam into an express wagon stalled on the track that you could see for a mile. Failure to concentrate upon his own job and to take into consideration the surroundings.

We cannot always have a foreman alongside of the individual workman to watch his every move. As I see it, it is an individual matter, as has been stated here, and we must reach the individual. Get him to use his own brain, and get the proper mental attitude. That is what we are endeavoring to do through our group safety meetings.

Not long ago a man went down Halsted Street in Chicago, where the children have no other place to play than in the street because they are tenement residences. The street was literally covered with children and this fellow, whom the papers referred to as a "Wop"—I don't like the term—went through that group of children thirty-five miles an hour. They scampered and fortunately escaped injury. The man was arrested and gave as his excuse that he wanted to get there "queek." No regard for the safety of those little ones. What was back of that was wrong mental attitude.

We have a rule that requires our trucks to stop at all railroad crossings, and they carry such a sign on the rear of their trucks. It is a positive rule and yet some men will not do it. The matter is wrong attitude. The "I won't" fellow. That is the fellow we must reach and win him by all possible means to a right attitude toward the whole situation.

I don't believe we shall ever stop railroad crossing accidents until we get the thought into the mind of the fellow or the woman behind the wheel that it is an individual matter at railroad crossings. Not to depend upon gates, wig-wags, bells, flagging, or anything else. They all fail. Railroads are properly marked to indicate to the drivers that they are approaching a railroad crossing; that is all that is necessary for safety of the automobile driver and we must approach the railroad crossing accordingly.

Two fellows from Chicago going through one of the smaller towns recently saw a train coming and waited. The train went whizzing by and the gates didn't go down. Rather peeved they said to a by-stander, "Don't they put these gates down for a train?"

He said, "Didn't they go down?" and when they said, "No," the man said, "There must be something wrong over at the shanty. I'll go over and investigate," and he went over there and found the watchman dead. Had they depended upon those gates for their protection, it would have been just too bad, as we say.

A policeman in one of our cities noticed that the gates didn't go down for a train. He went over to investigate and found the watchman asleep in the daytime, shook him and tried to awaken him and found he was so drunk he didn't know what he was there for. And we put our lives into the hands of men like that! I won't say that they are all alike.

Between two and three o'clock one of our automobiles was struck. The driver depended upon the gates for protection. No one was hurt, but the automobile was so badly damaged they couldn't proceed. The crew reported it to the officials and the supervisor rushed out there in a few minutes. He asked the driver where the watchman was, and he said, "We haven't been able to find him."

"Well, I wonder what has become of the fellow. He's supposed to be here all night." And they went to the man's home to inquire to see if his folks knew where he was, and they said, "Yes, he's in bed asleep."

They asked him why he left his crossing when he was paid to stay all night, and he said, "I figured there were so few automobiles and so few trains late at night that it was foolish to stay there." That's the type of minds we are dealing with at railroad crossings!

Two high school boys approached one of our steam railroad crossings. The tower man was down watching the men adjust the weights on the gate. The train was coming. You could see it a half mile away around the curve, coming a mile a minute, a lot of noise and kicking up a lot of dust. The two high school boys drove their car immediately in front of this oncoming train and both were instantly killed. Had these boys used individual care, it wouldn't have made any difference that that flagman was on the ground where he shouldn't have been, of course, or whether he was in his tower.

LEWIS MACBRAYNE (Massachusetts Safety Council): I want to answer the question that Mr. DeBlois asked. We have collected in Massachusetts considerable information among motorists involved in accidents and find the same is true there, that minor accidents lead to major ones, as Dr. Slocombe found in Boston.

I am familiar with Dr. Slocombe's work. The operator for whom that work was carried on, is one of the very active members of the Safety Council, and I think there is a conclusion beyond what the speaker discussed; that Dr. Slocombe has found that when you make an impression in this pool of accident characters, it slowly fills up again.

I don't believe that we have eliminated the problem when we take that twenty-five per cent and work them back to the normal accident proneness. Other causes and other men slowly creep in again who will form a new pool. So it becomes a very permanent and very important work.

I believe that the next step we are going to take, and I make this in the nature of a prediction, will be the extension of this study of motorists on a very large scale. I think we will see very soon some advanced state willing, through its legislature, to call up for examination all drivers who have had accidents, rather than those upon whom the responsibility was fixed, to give them an examination as to whether or not they are not disqualified to drive.

We have 30,000 people in the state of Massachusetts who were involved in accidents last year resulting in personal injury. In that group are the accident characters and if we can find them and take them off the highways, we shall accomplish something. And I think this session is very important, is probably leading in that direction—the study of the accident carriers who are now on the highways.

J. W. McCLOY (*Electric Railway Journal*, New York City): Possibly I misunderstood one of the speakers in saying that there was a heavy increase in electric railway traffic accidents. I believe from studies made recently that in spite of the largely increasing number of highway accidents the number in which street cars are involved, either blamelessly or otherwise, is actually decreasing. Of course, all the credit goes to the trainmen.

CHAIRMAN BINGHAM: To them goes the credit and to the supervisors who are more and more attentive to the training and supervision of the men.

I want to forestall one or two misapprehensions that may have been raised as to the share which the psychologist or the safety engineer has and the share which the front line has in dealing with the high accident men. No diagnosis or prescription of treatment is going to be of use without the foremen, the supervisors, the inspectors to follow through with it—men who are intelligently in sympathy with this line of approach, who understand what it is all about and who are skillful and competent in doing their end of the follow-up work. To them belongs the credit, as well as to the men themselves who improve their accident records.

Part of our duties in this particular street railway have been in connection with

the development of the necessary supervisory skill, and attention to follow-up work on the part of many supervisors.

One other point. Mr. DeBlois has emphasized the importance of the morale produced through mass effort and education and stimulating group conferences. The great value of that kind of effort is partly due to the fact that it helps the supervisors to bring more individual pressure on the men they supervise. From the very beginning of the safety movement, a great deal of individual work has been done by the foremen, without any thought of psychological terminology. They have been eager to cut down accidents. They have watched this particular man and noticed, not that he has had a serious accident, but that he occasionally drops a tool or jams the gears, or ruins a little more work than his neighbors, or starts his motor rapidly and blows a fuse. None of these mishaps results in what could be called an accident; but the foreman knows that this man is a potential accident man. So he brings pressure to bear on him. He tries to get the right attitude into him and the necessary competence, and if he fails, if he cannot change the man's attitude, he changes his job. He puts him where he will not have to face so many hazards. In doing so the foreman has as a matter of fact been practicing this same applied psychology, and in a sensible way has gotten good results.

That is one reason why the safety movement has had the success it has. On top of the mass education, the foremen and the supervisors have been superimposing this individual effort.

Sometimes the superintendent or the supervisor has looked into the man's family circumstances. He has discovered the worries, the causes of irritation, the pessimistic reveries that are leading the man to be absent minded and careless. He has done what he could to help straighten out family difficulties, perhaps with a little loan of money or some rearrangement that has relieved these worries.

Supervisors have been applying this kind of common-sense psychology throughout the years. To give it a new name or technical high-sounding phrase does not change the essential nature of the safety activities that have been under way; and so I consider that these more technical systematic approaches now being undertaken are simply intensifications of that same effort. Its procedures are refinements of a process that is essentially common-sense.

D. A. DREW (R. H. Macy Co., New York City): I would like to ask if in your study of the Boston Elevated Railway you took the age of the applicant for the job of bus driver into consideration, and did you make a study of about what time of day the majority of your accidents happened?

CHAIRMAN BINGHAM: I am glad to hear from a department of Macy's which has been doing very significant work in this safety movement.

Except for the accident peak in the afternoon rush hour, the figures on time of day are far from conclusive. They are disconcerting in some respects because we do not find any close relationship between length of time a man has been at work and his proneness to accidents. Even the men who are working overtime hours do not seem to have any more accidents in their overtime than during the regular hours. If there is a bad effect from fatigue it apparently carries over to the next morning and distributes itself through the next day quite as much as it does during the overtime hours.

As to age, that has really not been much of a problem with us because we have no very young men on bus operation. In recruiting the bus operators the first opportunity goes to the men who are already senior motormen. If they want to go to the training school and qualify as bus operators (which pays a slightly higher hourly rate) they may do so; and so our bus operators are for the most part mature men, already experienced in street car operation. There is no such problem with the younger men as you have in your delivery force.

Will you tell the group what your findings have been on that point?

MR. DREW: Before we go into this I would like to ask Miss Engel, who is in charge of the psychology department, to tell you something of their work, and then I will tell you of our plan of salary for our drivers and the way we are trying to cut down our accidents through our motor school.

MISS STELLA ENGEL (R. H. Macy Co., New York City): We haven't done much with the age question, but we did make a study of about 150 drivers over a period of six months and found that the men under twenty-three years of age who constituted about fifty per cent of our force, were contributing seventy-five per cent of the accidents. We haven't gone further into the study to know exactly how much of that is due to the age factor.

MR. DREW: Our helpers before they are permitted to go to our motor school for training, must go through a psychological test which is given by Miss Engel. If the man qualifies after having taken the psychological test and Miss Engel thinks he would be a likely chap for a driver, he comes to our motor school, which is located at Long Island City.

We give him three days of instruction, and three days of instruction will take care of every phase of practically every condition of the roads and streets of New York, and then he is given a final test by Miss Engel. If he passes that test he is permitted to go on a test with an instructing driver. This instructing driver is with him for six days. At the end of six days we have a very conscientious follow-up on that boy. If he is doing a good job we commend him for it.

We have what we call a spot check, and if we see him any violating any traffic rule or any regulation set down by our concern, he is immediately told about it. We don't wait until he gets in that night and settles with the superintendent of delivery. We reprimand him in a nice way and try not to be too hard, because they are only kids after all.

It might be interesting for you to know that of a group of about 135 men driving out of the delivery department in New York City, this year, we have only employed one driver, that is since the first of February to date, and we feel reasonably sure that we will be able to get through until the first of December before we have to hire any extra drivers to take care of our Christmas season.

We are doing everything in our power to make the help stay with us and decrease our turnover by giving them advancement. That advancement is going into the driver class. After a man has been a driver with us three months, we have a salary review which is taken care of by the superintendent of delivery, the assistant general manager in charge of the delivery department, the assistant general manager in charge of the budgets of the store, and myself, the director of the motor school of training. We all meet and review the man's case and decide whether he is worthy of an increase or not. The important thing is whether he has had an accident. If a man can drive for three or six months without an accident, he is worthy of an increase and he gets one. If he doesn't get an increase, he is told why. It may be because of some violation on the road, something that might have resulted in an accident. We also take other things into consideration, such as damage to merchandise, etc.

We have eliminated our bonus system and substituted our salary review system, which we believe has brought about wonderful results, as a man knows he will get paid for what he does. If he does a poor job, at the end of six months we automatically let him go. In other words, a man must be able to get the increase at the end of six months. If he is not able to qualify to get the salary due, there is somebody else in the division who can do a much better job and we give that fellow a chance.

LAWRENCE K. BORGES (New York Telephone Co., Brooklyn, New York): I have often read articles on this so-called psychology test, and of the many articles that I have read very few of them are alike as to just what a psychology test should or does consist of.

I wonder if any of you people who have had some experience with these psychology tests could tell us just how they are made. Do you just use questions or do you use some of the new apparatus that is spoken of in some of the journals and magazines?

CHAIRMAN BINGHAM: We have representatives here from two companies which have had experience both with the personal interview type of inquiry and with the type of examination which involves the use of apparatus. The standardized test aims to simplify the task and give the prospective operator, or the driver a standardized situation in which it is possible for him to indicate precisely by his performance how quickly he can respond, how quickly he can discriminate and how accurately he can do his job.

Miss Engel, won't you tell us what the main psychological tests are you are now using? We haven't time for a full description of all of them. I just want the group to be aware of the fact that there is no one psychological test for expertness as a motorman or for safe operation. We have to use quite a variety of tests or standard tasks.

Miss ENGEL: We are using several types of tests. We also use intelligence tests and happen to be using the Otis test right now and we also use Terman test of intelligence.

We have an apparatus built to test reaction time in responding to various lights and signals on the flash boards.

We are also just starting to experiment with a special relations test, that is a train moving at a certain speed having the operator control one and the examiner control the other.

We are giving vision tests and also have a complete physical examination.

The apparatus is quite complicated and I don't think I can give you a description of it here.

CHAIRMAN BINGHAM: You use as your reaction apparatus the front end of an automobile?

Miss ENGEL: We use the front end of an automobile with gear, brake, pedal, clutch and one light.

CHAIRMAN BINGHAM: One light means put your foot on the brake, another means press the accelerator, and so on. The different sorts of situations that the driver has to meet are simply presented to him under conditions where it is possible to measure the speed and correctness of response to those situations.

I want to add just one note. In this effort toward reduction of accidents through approach to the individual differences of people who are operating on highways, in automobiles, street cars or busses, we are at the same time engaged not only in reducing accidents but in bringing about a better occupational adjustment of many of these men—making them more competent in their work, giving them greater satisfaction in it, and greater earning power.

If they are constitutionally unqualified for this work it is a real kindness to them to move in the direction of getting them adjusted to something which they can do more satisfactorily to themselves and to society. In other words the safety movement and the movement for occupational adjustment are two phases of the same effort towards increased happiness, satisfaction and earning power of the workers of the world.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Education Division

October 2, 1928

The Technique of Safety Education in the Elementary and Secondary Schools

ROBERT J. FROST, Chairman
District Superintendent, New York City Schools

The first session of the Education Division at the Seventeenth Annual Safety Congress was called to order at nine-fifty o'clock by the chairman, Robt. J. Frost, District Superintendent, New York City Schools.

CHAIRMAN FROST: I want to say it is quite a new sensation for the chairman to appear at the Waldorf-Astoria at such a very early hour in the morning. In my regular life, or daily life, it is my custom once in a while to address school assemblies. I felt very much this morning like saying "Good morning children," but I presume that would not be just right. Let me say it is most gratifying to see such interest taken in the matter of safety.

I think you have all had opportunity before you entered this room of traveling through the corridors, seeing the other parts of the convention that were going into session, and also observing the exhibit. It simply puts this thought into our minds—that while the millions of workers are at their daily tasks in the various industries of our city, here we are at the invitation of a group of—well I would call them "Altruists"—the finest kind of altruists—to discuss the best ways of conserving life and limb of the millions who are not able to attend this convention this morning. I say, when a small group of men and women band themselves together to think out some way of conserving the life of the millions of others who cannot be present, that is what you would call real altruism.

Practical Cooperation for Safety

But of course there is another side to it. There is something practical in what a good many of these men and women are doing. Some are interested in mining; some are interested in the automobile line; some are interested in the railroads; and, of course, it is to their own benefit and advantage to see what they can do to teach the general public the matter of safety. Now I don't know who or how many in this hall can recall the high-wheeled bicycle, but I recall that as a boy. I remember the old lucifer match; I remember the old oil lamp. All of these things have passed away, giving place to what we call "safety matches," "safety bicycles," and I suppose we could say "safety lamps" or the electric bulbs.

The object of this morning's gathering is to see what we can glean from the

papers and talks of those who are to speak—just how we are to carry the message out to the various divisions, departments and schools that we represent.

Now we may talk safety; we may talk rules for safety and safety devices, but if there is any failure in any one of the safety elements, the safety device may be worthless. What we want as school people is to educate the young and the old to use the human intelligence, to use their brains, to be ever on the alert, to keep thinking of what should be done in case an accident should happen.

Now as to the schools of New York. I am assigned here by Superintendent Wm. J. O'Shea. As his representative it is not in my province to say anything that is too much in laudation of the New York City schools to the exclusion of the schools of other cities. I think the schools of every city in the country are on their guard to teach the children what should be taught in the saving of life and limb. In New York City we have a Safety Committee. We organized a course of study in fire prevention and safety—we link the two together—and in all grades of our schools teachers are instructed and directed to give the lessons that are outlined in this course of study. We have a course of study designed for classification I-A and up to 8-B. We have in the lower grades jingles and rhymes, the little things that children remember. In the upper grades we have the civic side of safety emphasized. We tell the children that it is their duty to guard their lives and to guard and protect the lives of others. We tell them it is incumbent on them as good citizens to study the safest way of doing the ordinary daily acts.

There is a committee of District Superintendents appointed by the Superintendent of Schools, and I just wish to read a little outline of what this committee recommended and what is going on in the schools.

Safety Work in the Public Schools

By ROBERT J. FROST

District Superintendent, New York City Schools

The safety of school children in the streets of the city of New York has had the earnest and continuous attention of the Department of Education.

Dr. William J. O'Shea, Superintendent of Schools, taking notice of the increased mortality among children in the city streets, directed that public meetings be held on the evening of December 9, 1926, in all of the seven hundred schools in the five boroughs. These meetings were held under the auspices of teachers and principals; speakers of note were invited to be present, and all of the parents were asked to attend as guests.

The activity had also the advantage of cooperation from the various radio stations, with a very decided expression of interest by the Reverend S. Parkes Cadman, in his Sunday afternoon radio discourse.

Dr. O'Shea requested that a committee of the District Superintendents of Schools, representing each of the five boroughs, be appointed, and this committee has been in monthly communication on the matter since that time.

The Police Department of the city of New York has maintained an earnest cooperation with the school authorities in correction of conditions, and a monthly statement is sent to each of the 23 District Superintendents in the five boroughs, recording the time, place, and character of accidents and fatalities. These reports serve as constant reminders to the school principals and teachers, and are used as the basis for admonition to pupils.

At the latest meeting of the committee of District Superintendents, held on Friday, June 8, the following statement of unanimous opinion was adopted, and its transmission directed to Dr. William J. O'Shea, Superintendent of Schools:

"It is the concensus of the committee that our studies of the problems of the safety of children in the streets show the urgent need for more play spaces. It is suggested that all play spaces around school buildings be left open, if possible.*

"The committee suggests that police legislation should be enacted providing that right corner turns should be stopped when the right of way is straight ahead.

"The committee desires to suggest that you be asked to publish and issue an appeal to parents which will show the causes of accidents disclosed by our committee, as noted in attached memorandum, urging upon parents closer supervision of their children on city streets, and that you ask all district superintendents and principals to speak of this matter at coming graduation exercises.

"The committee was united in the opinion that the work done by principals and teachers in the schools in this matter is commendable, and that the present urgent need is for the education of parents in a realization of the dangers to children, the fact being that most accidents occur outside of school hours."

I have an announcement—a telegram from one of our speakers, the first on the program, Mr. Frank A. Bouelle, Assistant Superintendent of Schools at Los Angeles, saying he will not be able to attend the Congress. In place of Mr. Bouelle, Mr. E. B. Lefferts, manager of the Public Safety Department, Automobile Club of Southern California, will deliver the first address or paper.

E. B. LEFFERTS: A telegram is always a very brief communication, and I know from the interest that Mr. Bouelle took in the proposed deliberations here in New York that it is a source of a great deal of regret to him that he is unable to be here and enter into the discussion this morning. He has sent me his paper, and having been very closely in touch with the work as carried on in Los Angeles and Southern California, I think that I can answer most questions which might occur to you as a result of his presentation of what is being done on the Coast.

Safety Teaching Through Extra Curricular Activities

By FRANK A. BOUELLE

Assistant Superintendent, Los Angeles City Schools

Many of the earlier attempts in safety teaching in the public schools were based solely on the so-called extra curricular activities such as annual safety days and safety weeks, when the idea of safety was stressed for a brief period and then forgotten for the remainder of the year. Such observances might have been considered sufficient to meet the problems of a former era, but they lack the scope necessary to meet present day conditions.

The last decade has witnessed more changes in the ideals and goals of society than any other period in the history of recent times. The strides made in industry, due to the stimulus of war needs, have had a reflex in nearly every field of human endeavor. We are now in the midst of a great mechanical age, with all its benefits and responsibilities. The tremendous advances in industry have come about largely as a result of the multitude of discoveries which have been made in modern science. The end of this progress seems remote, due to the prominent place given to science and its discoveries in modern thinking.

While standards of living have been raised and more time for leisure has resulted through the advances made by science and industry working together, it is also

*On June 14, 1928, 241 of these after-school outdoor playgrounds were made available to the children in the five boroughs.

true that problems have arisen as a consequence which are compelling serious consideration from every community. The constantly increasing number of accidents and deaths due to the introduction of modern machinery has become one of the major problems of the present age. Decided progress has been made in some fields where the problem has been attacked in the right way. Much remains to be done, however, judging by our continued bad records of accidents in other fields.

The modern school is distinguished from its predecessor in that it is for the first time in history making a serious attempt to relate the work of the school to the problems of modern life. It is here that we may find a justification, if any were needed, for the introduction of the subject of safety education in our school curriculum. Many school systems have already responded to the urgent call and a good beginning has been made. Development in the schools has lagged, in some instances, due to lack of an available technique. Different sections of the country have approached the problem from the standpoint of their varying needs and as a consequence practice has shown considerable variation.

An attempt will be made in this brief discussion to outline some of the methods being used in Southern California to carry on a program of safety education.

The present school law of California makes no provision for a general program of safety education. Only thrift and fire prevention, which may be considered as phases of safety education, are mentioned in the list of prescribed studies. Hence, strictly speaking, most of the work in safety education now being done in our schools is extra curricular. Already preliminary steps have been taken to amend our state law, with a view to the incorporation of safety education as a required subject in the elementary schools.

In spite of the lack of provision in the state law, insistent demands on the part of the public and educational leaders have caused most school districts and cities throughout the state to find a place for safety education in their school programs. The southern part of the state, comprising 13 counties, has perhaps a more unified plan of work than any other section of the state, due to the well directed efforts of the Automobile Club of Southern California, which has carried on a safety program through its Department of Public Safety for a period of years. This organization has afforded teachers and school officials an opportunity to pool their experiences and adopt those methods which have proven the most successful in actual practice.

The first serious attempts to teach safety education were made through the medium of the extra curricular activity variously designated as safety patrol or safety committee. The duties and responsibilities of such organizations are about the same throughout the country, though they may vary in detail. The general aim is to arouse the interest of the child through actual participation in the activity. Safety committees are usually given charge of the traffic in the halls, and cooperate with the playground teachers in requiring proper use of playground apparatus. Both boys and girls serve on safety committees, thus insuring the active interest of the whole school in the common problem.

Such committees also assist to some extent in the street traffic. Committeemen are never permitted to stand in the street to direct traffic. Their activity is limited to the curb line for it is generally felt that the direction of traffic is a man's job and should not be delegated to children. Several unfortunate experiments where children have been assigned as traffic officers have convinced local authorities that the hazards are too great for most children in the elementary schools to assume the risk involved. Where an officer is on duty, however, committeemen prove a very valuable adjunct by controlling the children, thereby relieving the officer to that extent and enabling him to give more attention to the flow of traffic.

Members of safety committees have also been assigned to the forty pedestrian subways recently constructed by the city, thus helping in their continual use by pupils.

During the past summer, safety committees were organized on all the ninety

vacation playgrounds, with the result that only a few accidents were reported in this activity.

At the present time safety committees have been organized in most of the two hundred ninety-three elementary schools of Los Angeles; in all of the twenty junior high schools and in several of the thirty-one senior high schools. No completely satisfactory type of organization has been worked out for the senior high schools up to the present time, and this will account for the smaller number of safety committees in this group of schools. Plans now under way will doubtless improve this condition in the near future.

While the extra curricular phases of safety education have received considerable attention during past years the most notable advances in recent years have been made in a different field—that of correlating the work in safety education with the subjects of the curriculum itself. As this phase of safety education will probably be discussed by others, only a brief resume of this work will be made here.

Beginning with the kindergarten, largely through games, the children are taught the safe way to do things. One game which is much used is known as the "Traffic Game." A street intersection is outlined on the classroom floor. One child then acts as a traffic officer, and others as street cars, automobiles and pedestrians. Upon the blowing of a whistle by the traffic officer the traffic moves, and the pedestrians are governed by the general traffic movement, as all pedestrians are required to do under the traffic regulations in our community. Sometimes the children are invited to bring their little scooters and toy automobiles to make the game more realistic. The "Lost Child Game" is another game in which the child is taught his name, address and telephone number, the purpose of which is obvious.

Dramatization is much used in all the grades, pupils oftentimes writing their own safety plays. Different grades take part in the presentation of the plays at school assemblies. Members of one school recently visited a traffic court room in order to obtain first hand information about court surroundings, and court procedure, thus insuring a correct stage representation. By such methods the work in safety education is made a real problem and related to modern life.

Language affords a splendid approach. Children occasionally write essays about accidents which have happened at home or on the playground, or danger hazards which they have observed in the community. Some schools have organized clipping bureaus and pupils are invited to bring newspaper clippings of accidents which are used in connection with work in language.

The thought must be made clear that nowhere in the program of safety education are gruesome features of accidents emphasized or made prominent. The creation of a fear complex is always avoided and the work is based on the idea of teaching pupils the proper way to do things, which is the safe way. It is a program of "do" in the right way rather than one of "don't" because it is wrong. Oral reports are prepared on the way to prevent accidents on the playground, in the home, and on the street. Upper grade pupils are invited to give talks to the lower grades, and in this manner a direct contact is established between all members of the school community.

In civics, besides the study of traffic regulations and their strict observance, pupils have been encouraged to search for the sources of information regarding accidents, their location, and cause. Reports of the police department, coroner's office, and other government agencies have been obtained and studied. In some cases it has been possible without interfering with the business of these departments of government to establish direct contact with someone who could furnish valuable information pertaining to accidents. Statistical data obtained from these sources have been used as the basis for problems in arithmetic.

Nature study is another fertile field offering a wealth of materials. Safety education is in reality but a part of the larger problem of conservation. This includes not only human life but animal and plant life as well. Two of our most

important sectional problems in conservation, those of reforestation and protection of water sheds, are receiving particular attention locally at this time, due to the number of forest fires which have devastated large mountain areas. Classes in reforestation have actually been organized in the schools. Thousands of trees have been planted on important water sheds to replace a portion of those lost through forest fires. Nature's devices to protect animal life such as may be found in the lizard, the turtle, the deer, the rabbit, and the different species of birds, furnish appropriate material for many interesting discussions.

Some phases of history teaching lend themselves to discussions in safety education. Take, for instance, the problems confronting modern communities in transportation matters. Los Angeles County with its 700,000 automobiles faces a problem that was utterly unknown in this country as recently as a quarter of a century ago. It has been said that to truly appreciate history it is necessary for the student to identify himself with the period about which he is studying. Hence a study of the intricate problems of modern life can be made to help the student better to understand the problems of former generations.

As part of the geography work some schools have had pupils write letters to children in other lands, telling them about conditions on the streets and highways in this country, together with their own work as members of safety committees. The answers usually bring forth a reply describing the methods of transportation and difficulties of traffic, if any, in the other country, and sometimes enclosing pictures showing the peculiar conditions existing in the foreign land.

Over 50 per cent of the accidents occurring in our local schools happen on the school grounds. By enlisting the active interest and support of the department of physical education, progress has been made in reducing the number of such accidents. A pamphlet giving the safe way of using playground apparatus has been worked out by this department and placed in the hands of teachers of this subject and squad leaders of physical education classes. The results during the past year indicate that there has been a reduction in the number of certain types of playground accidents, especially those on playground apparatus.

There are in Southern California at the present time over ten thousand active members of safety committees. This large organization represents a practical application of the work in citizenship being carried on in our schools. The children are led to a better understanding of the purposes of many of our governmental activities because of the active part taken by them in their various school safety organizations. The work done by pupil committees on health, traffic control in the halls, cafeterias, and on the playground, monthly fire drills, inspection of fire fighting apparatus, should have a very direct bearing on their whole civic outlook. At least it has given them a direct participation in some of the problems which they must face only a few years hence as adult citizens.

It may be of interest to give a brief description of the school accident work as carried on in this city.

Every accident which happens to pupils from the time they leave home in the morning to the time they return to their homes from their respective schools is reported on the official accident report blank provided for that purpose. The report is made out at once by the teacher under whose jurisdiction the accident occurs, and is sent to the principal's office. The completed accident report is then sent to the office of the assistant superintendent in charge of safety education. They are there checked and at the end of the school month a summary is made, which is forwarded to the heads of the various administrative and supervisory departments. Copies of all accident reports received during the month are sent to the various departments involved, where an immediate investigation is made to discover causes and remedies. This plan has proved effective in reducing accidents in certain departments, where accidents indicated an upward tendency. It has also served to call attention to certain accident hazards which have been corrected at once by

the proper officials. Continuous study of the school accident problem has already brought about the elimination of three pieces of playground apparatus which were causing many accidents and were of doubtful value from the standpoint of physical education, namely, the see-saw, the high slide and the high swings.

A number of schools are using the plan just described for keeping track of the school accidents happening under their immediate jurisdiction. Members of safety committees make it a part of their business to investigate the conditions that appear to be responsible for accidents and make recommendations to the principal of the school for their correction.

Another feature of our safety work has been the organization of the Superintendents' Safety Committee, composed of supervisors, principals, teachers and members of the business department. At the present time the committee is composed of thirty members. Every department which is in any way connected with the problem of safety is represented in the membership of the committee. Meetings are held monthly, and plans are discussed to further the work of safety education in our schools. Members of this committee are responsible for the making of the present course of study in safety education, which is used throughout Southern California.

The exhibits on display at the conference will indicate some of the methods being used to carry on the safety program in Southern California schools. Methods vary in different cities in our country, and doubtless many ways will be suggested by other workers to reach the goal in which we are all interested.

Much progress will be made in safety education through conferences such as the present one where the results of the active workers in the field may be presented and evaluated. The National Safety Council deserves much credit for giving a place in its program for such discussions.

In conclusion, it is perhaps impossible to eliminate all danger in the life of today. A hazardless life might prove to be most uninteresting and empty. The aim of safety teaching, it seems to the writer, should be to teach children the folly of taking unnecessary chances which are certain to result in injury to themselves or to others. Appreciation of relative values should be stressed early in life so that the child will turn instinctively to the right way of doing things; thus our work in safety education through the elimination of all the avoidable accidents possible will have done its part in helping humanity to live happier and more useful lives.

MISS A. GERTRUDE JACOB (New York): I would like to ask whether in teaching High School students you would not emphasize the result of accidents or give illustrations of bad accidents?

MR. LEFFERTS: By that do you mean to give an actual photograph of all the details of the accident, or simply the results?

MISS JACOBS: Would you give a concrete example of the shirtwaist factory fire that happened in New York and give an illustration of what happened and show how fire drill would have helped?

MR. LEFFERTS: Describing how these people were burned to death would not help. It would emphasize the need of a fire escape. But it would not be necessary to emphasize what they went through. We give them the result. Here is a table, for instance, that is being used in the Junior High Schools for correlation in mathematics. It shows the different types of accidents that have resulted fatally in the City of Los Angeles in 1926 and 1927. Those figures are used in mathematics. But it is not going into all the gruesome details as to how the accident happened with the idea of scaring the child into not doing it. That is what I think Mr. Bouelle meant.

MR. HARRISON (Milwaukee, Wis.): We found that with the Safety Patrol or Safety Squads a question of responsibility arose. I notice Mr. Bouelle said nothing

about the organization being responsible. I should like to know if there is any case on record that would give an answer to the question. Is there any evidence to indicate that the child has recourse against the principal for being placed at any particular place?

MR. LEFFERTS: I can answer that for California. In our state the Board of Education is responsible for the child from the time it leaves home until the time it returns home at night, and if an accident happens to that child they are individually and collectively liable. In one of the schools a child was burned at an incinerator on the school grounds which evidence showed had not been properly guarded. Damages were collected from the Board of Education for their negligence. Some communities have had a release signed by the parents to release them from liability. We haven't felt in Los Angeles that traffic regulation was a job for the child to take but that it was a community responsibility and not a school responsibility. In one or two instances it was tried and the child was knocked down and injured. No suit was brought against the school in those instances. But this put a damper on the use of children in our communities for traffic regulation.

MISS HYACINTH RIGGIO (P. S. No. 172, New York): I notice that in your report it says "the education of the parents," and I was wondering if in your schools you educate the parents?

MR. LEFFERTS: We have the Parent-Teacher Association which has practically a one hundred per cent registration. They put on a program every month in some of them, and at least once a year in the others. The Parent-Teacher Association assists in that way.

CHAIRMAN FROST: The second number will be handled by Mr. Albert Loewinthan, Principal, P. S. 30, that is the Yorkville Junior High School, Manhattan.

Work of New York City Schools in Educating for Safety on the Streets and in the Home

By ALBERT LOEWINTHAN

Principal of the Yorkville Junior High School, New York City

I take it that I am to present to you as broad and as wide a scope of the work done in the New York City schools as possible. We are all groping for knowledge. We are all looking for information to aid us in this task of safeguarding the lives of our school children. It is our hope that what has been done in New York City schools might be helpful in the educational activities along the line of safety in other cities.

According to a statement made in this program, about 20,000 children of school age are killed throughout the country each year. The statement is also made that, at least, 50 per cent of these lives can be saved through safety education and that this work can be done without additional teachers and without additional time. To me, it seems that that statement is a truism, for here in New York City, by virtue of the expensiveness of the work on safety education, much has been done to relieve the situation. I know personally and intimately of the work done in Public School No. 30, Manhattan, and I know that the intensive application to work in safety has netted splendid results so far as our children are concerned.

What has New York City done in educating for safety in the street and in the home?

On May 14, 1924, the Board of Education of New York City, adopted a course of study and syllabus in Fire and Accident Prevention, which outlined the work that was to be done in the schools throughout the city. It might be possible for

those who are interested, to get a copy of that syllabus by applying to the Board of Education, 500 Park Avenue.

It was just about that same time, that Dr. William J. O'Shea, Superintendent of Schools of New York City, animated by a desire to spread the news of safety work and to have a medium for the exchange of ideas on safety, upon authorization of the Board of Education, had the *Safety News* issued in the interest of the safety of the children of New York City.

On November 17, 1926, Dr. O'Shea issued General Circular No. 16 on the "Safety of School Children." In it the Superintendent of Schools made it clear that both police department and public schools had conducted active campaigns for many years to impress upon the children and adults the importance of exercising extreme care in crossing streets. Here is what the Superintendent of Schools said:

Safety of School Children

"As you know, both the Police Department and the public schools have been conducting active campaigns for many years to impress upon children and adults the necessity of exercising extreme care in crossing streets. To increase the efficiency of this campaign, arrangements have been made with Commissioner McLaughlin whereby the Police Department will send to me every month a report showing the number of children under sixteen years of age who are killed or injured as the result of accidents on the streets, arranged so as to show the number of accidents in each school district and the causes of the accidents. By this means we hope to bring home more closely to principals, teachers and citizens generally the loss of life and the large number of serious injuries to children which result every month—indeed every day—in our streets."

These reports submitted by the Police Department were turned over to the District Superintendents and discussed by them with the principals at various principals' conferences. In that way the matter of safety was kept alive in all schools.

General Circular No. 16, issued November 17, 1926, goes on to say "although the schools are called upon to perform many functions, there is no work more important for them than the teaching of lessons of safety to our children. Nothing is sadder than the sudden death of a child, taken from his parents without warning; blasting his hopes for a future career and leaving a memory of grief that will last as long as the parents live. Many of the children who are injured will carry for the remainder of their lives the effects of their injuries. While other aims of school are important, yet we must emphasize continually this campaign of safety. Because, if by our efforts, one child is saved from death, or serious injury, the work of the public schools will have been of decided benefit. Special attention should be given to our course of study on safety. This should be supplemented by motion and still pictures; safety games and plays, special talks and lessons on safety and many other devices. Will you please call the attention of the parents of your pupils to this matter, because the cooperation of parents is of prime importance."

Thus, the Superintendent of New York City Schools calls the principals and teachers of New York City to arms in clear trumpet-like tones to do battle for the safety of the children of New York City. The fundamental aim in this campaign of safety is definitely and clearly outlined.

In General Circular No. 18, issued November 30, 1926, titled "Safety Movement in Schools," the Superintendent of Schools wrote, "in view of the large number of children who are killed or injured in street accidents, it is desired to extend the safety campaign as far as possible. Therefore, you are requested to hold a meet-

ing of parents and others interested in schools, at your school on Thursday, December 9, at 8:00 o'clock p. m."

In this circular the superintendent offered suggestions for program; suggestions for publicity; outlined points suggested for discussion. The following points were outlined for attention:

- a. Principals were asked to refresh their memories by reading the syllabus on Fire and Accident Prevention, 1924.
- b. Reference was to be made to the tabulation on mortality and casuary prepared by the Police Department.
- c. Special stress was to be placed on the adaptation of these facts to our own locality. This data was to be discussed by the District Superintendent at his conference.
- d. A clear and explicit explanation for the regulations for the movements of children, i. e., either going to and leaving school building and a call for cooperation by parents in the observance of these regulations was to be made.
- e. The agencies for cooperation in lessening the dangers were to be discussed thoroughly, i. e.,
 1. School
 2. Police
 3. Family

Principals were asked to stress the responsibility of parents in the matter of safety. The parents should be impressed with the need of following up the safety movement and not allowing interest and attention in it to be relaxed.

The Superintendent of Schools wrote,

"The school relies for improvement in condition largely on parent's cooperation. It is in truth a problem for parents, it bears upon that which is their dearest possession—their own children.

Teachers will be asked to make it a habit as they do in the daily health examination to caution their pupils before every dismissal—1. care in crossing street corners. District superintendents will make the monthly reports issued by the police department the subject of discussion at their conferences monthly with principals.

Principals in turn will make the data the subject of their conferences with their teachers, the purpose being to permit at no point hereafter any relaxation in our efforts."

That was the purport of the circular of November 30, 1926, issued by Dr. William J. O'Shea, Superintendent of Schools to district superintendents and principals. It made definite the ideas conveyed in previous circulars and it placed a decided responsibility upon the schools and their organizations to teach effectively the lessons of safety.

On April 19, 1927, in General Circular No. 38 issued to district superintendents and principals by the superintendents of schools, the school safety campaign is again stressed:

- a) There is a paragraph about accidents to school children in the streets.
- b) There is a caption headed: increase of accidents in March.
- c) There is a statement giving the principal causes of accidents.
- d) There is a definite call to set aside April 26 as a day for safety instruction.

The statement is precise and definite.

The superintendent of schools says: "Will you please, therefore, set aside Tuesday, April 26th, as a day for calling the attention of all children to the dangers of the streets and to the cautions as to safety which you have imparted previously. Please have talks given in every assembly room and by all teachers to their classes. Please emphasize the dangers of roller

skating in the roadway and playing in the roadway, and call to the attention of children the simple precautions which were set forth in previous communications on this subject. If there are playgrounds near your school encourage the children to use them. Observation shows that in many cases large numbers of children are found playing in the streets although the number of children using the playgrounds is not equal to the accommodations provided in some playgrounds. If there are special danger points near your school call the attention of the children to them. Repeat the simple rules which you made previously as to the corners at which they should cross dangerous streets. Other matters that should be presented to the pupils as part of the day's instructions are left to your own judgment and knowledge of neighborhood conditions.

Valuable information on this subject will be found in the following:

25th Year Book of the National Society for the Study of Education, Part I—Published by Public School Publishing Co., Bloomington, Ill.

"Safety Education in the Elementary Schools," by Ruth Streitz—Published by the National Bureau of Casualty and Surety Underwriters, 120 West 42nd Street.

"A Program of Education in Accident Prevention," Bulletin 1,922, No. 32, Published by the Bureau of Education, Department of Interior, Washington, D. C.

These pamphlets contain full bibliographies.

General Circular No. 20—December 8, 1926.

General Circular No. 21—Items V and VIII—December 10, 1926.

As a direct result of the inspirational utterances of the Superintendent of Schools, a great deal of constructive work has been done in the matter of educating for safety on the streets and in the home. It is impossible to give in the short space of twenty minutes an account of what has been done in safety education in our Metropolitan City with its more than 1,000,000 school children, over 30,000 teachers and about 700 school buildings. Because I feel that my talk in this brief period can hardly do justice to the scope and sweep of the work in New York City, I have prepared a number of mimeographed sheets giving in detail the work that has been done in one of our schools in New York City. I know that that work represents a cross section of the endeavors of the schools of New York City and I offer it to you for your information and kindly consideration.

The first of these mimeographed sheets gives an outline of the Safety Program planned for this term, September, 1928, to February, 1929, in Public School No. 30, Manhattan, the Yorkville Junior High School. The plan shows how week by week the matter of Safety Education will be kept alive and varied and how without giving extra time, without requiring extra teachers, without entailing extra expense, safety will be taught.

Then there is presented a progressive day by day record of the work carried on in the school from March to June, 1924, that work culminating in a Safety Demonstration and Exhibition under the auspices of the National Safety Council. Then, too, there is an outline of curricular activities by grades, correlated with the course of study and curricular activities by subjects. There is also a statement giving a comprehensive plan of, the safety demonstration and exhibition held in Public School No. 30, Manhattan, under the auspices of the National Safety Council, including an outline of the general projects for school work from 3A through 8B. Extra curricular activities in the form of Safety Court and Safety Patrol are explained.

I have on hand a limited number of copies of the "Safety News," published by a Committee of Teachers of the City of New York, and a pamphlet showing the organization of the Street Safety School Patrol, printed by the New York Automobile Club, and approved by Dr. William J. O'Shea, Superintendent of Schools.

CHAIRMAN FROST: I am sure we are very grateful for Mr. Loewinthan's talk.

MISS A. P. LAWRENCE (P. S. 40, Bronx, N. Y.): I want to know if the responsibility of the school begins when the child leaves the home and ends when the child returns home, or does it begin when the child is given into the hands of the teacher and end when it leaves the teacher?

MR. LOEWINTHAN: I am not so versed in the law. It is possible that our Superintendent is better versed.

CHAIRMAN FROST: The question was "Has the school responsibility from the time the child leaves the home until it returns." In New York schools we assume no responsibility once the children are dismissed and out of the care of the teacher. Then the Police Department takes up the care of the child. Dr. O'Shea forbade any of the Safety Patrol to go out and act as patrolmen. Of course, if a child is sent out by authority of the school to a certain place, then the school assumes responsibility, or I judge the law would hold the school liable.

MR. LASHER (Georgia Car Co., Atlanta, Ga.): May I ask in what grade you start your work of artificial resuscitation?

MR. LOEWINTHAN: From 7-A to 9-B. We have a Junior High School and this work is taken care of by the Health Department in cooperation with the school swimming instructor.

CHAIRMAN FROST: The next number on the program is by Mary O. Pottenger, Supervisor, Elementary Education, Springfield, Mass.

The Place of Safety in the Elementary School Curriculum

By **MARY O. POTTENGER**

Supervisor, Elementary Education, Springfield, Mass.

In discussing the subject which has been announced I shall attempt to consider

1. Child fatalities and their causes.
2. The relation of safety to education.
3. The school of the present as a medium through which safety instruction may be effected.
4. Educational methods.
5. Present day practices in educational systems.
6. Results of safety instruction and desirable outcomes.

I. During the year 1927, of the 95,500 fatalities in the United States approximately 20,000 were children under 15 years of age. The National Safety Council in a study of the death rate of children ranging in age from infancy to fifteen years came to the following conclusions:

0 to 4	5 to 9	9 to 14
1. Bronchial pneumonia	1. Accidents	1. Accidents
2. Diarrhea	2. Diphtheria	2. Tuberculosis
3. Accidents	3. Tuberculosis	3. Heart disease

These figures at once compel the interest and thoughtful consideration of educators.

The causes of these accidents may be attributed to young children's unconsciousness of danger, the adventurous spirit of youth, and the multiplicity of situations in modern life which involve danger. The last factor named determines much of the subject matter of safety instruction.

II. The fundamental aims of education would enable the child to adjust himself to the social group of which he is a part and to present-day living conditions. Moreover, they would fit the child to meet the needs of the future. This involves a steadily growing experience and in a measure, power to direct the future. Any condition which affects the child's present experience and his future success and happiness is of educational significance. Any condition which may thwart his development presents a problem for solution by those who are in the business of education. There are no more serious problems than those which have to do with the child's successful adjustments to his environment with relation to safety. This responsibility is recognized by those associated with the schools and in a large measure is being assumed by them.

III. Almost as great a contrast is seen within the walls of the schools of the present compared with the schools of the past as is seen in comparing the homes and the streets of the present with the homes and the streets of the past.

The school of the present places its emphasis not on formal instruction but on activity as a basis for learning. This type of school affords opportunity for children to engage in individual and group interests. We believe that children learn through living together, playing together, working together; through engaging in experiences first hand; through attempting to solve their own problems; through making their own mistakes, achieving their own successes, and having these successes do to them what success does to you and to me.

This type of school has become flexible in the nature of its program and its time schedule. The time schedule in the past was limited by the five hour day. The distribution of time was made among the various subjects without regard to their social values. So many minutes a day were allotted to each subject, arithmetic taking the lead. The program did not permit time to vary nor special interest to be pursued. The present time schedule, while limited by the five hour day, has transferred the emphasis to those subjects which are of greatest social value and is sufficiently flexible to permit individual and group interests to be pursued.

The tendency of the past was to organize each new field of subject matter into a subject of study. At present the reverse is true and we find fusion in place of differentiation, units of teaching involving related subject matters in place of unrelated lessons in geography, history, civics, etc. Convinced as we are that these methods are based on the best psychology of learning known to us at present we believe that safety should find its place in the curriculum, not as a separate subject, but when and where it is related to the problems under consideration, e.g., it is closely related to the social studies. It is used as a medium for development of oral and written language. The safety problems of the community become arithmetic. It is an important factor in physical education for skill in the control of bodily movement may be the means of saving life.

IV. Spectacular methods of teaching safety are responsible for much discredit which has fallen on safety teaching. We have mutilated our Mother Goose Rhymes, indulged in an inferior type of songs and plays, and generally lowered our standards of teaching. When we base safety teaching on the same fundamental principles which apply to all good teaching we may hope to live down this record.

I would suggest three methods of safety instruction which in my judgment are in keeping with the best teaching procedure.

First, making safety a part of the school program whenever the subject matter of safety is related to the subject under consideration, e.g., in the social studies, storm warning and the work of the weather bureau in reducing hurricane disasters,

safety precautions taken by Commander Byrd in his trip to the South Pole, equipping machinery with mechanical devices for reducing industrial accidents as a factor in industrial geography.

Second, teaching safety in actual situations where the need for safety is apparent, e. g., the child on the street in relation to traffic or the safe use of playground equipment.

Third, the organization of safety patrols and junior safety councils. This method being discussed by another, I only hint at its importance.

V. Educational work in safety in the following cities:

St. Louis—Old and new courses.

Kansas City.

Detroit.

Louisville.

Newark.

Worcester

Springfield—Mass state course.

Place in curriculum.

Illustrative program.

VI. At the present time our information is not sufficiently reliable for judging the measure in which safety teaching in the schools is responsible for reducing accidents to children, nor can we measure the degree to which safety habits formed in the elementary grades carry over into the junior and senior high schools. There are too many factors to be considered and adequate statistics are not available. There are indications, however, that this work is not without its reward in preserving life and reducing those accidents which result in permanent injuries thus handicapping children for life.

In addition to reduction and eventually to the elimination of preventable accidents let us hope that safety teaching may develop right attitudes which make for a high type of citizenship, namely, willingness to assume responsibility for the safety of self and others, willingness to cooperate in organized efforts to secure safety, interest in the social significance of safety, and respect for law and officers of the law.

CHAIRMAN FROST: No questions? This is taken from the New York pamphlet "Course of Study and Syllabus in Fire and Accident Prevention." "No set time is required to be assigned on the daily time schedule for this instruction. Better results are to be obtained from skilful correlation with the various subjects already in the curriculum."

The next lecture will be ten-minute talks, and unless there is great need for it we will have to dispense with the discussion owing to the time. The first talk will be "The Social Studies" by H. Louise Cottrell, Head Teacher, Stockton School, East Orange, New Jersey.

Social Studies

By MISS H. LOUISE COTTRELL

Head Teacher, Stockton School, East Orange, N. J.

I have chosen to open my brief discussion this morning with a letter written by our City Engineer in East Orange to a Sixth Grade boy.

"Master Nelson Benedict, Stockton School, East Orange, New Jersey. My dear Master Benedict: Your letter asking for material for a safety exhibit was received, and I have been in some doubt as to how I can help you. I am anxious to do what I can, however, and would suggest that you call on me at my office

at the City Hall some afternoon between 3:00 and 4:00 o'clock so we can talk it over. Yours very truly, W. D. Willigerod, City Engineer."

The spirit of that letter from a busy city engineer to a Sixth Grade boy explains my presence here today. Across the river are groups of Sixth Grade boys and girls who learn each year to know their community better, not merely a lot of facts about it, but the meaning of community life—what it does for them—how it does it—what the community has a right to expect of them and how they may fulfill their obligations. Thus the sixth grades make a study of the organized agencies of the city. Did you ever stop to think how many different departments of the city are really organized to protect life, health and property? Unconsciously then, those children are developing social attitudes related to safety, directly or indirectly. I am here merely as their spokesman to tell you a few of their class activities which have helped to develop these right attitudes. The average sixth grade child has a most morbid idea of safety. He likes to tell you about and bring in clippings of terrible accidents. Therefore, the emphasis is placed on deeper appreciation of accident prevention, to be obtained in a positive, wholesome way.

Accident prevention, like any other teaching, requires definite planning. The teacher, however, must be ready to seize any opportunity to utilize unexpected happenings in the classroom to make such teachings vital. For example, last year the reading of a composition written by a Boy Scout brought forth criticism from members of the class. A safety rule had been broken. It was a composition regarding a hike that he had taken. Since, in the brief remainder of the period, several boys could not be convinced that hitching on the side of automobiles was wrong, the children decided that their "Help, Study and Obey Club," the sixth grade civic organization, should take up the matter, and their teacher feeling the need of an entirely different attitude on the part of some members of the class toward safety, and noting the enthusiasm of the class as a whole to continue the discussion, decided on something more strenuous than a club program—namely a correlation of all school subjects with highway safety. My remarks today will be confined simply to those safety activities correlated with the Social Studies.

I was surprised the next morning after the reading of the composition to have one of the smallest girls say to me, "My cousin is a policeman, so Edwarda and I went up to the police station yesterday to find out about accidents in East Orange." Her informal report made a splendid introduction to the next town and city life lesson.

The children were so enthusiastic that they decided to form groups to make a city survey, as had been done before in solving another problem. These are the questions each group was to answer: "What is the city doing for me?" "How is it being done?" "What does the community expect from me?" "How may I assist?" Let me tell you what these groups did.

Several of the boys at the invitation of Mr. Willigerod, the City Engineer, spent part of an afternoon going about the city in his automobile. At his suggestion they were armed with paper, pencil and cameras. Next day they showed the class the drawings they had made. For example, a corner rounded off to make it easier for autos to turn corners. In a few days the photographs appeared—rough pavements on hills to prevent skidding, new traffic lights, and so on. I wish I had a copy of the report those boys made to the class. It certainly gave them a better idea than they had before of what the Street Department was doing to prevent accidents.

The group who visited the Recreation Department came back with maps showing where the various playgrounds were located and a series of pictures of playground activities to show how much more attractive such places are for play than the dangerous streets.

The Police Department played its part too in this city survey. From that centre much of the information was obtained for the "spot maps" which the children made,

showing where accidents happen, where the traffic lights are located, where traffic officers are stationed, and so on.

Later, when the Stockton Traffic Court was organized, it was to the traffic officer that the newly elected "clerk" turned to get the proper wording for the very necessary summons. One night the judge and other members of this little school court attended the City Traffic Court. Judge Stasse had the children sit right near him and gave them a great deal of help and attention. When asked what changes they would make in conducting their own proceedings after a visit to a real traffic court, the youthful "judge" replied: "I am going to make everybody stand up when I come into the room and I'll have to have a 'gravel' (gavel)" as he put it, "to pound the desk with." It was a rather amusing but disappointing answer. However, that group must have received some training in citizenship far beyond the immediate purpose for which the Safety Council was organized.

The writing of letters helped the children to establish contacts outside of city limits. From such state organizations as the State Motor Vehicle Department and the State Highway Commission, which are interested in the protection of lives, came hearty cooperation and much printed material which made a splendid addition to the June Safety Exhibit which brings the safety work to a close each year. The letter of one child, who was a member of a committee working to find out what the commercial world was doing to prevent accidents, brought to the building a representative of a certain company with a real traffic light. Can you imagine the thrill those boys had in the opportunity to manipulate a real safety light? And he drove home lessons in safety that a school teacher could never hope to accomplish. I have some times marveled at the amount of time busy men have been willing to give these children. It is probably because they have come to realize the value and possibilities of the endeavors of the schools to reduce accidents.

The experiences drawn upon are common to adult as well as to youth. Is not safety teaching then a most important means of developing a sense of social and civic responsibility? Would that the social outcomes could be measured; the desire to help rather than hinder; the cooperation in collecting valuable facts and information; contacts with local and state officials, also agencies, all working for the same worthy purpose—the saving of human life.

The problem of "How May I Best Help Others?" was solved by a month's campaign, conducted by the sixth grade to teach and influence the lower grades. I haven't time to go into that but here was a social attitude of another type being developed—the contacts of older children with younger children. In helping the younger to protect themselves they were learning to respect social responsibility.

And now let me turn rather abruptly to another phase of the Social Studies work. History is no longer learned as a succession of dates and battles; nor geography as so many isolated facts, definitions and locations, but what is more vital—how man, despite obstacles, formed a better civilization. Let me mention some of the situations, which naturally arise in a Social Studies course, which may be utilized to help a child to meet the hazards of the complex life about him.

Good roads have had much to do with progress. In olden times the nations who built the good roads became the great peoples of the earth. Rome became the leader of the world because she was crossed and re-crossed by good roads. France in the late war owed much of her success to the condition of roads. The development of our own country parallels the history of road building—deer paths—pioneer roads. (At this time the children enjoy the poem which tells of the difficulties Farmer John had in getting to town on a rainy day and includes this stanza: "They sink, now just the horses' ears, still struggling through the flood; now nothing but John's hat appears above that sea of mud.") Then the national roads, and our fine modern highways. This led up to the problem last year—"Is the State of New Jersey justified in spending millions of dollars on new highways and repairs

for the old?" The following conclusions may be drawn: Good roads and safety devices help to prevent accidents, but since a great number of accidents still occur on good roads, the people are to blame. Accidents will not decrease until the people choose to be safe. Should not such study bring the subject of highway safety closer to the children?

There is other Social Studies materials which is related directly or indirectly to safety problems today. Mr. Lew R. Palmer says: "The history of safety can well be said to parallel the history of man." What were the dangers of the Cave Man? How did he meet them? The common thought—safety—was emphasized in the lives of these, as well as other early peoples—whether it was animals, disease, cold, hunger, the powerful forces of Nature—fight they had to and conquer they must for self-preservation. And so civilization progressed.

Just at this time—as Fire Prevention Week approaches—the history of fire, which is the history of progress, is introduced. Starting with the simple story of how sparks flying from two stones struck together changed the life of the Cave Man, the children are led to see how man learned gradually to tame the "red monster" and make him his servant, thus developing one of the greatest forces of nature—that, if properly treated, Fire has been, and still is, a great friend of man. Then, in the proper places, is emphasized the thought that by education and science other dangers have been overcome—many diseases, fear of the sea, water supplies, etc. But, in turn, other problems of safety have arisen—autos, electricity, railroads and science and education are continually striving to solve these problems. Should not the study of civilization from this viewpoint make the child realize that safety has been and probably always will be a major problem with all, and take away that feeling that safety is merely set after set of dry rules to keep children from doing things they want to do? And that, after all—"The desire of a man to be careful is the greatest safety device known?"

CHAIRMAN FROST: We will now hear from Mr. Thomas F. Power, Assistant Superintendent of Schools, Worcester, Mass.

The Development of a Unit in Safety Education, Usable from Kindergarten to Grade 9

By THOMAS F. POWER

Assistant Superintendent of Schools, Worcester, Massachusetts

Before an exposition can be given of the development of a complete unit in safety education, several premises must be assumed or established. This address assumes two propositions: first, that from economic and psychological points of view there is a need of educating children for safety; second, that there is a responsibility upon school people to place safety education in the curriculum. The latter assumes the further premise that educating for safety is justifiable pedagogically. These two major assumptions and the minor one can be proved and have been proved in other addresses and in other papers by others and by the speaker, as well. The major objective of this address is to demonstrate how to develop one particular unit throughout the eight grades and in relation to the already established subjects of the curriculum.

In May of this year, the speaker secured and distributed through the public grammar schools of Worcester, Mass., statistics on accidents to children on railroads of the United States, including New England, and particularly on a certain railroad operating through Worcester. In brief, these figures showed: total number of children killed and injured while trespassing on railroad property, and the classification of these by causes, that is, the tables showed "what" happened and "why" they happened—throughout the United States. Similar tables were

arranged for accidents on some railroads in New England; and other tables for accidents to children on a particular railroad through Worcester.

The speaker bulletined all these data to the 900 teachers of kindergarten and grades 1 to 8 with the instruction that the material be treated as lesson material in safety according to the suggestions and procedures supplied in our safety course, issued in 1927.

A summary of how the material was used by the teachers is as follows: booklets were made by individual schools, rooms or pupils containing examples of the correlation of the data with handwork in the kindergarten and primary grades, with language work in the primary grades, compositions in English in the intermediate grades, drawing in the intermediate grades; problems in arithmetic involving simple processes in intermediate grades, letters in English, construction of safety rules, construction of graphs, broken line, bar and circular, more difficult problems in percentage, etc., etc., in the upper grades.

A typical school booklet would be constructed as follows: a clipped picture from a National Safety Council Calendar of a railroad engineer looking out of his cab would appear as a preface. The title is "Will they stop, look and listen?" This was cut out by a kindergarten child. Other kindergarten offerings were simple drawings of one or two railroad cars drawn by a locomotive. Grade one offered other simple drawings of railroad trains, but gave the pictures titles, such as, "Stop, Look, Listen." Grade two presented compositions of three or four sentences on such topics as "The Railroad Crossing Near Our Schoolhouse," "The Ambulance," etc., calling attention to accidents from crossing the railroad while the gates are down. These compositions were illustrated with colored crayons. Problems in simple, easy processes of addition and subtraction were made and worked out by pupils in grades two and three. A few examples of these are: in Massachusetts 41 people were killed and 47 injured. How many more were injured than killed? In Rhode Island 11 people were killed and 7 injured. How many were killed and injured? In walking along a railroad, 444 people were killed and 459 were injured. How many were killed and injured? What was the difference between the number of those injured and of those killed?

In grades 4, 5 and 6 pupils wrote letters of personification; imagining the locomotive could talk to school children and tell what it sees as it goes over the tracks. One example will serve the purpose here: "Dear children, yesterday, I was going to Springfield. I saw two boys picking up coal on the tracks. I snorted and puffed at them, but they did not heed me. They did not run until I was a few feet away from them. If they had not started to run they would have been killed. So please keep away from my yard. It is a dangerous playground. Yours truly, Eddie Engine."

Here are some rules for safety worked up as a class project in grade 4. These were copied as formal exercises in penmanship.

A Soldier of Safety

1. Keeps away from railroad tracks.
2. Looks both ways before crossing tracks.
3. Does not hop on or off moving cars.
4. Heeds the warning of lights and bells.
5. Never walks on tracks.
6. Waits until gates are up.
7. Keeps out of the freight yards.
8. Never picks up coal on the railroad tracks.
9. Stops, looks, listens.

Under the title "Cross Crossings Cautiously," the following composition was sent in from grade 4.

"One day when Careful and Careless were going to school, they saw that the gates were down, over the tracks. Careless thought that he would be late for school. So when Careful had turned his back to see an auto that was coming down the road, Careless thought it his chance. He ran under the gates. He thought that he could get across safely but the train was too quick for him. The first thing he knew, he was in the hospital. When he came home again, he said he would never be careless again. This accident could have been avoided if he had not run under the gates."

Grade 5 wrote compositions on how the school safety patrols assist children in crossing railroad tracks near the schoolhouse, and on other railroad dangers near our school.

Grade 6 constructed a line graph on graph paper showing the percentage of the causes of railroad accidents referred to in the bulletin which I circulated. The pupils worked the percentages beside the graph. Another graph showed by colored lines the number killed and the number injured throughout the country.

From grade 7, bar graphs were sent in showing the total number killed on a railroad that operates through Worcester. The lettering on these graphs was made an exercise in drawing.

The graphs from grade 8 were circular and showed the percentages of the causes of the accidents. The construction of these graphs followed the working of such a problem as: What per cent of the total fatalities was caused by each type of accident?

This necessarily short paper serves to show how material relating to accidents serves the aim of elementary school objectives and procedures. Such material is not contrary in either respect to the generally used material of the grades. It introduces no extraneous matter. It is modern, fresh, interesting matter to both pupil and teacher. It does help to build an atmosphere which influences consciousness and habit-formation that has practical results in conserving life and preventing the maiming of children.

CHAIRMAN FROST: We will have to dispense with the discussions. We will proceed with the little talk by Miss Emma A. Schad, supervisor, intermediate grades, Baltimore, Maryland.

The Work in English

By EMMA A. SCHAD

Supervisor, Intermediate Grades, Baltimore, Md.

It is not our purpose to insert in an already over-crowded curriculum another course of study, but our desire to weave safety education into the now instituted subjects. I propose to show briefly what safety education brings to one phase of the English work—oral and written composition.

The weakness of school English has been its isolation, its separation from the child's experience, so that it has been looked upon as something to be left behind in school and therefore has not functioned in life. Children too often are asked to talk or write on subjects in which they have no real interest. Sheridan in one sentence gives the keynote to the whole situation—"It is better to have something to say than to have to say something." Good subjects are vital, realized experiences of the child's own that naturally call for verbal expression, and safety education offers manifold opportunities for drawing out the actual experiences of the child.

When I introduce a class to the safety work, I usually begin with an informal discussion concerning the idea "Safety First." "What does 'Safety First' mean to you?" The answers generally are a series of "don'ts"—Don't run down the steps—Don't hitch on to trucks—Don't jay-walk—and many others. These "don'ts" offer

a fine opportunity to explain to the children Mr. Whitney's idea of the slogan, "Safety First." I heard Mr. Whitney speak at the National Education Association in 1925, in Washington, where for the first time I was made to realize how poor an expression that slogan is because of the selfish connotation that may be applied to it. Mr. Whitney emphasized the fact that we must teach children that there are good and bad adventures in life and that we, as teachers, must help them to choose the good adventure and help them to understand that "safety is the preservation of life to continue adventure of life."

An interesting device to bring out more about the word, adventure, is the use of the dictionary which defines it as "a risk," "a daring feat," "a bold or hazardous undertaking," "an exciting or extraordinary experience." The question, "Was Lindbergh's adventure a good or bad one?" never fails to bring every child to his feet. I try to impress upon the children the fact that before Lindbergh dared to fly across the Atlantic he made sure that his plane was equipped with the safest modern devices, that all equipment was complete, that weather conditions were favorable—in other words, he played safe before he ventured into that great unknown danger.

Some of the thrill in life is in meeting its dangers. Civilization would not be so far advanced if it had not been for the explorers, the pioneers, the inventors, the scientists, who were not afraid to take a chance.

From out of the field of safety education come many opportunities for English activities—activities that are worthwhile and that are a part of the child's life. Safety education supplies a real motive for oral expression. The Junior Safety Council meetings present a real reason to teach the children simple parliamentary procedures, to train boys and girls to think on their feet, and to stand before a group and present their case clearly. Older boys and girls delight in going into lower grades to talk to younger children, and there is an active part, too, for the smaller boys and girls to take in promoting the safety program of their school.

Last year an amusing incident happened at the annual Baltimore Safety Council dinner. It is the custom in Baltimore to have the schools represented that night by a group of children, the presidents of the various Junior Safety Councils that have taken an active part in the safety work during the year. Joe Tarlecki from one of the poorer sections of the city was selected to address the gathering of men and women interested in both educational and industrial safety. Joe began his talk by stating how great the need was for safety work in his school, because it was located on one of the busiest thoroughfares of the city. After telling of the work his council did, he concluded by saying, "Time doesn't permit me this evening to tell you anymore, but if any of you are interested, we'd be glad to have you come down to one of our meetings any Monday afternoon at three-thirty." It is needless to say that Joe was the hit of the evening.

Out of these oral talks grows the desire to put these thoughts on paper, and so a class safety book or a school safety bulletin is started, a safety slogan or a safety essay contest entered into with great zeal. A real motive for letter writing is provided. It is necessary to write to the director of the local or national safety council for information; letters to parents are sent home advising them to start their children to school in sufficient time so as to prevent needless hurrying, or to tell them what the school is planning to do to cooperate with Fire Prevention Week; thank-you letters must be written to show appreciation for help given.

There is no need to go further into these or other activities in the composition work which is made to live through its contact with safety education. You realize after hearing the various units of work in safety education presented that the English work is involved in all and that safety education not only vitalizes the English work and the other subjects in our curriculum, but speaking and writing about "safety" clarifies the children's ideas on this subject, and stimulates forming habits of safety. What is thought about, spoken and written about, is likely to carry over into action.

Increased public consciousness and group action are absolutely necessary if the number of accidents is to be lessened. Safety education not only makes the English work live but it brings to the children, and through them to the community, a full realization of the dangerous situations that confront them daily and helps them choose between the good and bad adventures.

Safety education in attaining its primary objective, habits of safe action, stimulates in children right attitudes; develops their initiative and leadership; and exercises with satisfaction their ability to say something, to say it well, to say it interestingly and convincingly, which is the ultimate dream of every English teacher.

CHAIRMAN FROST: The next number by Katherine Keeler, Lincoln School, New York City.

A Community Study

By KATHERINE KEELER
Lincoln School, New York City

My subject covers a study of the community in which safety education is an integral part. When the modern teacher plans for a year's work for one of the grades, she no longer thinks merely in terms of the fact that the children must learn, but she thinks of the whole child's needs for his best development.

The four points frequently considered are: First: He must be well and happy and normally growing and active. Therefore, we must allow him to be physically active at school and plan tasks and projects that require his moving about and getting plenty of exercise for his larger muscles. Second: He is an individualist—possibly with special talents. So the school day must provide opportunities for him to be creative—to build, to construct, and to express his feelings in various ways. Third: He is an inheritor of all the culture of the world. The school work must be rich in ideas and information and have associations with history, art and the sciences. Fourth: He is a part of a social group and must learn to bear his share of responsibility.

A study of the community seems to supply valuable situations and experiences for an all-round growth for these young children. They are interested in the life about them; their experiences are limited, and through a study of the environment we can enrich and extend their associations. We take them on trips to see interesting things in the city. For instances—we visit a bakery to see how clean everything is and how a loaf of bread can be made without being touched by human hands. A trip to the cold storage plant is filled with new experiences related to food preservation. The congested wholesale district presents new problems of traffic handling. The policemen are welcome friends, and the children are grateful for their assistance. On returning to school the children re-live these experiences and build the things they have seen. They begin to construct a play city and play the things they have seen. Trucks and trains go busily about with great dramatic emphasis upon traffic signals. It is managed by very efficient traffic officers with "Stop" and "Go" signs. Physically and intellectually the pupils need this construction and this dramatic play. With blocks, toy trucks and cars, with packing boxes and a few tools they transform the school room into a miniature city and reproduce the things they have seen.

A visit to the fire engine house is always one of great interest. We see how and where the firemen sleep and eat, how signals come in, how the firemen slide down the pole and how alert they are to any call. After all was carefully explained and many questions answered, one more child had a question. He asked if he might put on the fireman's hat and sit in the driver's seat by the wheel. The fire-

men consulted one another and they decided that this could be done if one would stand ready to take the child in case a signal should come at that moment. This brought home to the pupils more strongly than before the great necessity for vigilance and speed. Their respect for firemen was great indeed. Through this play we find their limitations, and by means of class discussions we help them to understand the significance of some of the common things about us. They find beauty in the commonplace and many opportunities for art expression. They follow step by step, in some of these studies, the complicated activities that lead to the getting of our food, our clothing, or the houses we live in.

Hygiene, sanitation and safety are important factors in all of these community studies. Still another example will show how ever-present the topic is without its having been forced into the situations. When a group of children build an apartment house out of packing boxes, the problems of fire escapes and fire proof materials are discussed. Fire prevention and fire laws are discussed. The fire department is always important in their play cities, and they visit and learn to know the firemen.

On our trips about the city, the children are taught how to cross the streets and to watch for signals. They are interested too in the river traffic with its signals. Here is a poem of a seven-year-old. She was too young to write it out but she told it to the teacher and the teacher wrote it for her. It is called "The Boat and the Bridge." "Toot!" said a boat as it came to a bridge, "Toot! Toot! I want to go through!" The bridge in reply said, 'I'll open for you,' and gave a warning "Toot! Toot!" As the bridge swung around, The boat went through, instead of "Toot! Toot!" the boat said "Thank you."

The play which they engage in we consider is quite a large part of their education, because it is through that play, as I said, that we can see their limitations. After a trip to a freight station, the children came back and realized that in their play city they must have some freight trains and some trucks, so they just made them hit-or-miss they ran over the floor. They had to be adjusted and they worked out that problem. The class that had worked out a farm and a city with its inner connections, one time played that they wanted to go to visit their grandmother who lived in another city. That entailed the arrangements to go on the trip—writing to grandmother, packing, going to the railroad station, waiting in the station for the train, and so on. There was one boy who wanted to put a door-bell on his house. He found he had front steps and a porch, but he had no door.

One of the little books they delight in is one called "We Live in a City," and one of the poems in it is about the fire escape (and I wanted to say that in constructing an apartment house the question of fire escapes always comes up). This little poem is: "We have a fire escape, but I am not allowed to be upon it. It has some iron steps and an iron railing too, but I am not allowed to be upon it. I know that I could climb the iron steps from our landing to the net, but I am not allowed to be upon it."

But safety is a part of everything that they do. Safety is not taught one period a week nor on any certain day, but comes at all times as an integral part of school and community life. The children are taught how to take care of themselves in their games. In playing in the gymnasium all of the games are arranged with the idea of preventing accidents. So many children in the early days of our school ran into the walls in their races and occasionally had had a broken arm, but now we have a black line and that is the goal; the wall is never the goal any more. They are taught how to light the gas stove, for they cook frequently at school. They learn the traffic laws on the streets; laws governing some phases of sanitation and health. They become acquainted with many things in the city through first-hand experiences.

Safety and sanitation are then a part of their thinking, and they become conscious of their share in these measures as responsible members of an ever larger community.

CHAIRMAN FROST: The next number is by Miss Amelia Schaller, principal, P. S. 103, Manhattan.

Safety Habit Formation

By AMELIA SCHALLER

P. S. 103, 49 East 119th Street, New York City

One swallow never made a spring, neither will one performance of any act form or break a habit. It is the constant drip, drip, drip of the water that wears away the stone, and the slow, steady piling up of the sand that makes our pleasant land. Let us not be discouraged if we feel that the safety habit has not been formed. We are nearer perfection today than we were last year, and what we are doing here must bear good fruit. The topics that concern us most in the question of safety are:

- 1—What habits should be formed?
- 2—How shall we proceed to establish safety habits?
- 3—When shall we begin the work of safety habit formation?
- 4—Where shall this work be done?

What habits should be formed? In our educational work we have always stressed habits of obedience, regularity, punctuality, concentration, diligence, etc. How about the habit of self-reliance, the habit of helping others, the habit of unselfishness, the habit of self-effacement, the habit of reflection and introspection? Too often we find people who prepare wonderful posters for this work, most excellent slogans, a faultless course of study which is carried out into practice by the pupils during their school life so that we have few or no accidents. Do our children when they leave school exercise the same care, the same vigilance? I do not mean leaving school each afternoon, I refer to the time when the pupil leaves the school or the university to become a citizen of these U. S. of America.

In my own school we have splendid slogans, we have written letters to the parents, we know that each parent received one of these letters, we have had plays, pageants, songs, games, we have correlated this safety work with arithmetic, English, composition, dictation, physical training, etc. All this is excellent, but what can we do to make our junior citizen feel that over and above all this work just mentioned are the habits of self-reliance, unselfishness, altruism, and self-effacement. If by our own example we can create in the child a desire to be self-reliant, unselfish, altruistic, and willing to sacrifice self for the glory of our country and its future welfare, then indeed may we say that we, as educators, are an inspirational force in this campaign for safety habits. To make this country safe for democracy we must educate in such a way that the citizens of the next generation will be far superior to those of the present generation. But we must make our citizens, old and young, conscious of the fact that we must value life and limb. The civic consciousness must be aroused and a civic conscience developed so that to be accused of recklessness, of selfish personal enjoyment at the expense of another's life, would be something of which we should be ashamed.

Some of you may say I am asking too much of the elementary school child when I wish him to practice the habits of introspection, self-reliance, unselfishness. Do not misunderstand me, I am aiming for this, yes, through the medium of the adult. Present conditions demand sacrifice and unselfishness in order that we may teach the world.

Will each adult, will each parent, form himself into a committee of one to see that he or she is a shining example of right safety habits for our little people to follow? By this question I have just asked, I have entered upon No. 2, namely: How shall we proceed to establish safety habits? The living example of correct safety habits as embodied in the adult citizens of our country is the best way of teaching our young people, and of improving present conditions. In place of giving each child a card with twenty-five or thirty questions in safety habits for him to answer, I think we might change the order of things and ask the parents and citizens of our city to truthfully answer them. Set a good example yourselves and the little people will soon follow in line, for they generally do what they see their elders do. The methods we are now pursuing for safety are excellent, but very often when the child takes to the home the standards we have tried to implant he is given little or no encouragement to continue. Those homes that practice daily habits of care, efficiency, unselfishness and a real bonafide desire to be helpful send to the school a child that requires little or no teaching in character. He learns by example and example is far better than precept. This task of reaching the adult in the matter of safety will not be an easy one by any means. It is far easier for me to tell twenty people what it is right to do, than be one of the twenty to follow my own teaching. Of the many cases in my school experience where I have been obliged to train not only the pupil but the parent to form correct safety habits, I should like to mention two. One parent came to me and when I remonstrated with him concerning the selfish motive that prompted his acts, said, "Oh, Miss Schaller, you're too particular, you'll never get anywhere in this world. If you want anything you must cheat, deceive, or do anything at all so long as you get it. Then when you have it, you can be honest."

Another, upon being told that if he disregarded the law and permitted his child to go to work without the proper employment certificate, he might be fined, replied, "My boy earns big money, and here in this country they don't ketch him so quick, by the time they got him, I have enough money to pay the fine and I have some money over. I take a chance." The moral code laid down in that household can be readily imagined. But I think you will agree with me that in too many homes we have the Rule of Gold in place of the Golden Rule.

Just as soon as we can get the civic conscience working overtime, now if necessary to make up for lost time, just so soon will our safety problem become a very simple one, or it will no longer be a problem at all.

Motivation in our acts should be emphasized. A slight accident occurred in the country not long ago when the following dialogue took place, "What's the big idea, Buddy? Do you think you're the only pebble on the beach? What you've done may make you happy, but haven't I a right to be considered? I don't want to be miserable because you're happy."

3—When shall we begin the work of Safety Habit Formation? We can't begin too soon, heredity plays a great part in making desirable citizens and in preserving life, but education and environment have worked miracles. The well ordered home where matches are kept in tin receptacles, where oily rags are not permitted to accumulate, where matches and cigars are always put out before being thrown away, seldom have fires. Is it not wise to ask the questions: What causes so many fires in certain neighborhoods? What causes the continuance of law-breaking? Is the latter common because we are too lenient with our offenders? Is the punishment so slight and the civic conscience so entirely lacking that law-abiding citizens become the innocent victims?

My reply to No. 4 is—this work in Safety Habit Formation should be pursued not only in the schools but in the homes, the streets, the courts of justice and in all those departments of the city that deal with measures to insure safety to our law-abiding citizens. If we wish to make a success of this work, we can never

give up. Some must sacrifice, the flaming torch must be picked up by others until we win. It is a case of eternal vigilance. Let us all be heroic enough to keep up the struggle for we all know that the reward of well doing is the ability to do better.

Our whole aim in this work is to build a fine character, and character is merely a bundle of habits. If we have citizens practicing daily the habits of self-reliance, unselfishness, habits of altruism and self-effacement, if our people will follow the Golden Rule rather than the Rule of Gold, we shall accomplish what we are aiming for now, and we shall build in our young people such a bundle of habits that the nobility of their characters will make for the highest happiness.

But the selfish ones should be held to a strict account so that those who are working to make fine characters will not be cut off in the prime of life and the undesirable ones become so powerful that lawlessness becomes common.

Let us never falter in our high aims, for all honest work is worship; all useful service is prayer.

CHAIRMAN FROST: There is one more speaker. We will hear from Mr. Herbert J. Stack, supervisor, Secondary Schools, Johnstown, Pennsylvania.

A Unit for the Junior and Senior High School

By HERBERT J. STACK

Supervisor, Secondary Schools, Johnstown, Pa.

You are, and I was impressed by the wonderful things that have been said to us on safety. We are all tremendously impressed. It is for this reason that I am spending this year at Columbia University as a Fellow. I believe that our secondary schools, our junior and senior high schools, have a very great contribution to make. As I listen to the elementary school people, I think, just wait until the next Safety Council next year and see what we have to say to you on what our secondary schools have done.

It has always been quite difficult to introduce relatively new materials into the secondary schools. The traditional idea that the high school existed primarily for training, for college has been very thoroughly ingrained in the minds of teachers and school patrons. Vested interests have kept a strong control on the secondary curriculum and many subjects such as industrial arts, domestic arts, commercial subjects, home training and even physical training, knocked at the doors of our high schools many years before they were finally recognized and admitted into the curriculum.

It is a well known fact that only a small percentage of the pupils in our secondary schools go on to college. In Johnstown, Pennsylvania, for example, some 7 per cent go to college, 7 per cent to normal school, 13 per cent leave school to help at home, 34 per cent are taken into the industries of the city, and 25 per cent go into clerical, sales or office work, with the remainder scattered in various fields. Primarily then, high school training must be for life activities and the solution of real life problems. The major objectives of secondary education—health, command of fundamental tools, good citizenship, vocation, worthy use of leisure time, worthy home membership and ethical training are therefore most important in the secondary school.

It is altogether natural that the newer objectives in high school training such as health, character and safety are having rather a difficult time. High school teachers have been primarily "subject specialists." It is not easy for the teacher who has been teaching the classics, higher mathematics or foreign languages for many years to see much of value in character education or safety education. Moreover,

if they will admit the values of such objectives, they feel that there isn't time for them to spare from what they feel is more important. Herein lies the great weakness of the secondary schools. The curriculum is so full of subject matter that there is little time for the teacher to get to the real objectives of the subject field. It is wonderful what beautiful objectives we can organize for our courses of study in high school, but too often these objectives are placed at the first of the course and promptly forgotten.

The prime reason why we study subjects in high school is after all not to pass college examinations, but to help us solve life problems, find happiness in our environment, become worthy home members and good citizens. We feel that in safety education we have an objective which is basic in many of the high school subjects.

Through the fields of chemistry, physics, general science and biology we learn how to use and control our environment. We learn how to avoid dangers and pitfalls, plan wisely and prepare for adventures of life with an idea of safety. Through community civics, problems of democracy, we may learn how to choose right methods of living and right habits of citizenship. It is rather significant that in one of the newer general science books, the author of which is a New York City teacher, there are over seventy-five specific references to safety—safety in health, safety in business, safety in transportation, electricity, sources of water, foods, exercise, fire, and a host of other subjects.

In our practical arts for girls and industrial arts courses there is a remarkable field of safety education. In fact, in a large share of the high school subjects the wise teacher can through the regular subject matter bring out desirable attitudes and ideals, can stress safe conduct and the good adventure.

In the extra curricular activities there is a splendid place for teaching safety. The Safety Councils, Boy Scout Clubs, Aviation Clubs, Girl Scout Clubs, First Aid Clubs and many others, have a definite contribution to make. It is altogether natural that perhaps the best work in safety in our high schools is done through such extra curricular activities, the school assembly and home room period.

The project lends itself readily to safety teaching primarily because it involves purposeful activity in connection with the subject matter being studied. Projects in general science in safety can readily be organized, such as, First: "How our water supply is kept safe." What a fine thing for you people here in New York City to get your children to know about the Kensico and the Ashokan plants. Second: "How Uncle Sam with the watchful eye of the Weather Bureau safeguards the farmer." Third: (This is one of our best ones) "Securing a safety cabinet for our school." Fourth: "How radio assists in keeping us safe." Fifth: "How our railroads safeguard traffic." Sixth: "How the fire department safeguards our city." (And then fire hazards in our city. How insurance protects our people. What a remarkable field there.) Replanting deforested hills is an excellent problem for the eighth grade. In Johnstown they had an assembly on Tree Day, when they dispensed with the assembly exercises and planted ten thousand trees on the hillside of our once beautiful city. Then there is first aid in the chemistry laboratory—and I could give you many others.

One of the most interesting of these projects that I have seen was organized in my school last year on "How Aviation Is Being Made Safer." I think it is one that any of you people in your own grades can do very nicely—fifth, sixth or seventh grade, or even in the high school. This project involved, first: building and demonstrating various types of planes; second: building landing fields and locating beams; third: talks and demonstrations in regard to improved planes and motors; fourth: building a weather bureau station and demonstrating how observations affect aviation; fifth: building and demonstrating model parachutes (to show how something could be brought down from the plane. They made the

parachutes from silk or linen handkerchiefs); sixth: demonstrations in regard to airplane instruments; seventh: demonstrations of the use of radio and direction finders; eighth: examinations for candidates for aviation schools. The project, as one can readily see, involved the subject matter of general science—air, electricity, engineering, lighting, weather, health and physical training.

The keynote throughout the entire project, of course, was safety. The entire project was given by the class before the entire school at an assembly, and proved to be one of the most interesting and helpful of our school programs, with the specific activities of flying the model planes, landing at landing fields, taking weather observations, demonstrating model parachutes and examining prospective aviators for eyesight, hearing, strength, alertness and the "whirling chair" test. One boy represents the doctor, and a number of boys, about fifteen, come in to be examined by the doctor to enter the flying school. The first boy is rejected because his eyes are weak. The second is rejected because he isn't physically strong enough. The third boy is accepted. One is rejected for hearing defects. One is rejected because he has a weak heart or weak lungs. Someone is put on a swivel chair and given the "whirling chair" test. The children were sitting there with their mouths wide open. What is the point of view in having these boys go through all that? A lesson like that will sometimes do more than miles and miles of moralizing about strength or taking care of your eyes to protect your health.

In just this way many interesting projects can be worked out. It remains for us as high school teachers to be sure when we go through certain subject matter to bring home to the pupils the significance of such subject matter with life realities—suggests guides for safe adventures. If there be character education in subject matter, bring it home to the pupils. If there be health and safety education, press home the essential facts. Don't expect that all of our beautiful objectives of subject matter automatically are realized as pupils pass through the work. It is for us to lead, to guide, to make the way clearer here and give experiences that will hasten good adventures and discourage bad adventures.

ADJOURNMENT

October 2, 1928

The Technique of Safety Education in the Vocational School

OAKLEY FURNEY, Chairman
Chief of the Bureau of Industrial Education
New York State

The second session of the Educational Division was called to order at nine-thirty o'clock by the chairman, Mr. Oakley Furney, Chief of the Bureau of Industrial Education, New York State.

CHAIRMAN FURNEY: The subject of Safety Education in Vocational Schools is one of tremendous importance.

Originally, when we first commenced to have vocational schools under public supervision and control, the matter of safety was pretty largely one of safety first for the teacher in charge of the class. I recall very well one of the stories which Dr. Dean originally told, when he was a Deputy in charge of State Education in the City of New York.

He visited a new trade class, I think it was in Rochester somewhere upstate, and at that time our vocational schools were then pretty largely populated by average and undergrade 14, 15 and 16 year old boys, and the doctor had been there for a little while and was looking around, and he happened to notice in the back of the teacher's desk there was a large break in the plaster. He said to the teacher in charge of the class, "What is that, what is that broken plaster there?" And the teacher replied that a boy had thrown a block of wood, he said, "A boy threw a block of wood at me and he missed me." So that was the original safety problem.

Through the very friendly cooperation of the State Department of Labor, we have been trying to do something in our state in the last two or three years in improving the situation in the vocational schools as regards safety, and Mr. McDowell, our second speaker, is going to tell some of the things he has accomplished, and his department has accomplished, and how he went about it.

Not Enough Knowledge of Safety

Curiously enough, in spite of the fact that we have recruited the best men, supposedly the best men from the trades, those men are not well-informed with respect to the technique of safety devices and safety instruction in the classes, and the whole problem generally of personal hygiene in relation to factory work. With the tremendous spread of vocational work, not only in New York State but in all of the states, the growing number of full time day trade schools and the enormous number of children in vocational classes in vocational schools—last year we had something like one hundred and fifty or two hundred thousand working girls attending vocational schools, evening schools, and so forth—why, we need to give more attention to the problem of safety than ever before. It is absurd for us to pretend to train boys and girls for industrial occupations and not have at least as favorable conditions in the schools, in the public schools, as when they shall go out into industry. Children have a right to expect that our schools be well taken care of, they have a right to be well taken care of in the way of safety education. And industry and their employers also have that right.

Commissioner Hamilton has suggested that the superintendents of the State Educational departments ought to make some move in the matter of compensation for teachers in vocational schools, and acting on his suggestion and on the suggestion of Commissioner Wilson, we sent out to all of the Superintendents in the State, the different cities and the boroughs of the city, asked them to report to us all the accidents of every character that took place in the schools of the State, in the last five years. And when we get these we will make an outline and present it to the industrial commissioner with the hope that some action will be taken to amend the compensation law for both the teachers and pupils.

While the number of accidents has not been large, there have been enough accidents in the schools so that some study of the situation ought to be made, and some remedy should be provided for it. If a boy is permanently injured it is a shame for him not to be properly compensated. I guess it is a shame for accidents to happen anyway, but accidents are unavoidable. We need to be fair to the boy, and we need to be fair to their parents and we need to be fair to society in general, and so should make some provision for him.

The Commissioner regrets that he can not be here today, but this is a time of the year when the budget is in the course of preparation and there are a great many things to take care of. And generally when he can not come himself he sends someone who is obliged to go, whether he wants to or not. So here I am.

Now, I think it would be better if we have the two discussion topics presented first, and then we can open the meeting for any discussion as you may care to have, and for any questions you want to ask.

Our first paper is on the teaching of safety in vocational schools, by Mr. Ronald Kent, Assistant Director, Essex County Vocational School, Newark, New Jersey.

Teaching Safety in Vocational Schools

By RONALD KENT

Assistant Director, Essex County Vocational School, Newark, N. J.

Last year up at Oswego, at the State Conference, there was a discussion one day on the topic of safety in vocational schools, and Dr. Wilson happened to come in and wanted to know if I would come down here and talk on the subject. I asked him if he thought I could give them everything he wanted, and he said he thought so. Of course, I have my own idea as to that. But I will simply present to you just a brief outline of what we are trying to do in this field. Probably you would classify it rather as an experiment, because although we have been working on it for some time, lining up and working the thing out, we can not give you any distinct data as to how successful it is, at least at the present time, excepting that we believe it is based on certain sound principles.

I think I will start by simply reading the directions we put out in our monographs, outlining the duties of certain instructors. That will show you in a general way what the idea is, and then after reading that I will try and elaborate. Here is a paragraph taken from the monograph:

"Hygiene, Safety and Physical Training Instructors will be responsible for the teaching of the general health and safety knowledges and practices listed in the monograph on Health Education. They will not be responsible for the teaching of specific and detailed health and safety knowledges and practices which are peculiar to each trade. This material is listed in the trade outlines under Safety Precautions and will be taught by the shop and technical instructors. They will be responsible, however, for conducting safety campaigns, organizing shop com-

mittees and shop competition, or using any other approved methods for calling general attention to, and arousing interest in these specific and peculiar practices, and for helping shop and technical instructors develop similar or other teaching devices in the field."

To make that clear, I will have to go back just a minute and tell you what our general lay-out is, to which we have fitted these devices that we are trying out. Our schedule and our program for the students and the teachers is something like as follows:

We have the week broken up into 40 periods, 20 periods or half of the time being devoted to shop work, in charge of what we call the shop instructor.

Then 10 periods or one-quarter of the total time is devoted to what we call technical work, which is split up in the usual way into mathematics, and the various subjects, which are in charge of super-instructors; that is, taught by one instructor, a single instructor handling all of those subjects. This instruction includes all such things as safety instruction and safety precautions; I take "safety precautions" to mean safety in the health—what might impair the health, as opposed to accidents, hurting the bodily structure through some injury.

Then the remainder of the 10 periods are broken up or divided as follows:

For Social Science and English, five periods. Library, two periods. Physical Training, two periods. And Hygiene and Safety, one period a week.

The last is given by a teacher who specializes in that work, and that one period a week is set aside for him.

Now we distinguish between what we call the general health and safety, and what we call the specific trade safety. We classify under general safety and hygiene, for example, such things as one's personal health knowledge and habits, the hygiene of the home, social hygiene, first aid, safety in the home, safety on the street, and what we might term general industrial safety, such as carefulness in the plant, carefulness for each person in any shop.

Then we classify what we might term technical safety or specific trade safety in each one of the trades, and we include there safety to the man, the human side of it, safety to the job he is working on, which sometimes in turn means safety to the individual, they are tied closely together; and safety to tools, which again may mean safety to somebody else later on or somebody near the worker.

Now, why did we make this kind of a set-up? First of all, we believe that the big point is the building up of safety habits out in the shop. The big thing is not putting across the knowledge, or information, but building up of habits in the shop; and the whole thing is centered around that. We do have to put across the information, of course, before we can conceive the habit; but we find this thing happens. For example, the hygiene instructor says, "Of course, I can give the fellows an examination on their knowledge, and they can give me their answers. They may not be right at all, and yet I know that they are practicing these things. But if I try to give them the reason why, they simply fall down on it. And yet they are practicing many of the things that they do not know the reason for." They practice hygiene even though they can not put it in words.

So if we once put the knowledge across, we try to get the habit and then we do not concern ourselves about the knowledge once they get the habit. We teach in the actual environment in which the boys are working, which we believe is sound psychology.

Then we supplement this instruction by work with the technical instructor, who tries to give information in the technical room that will fit in with the type of job the student is doing in the shop.

Next we supplement our training by work with the general safety instructor, from the standpoint of general safety outside of the shop, and of emphasizing the shop instructor's work generally. For example, we must have the proper

machinery to do this work, the proper organization. This general safety man organizes safety committees throughout the school. His efforts to keep the shop instructor and his work up to the standard are continuous. If we simply let the shop instructor handle these things himself, he might be apt to let them slide. We attempt to keep him and the students and everybody up on their toes through certain safety campaigns, for which the safety instructor is responsible. These campaigns are conducted throughout the school. We also have shop committees all working to the ultimate end of safety.

And now, why we have these technical instructors teach safety as applied in each particular phase, under each particular condition, instead of the general safety man?

Well, if you have a school with 12 or 13 or 14 shops in it, and you have a man trying to teach this detailed safety for that number of trades, I believe that it is too involved for one man to do properly. Safety is very highly specialized and we believe it requires a thorough working knowledge of each trade, to teach it properly.

And safety in work is often tied up with personal safety and requires a very intimate knowledge of the trade. In the automobile mechanics trade, for example, we have listed there for one unit, jobs involving the installing of engine cam shafts, cam shaft bushings, timing gears, timing chains, and tuning the engine, etc. Here are the safety precautions listed.

First, disconnect storage battery. See that lifting devices are properly applied before removing the springs. Now that is a proposition that a man must understand thoroughly in order to teach it properly. You must show the boy exactly how it is done, and a man can not do it and show the boy how it is properly done unless he knows exactly how it is done himself. It is not a case of just being careful, but how to be careful.

Another example. In jobs involving the checking of the levels, the lining up of front wheels and leveling the wheels the safety points to be observed are: Do not strike the cones or races with a hammer other than a lead hammer, and install the proper locking device in the correct manner. So that somebody later on driving the car will be safe. Some general man can not teach that. Only a man with a thorough knowledge of how that is done can teach it properly.

Again, jobs involving the making of simple tests and replacements and adjustments, on the lighting systems of automobiles. And the safety precautions. The boy should be sure to remove the fuses and disconnect the battery. Also avoid contact with live wires. You can not give him the precautions as to live wires, but he must be told how to avoid them.

And so on, and so forth. I might name a good many others, but I think that will give you what I am driving at. Well, I might add this one more.

Machine shops involving the grinding of one surface of work fastened to the platen of the grinder. The precautions there would be: Be sure to properly fasten and tense. The work must be properly fastened to the platen, and keep hands away from the wheel. Also guard the eyes properly. Those are points that the general man can not put across. You have got to know the technique of the thing to get it across.

All right, then we have all these things, all these habits to be acquired. We put a technical man in who is responsible for the technical safety, and another man on the outside for the general safety, and we have safety committees responsible for the continual safety throughout the school. If the committee reports that "this man has his machine unguarded, or these boys are not following the practices that we have listed," then we go after that shop instructor and bring him up to the standard in these respects.

May I just summarize a little and add some more points on this one thing. How do we make sure that our instructors will not neglect safety?

First of all, each instructor is given an analysis of his trade, which lists such items as I have pointed out, and the safety precautions to be taken. That does not mean, of course, that he is going to follow them, but at least it will help.

Then we attempt to include, as far as possible, in the lesson sheets these same safety points. When the boy gets the lesson sheet to go on the job, there are certain safety precautions listed, certain questions that he must answer before going on the job. So if we get these incorporated in the lesson sheets and in the instructions for the shop teacher, we are fairly sure we can cover them in that way.

Of course there are some things that you won't get in a long time and in some shops you won't get everything in the lesson sheets. But we must try to get our people up on their toes, just as they do out in industry on their safety committees.

We also make use of certain shop posters, particularly posters that have to do with the human element. We want to draw out the particularly true vital point of safety for humanity, safety for the boy himself. We have them posted in the shops, where the boys can see them. Then we are continually using current happenings in the school. As accidents happen we use them for instruction work in the shop where the accident happened, as well as in the other shops.

We should compile our accident reports. One instructor has already done a very fine job in that respect in one school. From these accident reports we are able to locate things that are particularly troublesome, and get the material to conduct campaigns. We also get material from these reports for lesson sheets.

Now I have simply given you a brief outline of our set-up. As I said before, we are trying an experiment and we think we are just beginning and there are many things that can be done yet. I shall be very glad to answer any questions if you have any.

CHAIRMAN FURNEY: We thank Mr. Kent very much indeed for his very excellent presentation of the safety program in Essex County, and at the close of the next paper we will throw the meeting open for general discussion.

We in New York State feel we are under a deep obligation to the State Labor Department and to Mr. McDowell, the next speaker, for the various services performed in the way of outside instruction to the trade and industrial schools and general industrial shops throughout the state. And Mr. McDowell can give anyone a wealth of information as to safety devices and how to take care of the mechanical side of a safety program in the schools. I think we will all be glad to hear from Mr. John M. McDowell, safety inspector, State Department of Labor, Albany.

Safeguarding Vocational School Equipment

By JOHN M. McDOWELL

Safety Inspector, State Department of Labor, Albany, N. Y.

When I received the invitation to speak at this meeting of the National Safety Congress, I accepted it gladly, for the reason that the New York State Department of Labor, through the Bureau of Industrial Hygiene, has preached the same gospel as your own organization, the prevention of accidents and the preservation of human lives. Surely no aims could be higher than these.

It was just about two years ago that the State Department of Education, through its Division of Vocational Education, requested the State Department of Labor through its Bureau of Industrial Hygiene to make an inspection of all of the shop equipment in the vocational schools and in the industrial shops of the

elementary and secondary schools in the State, in order to determine whether they were properly safeguarded.

Since that time we have inspected over one hundred and fifty schools located in all parts of the State, and these inspections were not prearranged, but were made any time we found it convenient. All the machinery was carefully examined and the hazards explained to the person in charge. In this first inspection I found over 2,000 violations of what we consider the established practice for safeguarding equipment.

After each inspection a letter embodying my recommendations regarding equipment and shop conditions was sent to the superintendent of schools and a copy forwarded to the State Department of Education. It thus became the duty of both parties to see that the recommendations were carried out. The first inspection after ample time had been allowed, was followed by a second, in order to learn to what extent the recommendations had been complied with. I am glad to say that in about seventy-five per cent of the cases I found that this had been done. The school authorities, in general, had cheerfully and faithfully complied with these requests, especially when they learned that we were endeavoring to guard the work shops of the schools just as we did the shops and factories in industry. The safety movement, as you know, really begins in the school as the children of today soon grow into the workers of tomorrow.

It may seem odd to some of you that shop equipment in schools needs to be inspected, when a law is already in existence requiring this equipment to be properly protected. Unfortunately the law applies only to shops and factories in which work is turned out for a profit and not to any educational institution where shopwork equipment is used for teaching purposes and not for manufacturing.

It is natural to suppose also that all shop equipment in school shops would be guarded. The equipment is modern, the instructors must be men of practical experience. Why has this other essential been neglected? In my experience with school men of the state I have come to the following conclusion regarding this matter:

In the first place, one of the main faults lies in the way in which shop equipment for schools is purchased. Machines for schools are usually sold on a competitive basis and this often results in a machine being purchased under the regular price, but without the usual standard guards.

Secondly, I have found some school boards who have failed to purchase machine guards because of the expense involved.

In the third place, a considerable number of shop instructors still fail to realize the importance of having all exposed parts of machinery properly guarded. They are willing to have this done for the principal danger points of a machine, but fail to realize the importance of guarding all moving parts of machinery, no matter where located.

Shop teachers neglect also to provide safe working conditions. In many cases these dangerous conditions were not confined to unguarded machinery or unsafe floors but to shafting, pulleys, lack of first aid kits, etc.

Nature of the violations; you may be interested in knowing something about the nature of the violations in school shops. These may be divided into general and specific.

In general I found in the case of shafting, that where it came within six feet of the floor it was dangerous unless encased. This I recommended to be changed.

In some instances I found pieces broken out of iron pulleys. These I recommended to be removed.

In numerous instances I noticed floors unsafe, broken or slippery, and I advised that these be repaired. Where the floor around woodworking machines was slippery I ordered it to be made slip-proof by installing rubber mats or by pouring hot glue on the floor and dusting it with light sand.

Dust, fumes or gases, wherever found, always carry a certain degree of health and fire hazard. Wherever I found melting pots in which dangerous gases or fumes were being generated and woodworking machinery creating wood dust, I recommended that an exhaust system be installed. In schools where automobile work was being carried on and engines being run, an amount of the deadly carbon monoxide gas is generated. I suggested in these cases that the carbon monoxide gas be removed by mechanical means.

In this connection, I always explained to the school authorities that the Bureau of Industrial Hygiene maintains a plan division with competent engineers to advise on blower systems, exhausts, etc., and that these men were at their service. A number of schools have taken advantage of this aid.

In one shop I found that an emory wheel jack had not been provided and that the shop teacher had made a spindle to hold the wheel, hooking it up to the wood turning lathe. The emory wheel usually revolves at a speed of about two thousand revolutions. Under the changed arrangement it was making at least ten thousand revolutions, which in case of bursting, made it a menace to everyone in the school shop. I wasted no time in explaining to the teacher the danger of this practice.

In many instances in my visiting through school shops, I found evidences of poor housekeeping. Lumber in woodworking shops which should have been neatly stacked in racks was piled loosely on floors, unused pieces lying about on work benches or floors. At times shellac and varnish cans were found uncovered. In machine shops, tools were often strewn about on benches instead of being returned to tool rooms. Carelessness was shown also in some shops in having bits of iron, pipe, wood and other materials left on floors and passageways for someone to stumble over. Passageways between equipment were often needlessly cluttered up. While these may be considered minor points by some, to an inspector they are evidences of bad housekeeping and indicate slovenliness on the part of a teacher which may even extend to his teaching.

The school shops may be broadly divided into the following departments: Woodworking, machine, electrical, plumbing, automobile, printing, sheet metal, and foundry.

As woodworking is the most dangerous, I shall give that the first consideration. It is essential that all machinery be properly lighted, especially woodworking machinery which operates saws and other woodworking tools at high speed. In many instances I recommended that the working parts of these machines be properly lighted by shaded or frosted globes in order to destroy eye strain.

In many instances the guards were not properly installed on circular saws; in others, the guard was not automatic and left the saw exposed while in operation. On swing saws I recommend that stops be provided so that the saw would not come beyond the bench and thus endanger the operators' fingers or body. Band saws I often found unprotected at the rear of the table. Fly wheels were also not properly guarded. These defects I ordered remedied.

In the case of the shaper, not many of which are used in school, I recommended that boys be prevented from using them and that they should no longer be purchased as school equipment. The planer, another tool used in woodworking shops, was often found entirely exposed, as well as the drive shaft at the rear. These also I ordered protected.

In the school machine shops, more attention needs to be given to the guarding of belt and gears. Wherever belts were shifted by hand I recommended that only rawhide lacing be used. In one instance a nail had been used to do duty as belt lacing. I suggested that belts running idle should be provided with hangers. With regard to other equipment in the machine shop, lack of guards was found to be the principal hazard; unguarded emory wheels, drill-press spindles, hack saws, boring mills, etc. These I always recommended to be guarded. Mushroomed hand tools, such as chisels and punches, I suggested be repaired or discarded.

In electrical shops, the chief danger comes from shocks, and here I always suggested that rubber mats be used on floors beside machines generating over 110 volts. I stressed the importance of guarding couplings between motors and generators and also that switch boxes should be properly guarded.

Industrial hygiene was necessary to the plumbing shops, and I impressed upon the instructors the importance of having boys carefully wash their hands after using white lead.

Where courses in automobile mechanics were being taught, I spoke to the school authorities about the danger of carbon monoxide gases, and the mechanical means of removing it. I also called attention to the necessity of providing fire-proof receptacles to hold oily waste and rags and thus reduce the menace from fire.

In the school printing shop, improper guarding of machines was the chief danger. I stressed the importance of having platen guards for presses and that fly wheels be properly encased. I recommended as highly essential the guarding of all knives in paper cutters. I also recommended that there be a plentiful use of hot and cold water, towels and soap for boys engaged in handling lead.

In sheet metal work, guarding of machinery was again the prime essential lacking to school shops. I recommended that squaring shears be guarded so that at no time could a boy get his hand between the blade and the bed of the machine.

Finally, there is the school foundry and here guard rails and removal of deadly fumes were the protective devices recommended. For all elevated platforms I suggested that a guard rail and toe board be installed. In foundries where metal was melted, I recommended that exhausts be provided to remove fumes.

Summarizing my inspections, I may say that in general I tried to do two things:

(1) To provide shop teachers and school authorities with technical information relating to the safeguarding of equipment in the school shops, and,

Second, to discuss with superintendents, principals and teachers the importance of teaching right habits of shops practice.

In a few years these boys will be found employed in all the industries of the state, and if in the formative years of their lives, they are taught the proper way to handle tools and machines and the safeguarding of equipment, this knowledge will become indelibly stamped upon their memories so that when they enter industry it will be rightly applied. The result will be fewer accidents in the industries of our state, and a man-power that is active, efficient and careful.

In closing, I want to say that I feel this inspection has brought about a better understanding of the work of the State Department of Labor, on the part of the school authorities; a better appreciation of its magnitude and the importance played by the humblest shop teacher in safeguarding the machines under his care. This work is still in the pioneer stage, but it has so far justified itself that it is to be continued. However, it is only through the close cooperation of the state and the school that this new fight for "safety first" can be carried to a successful conclusion.

CHAIRMAN FURNEY: Thank you very much indeed, Mr. McDowell. Now we have had the problem of safety education in vocational schools presented from two angles. First, from the angle of the supervisor or principal who is primarily responsible for the work of the instruction and protection of the vocational schools; and the other, from the standpoint of the outside agency interested in safety coming in and doing what it can to improve the situation in the schools. And I think the two points presented have been presented in a very able manner, and I think they are tremendously helpful.

If there are any questions, I am sure the speakers will be glad to answer them.

I wonder if there are any questions you would like to ask Mr. Kent or Mr. McDowell in regard to the points presented or any other matters in which you may be interested.

MR. GRAHAM (Detroit): I would like to ask Mr. McDowell concerning the recommendation of the use of wood shavers by students being prohibited, if he feels that this recommendation is justified. I do not, for this reason: That thousands of new employees enter the woodworking business every year, and if they are not able to—well, they have to learn to operate these machines somewhere. Isn't it better to teach them to operate these machines in the school shops and teach them operation in a safe manner, rather than to throw them out into the high speed production of our industries and let them pick up what they can there, under conditions far more hazardous than they might be in the school shops?

MR. McDOWELL: I assume that the woodworking industry today is carried on in the same way as we learned the trade a number of years ago. When a boy went into the machine shops to learn the trade he was taught the machines. I do not see why the school authorities should be responsible for the knowledge of the machines that are most dangerous in the industry. We have the machines in the schools, and the teachers get alongside of the machine and teach them the operation; I am in accord with that. But when it comes to putting a boy of 15 or 16 years of age to work on them, I do not think that is right. We find the majority of the accidents is on saws, and machines of that kind, cutting machines.

MR. GRAHAM: In the Detroit school shops we have a circle painted around these machines, about three or four feet in diameter, and every student has to have an instructor standing within that distance of the machine at the time it is operated, and operation of the machine is done only under the closest supervision. Students are never left with high speed machines of any sort unattended, and we believe, it is our attitude that it is our duty to teach the youngsters the dangerous points of these machines so that when they get out into industry, itself, with the high speed methods, that they are not simply tossed into the thing with no knowledge of the fundamentals of safety at all.

Too often a man will go into a factory looking for employment, and the foreman will say, "You are a shaver?" And he will say he is, and he may never have seen a machine of that kind before, and he starts to operate that machine, and there is a greater potentiality of accident there than if he were properly instructed before he went out into the industry.

MR. McDOWELL: Well, that is hiring people not journeymen to the trade.

MR. GRAHAM: Well, that is the situation. They have to learn sometime, somewhere, some place, and we feel that it is better that they learn in the schools, under the proper supervision, where there is a definite attitude toward safety, than by putting him in the hands of some job setter or foreman, who has little knowledge in that respect, or cares little about it.

CHAIRMAN FURNEY: The general point you present I think is well taken. A little while ago we made a rather extensive study of some 14 to 16 year old girls and boys on part time in the continuation schools in the State. We divided them into two classes, those employed on machinery and the other group. And in making the study of the group that had been employed on machines, we found that roughly one child in every five that had worked on a machine of some sort or other had suffered an accident that required the child being absent from work or tied up at least for one week. That indicated clearly that a good many people are in industry working on jobs that they are not fitted for, for which they have not had the proper preparation.

Now, if we are going to teach this industrial work in the schools, it seems to

me that we ought to properly prepare them for the situations that they will find in their employment.

MR. GRAHAM: I am interested to know whether that study of those people included woodworkers who had worked on shapers?

CHAIRMAN FURNEY: Probably not, because—well, what is the general regulation in regard to employment on machines of that type?

MR. McDOWELL: Very few shapers are found in the State of New York schools.

CHAIRMAN FURNEY: And in the industry itself?

MR. McDOWELL: No boy under eighteen years of age.

MR. BURRIDGE: I am very much interested in this statement concerning the foremen in the industry. Our foreman of the woodworking plant, in Detroit, refused to put on a cooperative student who is twenty years of age, before I had said anything to the student, saying that he did not want to take a chance. I just say that to indicate that there are foremen who understand the danger.

MR. McDOWELL: I do not question that, at all. But in the small shops it is different; the youngsters goes into the small woodworking shop or other shop as a sort of jack-of-all-trades; he does odd jobs here and there; and under pressure of circumstances at certain times he is probably asked if he knows how to operate such a machine and he says sure, he knows all about it. It isn't long before something happens.

Particularly, boys think that if they watch the operation a certain length of time they know all about it; and there are a great many things that their observation has not taken in. I think that is where the greatest danger lies.

There are safety departments that have direct contact with all of the employees hired, and in many cases that contact includes talking to by the safety director, to ascertain the actual safety knowledge of actual machines, and precautions of that nature.

But a study of the employment distribution over the small and large industries shows that there is a small percentage employed in the big industries. A great mass of industrial employees are spread out in factories employing less than five hundred men. The large majority are employed in small shops.

CHAIRMAN FURNEY: I have some figures that bear out your point. According to the 1919 census in this state, we had something like fifty thousand manufacturers, with one million, two hundred thousand workers. The number of establishments which had from one to five employees was 21,000. The number having six to 20 employees was 11,000. Those having 21 to 50 employees, 5,000; 51 to 100 employees, 2,000; 101 to 250, only 1,000; 251 to 500 employees, only 432. And those having 500 to 1,000, 50; over 1,000, 10. Showing the great bulk of all the shops employ a small number of workers.

And in those small concerns, of course there is less attention given to the whole question of safety. The larger concerns like the General Electric Company, and so forth, give a great deal of time and attention to the whole matter of safety and sometimes have two or three or five people looking after the problem of safety, and organizing safety committees, and working all the time on the problem of safety. But in these plants employing less than 100, very little attention is ever given to that.

MR. McDOWELL: Mr. Chairman, the State of New York has a labor law, and this labor law applies to the small factory as well as the large factory. Under this law they specify the dangerous machines, and among them is the shaper in the woodworking industry, for boys under eighteen years of age.

MR. GRAHAM: I do not question it is one of the most dangerous machines in the industry. But that is all the more reason for properly training the boys so that when they get out in the industry they have the fundamentals of safety on

which to rely, rather than trusting to the haphazard safety instruction which they may get wherever they go.

CHAIRMAN FURNEY: I do not believe you found more than one or two shapers in the schools—one in Rochester, I think, and one in Buffalo.

MR. McDOWELL: I might mention this, in connection with the shaper. I had been up in Elmira, and a gentleman came up to me and touched me on the shoulder, and he gave me the name of his school, and he said, "I want to congratulate you." And I said, what for? He said, "Because you did away with the use of the shaper in our school." He happened to be one of them that had had an unfortunate accident in his school.

CHAIRMAN FURNEY: I wonder what the general feeling of the group is in regard to having the school shops inspected by the State Department of Labor, and whether the State Department of Labor should have some authority over the school shops—that is, have the same authority over the school shops as over the industrial shops. The truth is that several letters have gone over my desk, in which the principals of schools have given us this excuse: "We can not do the thing that the State Department of Labor has recommended, because we have not the funds."

MR. EATON (Yonkers): I have had some general experience with outside agencies coming in, and found it entirely satisfactory. As far as this proposition of getting funds is concerned, from the school standpoint I would welcome it. I do not think there is anything would force a tax body to give you the money as quickly as such a thing. I ran a school for about three years, for disabled soldiers; a sort of private, semi-private affair, and we were inspected by the State Factory Inspector. He continually found hazardous things that we did not know anything about.

MR. GRAHAM: It might be interesting, that in Detroit our Board had a Chairman who was very interested in this matter, and he induced the Board of Education to appoint a committee for the purpose of inspecting the schools and to determine exactly what the condition might be with respect to safety from the mechanical standpoint. This committee, consisting of representatives of the State Department, State Safety Engineers' Office, two representatives from the Board of Health, the Industrial Safety Engineer, from the Local Safety Council, and one or two others, made a very careful and thorough inspection of all of the school shops, and made recommendations calling for the expenditure of eight or ten thousand dollars. The report was approved, and the funds were created for the purpose of carrying out these recommendations, yet the State of Michigan Board of Education has not required them to take cognizance of any orders issued by the Department of Civil Engineering or the Department of Labor. It is a cooperative thing, and they feel it is the thing to do.

Every new school shop is inspected prior to its opening, by a representative of the State Department of Labor and Industry, and subsequent to this inspection I spoke of, the Board of Education saw fit to appoint a safety engineer to handle the details of mechanical safety as well as educational work, and the safety engineer likewise inspects and approves any new shop, prior to its being put into operation.

CHAIRMAN FURNEY: I wonder if there are any questions you wish to ask Mr. Kent in regard to their method of handling safety instruction in the schools.

MR. BURRIDGE: I would like to ask Mr. Kent whether there is any first aid in the schools?

MR. KENT: Yes, we have in the larger schools a nurse, assigned to the school on full time. When she is not there the man in charge of the safety has charge of the first aid kit.

In the smaller schools, where we can not have a nurse, the safety man is in charge. There is a room in every school to which the boy or girl can be taken,

The rule is that every boy who is hurt must immediately go to that room. Every accident must be reported immediately.

MR. AXELROD (Bayonne): Mr. Chairman, I am in charge of safety training in Bayonne. I just want to ask whether that would not be Mr. Henig's work?

I happen to be in charge of the machine shop science and also the electric shop science. In this book he has the specific hazards pertaining to those two shops. Now, I think I can not teach the subject of safety as it should be, but by giving a general course, that is, the general rules, I think we do a whole lot in our particular school.

As far as I can remember, we had, I think, last year four or five major accidents, where some person lost part of his finger, and about ten or fifteen minor accidents. What would you suggest that I do, in order to cut it out entirely.

MR. KENT: We used that in a combination of ways. We used it, in the first place, in our analysis of our accidents in the various trades, checking up to be sure we got these things in. We use it to find out where to place the emphasis, what points are particularly bad, and also where to put up posters and conduct a campaign.

ADJOURNMENT

October 2, 1928

Education for the Modern World

DR. WILLIAM J. O'SHEA, Chairman
Superintendent of Schools, New York City

The third session of the Education Division was called to order at two-twenty o'clock by the chairman, Dr. William J. O'Shea, superintendent of schools, New York City.

CHAIRMAN O'SHEA: The National Safety Council bids you welcome at this meeting this afternoon. The purpose of the meeting is to promote our efforts in securing the safety of the people of this country, and particularly of the children. The first great problem that confronts us is one of economical development, development of our time, and particularly of our country. There are fewer people in industry, as the years go on. There are fewer children between the ages of fourteen and sixteen now employed in the industries. That is more leisure time on the part of adults, on the part of young folks, than there used to be. This necessitates a change in education. In this city and in other cities of the country we have met the situation to some extent, but have not completely solved the problem. There will develop this afternoon, through the speakers who will address you, suggestions that you can carry to your respective cities, to your respective schools, that will help you in solving the problem of safety.

In this city we have done a great deal. The schools, numbering over nine hundred in all and containing more than a million children, have set their eye and their mind on developing new thoughts which will help to reduce the number of accidents from automobiles and other vehicles. We have been very successful. We are proud of that fact. The public knows but little of the great efforts that have been made by teachers and by principals to save the lives of children.

Two years ago I called a meeting of all the parents and relatives of children attending all of the public schools of this city. There were about a million people in all that attended these gatherings, and from that time on we have made an intensive campaign in the matter of safety.

As chairman I am not supposed to do more than introduce the speakers of the day. I will proceed, therefore, to perform the duty devolving upon me by introducing as the first speaker of the day, Mr. Albert W. Whitney, associate general manager, National Bureau of Casualty and Surety Underwriters, New York City.

What Can Safety Education Contribute?

By ALBERT W. WHITNEY
Associate General Manager, National Bureau of Casualty & Surety
Underwriters, New York City

Our two meetings this morning had to do with the actual detail of safety teaching. The meeting this afternoon is for an entirely different purpose, namely to find where Safety Education belongs in the general scheme of education for the modern world.

Safety Education grew out of the feeling that the elements of our modern life and particularly the automobile, had become so dangerous that the home was unable, unaided, to cope with the situation and that the school must perforce come to the rescue. It began in most cases with such simple activities as the bringing into the

schools of policemen to talk to the children, and its first developments had neither a method nor a philosophy behind them. The end in view has merely the preservation of life and the educational value of the teaching itself was hardly thought of.

It became apparent however very soon that we were dealing with a subject that had distinct educational possibilities measured not only in its effect in the preservation of life but in its effect upon the development of personality; the progress since that time has been not merely in the building up of a richer content but in the development of a philosophy that would serve to rationalize the possibilities that were becoming apparent.

Briefly, the present situation is this: probably a large proportion of the schools of the country are now giving some instruction in safety, although in relatively few of these is the work of high quality. In the country as a whole while the automobile fatalities to adults are rapidly increasing, the deaths of children have been going down since 1923, which marks about the beginning of any considerable activity in the schools. In schools where the best type of instruction is being carried on actual statistics show a saving of lives of fifty to seventy-five per cent.

I am quite sure that I am expressing the sentiments of people having to do with education in saying that at first sight Safety Education is not merely unattractive but repellant. This is for two reasons, first, because of its apparently negative character, and second, because it seems too thin and too humble a subject to be given consideration in the schools. We in the safety movement had much the same feelings ourselves and we entered upon work in this field with misgivings and with much doubt of its practical effect either in the saving of life or in the development of personality. The results are quite frankly as much of a surprise to us as to anyone else.

The situation, we are convinced however, can be explained in no other way than by the hypothesis that we have stumbled into a really important educational field, the unexpected success of the movement is only another evidence of how much more unerring the instinctive reactions of children are than the sophistication of their elders.

Let me give you a side-light from the industrial field. There too the safety movement was in the first place viewed as distinctly a matter of minor executive importance, something that had to be looked after of course but a matter of quite secondary significance. One who will put himself in the way of feeling the pulse of this great Congress of which this meeting is only a small part, will suspect however that something was at fault in this judgment. Safety instead of being only an embroidery upon industry has now turned out to be an intrinsic element in its right functioning. It has been now proved beyond doubt that the safe factory is the efficient and successful factory and the efficient factory is the safe factory; in other words, safety and efficiency are only particular aspects of an industry that is functioning rightly. The same causes that produce accidents are also responsible for inefficient production. A box, for instance, falling from a badly-piled truck will cause a physical injury perhaps only once in a hundred times but in every case either the box is broken or at least the truck has to be stopped and repiled.

The correlation however goes deeper than that. The safety movement was the first field of importance in which management and labor came together on a basis of mutual self-interest. The old so-called "welfare movement" was not founded on a genuine basis of self-interest and was furthermore largely insincere, and it has consequently passed. The works safety committee made up of representatives of both management and labor was the first forum in which the two parties to the industrial enterprise met on a common, dispassionate basis to attain a result of genuine importance to each. It is well worth noting what came out of this situation. What happened was this: the members of the committees became intrigued with the human quality of the problem and found that they could work together not only with effectiveness but with mutual satisfaction and respect. Having got

results by such cooperative efforts in the safety field, they then found that they could get results in other fields, and the works safety committees not only led to the establishment of better working relationships in general between labor and management, but have been used in a multitude of cases for the solution of other specific problems in the field of industrial relations.

Many elements have contributed to bring about the better industrial relations in the United States which are so manifestly present today; it is not merely my own opinion but an opinion that is shared by a number of important leaders in the fields both of labor and management that of these the industrial safety movement has been the most important. A humble, human activity that went to the very core of life proved to be the key to a door that had not been unlocked by other efforts more ambitious and apparently more powerful.

There are just as serious problems in the field of education today as there were in the field of industry twenty years ago. I am bold enough to believe that the success that has come in the industrial field through this simple, humble, human approach may be possible of duplication in the educational field. It may be that the key to a better education may be found in the meeting of these lowly simple needs, rather than in the more elevated fields where we have been looking for help.

The effect of safety teaching in the saving of life is a matter of statistical record. In Louisville the year before work was begun in the schools the motor fatalities to children were 23, they dropped to 14 the next year, to 8 the next year, to five the next year, and they are continuing on about this basis. In the ten years that safety work has been done in the Detroit schools the saving of lives has been over fifty per cent and amounts to over 1,000 lives. At least equally favorable results have been secured in other cities such as Springfield and Worcester. There are 20,000 children killed by accident in the United States each year and if safety were taught in all the schools in the proper way, it is safe to say that the result would be a saving of at least 10,000 lives a year. The case is so clear from an accident prevention point of view that no more need be said about it.

The part of the case that is by no means so clear is the educational effect of safety teaching, the effect measured in the development of personality. We do not teach chemistry alone or primarily because of those that are going to become chemists. We teach it because it has a value in fitting a person to understand the modern world and take his place in it. 20,000 deaths a year among children after all represent not more than 1 or 2 deaths out of every 1,000 children of school age. What is the effect of our safety teaching upon the 998 that will not be killed by accident even if they receive no instruction? It is questionable whether we have the right in a crowded curriculum to require 998 children to submit to a discipline that has no value in the development of personality. The case for safety education in a consideration of education for the modern world must stand or fall upon the question of whether safety teaching itself has educational value, and the rest of what I have to say will be directed entirely toward that aspect of the subject.

Before discussing the matter in detail however let me say, speaking prospectively, that it is exceedingly unlikely that anything that is so closely tied up with the passing on of life should fail to show itself also in its effect upon personality. That is not the nature of the world. Education and the development of character are not an embroidery upon life; they are part and parcel of the problem of living and anything that has a fundamental relationship to living must in the very nature of things have an intimate relationship to the development of character and personality.

We must look for the nature of the educational value of safety teaching in an analysis of the safety concept and in the psychology of the child.

It is curious how largely an enterprise is conditioned by the terms which are used to describe it. The fundamental fact of the safety movement is avoidance of accidents. Having no accidents is an awkward idea to embody in words how-

ever and safety seems to have been the only practicable term that was to be had. Safety and having no accidents are however not synonymous and if the word "safety" is to be used, it is necessary to explain in what sense it is to be used and to call attention to certain untoward connotations.

The thoughtlessness with which one strays from the idea itself when one has a word to take the place of the idea is illustrated by the use of the term "Safety First." This slogan apparently originated in the railroad field and both there and in the industrial field it has a legitimate and literal application, for we certainly should not desire either speed or ladies' maids on the one hand, or greater industrial production on the other if they can be had only at the sacrifice of safety. This slogan was carried over into the educational field with complete naivete. It is manifestly out of place however for there are certainly a host of things in life that are more important than physical safety—love, friendship, honor, patriotism, for instance, and we cannot educate our children to the idea that safety is the first consideration.

The word "safety" itself must however be given equally close scrutiny. Being safe and avoiding accidents do not mean exactly the same thing. Avoiding accidents does not limit us in the least in the choice of adventure. We may choose to go to the South Pole, we may choose to fly across the continent, we may choose to fight yellow fever in Africa, we may choose (or not choose) to be a candidate for President. Avoiding accidents has nothing to do with the choice itself. Avoiding accidents merely means that having made our choice we must carry the enterprise out successfully and conformably with our purpose. All that the no accident movement says regarding adventure is: "Carry your adventure through instead of letting it go to pieces on the rocks of mischance."

Being safe, on the other hand, does seem to have something to do with the choice of the adventure itself. To be "safe," using the word in an absolute sense, would probably land us in Nirvana or some other spiritual safe deposit vault. However, the word "safe" as a practical matter is always qualified, either explicitly or implicitly. We must know what we are to be safe from. There is however another preposition that is equally applicable and in fact correlative, namely "for." Safety as a practical working conception has no value until we see clearly what we are to be safe from and what we are to be safe for. Safety therefore is substitutional. To be safe does qualify our adventure. It implies a criterion by which we can distinguish between the good adventure and the bad adventure. Safety however not only does not prevent adventure but it flaunts adventure in our face, namely by calling us to secure safety *for* the good adventure.

Now both the concept of avoiding accidents and of practicing safety for the good adventure has extremely important educational implications in the life of the modern world.

The world is full of adventures, more full than ever before. The problem of choice is more important and more pressing than ever before. There are more good choices to be made and there are more ways to go wrong. We need a modern theory of relative values. Some of the old criteria have disappeared, some are not applicable to modern conditions. Furthermore most of the old approaches are gone. We need a new approach to the problem of appraising the values in human life. I do not make the claim for safety that it will supply criteria for choice but I do believe that it furnishes a natural, normal approach to the problem of relative values in a field in which the child is thoroughly emotionalized, and one that is rich in its connotations.

On the other hand there is nothing more modern than the conception of not having accidents. Chance and accident belonged in the world when it was being guided by natural selection, for the variations upon which progress was based were necessarily fortuitous. It has little place however in the world of today. The world of today is characterized by the completeness with which it is under control.

Man is no longer a creature of circumstance but he is imposing his will upon the world and bending it to fit the image in his own mind. In the modern world we know what we are doing, we are acting in a purposeful way, to produce a result and we will brook no interference particularly from the blind, controllable forces which produce accidents. Nothing is more in the spirit of the modern world than an education which focusses attention on purposeful living.

Safety furnishes no criteria for the good adventure nor for the good purpose in life, but it does, I claim, furnish a valuable approach to both problems, and for two particular reasons, first because the approach is emotional and second because it has a negative quality.

A good educational field must not merely deal with forces that have an important bearing upon life but there must be ready access to the minds and hearts of the students. Spelling may have a certain amount of educational value but it has certainly had to get its motivation not from anything intrinsic but from such fields as the desire to excel. No field however is more thoroughly emotionalized than the field of safety. The survival of the fit has been in general the survival of the safe, using the term in its broadest sense, and children have interest in safety because they are themselves the product of a long line of ancestors that owe their existence to their success in learning their safety lessons.

The intense human interest which children show in Safety Education is ample proof of its emotional quality and an evidence also of the ability of children to grasp the fundamental nature of things.

The second reason why safety is a valuable educational approach is the very fact of its negative character. Every important field of human endeavor, so far as I know, has started on the negative side. Education began with inhibitions, religion began with taboos, psychology began with abnormal psychology, medicine was curative before it was preventive. The positive approach characterizes those fields in which the race accommodations have been well-established. The negative approach is found in those fields that have never been brought completely under subjugation. These are the fields of the unsolved problem and therefore the fields in which the fires of progress burn most brightly. If education is to be the instrument of progress it cannot afford to confine itself to fields that are completely positive. We need the challenge of the negative, the incomplete, the unsubdued, the dangerous. And an approach to a positive outcome through a negative field instead of being an element of weakness is an element of strength.

Now I must hasten on to what I consider the most important part of what I have to say, a field in which I hope that safety teaching may make a genuine contribution to modern education.

Safety can be taught by the methods of either the old education or the new education. Under the old system it will usually be taught as a separate subject and instruction will be given in the form of maxims and inhibitions. The subject this afternoon however is education for the modern world and so I shall confine myself to the discussion of modern methods.

Modern education thinks of the child's mind as a seed, containing the elements of the inner world and education as a process of unfolding and growth. The seed has within itself an organizing power that will make it grow into a tree and all that we need to do or can do in fact is to furnish it light and nourishment. Similarly also with the mind of the child.

The child in the course of its development both physical and mental must traverse essentially the same path as the race itself, but this must be done at an enormously accelerated rate, and largely under special conditions. The first nine months of a child's life for instance are passed with no direct contact with the world. A large part of education, and I am including adult education as well, must perforce be done through the medium of play, recreation and art, all of which are

primarily and intrinsically media for receiving a larger experience of life than can possibly be had directly.

Golf is an epitome of the world and a man can in an afternoon's play, with the thrill of drives down the fairway and the equal thrill of getting out of bunkers, get the equivalent of years of direct experience of the world. The drama is a way of experiencing life vicariously and still less directly. Education must perforce make use of these methods for enlarging experience, but there must also be a direct contact with the world. Playing dolls and playing store and playing railroad train, with the projects that they involve, are excellent for part of the time but they must also be balanced by a tasting of the world itself that is not in play but in earnest. Birth itself is an evidence of the fact that our development and education must not all be sheltered and indirect. A butterfly has apparently little to learn from the world and so when it comes out of the chrysalis it is complete.

The rallying cry of the newer education has been self-expression, the need of unlocking the spiritual energy within. This is equivalent to the bursting of the jacket of the seed and the putting out of its first green leaves, but the seed has within itself an energy that will not be satisfied until the infant plant has struck its roots into the soil and finally found expression in the form of a tree. So the nature of the child is not satisfied until its energies are brought into contact with reality and have found expression in activities which are similarly directed toward the goal of human life.

The newer education has been so successful in its efforts to give the spiritual energy of the child expression that it can now turn itself to this next great task of integrating this spiritual energy in the form of purposeful living.

Now it is certainly not in the upper reaches of life where a child first comes into contact with reality but in such lowly fields as safety where the needs are simple and immediate. This is the place where the child's roots begin to strike into the soil and he gets a firm grip on the world as it is, by no means a wholly pleasant world but nevertheless the world that he has to live in.

Not till the plant gets rooted and begins to draw nourishment from the earth itself can it seriously begin to fulfill its destiny and become a tree. So with the child. The need for self-expression is like the stored up energy of the seed but it must be supplemented by fresh energy drawn from contact with the world itself before the child can begin to work out his destiny as a man.

Safety furnishes however not merely this primitive contact with reality that the child needs but it also furnishes an objective toward which growth can be directed. This is amply borne out by our actual experience. Far the most important and successful work in safety is being done by making use of it as an objective toward which the work of all classes can be directed. And in so doing we have discovered the curious fact that safety can be so taught without the use of more time, more money or more teachers. In other words there proved to be an actual vacancy in education as had been suspected; techniques were being taught but not applied to life.

To draw to a close the treatment of a subject which is too large for the time at my disposal let me say in recapitulation that I believe the next great step must be to bring education more directly into contact with reality and to direct it toward the development of purposeful living, and in this endeavor I should seriously like to present the claims of Safety Education on three grounds, first, as a natural and effective approach to the problem of purposeful living, second, as a place where a simple and successful first-hand contact with reality can be had and, third, as furnishing an objective about which the activities of the curriculum can be integrated.

CHAIRMAN O'SHEA: I am sure that I voice the sentiments of the audience in expressing to you our gratitude for that splendid talk.

What Mr. Whitney has said relative to the importance of inculcating habits of safety, agrees fully with my views on the subject. I think the teaching that we have done in the schools along these lines has helped to increase and teach self control, self protection, obedience and many other virtues, that were to some extent lost sight of. The intensive campaign which has been waged along these lines is also an advantage to the teacher. As I said at the beginning, in introducing the speaker, we have departed in recent years from the mere teaching of the three R's. We have taken up health education, safety education; we have given more attention to moral education, and what we are doing along the lines of safety education is in line with the progress we are making in other directions.

It is now my pleasure to introduce to you Professor Rugg, well known for his work in curriculum revision. He is largely responsible for the movement to establish a unit course in social science, history, civics and geography. He, with several others, has written a series of text books along those lines.

What Does the World Need?

By HAROLD O. RUGG

**Professor of Education, Teachers College, Columbia University,
New York City**

I shall take my cue from the central thought in the admirable paper of Mr. Whitney, namely, that the world needs, more than anything else, an education which will prepare youth for a reasoned life of adventure.

I think a central thought might be stated as this—we must find some way by which in the short years of schooling, we can bring about a generation of youth who will be launched upon an effort of reason and the adventure of beauty—the effort of reason and the adventure of beauty.

The present situation in the American schools is the product of three centuries of the most spectacular transformation in economic and scientific lines that world history has revealed. Europe in the sixteen hundreds, located in the most stimulating climate, inheriting tremendous sources of coal, iron and other great natural resources, produced in the next three centuries a startling and totally unique civilization. Inductive science, growing out of the spectacular seventeenth century, turned, in the eighteenth, into the development of the formula, and produced in the nineteenth century this world-wide exploitation of natural resources.

The Puritan in 1600, in England, going into business, and going into government, produced attitudes of thrift and industry, hard work, adjustment, agreement, that eventually revolutionized the means of production and distribution of material good in the modern world.

I say to you that we are living too closely to the modern economic life to realize its significance to the public schools, because the philosophy under which American education has for the last 75 years developed itself into a great national system of schools, that philosophy has been so developed that it is practically impossible to produce out of it the philosophy of reasoned adventure which Mr. Whitney was talking about. This tremendous change that has come about in the modern world began to show itself especially in the late seventeen hundreds in the production, in a most startling and revolutionary way of the steam engine. Man learned how to produce artificial power and stopped for the first time in nobody knows how many million years, being his own draft animal, or stopped gradually the conditions under which his wife could be his draft animal; and at the same time developed with almost uncanny insight a scheme by which this mechanical power could be harnessed to wheels—and then changed the lives of human beings the world over. People came out of their handicraft homes and went to work in

cities, huddling together in densely populated regions. Little England, and other island nations led a century long race for land, for coal, iron, for world-wide markets, and produced, with the other European countries, the transformation of this entire modern world.

In America we outdid Europe because of our fortunate inheritance of all the land between two oceans, and with it the world's greatest concentration of the three basic natural resources, coal, oil and iron, and with it a stimulating cyclonic climate that kept our ancestors everlastingly at the job. And over night we, more spectacularly than Europe, produced great cities; and over night we, since 1850, produced the graded school. Children huddled together in towns and cities with their parents, and the graded grammar school was the necessary eventuation. And so rapidly did this phenomenon produce itself that our school men could do no more in the first fifty years than grade these children in groups and design for them, practically on makeshift methods, reading books, arithmetics, spelling books, geographies, histories and so on. The history of the American school curriculum is the history of thorough going opportunity. Our ancestors were compelled to do the job of housing, organizing, administering and securing, as best they could, over night, nearly a million teachers for 23,000,000 children.

About 1890 in the modern world, it became very apparent, especially in Western Europe, that the first stages of this rapid, economic transformation were about over.

Remember, that from 1600 to nearly 1900, creative art, creative thinking, outside of the field of applied science and mathematics and engineering, creative art and creative thinking were submerged, stamped upon. The tendency of the human mind was to apply itself to the immediate problems of production and developing a material civilization, and we today are intensely grateful that that job was done.

But in the 1890's there appeared in the various centers of culture and vision in Europe, rare, creative souls in painting. In music, in literature, in each of the outstanding arts, men and women appeared who said, "We must produce original ideas and original statements and original emotions." And since 1890 we have had the startling phenomenon of the appearance in France, in Germany, in the Scandinavian countries, in England and in America, of groups of creative artists who have said that the life of adventure can be lived only as each individual personality is permitted to develop its own capacities and to experience its innermost ideas and emotions.

Now the demand of the artist, the original, innovating, creative artist, apparently runs counter to the general philosophy of education under which the Western countries have developed their school systems. In the United States, after 1875, the very philosophy of education became phrased as pragmatism and the aim of education for elementary and secondary schools was set down as social efficiency. It was produced originally by an engineer, Charles Pearce, who influenced William James, and afterwards, John Dewey, and set, if you please, the whole philosophic stage. Now we have had, since 1900, the arising in America of a totally new educational movement.

In 1896, John Dewey relates how one afternoon in the fall of that year he went about from supply house to supply house in Chicago, asking for furniture for a new school that he was to establish. And as he went from one store to another he was answered in each case by the same reply, "No, we haven't the kind of furniture that you could use in your school." He had specified the requirements; he wanted flexible furniture, movable furniture, chairs and tables that could be used in terms of the needs of the children at any moment. And finally he came to a store where there was a young lady saleswoman, who, with more discernment than salesmanship, said, "No, we haven't it and you can't find it; what you want is furniture for the children to work at; in ours they can only listen."

Some of you may have seen on the screen of the Pathe Weekly not long since,

views illustrating the wreck caused by the recent storm in the South. Perhaps you saw, in the succession of rapid, kaleidoscopic views, the picture of the schoolhouse standing in the midst of the street after street of ruins. The street was flat, except for a part of the schoolhouse; the roof had been torn off, all the walls were gone, but the floor was rigid, and screwed religiously in place were the forty chairs and desks.

Now put together the two pictures, of John Dewey searching for flexible furniture that could be moved about and used in terms of the needs of the children, and the picture of the remains of the holocaust, and you have the old and the new education, or the new and the old education, adequately epitomized.

What kind of an education will produce, if it ever comes in America, the effort of reason and the adventure of beauty? First, a right-about-face in educational philosophy. There was a music master in Geneva by the name of Emil Jacques Dalcros. Some of you know that name, Dalcros, as the designer of a great system of musical education. Dalcros had a slogan that he was fond of using as an epitome of his whole educational theory. It was, "I would have a child say, not, 'I know,' but, 'I have experienced.'" And John Dewey, 3,000 miles away, almost at the same time seized upon the phrase, in 1890, in writing his first little monographs about the new school, said, "The central doctrine of learning and education shall be the reconstruction of experience; not until a child has taken in the world, taken in an idea, taken in an outside stimulus and reassimilated it into his own nervous system, not until that has happened has the child learned, and is the child on the road to true growth."

Now I take that slogan for the central thought of this method by which this new education, this new product of the effort of reason and the adventure of beauty, can be accomplished and attained, because the fundamental, psychological fact that you and I have to confront in producing the new education is that every one of these 23,000,000 children in America, and every one of these million children in New York City today is a unique personality. And the fundamental job that you and I face in American education is the development of that individual, unique personality to the maximum, all his powers. The psychologist has shown us very clearly that we are utterly and totally unique.

At birth a child is essentially a rhythmic bundle of capacities; he comes into the world with a certain heart beat, rhythmic, periodic, intermittent, with the rest pause a little longer than the action pause. He inherits a certain rhythmic, periodic rate of flow of breath; he begins to walk after a few months in a particular mode and style and rhythm as a time beat of locomotion. He begins to talk and to use his hands, use all parts of his body in an intricate, coordinated, integrated scheme of nervous life. So that as he grows from the age of birth he is becoming more and more his own unique, rhythmic self. And the foundation of his education must be an educational method that will start with the education of his body. And so Dalcros, and other great music masters, watching conductors of orchestras as they respond with brain, highly central nervous system, muscles, all the sensibilities, to the music, they are portraying, or the singer or the painter or the artist in any field, responding with his whole personality, so, I say, Dalcros, and these other great masters of education, have seized upon this central doctrine of individuality and of self expression.

Now if you go into one of the new schools, some of which are found in the publicly administered systems and some of which are found under private auspices, you find illustrations of the way in which this new theory is working out. You go to a certain school and ask to see the program of the work in that school. You ask to see English Composition, in the elementary or junior high schools, and you are told that they have no English Composition. And you ask the children, "Don't you write?"

"Yes, of course we write; we write a great deal."

"When do you write?"

"We write whenever there is occasion or need to."

In the spring, Saunders of the First Grade, is impelled to write to his teacher as follows:

"Dear Miss Harrison:

"I made up a song. This is it:

"The birds have come again;

"The birds have come again;

Irma of the Second Grade writes to the shop instructor:

"We have made patterns for our dolls' beds. Will you bring us some wood?"

The boys of the Third Grade visit the ships and the docks and cannot rest until they have made a complete record of every delicious detail.

The Fourth Grade writes a group play about Christopher Columbus, and this, of course, must be put in good written form, or how can the actors learn their parts?

But in the meantime the girls have been making cottage cheese in a new way and naturally the world and his wife should know something about it via a mimeographed recipe.

And out of this new environment which you observe in the new schools come in the most startling way exhibits of creative ability that we have no suspicion existed in these children.

Two Fifth Grade girls write a poem, call "Spring and Summer."

On an evening soft with mist
The moon shone on a silver brook.
Summer came from the shadowed glade
And Spring came from the wood.
Summer stepped across the brook
But Spring stood still.
They stayed together for one happy night,
Oh, the wonder of that night.
Night had gone and with it Spring,
Dawn found Summer all alone.

And you begin to inquire what kind of an environment it is that centers education upon the development of individual capacities. How is it done? How can children of not more than ordinary mental ability write so deeply and fundamentally, as, for example, this, a poem called "Heaven."

I went to church one day, and God
Sat by my side.
And we laughed at the preacher
And the people with their prayer books
Saying prayers to a god so far away.
"Heaven is pearly paved,"
Said the preacher,
"And golden angels sing His praises
On their harps. It is there that
You and I will some day go."
And God laughed and said to me
"Heaven is a broad field and the brook,
And the lean, scarred, beaten horse,
And the houseless cur,
And the hunted deer,
Will go there with me."

The child of 14 who had lived five years with a teacher, with other boys and girls had heard this teacher read day after day very wonderfully from great

writings about the life of adventure of beauty, and had entered into a very growing interplay of critical discussion with the teacher and each other about the readings that were being used in the class. And then in this school interesting discoveries are made, hidden reservoirs of wit and humor, that mark a great soul.

I remember well, Emma, who was more or less an outlaw in such a school, who was sent to me some years ago to be given (in the days when I did such things), an intelligence test, and Emma was discovered to have, in the jargon of the trade, a very high I. Q., indeed, nearly 150. The school couldn't understand quite how Emma could have that I. Q., but immediately took it upon itself to see if someone couldn't draw that out. And then a great teacher, an artist teacher, came, and Emma began to be found out. Two years later I found her out. She had written a poem about me, after the episode of the intelligence test, and it was called, "The Moron Turns, or The Danger of Obeying the Philosopher who said Nobody Thinks." And this is it:

At intelligence tests I am not at my best,
They are not my idea of a spree,
They possess no attractions for me.
There is no fascination or fervid elation
In slowly and patiently filling the blanks
That confront me in ranks.
There are other better ways
Of passing idle days
Than eternally perusing a hazy, confusing,
Ultimately disillusioning test.
And the things the test show
I'd much rather not know.

And I mustn't stop without letting you have this. Emma wrote about her classmates, too, and one was called "Johnny."

He used to find content
In standing always rather bent
Like an inverted letter "J."
His angry relatives would say,
"Stand up, don't slouch, you've got a spine,
Stand like a lamp post, not a vine."
One day they heard an awful crack,
He had stood up straight;
It broke his back.

And then, out of the environment in which Mr. Mearns, this artist teacher, described the central element as "permitting poetry and not summoning it"—that is not a half bad slogan for creative education. "Poetry cannot be summoned, it can only be permitted," said Mearns, paraphrasing in a way the words of a great Austrian painter-teacher, who, when asked how he produced the wonderful results with children in painting and drawing, said, "I take off the line, and other art masters clap it on; that is the difference."

But out of this environment of drawing out rather than pouring in, out of this environment of critical discussion, with full-hearted appreciation of beauty, came some very wonderful productions. I would like to read you one more, and my examples are before you. It is called, "The Door Stands Open," and came out of one of those critical discussions in which Mearns had said to the girl who had handed the poem in in its earlier form, "How can you do such things? There is one good line, 'The ever passing steps went by our door.' Now if you could write a poem about that it would be worth something."

And late that day the poem in this form came back:

The ever passing steps went by our door,
We did not listen then,
Nor did we look outside,
But now the door stands open.
Some hang back, afraid to join
The crowd that passes,
Some gather in the doorways
And watch eagerly.
I am not afraid; I am not eager.
I stand by the window and look
At the faces.
I would know what life is,
What the world is, before I go.
Those who come back are often
Sad and tired.
The stories they tell are not
Always pleasant.
And yet all who go out are happy,
And they hurry, looking ahead
At something just beyond.
There goes one now, she almost runs,
And there come some who are returning.
Their faces are lined and ugly,
But their eyes are wise,
Not all of them.
I see one coming back whose face
Is smooth and happy,
But her eyes are empty, foolish.
Why? I will find out.
There goes a face like mine
That searches for an answer.
What has she learned?
She may tell me; but she has passed.
I see a youth whose eyes are fixed
On something far away,
His is a face to follow in despair.
I lean out, "Where are you going?"
The vague, deep eyes turn slightly,
"Just over there." "Where?"
But he is gone.
Here returns a man whose face must
Once have been like that youth's,
His eyes are broken windows
And he babbles without sense.
What is this world that does such
Things to men?
There stands a man who watches
Those who start out.
He sees them drop unnoticed things of value,
For which he stoops and searches
In the dust.
He is one who went out and
Has returned with nothing.
I leave the window and look about
The empty room.

They all have gone; I cannot wonder.
 'Tis just as well.
 Youth's saving gift, I think,
 Is that it will not look and cannot see.
 I take a last glance back
 And gently close the door behind me.
 I catch a friendly hand
 That is half outstretched,
 And I am part of the crowd.

Now every one of the 23,000,000 children in America has some ability to produce out of his own developing experience something unique; if the school will listen to that child's personality. He can't help but produce something unique for he is unique himself. But the school, under the doctrine of adjustment and social efficiency, tries to groove him into a standardized goose-step sort of person.

Now creative self-expression, the production of individuality, a scheme of education in which we will permit poetry and music and the dance, and ideas, and not coerce or summon them—I said at the beginning that a slogan that would be fitting or adequate for the modern world, the education in it, would have to be two-fold. Not only the adventure of beauty do we want to launch these children on, but to fit them for a modern world that is full of the gravest and most difficult intellectual and emotional, as well as physical, dangers. We must launch them on the effort of reason. It is not only understanding of the modern world that we want, an understanding that is almost impossible to get under the hampering conditions of modern life, but it is tolerant understanding.

I was an eye witness to a little episode that illustrates perfectly what we want at this point in the modern world. I was going into one of the schools in Denver, one afternoon, with the superintendent of schools, and just as we were going into the high school, two boys came out, evidently from the gymnasium, engaged in a heated discussion. And as we passed them, one boy turned and said to the other, "Fred, your point is well taken, but what is your authority?" I gasped and said to the superintendent of schools, "Is that a representative product of your educational system?" He said, "I would like to think it, but I fear those children have been trained in deliberation outside the classroom as well as in."

But note what that boy had said—"Fred, your point is well taken"—(an open mind, a flexible mind, a mind that was willing to say, "Perhaps the other fellow has got a point?")—"but what is your authority?" A critical mind, a mind that was open, but as someone said, "Not a drafty mind, one open at both ends." A mind that was questioning, that said, "What are the facts; have we got them?" Put even more than that, a mind that had the uncanny instinct to say, "What is the faith back of that statement?" Because it is faith more than facts, after all, that determine our statements.

And that is the problem the school is up against, in this effort of reason, or producing a setting, producing problems, producing readings, and securing research enterprises and library materials and what-not, through the use of which children can be growing in their capacity to be open minded about these problems of immigration, of industry, of community life, of democracy, of international affairs, and so on.

And so it is this great two-fold problem of first discovering how we can set up an educational régime in our schools, an atmosphere in which we draw out the capacities, physical, emotional, intellectual, in these children, and on the other hand, by which we confront them day after day with issues, with problems. We don't dare not confront them with problems. We don't dare exclude from the schoolroom of the American schools the issues and problems of modern life.

Otherwise, if we do, conduct will continue in America to be governed by impulse and not by tolerant understanding.

CHAIRMAN O'SHEA: The rapt attention with which you received Prof. Rugg's beautiful talk, is an ample compensation to him, I am sure, for the effort he has made this afternoon.

We will now have the pleasure of listening to Prof. Overstreet of the College of the City of New York.

Round Table Discussion

Led By HARRY A. OBERSTREET

Professor of Philosophy, College of the City of New York

I hope you see the humor of this situation. This is now supposed to be a round table. I have looked around and I can't find anything but a long, green, oblong table, and a square room. And you may remember what Doctor Rugg said about inflexible furniture, and so on. I seem to see in front of me the kind of furniture in which you can only listen.

But what is a round table; and what is a round table that is led? I am supposed to lead something. For those of you who are totally ignorant of such exceedingly technical terms, let me tell you that that means that I am here not to tell you anything, but you are now to have your innings and to come back at these learned gentlemen and tell them—well, just tell them. I mean, tell them what you think about it. Now that is going to be a very difficult thing for us to do in a square room like this with square people sitting in front, and so on. But I think perhaps we can manage it.

We have had two very remarkable addresses. Old and bored to death as I am at all these educational things—of course anyone who is at all educational in his occupation gets rather bored at hearing other people talk, you know—but old and seasoned as I am, I must confess that I have never heard two addresses quite so fundamental, quite as challenging, as these two addresses. Both Mr. Whitney and Dr. Rugg were giving us pioneering ideas, ideas about a new kind of education—Mr. Whitney, with his philosophy of the adventurous life and of education, serving the purpose of putting us into the adventurous life in a reasoned, in a controlled way; and Dr. Rugg accepting that and going further and asking the question, "What is an adventurous life; what is the adventure about?" And then taking us into this fascinating new region of American and world life that is the region that goes way beyond the traditional, utilitarian concept of things, and takes us into a sense of something far more fascinating, far more beautiful than life may be. You remember his startling sentence that at a certain time the philosophy of education had to make a right-about-face, and the philosophy of education is making that right-about-face.

Now the discussion that I should like to be able to lead, if you will cooperate, really centers upon this question; granting that we are entering upon a new educational era, that with the world we are passing into something new—not that education has gone off on a nice little jazz party by itself, but that the world has changed, and that education has to change with the world. Now granting that, and that the philosophy of education, the fundamental concept of what the whole thing is about, has to make a right-about-face, I am wondering whether you will agree that both these gentlemen have said the final word, or have said the adequate word. I wonder whether there are perhaps dissenting voices in this audience. What really is education for as we see it today?

Now I should be very glad, if any of you have ideas about this, to have you speak. Perhaps it would help us if you would rise from your chairs, and in

order that this shall get to the larger audience, because millions and millions and millions of people are listening to us now, I shall repeat the gist of what you say. What about it? Are you all in agreement that the matter has now been settled and that we know what education is for? Who will be the first? Well, what is it for?

MRS. BURTZ (Peekskill, New York): To live life in the fullest possible way. No teacher can be satisfied in putting things inside; they must bring them out. You must fit your teachers to meet the needs of your class and the individual members of it.

PROF. OVERSTREET: The answer that I got was that education should be for the fullest possible life in the individual, and should not be simply a matter of learning lessons. There is one point of view—education is for the development of the individual personality and not simply for the learning of lessons. And therefore the training should be an individual training that pays attention to the individual, unique, qualities of a person.

MR. JONES: It is not education that you get through with but something that gets through you.

PROF. OVERSTREET: There is an epigram. Mr. Jones makes an epigram, yes; will someone make a speech?

MR. KNOELKE: I happen to be chairman of the Safety Commission of Milwaukee. I am not going to make a speech, but my thought is this, as I hear Dr. Rugg now and have heard him before, he loves to tell about education as a three-fold sweep, educating for a living, making a living, living with one another and living by one's self. I think you will admit that.

Now I think, as members of a group that are in conference on safety, we need to remember that that second point should be stressed. I am in hearty accord, as I feel that education should be an outpouring rather than a compression. At the same time we can't have any real individualization without a certain amount of socialization, living together, and it seems to me we ought to express that in the case of the work along safety instruction, in the case of a particular phase of this education.

I find great difficulty in trying to get people to regard the rights of others. In this consideration, in letting them know they have privileges which they are bound to express in wholesome, purposeful activity, I think that we need to remember, as educators, that there is such a thing, even in this day of free expression. There must be a certain restraint in the matter of deferring to the rights and privileges of others.

And in connection with safety I just want to call that thought forth and see what reaction that suggestion receives.

PROF. OVERSTREET: Mr. Knoelke objects to jargon and suggests that too much stress may possibly be laid upon the development of the individual in his unique individuality, and that attention must be paid to the fact that we live in a social world and the individual must be trained to live in that world with full consideration for others, so that group life may be successful.

What are we going to say about that? This certainly brings in the safety side of the issue and perhaps will enable us to take up Mr. Whitney's point, that the safety issue really is the integrating issue about which our educational objectives will be ranged.

Is there any further suggestion?

MR. CARLSON: I am not a teacher, simply a merchant. My idea of education is that it should teach children to think, and to think interesting thoughts.

PROF. OVERSTREET: Mr. Carlson says he thinks education should be for the purpose of teaching children to think and to think interesting thoughts. Who will rise to that challenge? There are two challenges now.

MRS. BURTZ: Education is for the purpose of a reasoned life of adventure. I suppose learning to think is part of the reasoned life of adventure.

MR. CARLSON: I should add to that, to carry the thought into direct action.

PROF. OVERSTREET: Have we overstressed the matter of the development of the unique personality of each individual? Have we understressed the fact that children have to live together in a world in which they must show consideration, in which they must know the people around them, and perhaps contribute to the common welfare of the world in which they live? Has that been overstressed?

MISS. RIEGER: I don't think it has been overstressed, but I think school teachers find it difficult to be able to emphasize it in the classroom. There are many problems and the time allotment is not sufficient to bring out the individual differences among all the children in the classroom. As a rule we have such a big curriculum to go over and so much ground to cover, that it is impossible to give 50 children in the class the actual individual time they need.

PROF. OVERSTREET: Miss Rieger suggests that the individual progress has not been overstressed; quite the contrary, as a matter of fact, that mass production in the schools—I suppose one could use that term—has made it quite impossible to pay any attention to the uniqueness of the individual, and so we have neither served the individual nor have we served the group. Would you agree with that? I mean to say, that neither has been accomplished?

MR. NOBLE: I think that in safety education it must be a matter of group consideration. If it is just education, per se, then we can think of the individual. But on safety education we must think of group work, because if we were an individual on a foreign isle there would be very little cause for safety work, while here in the city we must not only consider ourselves but others, and safety education that way would be greatly enhanced.

PROF. OVERSTREET: Mr. Noble suggests that safety education is really the point of approach whereby we may secure what was suggested in the way of group education. That is, safety education is essentially concerned with the individual in his group.

MR. SUTRO: Our worthy chairman would tell you that we have 1,250,000 children to teach in this city, with classrooms running up to 60 children or over.

If you want to get any results from this afternoon's conference, what is the practical result of this whole teaching? Shall we go back to the little red school house where each child can be individually taught? That would be impossible; the economic question would prevent that. And I would like to get the consensus of opinion, as far as possible, from the standpoint of the large city where we have millions of children to teach. I would like to hear from somebody. I am not able to give the solution myself as to how to teach the children so we can get the best out of them. It has been said that group teaching is necessary. We know that we are forced to that whether it is the best or worst method—I don't know. Some people claim that if a child wants to learn, he can. They cite Abe Lincoln to show how he learned, and they seem to think that no matter how careful you are to individualize, you will not get exactly the same result—this is not my opinion—as you will by group teaching, to educate the child to think as far as he can and to learn and develop his own mentality.

I would like to hear from somebody on this angle, if possible.

PROF. OVERSTREET: Mr. Sutro is asking a question. He paints the picture of the difficult situation we have in a city like New York, for example, with its millions of children and regimented classes, and he wants to know how we can teach so as to get the best out of each student.

Of course, before you take up that, may I suggest that what we are trying to discover this afternoon is a rather difficult thing. What are we trying to educate for? What is the whole thing about? Then it may be possible for us to know how to do it. Is there anyone who wants to answer that question?

EDWARD STAFF: May I be allowed to say that I am not a learned person, but I would like to say this—we are losing sight of the fact that society, in working for this education, has a purpose in view. It is perfectly well and fine to try to individualize a person, any person, child, grown-up, adult, or anybody else, but society, in going through all these pangs, I take it that the purpose it has in view is to make this person or those persons as valuable adjuncts as possible to the community in every way. Outside of that, and past that point, this person may be individualized, but until he reaches that point he must be taught according to the concept of society, in such a way that he will be a valuable adjunct to the community.

PROF. OVERSTREET: This gentleman makes the point that the object of education should be to make the individual a valuable adjunct to society. Now shall we let that pass unchallenged or shall we say, "What do you mean by valuable adjunct to society?"

MR. STACK: I am also an unlearned gentleman. I am a supervisor of secondary schools. I want to tell you just a few things because I think the whole secret of these things that you have been talking about today strikes particularly in the secondary schools, in the junior and senior high schools—and they give us a great deal of trouble. We know, in Johnstown, that just ten per cent of our boys and girls will go to college, but we also know that some 30 per cent of our girls will go into home life within a few years; and in five years some 50 per cent are married. We also know that some 25 per cent of our boys and girls will go into industries of our commercial establishments in our city. Therefore, I believe that all of this material that you are giving us is heartening to us, because instead now of thinking of our high schools wholly as the preparation for college, we, in our domestic arts courses, in our music, in our commercial courses, in our home baking courses, in our extra-curricular activities of various kinds, in our assemblies, in all of this safety work, are trying to give real life experiences. And so our secondary school curriculum is rapidly changing, and I believe there is coming a day when many of these home experiences, many of these vocational experiences to which you are listening today will become a part of the curriculum, so that our boys and our girls will be better home-makers, workers in the city, and the life in which they are engaged, better workers in their vocation, with a better appreciation of music and the fine arts, rather than the emphasis purely upon the college preparation.

PROF. OVERSTREET: Mr. Stack makes the statement, first, of the rather significant fact that only about ten per cent of the students in the high schools go to college; 30 per cent of the girls go into home life and 50 per cent marry. He didn't say what becomes of the remainder.

MR. STACK: That is within five years.

PROF. OVERSTREET: Some of them become school teachers. At any rate there is here the serious point that education should not be for the ten per cent; it should be for that larger number who go into the issues of life, either in the home or in industry and what-not. And he welcomes the fact that particularly through this safety education movement, the educational activity has become integral with the life activity. He welcomes that as one of the great advances in education.

MR. GOLDBERG: I think that the trouble is due to the fact that we baby our children too much in the schools and in the homes; we do entirely too much for them. When we help them day by day and take them across the street, lead them by the hand and keep them out of dangers, we are not doing them any favors at all. From the time that they are very young they should be given a chance to find out what they can do and to learn by their own experience. The ones who are hurt are probably, if we could investigate it, the ones who have been taken by the hand and have had everything done for them in the schools and in their youth. We do

entirely too much for them; they are babied along and that is where most of the trouble lies.

PROF. OVERSTREET: Mr. Goldberg suggests that we baby our children too much and the children who get hurt are probably those who have been taken by the hand and led across the street, until one day the hand was absent.

Mr. Whitney made the point earlier in part of his paper when he said—is safety education simply a sort of little extra thing thrown into the curriculum, or is it true that through safety education we develop a very fine kind of character in our children? Now I wonder whether we could pursue the point you made, Mr. Stack, and ask ourselves—are we getting more integrally into life situations with our children? Are we, through this attention paid to the safety matters, really developing a fine kind of character in our children? I happened to see as I was sitting here these placards: "Do It the Right Way." If you don't do it the right way, something happens. Any old stick won't do; you have got to have the right kind of stick. "What Will Happen When the Door Falls In?" If you don't have your door properly put on, something is going to happen. I just want to throw this out as a challenge. All those seem to be scientific statements to me. We have science in our schools, but why isn't this science: "Do It the Right Way." If you do it the wrong way you don't get the results. Is safety education a way of teaching science, and teaching science by actual manipulation of the life processes? "Don't Leave the Brake Handle Like This." That isn't the scientific way to leave a brake handle. "Don't Get Out of the Left Side of Your Automobile." That is the scientific way to die, but not to get out of your automobile.

Now I should like, rather, to see that question taken up—Is safety education a way in which we are now developing the scientific-mindedness of our children by actual application to life situations?

MR. KNOELKE: I think that your question resolves itself into two parts, the first of which is—Where do we plan to go with education? And the second—Does safety work, as it is being done in the schools, contribute?

I should say that if we accept, just for the sake of having a motion before the house, the usual objects of education that are given, health, vocational aptitude, the three R's, and citizenship as the fourth, and the aesthetic training—if you accept those as being guiding directions, whether they are absolutely perfect definitions or not, if you accept the direction indicated by those objectives as worth while, I want to point out that the lower order of those objectives—and I call them lower not because they are less important but because they come lower down in the scale—that is, citizenship, worthy home membership, aesthetic training, and preparation for leisure, if you take those four particularly, I believe your safety education does indicate tremendously how those things can be better achieved by causing people who are being, I will say, subjected to the present method of educating along that line, by telling them just how these things can be attained.

Citizenship—obviously I needn't go into that. Worthy home membership—by having the older boy or girl take care of the baby sister. Aesthetic training, surely, by being considerate of the rights and privileges of the weak, in crossing the street, for example. And preparation for leisure, surely, in that you regard your leisure time as something of more import than merely lowering your vitality in preparation for the next day's work.

As we are doing it at Milwaukee, I believe that the lower range of objectives is being very definitely aided in its attainment through safety education, and for that reason I think safety education worth while.

I submit that as an answer to the question submitted.

PROF. OVERSTREET: Mr. Knoelke makes the point that safety education becomes the central, integrating force in education. That is, if one takes citizenship, and cooperation in the home, and preparation for a life of leisure, and preparation for the aesthetic life as four of the objectives of education, each one of these is

furthered by safety education. Obviously, citizenship, because one is, I suppose you would say, not a good citizen if one is making possible the wrecking of the lives of others, of making possible the devitalization of one's own life. Preparation of citizenship, then would depend very largely on safety education.

Preparation for the aesthetic life, surely—consideration for others, and so on.

Preparation for home activity—the older boy taking care of the younger.

And preparation for leisure—no devitalization for the next day's work.

MR. SHERRARD: I have been much interested in this discussion and it seems to me that there is a great ethical background and social background in this work in safety in our schools. In the Pittsburgh schools we have perhaps 40,000 children who have taken the following pledge, and I will just take a minute to read this because I hope you will see what we think is the ethical and health side of this socializing work of safety.

I will work for the safety of others as I would want them to work for my safety. I will not take unnecessary chances for in doing so I may lead into danger a younger child who is not so well able to take care of himself as I am. I will do my part to reduce the number of accidents in this city this year. I will try to take care of my health and be clean in thought, word and deed. I will try to do right at all times, telling the truth and respecting the rights of others. All this I will do for the sake of humanity and for the honor of my school.

And just this last week I was called to an elementary school for the installation of officers, and there the boys and girls, without assistance, or with only partial assistance, had picked out the leaders of that school to be president and vice-president and secretary of this year's safety council.

I think it has a vast influence on the ethical training of our children.

PROF. OVERSTREET: This, it seems to me, is getting rather fundamental. Safety education is not a little thing on the outside but is the center of the whole thing, because here we are getting an ethical point of view in education and teaching ethics not by maxims or prescriptions, or, as Mr. Whitney said, by proverbs—thou shalt do this, or that—but teaching ethics in terms of actual, living, human relations.

MR. SHERRARD: May I say, before you read that for the radio audience, that every boy and girl, before he gets a safety button, has to commit the pledge and recite it.

(Prof. Overstreet repeated the Safety Pledge for the benefit of the radio audience.)

PROF. OVERSTREET: I suppose that has a very direct bearing on the points made, that while education should be for the development of the unique personality of the child, the very development of that unique personality means that the personality is being used in the service of humanity in the midst of which the child lives. And so we combine the individual and group objectives of education and give it a thoroughly ethical foundation.

It has been suggested that you might want a little vacation before the play comes on. We have had a number of points of view presented in this square round table. It has gone—very much better than I expected. I think it has gone rather nicely.

At any rate, I wonder whether we can simply sum it up by going back to Dr. Rugg and Mr. Whitney and agreeing with them that somehow, education is for the sake of training human beings to take their place in life. And what is one's place in life? Life is an adventure. It is not an adventure that is to be entered into haphazardly. It is not an adventure that is to permit any kind of capricious adventure or impulse to wreck it. It is an adventure that has to be entered into with understanding. And the business of life therefore is to be in this adventure,

and when we are in the adventure we don't want any accidents, as Mr. Whitney says, to wreck the adventure.

And so the very essential point of view which we must start in life is to see that we understand the conditions of life. To use the wrong kind of wood; to have the door hang the wrong way; to drop things from a four-story window; all of that is not facing life conditions as life conditions are.

So that the fundamental of education, then, is a positive thing. It is not simply learning from books, as has been suggested. It is rather getting our youngsters ready to enter upon something that is a thrilling enterprise, and that thrilling enterprise requires all the power of our scientific insight, and requires all the fine humaneness in which we pay consideration to the rights and the welfare of others.

Now from that point of view it looks as if the last shall be first, doesn't it? It looks as if this, which came into education as a little bit of sort of interloper, almost, hardly claiming any right in the curriculum, becomes the very center or the integrating center around which the objectives of education shape themselves.

Well, I am not so sure that we have settled anything, but it has been rather nice to talk together, and now Dr. O'Shea wants to say something.

CHAIRMAN O'SHEA: I am well advanced in years, but I find I am not too old to learn. There were some thoughts expressed here this afternoon which I think are valuable. To be practical about this matter of safety, we, here in New York, think that it is wise to give advice to children. As you train the twig, so we train the child. We give them certain pieces of advice with respect to crossing the streets; we give them other kinds of advice and furnish them with power. And in the regular work of the class we teach them how to study so that they will be independent of individuals and will have the advantages of a training that will enable them to eventually launch out for themselves, and not have the crutch by them all the time.

It is often said that the proof of the pudding is in the eating. The kind of training we are given here in New York, and Mr. Whitney will support me in this, is the kind that has shown continued progress so far as the saving of children's lives is concerned. I believe in advising children; I believe in giving them the helping hand at the beginning. I believe in playgrounds offering facilities which will enable them to spend their leisure time profitably. I believe in teaching boys and girls the kind of work that will enable them to spend their leisure hours to their own profit and advantage and the advantage of society.

A. W. WHITNEY: I want to speak about the play, but before doing that it occurs to me to back up what Superintendent O'Shea has said. I don't know whether these facts have been brought out, but they are very interesting facts, that in spite of the rapidly increasing population of New York, in spite of the rapidly increasing congestion of the streets, there has been a steady decline in the accidental deaths of children in New York since 1922. In other words the accidental deaths of children are going steadily downward, and everything else is going upward, including accidental deaths of adults.

Now at four-thirty there is to be a play given right on this stage; this is the setting for the play. It is to be given by the children of Public School No. 45, in the Bronx, of which Mr. Angelo Patri is principal. It is under the supervision of Mrs. Mabel Foote Hobbs, consultant on community drama for the Playground Recreation Association. Mrs. Hobbs and Mr. Patri and their assistants are doing a very, very lovely thing which you can't afford to miss.

(A fifteen-minute recess was taken which was followed by the presentation of the play, "The Lost Camping Place," which has been published and is for distribution by the Education Division, National Safety Council.)

ADJOURNMENT

October 5, 1928

Safety Patrol Rally

CHARLES H. MacCALL, Chairman
Director of Attendance, Public Schools, Newark, N. J.

The Safety Patrol Session convened at two-thirty o'clock, Mr. A. J. Van Brunt, Director of Safety Education, Public Service Corporation of New Jersey, presiding.

MR. VAN BRUNT: To me has been assigned the duty of telling those of you who do not know, what this is all about. In a small way it was intended to represent the daily experiences that you have on the streets, and we wanted to point out to you that the toll of life and legs and arms and feet was greater than it would be if you all did obey traffic.

The pedestrian is not getting the blame for the lack of traffic observance that the automobile driver is and in my estimation maybe there are cases where they are much more to blame, so that the Safety Patrol boys and the policeman are there for your assistance, and if you will only help them, we will cut down the accidents not only in this wonderful city, but also over in Jersey.

I want to introduce Mr. Charles H. MacCall, the Director of Child Welfare of the City of Newark, state of New Jersey, who will act as the Chairman.

CHAIRMAN MACCALL: As Mr. Van Brunt has so aptly put it, this little stunt that was carried on was intended to bring individually to your minds the dangers that every school child is brought face to face with every day. The actual work and this demonstration, were performed by Safety Patrol Officers who are doing that sort of thing on the public streets in and around school houses every day in the city of Newark. They are caring for 100,000 children four times each day and in eleven years we have had no accident to any school child while the public school Safety Patrol has been on duty. I think that is a record of which we may be very, very proud.

As chairman of this meeting it doesn't devolve upon me to make any extended speech and, therefore, we will go on with the program. The first number on the program will be a selection by the DeWitt Clinton High School Band.

(The DeWitt Clinton High School Band played a selection.)

CHAIRMAN MACCALL: It now gives me great pleasure to introduce to you a man who has been accustomed to welcoming royalty, queens, kings, princesses, dukes, and all that sort of thing, tennis champions, and even prize fighters. We all know him all through the country and we all love him. It gives me great pleasure to introduce to you Commissioner Grover A. Whalen. He is of the Mayor's Committee on Reception to Distinguished Guests of New York City.

Address

By **GROVER A. WHALEN**

Chairman, Mayor's Committee on Reception to Distinguished Guests
New York City

After an introduction of that kind it is rather hard to live up to it, but it makes me feel that today I am welcoming and facing the future kings and queens, only of America, and not of the rest of the world.

Somebody said that we were playing against Lindbergh today in that he is giving a talk at another hotel on something along the same lines, and I told our

Chairman that we weren't out of luck; we were just playing against loaded dice, and we boys understand what that means. It means that we just simply couldn't beat Lindbergh at an audience if we tried, no matter how interesting, but it is splendid to see so many of you young folks here interested in something so vital to the nation and, after all, we ought to begin to think of our young people very early in life so that they can make their contributions to the progress and prosperity and to the safety of the nation.

Boys and girls should not take chances. You might say to me, "Well, Lindbergh took a chance when he flew from New York to Paris, and the world has acclaimed him ever since." Yes, but Lindbergh took a justifiable chance because his chance was in the interest of science. He was a pioneer of the air. He was justified in taking every reasonable, or even an unreasonable chance to accomplish what he set out to do, so that when you take a chance in crossing the street at an improper time, you are not taking a Lindbergh chance. You are taking a chance that is not justified. Lindbergh could not have succeeded to the great heights to which he has risen today had he taken unnecessary chances in his youth. Any chance that he took was in connection with the advancement of a new science that deserved even the sacrifice of life that it might prosper and that it might continue to bring benefits to the rest of mankind.

Safety drives and safety congresses are good for all of us because they focus public attention on something that we are very apt to forget or think very little about during our everyday life. It used to be that it was the Good Samaritan who would provide safety features in business life. Today it is good business for industry to provide safe machinery, safety in food, and safety in wages. All those factors enter in very much to our everyday life of a community and so we find that the question of safety is one that interests everybody.

It interests the child. It interests the youth. It interests the grownup, and it interests the old folks, as well as interesting business and industry generally.

Statistics are very dry, I know, but sometimes they bring home to us very definitely the seriousness of it all. I am reminded that in the past year somewhere in the neighborhood of 20,000 children sacrificed their lives through accidents. What a frightful toll that is! How terrible that we should have lost from our population 20,000 of our prospective citizens! It is too great a toll for any nation to pay, even the United States of America.

Anything that you may do, and you can do much, to prevent accidents, needless accidents, is making a real contribution to our everyday life.

When we realize that aside from the children there were almost a hundred thousand people who were killed during the year from accidents, we realize further that it is even beyond the children's stage and goes into the life and daily work of our community and then when I think further that beyond the deaths, those that were fortunate enough to have accidents and not pay the supreme sacrifice—there were 10,000,000 injured in the United States during the past year, we realize how enormous a question confronts us today.

Newspapers have been interested to a certain extent in the proposition, but not to as great extent as we would like to have them.

I am reminded of a newspaper campaign that took place a short time ago in Brooklyn where there was a Golden Rule Campaign inaugurated for the safe operation of automobiles.

That took birth through the instrumentality of a very patriotic publisher in Brooklyn by the name of Mr. Paul Block, and through the columns of the *Brooklyn Standard Union* some eight thousand men and women in industry gathered and pledged their support to a campaign that had as its result a very material reduction in the accidents in Brooklyn during the progress of that campaign.

What does this indicate to us? It shows us very clearly that while public attention is centered upon the subject, some real progress in the prevention of accidents

takes place and the moment we forget about the subject, we become careless again.

Remember that in law there is a basic principle where the law of negligence operates, that the injured person must be free of negligence. If the person injured is not free of negligence, he has no means of redress. So that you, too, in your walk of life must be free of negligence if you intend to make any contribution to the great safety movement that we are all so much interested in at the present time.

I don't know of any subject that should engage our attention every day in the week more than this question that we are all so interested in. We all hope that as a result of this conference great good will be accomplished in many ways.

The other night some of us had the pleasure of listening to a talk from Dr. Rabbi Wise and he demonstrated to the entire satisfaction and to the great pleasure of the audience that was present at the Hotel Commodore, that safety begins with the human being, begins with the soul, and he developed an idea there that the priests of all religions had been in a safety drive campaign from the very earliest times and their success along that line has been demonstrated by the splendid humanity, the splendid governments, the splendid conditions that we now find throughout the United States and other parts of the world.

So that we find that in every phase of life in our religious phase, which is taken care of by the priests of all religions, we find that there have been safety drives conducted there. The safety drive in that particular sphere for the soul, and we should be interested primarily in the drive for the protection of the body. That is our job today and I don't know of any group in a community that can be more helpful than the teachers and the pupils.

After all, we don't always tell the teachers what we should about what we think of their work, what great contributions they are daily making to our common one and not always receiving the proper amount of praise and commendation. I don't know of any profession that is deserving of more kind words and approbation than is the teaching profession and I often wonder if the boys and girls of our public school system and our private schools realize the great debt that they owe to this fine group of men and women who are making daily sacrifices and imparting knowledge that is to be of benefit and advantage to the pupils in the school systems.

I know full well that if we have our school children center their attention in essays or in other fashion upon this subject that we will get much of interest and benefit from it and if I dare to make a suggestion today, it would be that the supervisors of our schools, of our children, if they have not already done so, adopt a program of writing an essay on the subject of safety, what they think of it, how they think the children of our city can make their contribution towards that end.

I wish to congratulate those who have had charge of this Congress to take care of some thousands of people, I think ten thousand attended this Congress, and to have them come in to a city such as New York with such ease and safety, and with such comfort as I understand that they have all experienced—it has been a job that has been really worth-while and it has been well done, and with great intelligence.

I know that the city itself has contributed in every way possible to assist in this movement and I am sure that through its Mayor and all the way down through the line of municipal offices that the Congress will always find a great helping hand in New York.

His Honor, the Mayor, was frightfully disappointed that because of pressing official duties he was unable to be here today, but he had hoped to come here and talk to you boys and girls personally, because he wanted you to know of his personal interest in this great work, and if I should leave a message with you at all today, it would be for you to continue your interest in a subject that is not the

other fellow's business, but it is your business and my business, not the business of just once a year to give an occasional thought to, but it is a subject that should engage your everyday attention.

I am sure that this has been a pleasure for me to come here this afternoon and to have this privilege of saying a word to you.

CHAIRMAN MACCALL: I am sure we are all very grateful to Commissioner Whalen for being with us and bringing to us the welcome of New York City and for his inspirational address. I might say for his benefit particularly that the teachers of this community, particularly around the Metropolitan District, are interested in the safety of the pupils to such an extent that they do have compositions written and they do have regular safety curriculum in the schools.

Before we begin the next item on the program, I want you all to consider yourselves as part of a public school auditorium; that is, that you have been assembled from your various classrooms to witness a demonstration of the Safety Patrol operation, and this demonstration will be under the direction of Officer John L. McBride, Supervisor of Safety Patrols, Trenton, N. J.

Remember that you are all children, and the first speaker to whom you are going to listen is Officer Harry Gurley, Director of the Safety Patrol, of Paterson, N. J.

Demonstration of Safety Patrol Operation

Under Direction of JOHN L. McBRIDE
Supervisor of Patrols, Trenton, N. J.

OFFICER HARRY GURLEY: Good afternoon, Boys!

Boys: Good afternoon!

OFFICER GURLEY: Boys, we are here this afternoon to perform a very important duty. Several weeks ago I called around to your school and in conference with your Principal it was decided to organize in the school a Safety Patrol. Entirely too many accidents have been happening to children while on the way to and from school. It was thought that the lives of the children could be saved by such an organization in the school.

You boys have been selected by your Principal, he tells me that you are up in your studies, your marks in deportment are very good, and he says that you boys will not only be a credit to the school, but a credit to the community. He has also told me he thinks you are the type of boys who will be willing to make a sacrifice of an hour of your play time each day for the safety of the children in your school. Is that right?

Boys: Yes, sir.

OFFICER GURLEY: I am glad that you boys have been selected. You are a very likely-looking group of boys. I hope when the school term has passed that you will be able to go back to your Principal and say that you were everything that he recommended you to be.

We are going to organize this patrol this afternoon and I wonder if you boys have given any thought to the Safety Patrol work or just what you are expected to do in this work. Have you any questions to ask?

Boy: Officer, are we supposed to stand in the street and stop the traffic, or stay on the sidewalk?

OFFICER GURLEY: You are to stand at the curblin. Your first consideration is the child at the curblin. You stand at the curblin and hold the child there until there is a break in the traffic and the path is clear for the youngster to pass.

Boy: What are we to do to the boys and girls who do not obey the school safety rules?

OFFICER GURLEY: Take the name of the girl or boy and turn it over to the Principal or teacher of the school. Are there any other questions?

Boy: Are we allowed to stop any children crossing any other points of the street?

OFFICER GURLEY: Absolutely. The cross walk is the bridge that crosses the river of traffic and that is the place for the children to cross.

Boy: Are we allowed to stop children playing on the street?

OFFICER GURLEY: The street is death's playground. If the children are out to play, they should play in the school playground, the public playground, the back yard, or on the sidewalk; never in the street.

Boy: How are we to report a boy for damaging school property?

OFFICER GURLEY: Take the name and turn it in to the principal of the school.

Boy: What would we do if a car sped swiftly by while the children were passing?

OFFICER GURLEY: Take the number of the car. See that it is turned in to the officer in charge of the Patrol. Are there any other questions?

Boys, you have been selected for this work and in order to carry it on, we ask each and every boy who takes up the Safety Patrol work to repeat the Safety Patrol Pledge. I will ask you to arise and repeat the pledge after me.

(The boys arose and, with their right hands raised, repeated the following pledge:)

"I promise on my honor that I will do my duty to God and my country and to obey the laws, to work for the safety of the pupils of our schools as I would want those appointed to safeguard our city; to work for my safety and the safety of my family and friends; to try to protect myself and those with whom I come in contact from the risk of unnecessary chances; to keep myself clean morally, mentally, and physically by being honest, trustworthy, loyal, helpful, obedient, and brave, and to do my part in helping to reduce the number of accidents during this year; by my example to make my school a model one for safety; to faithfully perform the duties as outlined for a Paterson School Safety Patrol Officer."

OFFICER GURLEY: Remain standing, please.

(Officer Gurley invests boys with their Safety Patrol badges.)

OFFICER GURLEY: Boys, you have made a pledge to try to make your school a model one for safety. That means it will be necessary for you to report at the school building or your post each morning just thirty minutes before the children are expected to be in the school building. At noontime at dismissal, you are to be at your post just a minute before the children are dismissed from school and stay at that post until the children have crossed and go on their way home from school. That means that you will be making a sacrifice of one hour each day of your play-time and remember that it is your duty to consider the children in your charge, that you are not to get out in the center of the street, that your place is on the curb and you are to stand and guard the children with outstretched arms until there is a break in the traffic and the coast is clear for them to cross the street.

The accident reports show that a great many of the children of grammar school age, especially, who are injured, are injured by starting out into the street.

If you do nothing more than stand at the curbline with your insignia on your arm, that will be a reminder to the boy or girl just after leaving school of just what you represent, that you are a member of a safety organization and a member of the school Safety Patrol and it is your duty to stay at that point and see that they do not cross at any other point than the cross walk and only when the path is clear for them to cross and they have been given the signal by you to do so.

Do you all understand that?

Boys: Yes, sir.

OFFICER GURLEY: Let's see how well you can carry on this work so that when the end of the school term rolls around, your principal will be able to say to me, "Mr. Gurley, we have gone through the term without a single accident in or around or about the school." Do you vote "Aye," or "No"? Let's see how you can get up and march off the platform.

(The boys marched off the platform amid applause.)

OFFICER GURLEY: This is the way the Safety Patrols are organized in our schools. A motion picture will be shown later showing just the kind of duty that the boys do on the public highway.

CHAIRMAN MACCALL: Now you will please remain still as pupils assembled in an auditorium, this time to be addressed by a Director of Public School Safety Patrol, who will tell the children just what to do and how to do it in order to be safe at all times.

Officer John L. McBride, Supervisor of Safety Patrols of Trenton, will deliver that address to the pupils.

OFFICER JOHN L. MCBRIDE: Mr. Chairman, Boys and Girls: In September of this year there came into existence in New Jersey a new traffic act, a reconstructed traffic act. Among other things, this act provided in particular a section concerning children begging rides from the roadway, saying that that shall not be allowed. That is prohibited. It also provides that unloading from automobiles at any other points than the curb shall be prohibited and throwing bundles from automobiles while in motion shall be prohibited. This applies particularly to you boys who deliver newspapers at the busy thoroughfares in the downtown district.

In making this traffic act, the committee spent a lot of time and a lot of effort was given to it. In addition to this your Police Department is charged by the Director of Public Safety with carrying on an active safety campaign during the entire tour of his duties each day. In addition to this, the school authorities of your city have charged the principals and teachers to make mention in their classrooms of the different items of safety that you should know. Further in addition to all this, we have around your school a Safety Patrol organization.

Now all this effort, all these agencies, and all this thought is directed at but one thing, that of accident prevention. Are we doing that? Do the police records show that there are no more accidents? In my opinion they do not, and you, too, know that they don't. We have but to analyze the police record of last year to prove that accidents are occurring on our streets with startling rapidity.

Let's look at the accident report for last year for our city. Let's assume that every accident that occurred during the year of 1927 occurred yesterday about four o'clock and every person injured in these accidents had been taken to a big hospital and placed in a large room. They have been placed on cots and the cots have been divided into groups according to the manner in which they received their injuries.

Here is what we will do today. We are going out to that hospital and look at those people and talk to them and ask how they have received their injuries and while we are asking these questions, we will check up on ourselves and ask if we have committed these offenses that have taken these people to the hospital and if we have, we will make our minds up that from today on we will stop or we will get a ride in the police ambulance. We will also check up on this phase of our conduct and ask ourselves if we have stood idly by and watched a little boy from the first, second, or third, or fourth grade dart out into the street between parked automobiles. We are going to ask ourselves if we stood idly by and watched them perched on the top of a new building and would make no effort to instruct them to stop the bad habits that lead to the hospital.

As we enter the hospital there is a group of five people who were brought in because they were struck by boys who carelessly rode bicycles. Every rule of the road that applies to the automobile applies also to the bicycle. The bicycle rider

must obey the signals just the same as the automobilist. He must not exceed the speed law and he must refrain from riding with his feet off the pedals or his hands off the handlebars, and he must not carry another boy on the handlebars.

Such an accident occurred at the corner of Market and Broad three months ago. Market and Broad are situated about the same as the crosswalk marked out here on the floor. A boy was coming down the street on a bicycle. He wanted to make a lefthand turn and go in that direction. There was an automobile coming in this direction. Wanting to go straight across the intersection. He gave the traffic officer a signal indicating that the boy on the bicycle should go ahead. He failed to give the signal that he wanted to turn and the result was that when the whistle blew and the traffic started in the direction they wanted to proceed, the bicycle started across the path of an automobile and he was struck by the automobile. The man in the automobile became confused when he saw the boy lying on the bumper of his car and his car shot across the street to the opposite sidewalk where a man and woman and child were waiting to cross the street under the direction of the traffic policeman. The little girl and her mother were crushed against the rear of a taxicab standing there and the little girl was killed. The automobile then made another sharp turn and shot across the street and the boy resting on the bumper received a broken leg against a telegraph pole. There were three people seriously injured and one of them killed. Why? Because a boy failed to realize that he must give signals when riding a bicycle. Does that stress the importance of obeying the rules of the road?

The next group in the hospital consists of twenty-six people and we find that every one of them is over the age of forty. They are the people who fell on the sidewalks and they fell in a great many cases because of the carelessness of children, because they failed to use the cans that are provided for trash around the schools and threw apple cores and banana peels on the sidewalks. Don't forget also that in using the cans provided for the remnants of your lunch, you keep your school clean and tidy in appearance and reflect credit on yourselves.

Then we have another group of twenty-six people, all over forty, and they were injured in the collisions of automobiles, and they were injured because men drove cars with defective brakes, drove them while intoxicated, or without giving the proper signals, in disregard of the speed laws, or exceeded the speed laws in turning corners and at street intersections. They drove their cars in such a reckless manner that these twenty-six people were taken to the hospital.

Why am I telling of this carelessness? So that when you go out of your school today to cross the street, you will remember that you don't know whether the man crossing down the street is a careless fellow or not, but take it for granted that he is and let him get by before you attempt to cross the street, and don't forget your little brother.

Next is a group of 367 persons. They are the pedestrians struck by automobiles going back and forth to school as you do each day, and in the case of the children, they were struck because they crossed improperly, hitched on back of vehicles, played in the streets—the most glaring example of that crossing improperly comes out in an accident that happened about three months ago. A little boy came out of the Cook School from the kindergarten to the corner of State and Oak Streets. It was necessary for him to cross the street at that point and we had a fireman stationed there, but he failed to cross right there. He skinned around the building to the center of the block and from there he rushed off the curb between two parked automobiles and was struck by an automobile and was instantly killed. Had he continued on to the next corner he would have been assisted across the street by the Safety Patrol boys and a uniformed policeman, but he failed to do that.

Perhaps he was afraid of a policeman and perhaps he was afraid of the fireman, and so I want you to carry this message to those little folks in your neighborhood, that the policeman is your friend and if they have any problems in regard to

safety in their neighborhood and home, they should take them to the policeman. He wants to be their friend and he will help them. He doesn't want them to leave the corners on which he is working and go to the middle of the block to cross the street.

In connection with hitching on back, we had several serious accidents so far this year. One boy was hanging on back with a sled and he shot to the lefthand side and was struck by an automobile coming in the opposite direction and he was instantly killed.

A young man of sixteen was riding a bicycle on a straight street and he pushed over by a trolley car taking on passengers and he took hold of the guard rails and with the other hand he held the handle bars and they started off down the block. He was a pretty big boy and he was supposed to have intelligence; the other boys on the street used to call him a "wise guy." Ahead of him there was a little rut in the pavement and it was too small for him to think of, but that cost that boy his arm. His front wheel struck it and began to wobble. The bicycle slipped. He went over and under the trolley car's trucks which went over his arm at the shoulder. I have often seen him at the gym at Junior High School playing basket ball but now he stands on the sidelines and he can no longer be an athlete. He used to play football and basket ball, but that one little accident has caused him to sacrifice a whole lifetime of many kinds of pleasure on the athletic field.

Is it worth it?

That is why we have a Safety Patrol in your school and ask you to cooperate one hundred per cent with the Safety Patrol. I am sure you are going to do it and to prove it, let's give the Safety Patrol boys one big round of applause.

Thank you, boys and girls!

CHAIRMAN MACCALL: I don't think any of you wonder why the Safety Patrol in the state of New Jersey in the various communities is successful when we have officers like those who have appeared before you and Officer Dunn who conducted the demonstration at the beginning of this meeting.

Now we may resume a state of mind which will be more normal to most of us, the adult state of mind. We have passed out of the school auditorium and we will have the great pleasure of listening to an address by Mr. Lewis E. MacBrayne, General Manager of the Massachusetts Safety Council.

The Safety Patrol—Its Place in the School, the Home, and the Community

By LEWIS E. MacBRAYNE

General Manager, Massachusetts Safety Council, Boston

You know, if Mr. Grover Whalen hadn't gone out, I was going to tell a story for him before I began the address at all.

Always when he is introduced they tell about his receiving and welcoming royalty. This summer I was in London and, you know, the King owns Buckingham Palace in London, but he does not own Windsor Castle. That belongs to the country and there is a written or an unwritten law that whenever the King goes out of Windsor, the public may go in. That rule does not apply to Buckingham Palace. I had heard much of the royal family and I thought I should like to go in the back door as they went out the front door and I got in so closely on their heels that when I went into the state dining room, I found the chairs were around the table as they were left when the family and their guests had arisen a short time before and I asked the old chap who was showing me around to tell me who had been seated at the different places and he did, and there were twenty-two in the party and when he came to one chair, that was pushed back further

than the others and he said, "Well, the Duke of So-and-So sat here and he has a rather nasty temper. He got into a jolly row last night and went home in a huff," so I presume when royalty isn't on an official visit, it is just like ordinary people at home and that is what I want to talk about, ordinary people and their problems and why we have the Patrols.

First of all, the Patrol is just a gesture to arrest the attention of our young people and wake up their minds to the fact that a third of all the automobile accidents in most communities are injuring them. Second, the Patrol is not primarily to prevent accidents in front of the school, because in my state at least, the statistics show that the accidents almost never occur while the boys or girls are going to and from school. Then why Patrols? Well, for two or three very important reasons. First of all, the school is the very important place where we go for training.

In the city of Boston we have in our course under the head of Character Training, citizenship. That means that somewhere in the course of the instruction young people must be shown their relation to the community and what is more important than cooperation with the police department in the greatest problem that the police have today? So the Patrol primarily is to give us instruction in what the officer says when he talks with his hands, instruction in the orderly use of the cross walks, instruction in giving the right of way to traffic when it has the right of way, instruction in self-control, and once we have formed the habit in front of the public or private school, to use the highway as the law requires, then during the hours from four to six, the hours of greatest hazard to young people, we are going to act according to the habit formed and give ourselves protection when we are away from the school.

So I say the School Patrol is justified in every school in every community. It is a gesture to arrest the attention of the young people to the fact that a third of them are being injured, but it goes beyond that and gives instruction in the habits which so many of our adults lack.

Occasionally in the community where the patrol is not in use, some rather crusty old chap in the school department says, "I don't want the boys standing in the street and getting the idea that they are policemen."

Well, it was quite apparent from the instruction here today that that is not the object and that is the type of instruction in 98 per cent of the Patrols, that the boy is not out there as a policeman. In Boston we give him this instruction: We say, "The police have asked your help and assistance. They have not delegated to you police power. You haven't the authority, as the policeman has, to stop street traffic at any time when conditions may warrant it. You are there under the common law or under the state regulations of traffic which say that the pedestrian has the right to cross on a crosswalk and that the motorist must permit him to cross," and so when the Patrol standing on the edge of the sidewalk at the intersection or the crosswalks, says to the motorist, "We are about to cross," he is merely giving notice under the law. "We have been waiting. Now is the reasonable break in traffic. Please give us the opportunity to cross," and in turn he says to the children, "Wait a moment. Traffic still has the right of way. Don't take the chance of crossing," and in due time he stops the traffic and says to the children, "Come along!"

Once we can establish that idea there are certain rights that the pedestrians have, but also certain rights of the motorist, then we shall have accomplished the first part of the problem, but it goes much further than that.

I heard one of the boys inquire about reporting damage to property. I want to tell you an interesting thing that happened in the University in the city of Cambridge across the river from Boston. In the first place we found that to be the most dangerous city in which to bring up a child. The death rate was double what it was in any other city of its size and when we made a survey we discovered

that the hazard of a city may have no relation to the population of the city whatsoever. Here was a city of 150,000 that in volume of traffic had the problem of a city of 300,000 and naturally did not have the police force to meet it, because it was on the main gateway into Boston.

Now in that city a police officer was assigned for this very work and he not only organized the Patrol, but he said, "Let's have a meeting of one group every Saturday morning. We want to keep you boys interested." After he told his story a couple of times, he invited the Fire Department to come in and two or three other people, to give talks of interest and containing information for the boys and occasionally some one of the local manufacturers would give a little theatre party for them and keep the boys interested—a small payment for what they were doing.

Although at the end of the year 200 more adults were injured in automobile accidents than in the previous year, accidents to boys and girls went down to the number of 87 and that wasn't all; not only had these Patrols accomplished the reduction in the face of the increase in grown-up accidents, but \$500 worth of stolen property was returned to the people from whom it was stolen through the efforts of these Junior Patrols.

I asked the officer what he meant by that when he reported it to me. "Well," he said, "the police will find a break occurred down the street here and it is the work of boys and I take it up with the Patrol and I say, 'Some fellow has gotten into trouble. Let's find out who he is,' and the Patrol finds out and the boy is brought in and has a talk with the officer and he is shown how he is losing his rights as a good citizen by doing those things and the boy makes restitution, and instead of being arrested, he is put on parole with that one traffic officer and he doesn't get into court at all."

Here was a by-product of the work of the Patrol that we had not thought of at all.

I am asked to discuss the relation of this Patrol to the home. Well, let me tell you that throughout the country where we have the Patrol, there is a downward trend in the fatal accidents to boys and girls of school age, but there is an upward trend in the accidents to the children under five years of age. That is one of the problems we are going to put up to the Patrols in our state this year. Go home and talk with mother about the accidents to the children younger than school age, because when we take the police reports, we find a child of three, three and one-half, four, four and one-half, and five, sometimes up to seven, but seven out of ten accidents to children are in that group and so the Patrols will find the way to reach the mothers with the information that the traffic-officer is giving as you say in the meeting this afternoon.

We made a study of accidents to old people. If I had a blackboard here I would draw a line representing accidents to old people, starting in October and going up until it reaches the peak in February. We are going to ask the young people if they won't during the months when these accidents are so high, do a kind deed to older people who are confused in their efforts to cross the street.

Some reference was made to Colonel Lindbergh. When I was at the conference in Richmond, someone made this statement, I am not sure that it was not Commander Byrd. He said, "Every time Colonel Lindbergh goes into the air, he does the dangerous thing, but he never does it carelessly," and the reason why so many men who have tried to cross the Atlantic have never been heard from is because they also did the dangerous thing, but did it carelessly, didn't have enough gas to take them across, the machine was only a little overweighted, but when Lindbergh flies, he never takes a chance on any of those safety factors.

Now we are not going to eliminate the danger of crossing the highway. It will be more dangerous next year than it is this or was last. It is a part of our problem in a world of young people to take it as we find it and do the dangerous thing care-

fully because crossing the street or driving the car is always dangerous, but if we perform the act carefully, it makes all the difference in the world.

I believe myself that through the patrol and these other agencies we are developing an alertness in young people that will give us not only a better generation in crossing the street, but in performing the other duties of civic life.

In one of our convention meetings this week a man from the West got up and he said, "I never saw such jay walkers in my life as I have seen in New York." Of course everybody said that was true except myself and the only reason why I didn't say it was because I made a study on a commission in Boston last year and we found that we have people walking in the street and we suppose we have the traditional right to walk in the street and walk there because we choose to, but when we made a scientific study, we found this: The point of saturation is reached when eight hundred of us per square foot per hour are trying to pass this table. Eight hundred of us per square foot per hour is the point of saturation and we discovered that one thousand people were trying to do it and two hundred got pushed into the street and in New York we have reached the point of saturation and the people continually pressing forward are pressing forward because there isn't any other place for them to be if they remain much more than a second, and the fact that that saturation point is pushing them out into the street, that fact is so well known to the motorist that we have a lower speed approaching intersections in New York than in almost any city in any other section of the country.

Of course, that is a minor factor, but I give it to show what an interesting problem traffic is and these boys who go out on duty before and after school and during the noon hour will find there is more to the problem than they ever dreamed, and the thing is so interesting that they will be able to carry the information to the parents and the older people in the family who need it.

CHAIRMAN MACCALL: I know you enjoyed listening to Mr. MacBrayne because he showed very plainly he knows what he is talking about and that is the kind of person we like to hear.

The next item on the program will be rather unique. It is a roll call of children representing cities having active Safety Patrol organizations. The Master of Ceremonies is the Honorable Philip D. Hoyt, Deputy Commissioner, Police Department, New York City.

HON. PHILIP D. HOYT: Mr. Chairman, Ladies and Gentlemen, Boys and Girls: A great army to operate successfully must have discipline. The individual soldier knows that he must submit himself to certain rules of conduct which, although they may for the time seem to him inconvenient or unnecessary, he knows are essential if it is to be an army and not a mob.

The greatest army that America has ever gathered together for military operations is a very small force compared to the army that is being mobilized and demobilized every day throughout the country, the school children. The task of moving that army safely and smoothly requires discipline and discipline requires leadership. The higher officers who direct this movement may be considered as a certain class of officers, the highest type of officer I know, the police officer.

Every army also has another group of officers, the non-commissioned officers, the men chosen from the ranks because they have exhibited special qualities of leadership, alertness, self-control, and the ability to command respect and obedience, so if the higher officers of this army are the police officers, the junior officers, who in military circles are often referred to as the backbone of the army, are the leaders of the School Patrol. The higher officers could not get along without them, and, speaking particularly for this city, I want to congratulate the leader of the School Patrol here for the great assistance they have given to the police department and I think it has been a great factor in the reduction of accidents among children here.

Today we are mobilizing from all parts of the country this Junior Patrol. There is hardly room enough in this room to get them all together at once, so we have chosen one representative from each unit which, in this case, is a city, and in order to show how many of these patrol leaders there are in each city, we are announcing each one. I will indicate the number of Patrol leaders; the members of the Patrol will indicate to you in their own way the number of children whom they are engaged in safeguarding.

(School boys and girls passed across the platform bearing cards with the names of cities.)

City	Number of Patrol Leaders	Number of Children Cared For by Patrol
New York	10,000	770,000
Philadelphia	2,900	225,000
Chicago	8,500	369,000
Detroit	225	140,000
Boston	500	103,000
Los Angeles	10,000	133,000
Cleveland	2,000	98,000
Newark	1,500	60,000
Memphis	330	28,000
Seattle		45,000
Kansas City	800	42,000
Baltimore	500	80,000
Pittsburgh	2,000	72,000
Jersey City		28,000
Rochester	1,500	30,000
Providence	375	40,000
Washington	1,128	49,000
Indianapolis		43,000
Louisville	750	32,000
Milwaukee		55,000
Portland	250	42,000
Birmingham	1,400	40,000
Minneapolis		46,000
Omaha	2,000	28,000
Toledo		35,000

CENTER BOY: Patrols of twenty-five cities are we, guarding 2,943,000 children, you see. Smaller cities with patrols are not mentioned here. Still there are cities without patrols, I fear. Patrols for all cities is our plea.

(The children left the platform amid applause.)

CHAIRMAN MACCALL: That was a demonstration showing you how many children are being protected by Safety Patrols in large cities. There are quite as many probably in the smaller cities, but we want you to take that as a message to your home towns and communities if you have no Safety Patrol. Be the pioneer. Start one, and you will see the fruit of your act for the rest of your life.

The final item on the program this afternoon will be the showing of the Safety Patrol film called, "The Knights of the Cross Roads," which we will show, giving you the definite action of a Patrol boy protecting the lives of school children.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Women's Session

October 5, 1928

MRS. FRANK HOPKINS BETHEL, Chairman
President, Scarsdale Women's Club, Scarsdale, N. Y.

The Women's Session at the Seventeenth Annual Safety Congress was called to order at nine forty-five o'clock by the chairman, Mrs. Frank Hopkins Bethell, President, Scarsdale Women's Club, Scarsdale, N. Y.

CHAIRMAN BETHELL: This meeting is in the nature of an experiment and we hope it will prove a successful one. We all feel that women's responsibility touches every phase of human life but perhaps in some communities we have been backward in recognizing the value of women's work in safety.

Today we have with us four speakers who will try to show us not only what the responsibility of women toward this movement is, but also how we may best assume our responsibility. Our first speaker is Dr. R. M. Little, Chief of the Bureau of Rehabilitation, State Department of Education, Albany, and I am sure that he will make us all feel the great importance of women's work in safety.

Women's Responsibility for Safety

By DR. R. M. LITTLE

Chief, Bureau of Rehabilitation, State Department of Education, Albany, N. Y.

If our meeting is not large, it is potential. Sixteen years ago there was a meeting not quite so large as this in New York of men interested in industrial safety. It was the second meeting of the group which forwarded the organization of the National Safety Council.

The preceding year five men met in a hotel one Sunday afternoon in Milwaukee. In that meeting there originated the idea of a Council and the next year here in New York a small select group organized the National Safety Council which is in session in this city with many divisions and many in attendance from all over America.

One of the remarkable things of our American life in the last score of years has been the organization, development, and spread of the National Safety movement in industry, in the home, in the schools and in public life, but notwithstanding what has been accomplished, there is a great deal yet to be achieved and men are discovering that they cannot accomplish what ought to be done in safety without the assistance of women. No vital and important subject of life can ever be promoted and made stable and beneficial to all of society without the joint effort of both men and women, and women can take up this subject of safety not merely in the home and school and community, but also in industry and by an

intelligent study of the subject and cooperation with what is being done in industry, in the schools and in the community and bring to us a safer and healthier, a happier and a more prolonged life with the majority of our people.

Dr. Dublin remarked the other day that accidents are seventh among the causes of death and of the 95,000 accidental deaths last year, 25 per cent of them were in the homes. That shows that the biological unit of the race, the home itself, has something to do concerning safety. The home dweller isn't very much safer than the industrial worker. It has been my observation since the development of safety work in our larger, better organized industries, that the conditions in plants often are better than in the streets around about the plants and better than the average home from which the workers come to the plants.

In other words, as difficult as it may be to promote industrial safety in the great basic industries where there is the relationship of human activity to mechanical activity with all of its natural hazards, that the safety thought, habit, and practice has been carried farther in the plants than in the homes from which the workers come.

The gross figures of accidental deaths in the country, the per cent of them in the homes, then the number in the streets, and then the large number of them of little children, a disproportionate number under five years of age shows that it will be absolutely necessary to get the intelligent interest and cooperation of fathers and mothers and brothers and sisters. Men and women have organized safety in plants and organized women's activities in clubs, and schools, and parents' associations, all taking up the thought and finding out the causes, gathering together the facts, laying out the program and putting into it and back of it a motive power of human interest and consideration that will gradually reduce the horrid toll from preventable accidents in the industries, on the streets, and in the homes.

It's a sort of indictment of us, is it not, that when we are having this large toll of accidental deaths, perhaps 50 per cent of which could be prevented, that we do not prevent them, and since 1911 the accidental deaths in the gross in this country have increased 20 per cent, even though it is true that in that period the automobile traffic has greatly developed.

The larger industries have been on the job for these fifteen years and in the major industries a very handsome accident reduction has been accomplished and with the prevention of the accidents, an improved morale has been established in the plants. Good housekeeping and order and system in industry is a productive thing in dollars and cents just as it is in happiness and good will and feeling within a well ordered home, or well ordered community.

So we have discovered that the safety thought and the safety practice are good business, good civics, good human relationship, that sweetens up and preserves all the values of human life and that is the reason why, ladies and gentlemen, there have come to New York City for this week some five to ten thousand men from all over the United States and a good many women here gathered in these various sectional and general meetings of the Congress, who are applying their minds as seriously as they can to the practical experience of the years past, the problems that are not yet solved, and seeing what may be done for the further prevention of accidents and the conservation of life.

That women can render a very important service in this line goes without speaking. As the Chairman has remarked, the women certainly have a very vital and fundamental interest in human welfare and the maternal instinct for its preservation and protection which we men can't claim original control of, and if the womanhood of our country were aroused and organized and made safety a part of their activities, particularly in the women's clubs and teachers' and parents' associations, and would lay hold of the material which is already available, they could have just as interesting meetings on the subject of safety as they could have on

the last novel or on such community problems as trying to clean up the streets or the parks.

Speaking about a woman's natural desire for the preservation of her offspring, which I suppose is inherited from the animal world and cultivated when the moral and spiritual nature arrives, I am thinking of one of the greatest men who has been developed in our safety movement in America, here in New York now, a man who as a boy went to work in the steel mills of the Middle West. His father was a mill worker and this chap had to turn to the mills just before he was through high school. It was quite a walk to the plant. There wasn't good transportation; his father walked and carried his lunch and so did he. His mother placed his lunch in a little tin bucket and the last thing she said was, "Arthur, be sure to watch and don't get hurt today." The mother said this to her boy because of the great toll of accident that was occurring in those mills every day and every week, and when the father and the boy would come back from the mills, they would tell of these horrid happenings, the loss of life and limb taking place in the great steel plant. Her heart was wrapped up in her boy and she wanted him to be careful.

He stayed with the steel company for a good while and went through the various stages of the work that were possible for him. When this organized safety work came along and into those plants of the Middle West, he had a keen interest in the project. He found his way into the Safety Committee of the plant, then became assistant supervisor of it and then head of the safety work, and he has gone on from one stage to another in the interest of better industrial life in America and throughout the world until today he is one of the leaders of the greatest industrial betterment organizations on the face of the earth. And I have always thought, as he told me that story of what his mother said to him, that she was sowing in his mind at that time the thought of safety, carefulness, the development of the safety habit and the safety practice and that she filled his mind and spirit with the safety philosophy and vision which is today making out of him one of the greatest and most effective men in industry in this country.

That is the result of sowing this seed in the fertile soil of the mind of the girl or boy by a loving mother's spirit, concerned for the preservation and protection of her own offspring and having the maternal instincts that would preserve and nourish and care for all of human life. If you could get that working broadly throughout the splendid womanhood of America, the National Safety movement will become dominant in American life and the home life of America will be more safe and comfortable and enjoyable and prolonged than at the present time.

This is my message to your meeting. Women here today are engaged in this line of work effectively, taking hold of it and sending it along through the communities, and this meeting is for the purpose of bringing our minds together that out from it there may go persons who may become interested leaders back in the various communities, who will lay hold on the organized women's movement to get the idea of safety lodged there so that it may become effective.

The whole subject is so replete with opportunity and so filled with human interest that I can't think of anything that would give more enthusiasm to the work of organized women's clubs than just to take up this subject of human safety and welfare.

CHAIRMAN BETHELL: Dr. Little has given us the inspiration for our meeting and I am sure, if any of you would like to ask questions of him personally, he will be very glad to answer them.

We need inspiration in safety work. Women have needed that very much because to them safety has simply meant to be safe and to adopt the slogan "Safety First." We are getting so far away from that now that we are realizing that this work of safety is going to make life a very much more perfect and a very much

more beautiful thing. To make our children safe for the adventures of life seems to be the keynote of this whole convention. Some women have already entered into this field, and some communities have taken up the work of women much more enthusiastically than others. One of these is Pittsburgh and our next speaker is going to speak to us on women drivers.

Women Drivers and Automobile Accidents

By MRS. D. EDWIN MILLER

Vice-President in Charge of Home Safety, Western Pennsylvania
Safety Council, Pittsburgh, Pa.

We were shocked at the number of deaths of American soldiers in France during the nineteen months of their occupation of war territory. We paid comparatively little attention to the number of deaths in this country during the same period. Yet, for every American soldier who nobly died in France, there were three deaths by accident in this country in the same time. We said smugly, "Accidents will happen," and pursued the even tenor of our way with little concern indeed over this appalling condition.

The war was over long ago, but every day—today, if you please—a mounting toll of life and limb is one of the serious problems of our vaunted civilization.

We hear much of the hazards of industry, but it is rather startling to learn that more than one-fourth of all accidents occur in and about the home. The one agency in society which exists as a haven of security and protection for the very young and the old, the helpless and the dependent, is the scene of almost as many accidental deaths as the American workshop where men are constantly exposed to all the dangers that surround the use of every type of machinery, the handling of huge masses of hot metal and the presence of moving locomotives and cranes.

It is not obvious that safety education in the home can yield wonderful results in the reduction of loss of time and of human misery? The introduction of power driven devices, the general use of gas and electricity, the all-pervading influence of the modern tendency to higher and higher speed in living, all contribute to the need for such education.

Within recent years another factor has entered into home life. The use of the automobile has become so common in the United States that a recent visitor from England, upon his return home, characterized us as "A Nation Upon Wheels." As a matter of fact, we have become accustomed to spending such a large part of our time riding in motor cars, that the automobile is becoming truly an extension of the home. Our home Safety program must therefore take account of this development and provide for cooperation with other agencies of public safety in meeting the hazards of this newest addition to home life.

Twenty-five years ago an automobile on the streets was a curiosity. Excited groups would gather about and speculate whether the contraption really would go. When it started off, which it didn't always do, many of the spectators could hardly believe their eyes.

Then automobiles began to appear in increasing numbers—great high affairs, but built like the circus band wagons. There was always something the matter with them, so that no one except a skilled mechanic dared undertake to drive one for any distance. The popular song of the day was "You'll Have to Get Out and Get Under," which was an accurate characterization of the motor car of that day.

Not only were the early automobiles hard to keep in condition, but they were heavy, clumsy things that were hard to handle, so much so that it took

all the endurance of a strong man to drive one throughout the day. Those were the days when men were men and women were only back seat drivers. Since then women have been gradually becoming emancipated and graduating to the front seat, left, back of the steering wheel, where they properly belong.

Today, the automobile is a mechanical masterpiece, a beautiful creature ready to respond instantly, easily and surely to practically every demand made upon it, so that the day of women drivers is here. Since we have truly become a "nation upon wheels," it is our business to see to it that the wheels run true. Inventive genius and manufacturing skill have produced a motor car that offers no problems that an alert trained woman cannot master. She must be alert and trained.

Women drivers have already made an enviable record of freedom from accidents in driving. In Allegheny County, Pennsylvania, with a population approaching two millions Coroner William J. McGregor reports that since 1923 only one woman driver has been involved in a fatal automobile accident. It is interesting to note that during the years 1923 to 1927, inclusive, there were 1,351 automobile fatalities in Allegheny County. While it is true that the woman drivers have been greatly outnumbered by men, nevertheless the record of only one woman in a total of more than 1,300 fatalities calls forcibly to our attention the fact that women are better, much better, drivers than they are commonly given credit for.

To stand on this record would be the height of folly. As women drivers are rapidly increasing in number, it is increasingly important that they be prepared in every way possible to meet the hazards of traffic. Not only has the death rate due to the automobile increased steadily throughout the United States from 9.3 per 100,000 population in 1918 to 19.6 per 100,000 population in 1927, but in addition, in 1927 the death rate per 100,000 automobiles registered jumped to 100.5 compared with 95.5 in the preceding year. It appears not only that automobiles are increasing rapidly in number, but that fatalities are increasing at a still more rapid rate.

A study of the causes of automobile accidents shows that they generally result from failure on the part of the driver, through ignorance of the law, disregard for the rights of others, recklessness, or incompetence chiefly due to physical disability or intoxication. Of 54,438 cases reported, 19,720 did not have right of way, 7,451 were exceeding the speed limit, 7,247 were on the wrong side of the road, 5,581 failed to signal intention, 4,280 cut in, and considerable numbers ignored rules of good driving by failing to stop when entering through traffic, by passing standing street cars, by turning improperly, by passing on the wrong side, by passing on hills and curves, by disregarding officers or signals, by driving through safety zones, and by parking improperly. Add to these causes of accident poor judgment in handling cars on hills, carelessness regarding brakes, recklessness in approaching grade crossings and we have a compendium of all that a driver should not do.

The gruesome records show, however, that drivers are continually, through ignorance or willfulness, violating the principles of safe driving. There can be no question as to the urgent need for safety education.

There is a common impression that women drivers are apt to go to extremes of driving; that either they are apt to drive with so much caution as to be indirectly responsible for accidents which are charged up to others, or that they may drive ahead with little caution, expecting others to give way to them because they are women.

It would be unfair to judge women drivers in general by the actions of the few that go to extremes, in the light of the generally excellent record of safety that women have made. Nevertheless we must recognize facts as they are. Naturally women expect others to give way to them as a matter of gallantry,

and we would never wish to suggest that the ladies receive less than their rightful due. Of course women must have their way—it has always been so—but we should make sure beforehand that it is the right way.

No one should question, either, woman's prerogative—her right to change her mind. It would be a wonderful thing, though, if a woman driver would always indicate to other drivers that she is changing her mind before she puts the change into effect. The whole world would be the happier for it.

Women, as a rule, do much less driving than men, and frequently little of that driving is in heavy traffic. As a result, when they get into a jam they are more likely, through lack of experience, to become timid or excited, with disastrous results. The obvious cure for such a condition is greater familiarity with conditions that are met while driving, and with proper methods of meeting all possible situations.

When we consider that frequently a large part of a woman's driving is in carrying children to and from school, the importance of safe driving is increased, not only for the safety of the children but as an example to them. That women should have opportunity for instruction is self-evident.

Recognizing this fact, and recognizing the automobile as an extension of the modern home, the Home Safety Division of the Western Pennsylvania Safety Council, as one of the phases of its work, organized the Safety Drivers School for Women, in Allegheny County, under the auspices of the Safety Council, with the following organizations cooperating: The Congress of Women's Clubs of Western Pennsylvania with 30,000 affiliated members; The Pittsburgh Better Traffic Committee; The Pittsburgh Automobile Dealers Association; and the Pittsburgh Post Gazette.

The Women's Safe Drivers Club was organized with a Central Committee of which the vice-president of the Western Pennsylvania Safety Council in charge of Home Safety was chairman. This committee included the manager of the Safety Council and chairmen of the following committees: Entertainment, Community Singing, Ushers, Halls and Fields, Speakers, Prizes, Publicity, Banquet and Attendance. The president of the Congress of Clubs as chairman of sponsors was also a member of the committee, with every president of a woman's club in Western Pennsylvania as a sponsor.

The first meeting of the Central Committee was held November 19, 1927, the second January 16 of this year and the third, January 24. Plans were made and an organization developed to reach every woman driver in Western Pennsylvania with information regarding the school. Two hundred and ten women's clubs were circularized three times. One 15 minute talk was given over radio station KDKA and numerous announcements of the school were given over stations KDKA, WCAE and WJAS. Newspaper publicity amounted to 850 inches, including seven editorials, with 20 pictures. Cards advertising the school were placed in all street cars and the Pittsburgh Railways publication, "The Transit Guest," available to all street car patrons, carried notices of the school. The result of this publicity was the registration of one thousand women for the school.

The projected program for the school included eight meetings extending from Monday, March 5, to Saturday, May 19. Because of heavy rain one meeting, Field Day Exercises under the direction of the Pittsburgh Automobile Dealers Association, was postponed to coincide with the Driving Contests with which the school closed.

The first four meetings were for the purpose of instruction and were held in the auditorium of the Pittsburgh Chamber of Commerce. The general plan for each of these meetings was as follows: Time, from 7:45 until 9:30, distributed thus—

7:45 to 7:55, ten minutes, Community singing from the Safety Song Bulletin; 7:55 to 8:55, 60 minutes, instruction by speakers; 8:55 to 9:20, 25 minutes, enter-

tainment; 9:20 to 9:30, ten minutes, announcements and distribution of attendance prizes.

The first meeting opened with a welcome on behalf of the Mayor of Pittsburgh. This was followed by brief talks on "Cooperation of Women's Clubs," "How the Safety Council is working for Greater Traffic Safety," "Safe Driving from a Woman's Point of View," and "Qualifications of a Safe and Efficient Driver." Entertainment was provided by the Congress of Women's Clubs.

At the second meeting, the subjects were "Steering Mechanism and Brakes," "The Schools Part in Traffic Safety," and "Traffic Safety in Allegheny County." Entertainment was provided by the Pittsburgh Public Schools.

The subjects discussed in the third meeting were, "Lubrication in Relation to Safety," "The Driver and the Fire Department" and "Safe Driving and Traffic Engineering." Entertainment was provided by the Philadelphia Company.

At the Fourth meeting, the subjects were, "The Power Plant (Engine, Carburetor and Cooling System)," "Traffic Safety in Pittsburgh," and "Traffic Safety and the New State Law." Entertainment for this meeting was provided by the Cab Company.

Each speaker was an official of the State, County or City, or of one of the organizations associated with the school, and was chosen because of his expert familiarity with the subject assigned him. Those in attendance took notes of all material presented for further study in preparation for the examination which was given later under the direction of a member of the Engineering Faculty of the University of Pittsburgh, who is also a member of the Better Traffic Committee.

At each meeting the names of those in attendance were placed on cards, the cards were mixed together, and the names drawn for attendance prizes. A large number of firms were very generous in providing, without cost to the committee, numerous prizes ranging in value up to ten dollars. During the four meetings a total of 59 attendance prizes were awarded. The average attendance at all meetings was 500. During the meetings copies of a booklet containing a brief summary of the State Traffic Laws published by the Gulf Refining Company for the school were distributed. The series of six leaflets, "You and Your Car," issued by the National Safety Council were placed on sale to members of the school, many of whom took advantage of this source of information on safe driving. Diplomas were issued to all those who attended three of the first five meetings.

At the written examination on material presented at the first four meetings, 150 women passed with a grade of 70 per cent or better. All those passing the examination were eligible for entrance to the Safe Drivers Contest with which the school closed. Before this Driving Contest, however, the banquet, attended by 248 members, was held at the Schenley Hotel. Entertainment was provided by the Joseph Horne Company, following the address upon the subject, "Safety with Courtesy." Diplomas were then given to those who had earned them.

On Saturday, May 19, the school came to a close with the Safe Driving Contest held on the oval in Schenley Park, under the direction and control of the Traffic Inspector of the Pittsburgh Police Department. The tests included stunts in driving through difficult turns; backing into imaginary garages marked by barrels placed on the field; and a practical test of driving over a marked course which provided tests of driving ability under a large variety of traffic conditions. Judges were stationed at points along the course which called for exhibition of skill in handling a car, and were provided with official tally cards for keeping score of each contestant on the various hazards offered. Immediately after the last contestant had passed the judges returned to the oval and their scores for each contestant were added and the results tabulated. Prizes were then awarded, based upon the best exhibition of driving alone, and upon the

best average obtained in driving and in the examination which followed the meetings for instruction. The Pittsburgh Automobile Dealers Association comprising 30 dealers had been assigned places around the oval where they had exhibits of their respective cars, with crews of mechanics and other experts to answer queries concerning their cars. Thus closed our first Safe Drivers School for Women.

A study of the statistics of the school reveals further that there were 723 cars registered, including 50 makes. One third of those enrolled were club women, while two-thirds were non-club members who were interested in the school through the general publicity provided through the newspaper columns, radio and car cards.

Our first Safe Drivers School for Women was distinctly a success. I am quite sure that any similar enterprise which commands intelligent and whole-hearted cooperation from a large number of able people will be a success. Every city in the country—every community, indeed, where there is any considerable number of women drivers,—should have its Women Drivers Club with the motto, "Pedestrians should be seen and not hurt;" a club where social considerations are kept in the background and where the common interest in the welfare and safety of all who use the roadways is the dominant note in all discussion and activity.

Women are leaders in many other matters of public and family welfare, and the influence they can exert to check the alarming increase in automobile accidents can be tremendous. First of all they must perfect their own driving ability and practice. Then through organization in Women's Drivers Schools they can become a distinct force for safety throughout the country. Once organized, these groups can well extend their interests to include cooperation with local safety councils or other organizations for various remedial measures in their communities.

What could be more fitting than that woman, the giver of life, should be in every respect its protector? Every woman driver should make it a point of honor to be not merely able to drive, but rather to drive expertly, not only that she may avoid accidents herself, but also that she may, by her example create a stronger and stronger sentiment against recklessness and lawlessness on the road.

Let us mobilize the women of the Nation in the interest of safety.

CHAIRMAN BETHELL: Mrs. Miller has given us inspiration and something else, too, which is the concrete expression of inspiration, without which inspiration is perhaps valueless. I hope that those of you who are here, I am sure in the interest of your own communities and groups, will ask something of Mrs. Miller, will either see her perhaps afterwards or perhaps you would like to ask her some questions about this very wonderful work.

JOHN A. OARTEL (Safety Director, Carnegie Steel Co., Pittsburgh, Pa.): I can't add anything to what Mrs. Miller has said in the way of information. I just want to inject, if you please, a thought that Dr. Little started. He talked about safety in industry which began fifteen years ago and we have seen the development of it in a large way. He has helped in that development.

I am a safety man from industry, from a steel mill, if you please. I haven't known much else in my life and yet when I think of it, we men who have charge of safety in steel mills have found that in order to make a safe worker, we have to make people safe in their homes and on the streets. When we get the women in the home, when we cooperate, when we work together, then we are going to make a reduction in that awful toll of 95,000 men, women, and children whose lives are snuffed out annually. I am very proud indeed that when this work, under the direction of Mrs. Miller, was started in Pittsburgh, I was President of the Western Pennsylvania Safety Council. That is going to be a lasting

memory and I want to tell you folks no matter where you live, you are going back to your communities to try to do something in the homes and with women drivers. I want to tell you that Mrs. Miller has demonstrated in western Pennsylvania that it can be done and that it is being done.

Safety in industry is no guess work any more. We have developed it into a science and we can say that by doing certain things we will get certain results in safety. The same thing can be said of safety in the home and on the streets.

CHAIRMAN BETHELL: Our next speaker is the head of the Children's Bureau in Kansas City and by virtue of that relationship, she has been able to do a great deal for home safety.

Women and Home Accidents

By ROSAMOND LOSH

Executive Secretary, Children's Bureau, Kansas City, Mo.

Save the child has become the watchword of the hour. During the past decade a gigantic "Child Conservation" movement has swept the entire country. "The Child's Age," it has been called.

We are told that the best single index to a community's civilization is its child death rate. We have learned how expensive, how extravagant, how wasteful of vitality is disease and every effort is being made to eliminate needless sacrifice of child life from preventable disease. We hear repeatedly that the toll taken by home accidents is as great as that by any single disease. The most marvelous bit of inconsistency to be found is, that disability or death by accident has not been considered in the child conservation movement.

It is quite evident that no program for child conservation is adequate that does not include accident prevention. A glance at the long list of tragic accidents, occurring yearly, is sufficient to convince the most skeptical of the need for a city wide program for home safety as well as health safety. The only way a city's death rate can ever be reduced to the minimum is through effective health and safety education in every one of its homes.

It is obvious that the health organizations offer an opportunity for safety education unequalled in scope and effectiveness and with practically no additional cost. The Kansas City Safety Council, last year, organized the Women's Activity Division in order to carry on an educational campaign among the women of this city, with the hope of being able to reduce the number of accidents in which women and the home are involved. Sub-committees were organized to deal with the various problems. These committees were as follows: (1) Statistical. (2) Legislation and Enforcement. (3) School for Women Drivers. (4) Publicity. (5) Home Fire Prevention. (6) Membership. (7) Home Safety. (8) Pre-School.

It is of the work of the Pre-School committee I wish to speak in detail. The pre-school committee was organized for the purpose of safeguarding the lives of the pre-school child through parent education.

The program was city wide in scope. It offered definite practical helps through personal conferences with each mother and through group instruction. Good leaders were selected and trained to carry the information into the home.

As a result of the activities of this committee last year, safety information was carried into each of the 25,000 pre-school homes of Kansas City.

The cost of a city wide program of these proportions would have been prohibitive unless undertaken by a functioning organization.

The chairman of the Women's Activities, recognized the possibilities for safety education through a child health organization and asked the executive secretary of the Children's Bureau to head the pre-school committee.

The Children's Bureau, doing a city wide work in child health and parent education, goes into every one of the pre-school homes in Kansas City. In addition to its paid Staff, it has a force of 3,000 volunteer workers of exceptional training and ability who aid in its work. The Bureau, aware of the need for greater effort along safety lines, readily agreed to extend its work to include the activities suggested by the Safety Council.

The purpose was effected by:

1. Using the school districts as a unit of organization.
2. Educating all workers in accident prevention.
3. Making a visit into every home at least once each year.
4. Providing a special worker for individual safety talks at each of the 116 annual health Examination Centers.
5. Exhibits and demonstrations of safety devices and measures. (The use of films and slides is a part of the plan.)
6. A follow-up visit in the home where a safety inspection, in cooperation with the mother, is made.
7. Educating parents and the general public in safety through individual conferences, and talks before pre-school groups, Parent Teacher association, social, civic and study clubs.

The first step was to select and train the special workers in the need for home safety work, and the best method of approach; what to observe and record; and in practical measures for home safety.

Group meetings were held in each school district for the purpose of instructing workers. The canvasser is given a block plan of the territory which she is to cover and is held responsible for every home in her district. The worker notes unsafe home practices and unsafe home equipment, on blanks provided for the canvass. The information is for the use of the Center worker who meets at least 85 per cent of these mothers two days later at the Examination Center.

A special trained worker is present at the Examination Center to talk with the mothers individually, or in a small informal group, on accident prevention. This conference affords a very satisfactory opportunity for safety discussion. A card, carrying warnings against the most common accidents, prepared by the Kansas City Safety Council, is given the mother. The most recent accident in the city provides an approach to the discussion of home safety and the fact that the work is carried into every home in the city removes all cause for resentment. We find the mother most willing to assume the responsibility for the home and eager to benefit by any help we can give.

An exhibit of safety devices at each center is of special interest to the mother. This exhibit consists of a few simple, practical suggestions that all mothers can put into effective use. The following are a few of the suggested safety measures forming the exhibit at the 116 centers.

1. Small bells on all poison bottles, that ring when the bottle is moved, warning mother that it is in dangerous hands.
2. Safety window screens and screen-hooks, fire screens.
3. Pins inverted in the tops of boxes containing poison tablets, that prick sufficiently to cause children to let them alone.
4. Box of sand for slippery steps and walks, a necessary equipment of the safe home.
5. Safetyized house furnishings. (No sharp corners.)
6. Safetyized play equipment. For the yard: (a) Round sand boxes. (b) Ladder for climbing with hand rails for the very young. (c) Play pens for in or outdoor use. (d) Screened-in beds. (e) Canvas covers for swing springs. (f) Round tables.
7. Sheaths for all scissors, both blunt and sharp pointed.

8. Defective floor sockets safetyized by inserting plugs.
9. Defective extension cords, wrapped with tape.
10. Covers for scrub buckets or tubs of water, screens for wringers, etc.
11. Gates for stairs, railings for porches.
12. Tightened gas cocks. (Test for degree of tightness necessary to prevent small ones turning gas on.)
13. Home-made pens to hold baby, made without cost from padded dry goods boxes.
14. Coffee cans for matches.

There is no attempt to cover in a single conference every conceivable type of accident. The aim is to stress the prevention of those of most frequent occurrence. At a later date other safety measures will be stressed.

Following the Examination Center, each child found to be in need of attention, is followed up in the home. This gives another opportunity for safety education. On this visit we endeavor to make the home safety inspection with the help of the mother.

The mother is led to see that home accidents are preventable, that a child can be made safe in his home, that practical safety devices reward with a feeling of security, and that safe habits aid in the preservation of the individual.

We find most mothers not only willing to assume the responsibility for their own homes, but willing to assist in solving the city's home accident problems as well. To encourage an interest outside their own homes, the mothers are asked to turn into the office lists of possible hazards noted in their own and in other homes of the community.

During the past year visits were made into 25,000 homes to interest the parents in bringing children to the Health Examination Center.

About 18,000 conferences were held with these mothers two days later, in the 116 Health Examination Centers; and 11,256 follow up visits were made following the Examination Centers—a total of over 36,000 home visits. Fifty-nine safety talks were given before Parent Teacher associations, social and civic clubs, community groups, etc. Sixty-one exhibits of safety posters and safety devices were held with an estimated attendance of 30,000. Twenty-five thousand pieces of safety literature were distributed. Three exhibits of model nursery equipment and three exhibits of model play equipment, of 14 days duration, were held.

The same procedure will be followed throughout each year and it is hoped that a marked decrease in home accidents will result from this continuous effort.

CHAIRMAN BETHELL: That seems to be a very logical way to introduce safety into the home, through a children's organization.

MRS. CORA E. FISKE (Weehawken, N. J.): There are some homes that have nothing to do with Parent-Teacher Associations and perhaps if an interested person called, he or she would not be let in. How would you overcome something like that?

MISS LOSH: We have not had any trouble of that kind. We go into every home and the fact that we are going into every home seems to remove the objections. We put on a large educational campaign before we began and we don't confine it to the Parent-Teacher Associations. We get our educational program before all clubs, even the Kiwanis Clubs and other men's clubs.

MRS. RALPH T. SIMMONS (White Plains, N. Y.): In our schools in White Plains they use a book on hygiene and they take up each week different phases of these home hazards. Our children come home and often tell us something we are doing wrong. One day I laid a small paper on top of my gas stove and my boy said, "In school the other day we were told we should not lay any papers on gas stoves," and things like that happen every few days. While the young children are studying these things, they bring home this advice to their parents.

F. C. LYNCH (Kansas City, Mo.): Having worked with Miss Losh on the work in Kansas City, I should like to say one thing and also I should like to contribute a little to Mrs. Fiske's question which seems to be unanswered. In the first place, the thought that Miss Losh gave you I think could well be emphasized and that is that the statistics show with the pre-school child between the ages of one and five years there are more accidental deaths than deaths from any one sickness.

The problem that came to Miss Losh was just the question you asked, just exactly that. She said, "I accept the responsibility. What shall we do?"

Naturally, the educational campaign had to be built up around whatever information was available, so we immediately made a survey of the home fatalities to the pre-school child. There was no record in our hospitals, practically no record of the non-fatal injuries, but we took over a period of years the fatalities to the pre-school child that occurred within the home, and then Miss Losh centered her campaign around those fatalities which were the most serious. She directed the attention of her three thousand workers to these causes and through this method she is gradually getting a lot of information about how the child is hurt.

She has models of the things she has designed. She has brought into cooperation with her the builders of the city and the architects and they have designed things such as the sandbox. These were always built square or rectangular. Mother made dad build them some evening and he nailed four pieces together and there were four sharp corners. Miss Losh has worked up propaganda against that and she demonstrates a model of the correct type of sandbox, and so it goes on, and through it comes the remedy for the elimination of the hazard.

She has a wonderful little screen model. It locks and the key may be put away and the child can't possibly fall out. That is spectacular and gets into the newspapers.

MISS JULIA KENNEDY (Detroit, Mich.): I was formerly in Kansas City and I know that the name of the Children's Bureau is a passport into any home in Kansas City. In making a house to house canvass, if you mention your organization when you step to the door, they are eager to let you in and talk about the children.

CHAIRMAN BETHELL: After the meeting is over, I am sure some of you would like to come up and look at the exhibits I have asked Miss Losh to put on the table. They look very interesting.

JOHN A. OARTEL (Carnegie Steel Co., Pittsburgh, Pa.): This is a wonderful work you are doing in Kansas City. I think we should take inspiration from this line of endeavor. There is a point of contact which I have seen for years and yet which we cannot use effectively and that is the contact with the ministers of the churches.

Every year in the month of November we have a No-Accident Campaign. We send out literature and yet in my own church my minister has never announced it. How can we line up the ministers of the Gospel?

MRS. BERTHA WINTER MAHONEY (Erie, Pa.): May I answer the gentleman? In Erie we have all the religious societies affiliated with our movement. They were delighted to take it up and they have stimulated our program in a very delightful manner.

MISS LOSH: I might add that among the clubs or groups we have gotten before I don't remember the number of ladies' aids and home missionary societies, but twelve or fourteen of them have been able to have a meeting on the subject of child health and it included accident prevention.

CHAIRMAN BETHELL: I think sometimes when a community is a little backward, and especially a smaller community, it becomes the responsibility and the duty of the women to stir things up. Erie isn't such a small community, but I happen to have been told privately that one woman is responsible for the development of

the safety work and of the women's responsibility in that community and that she has done some very remarkable things in Erie, Pa. It gives me great pleasure to introduce Mrs. Bertha Winter Mahoney, Vice-President of Home and School Safety, Erie Safety Council, Erie, Pa.

A Practical Program of Community Safety Work for Women's Organizations

By MRS. BERTHA WINTER MAHONEY

Vice-president for Home and School Safety, Erie Safety Council, Erie, Pa.

The gravity of the home accident situation has been elaborated upon by the preceding speakers. It is unnecessary for me to dwell further on why a systematic program of safety education for the homekeepers should be instituted in your community. Last September this problem was presented graphically to the delegates at the National Safety Congress, in Chicago, and many of us returned to our respective homes resolved to improve the existing conditions. I am hoping you will be inspired by these addresses today and will immediately face your home accident problem and make plans for its solution.

I shall endeavor to outline, point by point, a scheme of continuous education for the homekeepers of your city. It is the plan outlined by the National Safety Council in a series of lessons entitled, "A Course of Study in Home Accident Prevention." You will notice that I say "continuous education." With many local safety councils sending out literature to women's organizations periodically with more or less successful reactions, I wish to emphasize the difference between our plan and theirs.

We realize the value of mimeographed or printed sheets of accident information sent to the presidents or safety chairmen of various women's groups, but I question their value when read before such a group by an inexperienced member of the organization.

The homekeepers of today must be educated by men and women especially informed on the subject that they are presenting, that of home safety. We need the opportunity to question them on our particular problem as it faces us. A club president or chairman is unable to inform her fellow members ably on the subject, because she has had no special training or instruction. Therefore such addresses or reports should be given if possible by trained speakers.

If you are fortunate enough to have a local safety council, the Course of Study I have mentioned can be obtained through them. If not, you can procure it direct by writing the National Safety Council headquarters in Chicago. A study of this folder and its enclosed lessons will suggest to you immediately ways and means of injecting it into the regular programs of your local organization. We in Erie have followed the first lessons issued by the Council and are now using the revised edition, which is much more efficacious.

The general plan that we followed provided that a series of six lessons in home accident prevention be given one a month to every woman's group in the city.

I, being a member of the Executive Board of the Erie Safety Council, was appointed chairman of the new Home Division of the Council. With the able assistance of the three other women on our Executive Board, we planned a luncheon meeting, to which were invited the leaders of the business, professional and social groups of the city. They were appalled by

the mass of statistics regarding local home fatalities that we presented, and were delighted to include in the programs of the organizations they represented our system of education. With this group as a Board of Control, its various members were assigned to one of three committees: Speakers' Bureau Committee, Statistics Committee, Publicity Committee. Our initial step was completed.

The second phase of our venture began. We needed trained speakers to present the various lessons:

Lesson I—The House We Live In.

Lesson II—Outguessing the Child.

Lesson III—Electricity and Gas—Their Use and Abuse.

Lesson IV—Flaming America.

Lesson V—When Accidents Occur.

Lesson VI—Accidents a Community Problem.

The Speakers' Bureau immediately began the most difficult task. We succeeded in listing a bureau of fifty speakers who were fully equipped to instruct any group on the subject with which they were particularly identified and they were definitely instructed by us.

The speakers who presented each lesson were brought together before they would be called upon by organizations, and a round table discussion of their service in this educational scheme was extremely beneficial. In this way each group had its own meeting and the definite aims of its efforts determined.

May I say just a few words regarding the type of trained speakers who volunteered his services for this great humanitarian work? For Lessons I and II: the president of our Pro-School Children's Group, the safety chairman of the President's Council of the P. T. A., the president of the Daughters of the American Colonists, a member of the D. A. R. two former school teachers and various members of the P. T. A. and Women's Club.

For Lesson III: men identified with the two local electrical and public service companies, including both managers and assistants under their supervision.

For Lesson IV: the fire prevention board of the Chamber of Commerce, including various fire underwriters, one of whom is also the president of our Rotary Club. They were assisted by a demonstration team from the Erie Fire Department.

Lessons V and VI included physicians and registered nurses, also members of our Executive Board. With a skilled speakers' Bureau the second part of our program was completed.

Now began the lessons. The Parent Teacher Organization through the safety chairmen began immediately last December. They were followed by various organizations throughout the city. We now number seventy-five groups with a membership of 12,000, and many more still to be reached. This is a continuous plan, for many began their course in December and January, others in February and March, while some began this September. We have constant publicity, for on our Board of Control is the society editor of each of the local newspapers. A friendly spirit of rivalry exists between them, and all publicity sent to them is printed verbatim if requested. They realize the service they are rendering their community and the society pages are perused by every woman who reads. Naturally with notices of speakers and safety lessons being printed month after month in their columns those women unacquainted with the plan, are curious and desirous of participating.

This program of organized education had its influence felt elsewhere. How were we to reach the foreign element? How were we to enter the poverty-stricken homes, where ignorance and heedlessness so often exist? The foreign newspapers printed safety information in Italian, Polish and German. The International Institute with its safety trained case workers has taken this course to foreign clubs, and has given the lessons in the individual homes of the immigrants who have recently entered our country. Safe American customs and practices are taught them immediately in their own language.

Our night schools emphasize home safety principles. The neighborhood home schools for foreign mothers did likewise—not one lesson, but many—so that what was once heard would not be forgotten.

The Visiting Nurses of the City, after taking the Home Accident Course, proceeded to spread the gospel of home safety to all the families with whom they came in contact. Insurance collectors, especially of the five-ten-and-twenty cent policies, were also instructed how to point out to the women whom they met so regularly, the elimination of various serious hazards that were visible where they called. Ninety per cent of the homes of any community are visited at regular intervals by these insurance collectors. An admirable medium for the dissemination of safety principles. The third step of this plan was completed.

Meanwhile the Statistics Committee, cooperating with the Health Department, Police Department, Visiting Nurse Association and various hospitals, had compiled local home accident statistics that were of immeasurable value to the speakers when presenting their various lessons. We found several hospitals with only meager records of causes of accidents while one large hospital kept no record at all, merely listing the kind and extent of injury. The work of the Statistics Committee this year is to work on a uniform and complete method of accident reporting in hospitals, police department and the schools.

But realizing that women assume only a part of the responsibilities of the home, it was deemed important that our attention be centered on the men who naturally must be interested in the homes they are supporting. Men's organizations, all the luncheon clubs, the shops with their various shop publications, have included in their year's activities home safety programs and home safety columns. Their responsibility and their seeming lack of interest and attention have been stressed with the result that home safety is becoming more and more important as we continue our work.

These lessons have had their influence in the safety teaching in the schools. While Erie's educational program in safety has been hindered by the lack of interest in the State Department of Education, nevertheless popular demand from the parents of the city has resulted in a tentative course of study being written and included in all of our public schools. Our parochial schools have always been alert and interested, and with a foresightedness uncommon in most communities, have instituted definite safety teaching in their curricula. I may say here, that not until the mothers of the city became insistent did our Board of Education think it advisable to include such instruction. Another effect of Home Safety Education.

We have a broadcasting station in Erie, with a low wave length, station WEDH, owned and operated by the Dispatch Herald Publishing Co. The head of the Children's Radio Club donated part of his time, as often as we wished, to broadcast home safety talks. Twelve talks have been given so far on this subject. Then wishing to enlarge his field of usefulness for children, our famous "Uncle Charlie" organized a children's safety club. Stories, talks, buttons, pledges and various diversions make the club interesting to the kiddies and also bring in those children who have no radio. He

has devoted pages of publicity to the cause of the Home Division and publishes verbatim all the talks broadcasted pertaining to home and child safety. Another outcome of our scheme of education that cannot be measured or even estimated.

Our home division was the chief factor in passing an ordinance forbidding the sale or purchase of fireworks in our city. After a Fourth of July celebration and its resulting tetanus deaths the united plea and demand of the mothers caused our city fathers to authorize the framing of such an ordinance. To prevent, in so far as possible the bootlegging of fireworks, we are taking the necessary steps to have our ordinance adopted by the various townships and boroughs throughout the county. Several have already signified their willingness and others are waiting for further deliberation and observation.

With drowning included as a home accident, the home division conceived the idea of staging several life saving demonstrations by the life guards along our lake front. Short instructive talks were given and the Prone Pressure Method of Resuscitation demonstrated. The dangers of water sports were emphasized. The Water Commissioners who are in charge of portions of our bathing beaches, were so impressed that next year these demonstrations will be weekly performances. Several talks on swimming and lifesaving were broadcasted and published by the head of the Red Cross Chapter of Northwestern Pennsylvania.

You might ask how much such a program has cost us for our year's activities? The time, the thought, and the constant efforts of many interested men and women who have accomplished this work and \$231.15 in money.

This paid for the Manuals and lessons, printing and stationery, repairs on an old typewriter, the organization dinner and the regional conference dinner deficit.

When serious accidents can be prevented by the gospel you spread, when precious lives can be saved for the great work of the future, when our happy homes are kept intact—is it not worth while? There is a feeling of content and satisfaction in your heart for the part you have played in the fulfillment of such an ideal.

You need a spirit of unselfishness, helpfulness and willingness to work, which is best expressed by these two verses that are pinned above my desk at home:

It matters not where I may go,
To grammar school or college;
It matters not how much I know,
If I but use that knowledge
For others.

It matters not what men may say;
It matters not what men may give;
'Tis my resolve that, day by day,
I'll do my best to give and live
For others.

MISS HELEN PURCELL (Director of Elementary and Kindergarten Education, State of Pennsylvania, Harrisburg): I want to give the *fast speaker* some encouragement respecting the State Department and also to express gratification and to spread the news. I represent the State Department of Public Instruction at this meeting. I was sent by the State Superintendent of Public Instruction, Dr. John A. H. Keefe, and my expenses are paid by that department.

The state course of study for elementary schools published in 1923 does contain a very detailed course of study in safety education and the normal schools and

teachers' colleges are supposed to give their students the material in that course of study. If any normal school is not doing that, it is a special case and should be taken care of.

For myself, before coming to the State Department two years ago, I was a Director at Teachers' College at Stroudsburg, and I know we very thoroughly covered that course in safety education and I want to pledge the support and help of the Pennsylvania State Department of Public Instruction in any program for safety education.

DR. ETHELBERT STEWART (U. S. Commissioner of Labor Statistics): I have received more knowledge today than I have learned in a long time. I wondered whether there was any practical way of getting at the home accidents. My own experience has not been very satisfactory, with a young lady who is a university graduate and is working on statistics of accidents in the office, where, if she had done the same thing, I would fire her, at home gets on a rocking chair to hang a picture and if I say anything, she says, "O-o-o-oh, DAD!"

You women have got to do it.

Massachusetts was the first state to show that we were probably spending more money on protection of machinery than the facts justified; there were fewer accidents from machinery than from causes that could not have been prevented by any machinery guarded. Then they began to spend some money on something else.

I talked to the Textile Section the other day and in preparing the statement that I made to them, I found that 66 per cent of their accidents would have happened if there hadn't been a machine in the mill, had absolutely nothing to do with machinery.

Now we are beginning to find an increasingly large percentage, except in towns where such work as you have talked about today is being done, I have been perfectly amazed at the work that is being done in some towns and I can only say that when the report of what you are doing gets out to these other towns and cities where it seems hopeless, it should do great good.

MISS HOUSMAN (Hudson County Safety Council, Women's Division, New Jersey): I noticed today in the remarks that were made that in the program for education in home accidents we named every type of organization except one. We have great need of instruction through our women's clubs and visiting nurses and every facility that can be used, but I think we need to reach also the growing girls and get them interested.

We are just beginning our work in Hudson County, but I think pretty soon we will have a real program. Last year in attempting just a little work, we tried to reach the Girl Scout organization. I think it did some good and if we could add to our list Girl Scouts, Boy Scouts, Campfire Girls and all these young organizations, and show them the need of safety, it might be an additional means of spreading our gospel.

CHAIRMAN BETHELL: Are there any more questions or remarks? If not, I am going to ask Mr. Williams to take the meeting from me now and let us find out just how deeply you are interested in having this kind of meeting and an organization in the future.

SIDNEY J. WILLIAMS (Director, Public Safety Division, National Safety Council, Chicago): I don't want to take the meeting from the Chairman, but merely to present this question to you.

It has seemed to the headquarters organization of the National Safety Council that we ought to do something to tie together these different pioneer jobs that are going on, to encourage and help other communities that want to take up similar work, and to tie that all together with the National organizations of women or that consist largely of women who are in a position to promote the same sort of work in the communities they reach. It has occurred to us to ask the opinion

of this meeting today whether the time has come when the National Safety Council should set up a Committee which might be called either a Women's Committee or a Home Safety Committee; which tentatively would include a representative woman from each community Safety Council or any other community organization that is doing a real job or starting in to do a real job along this line in any community, and also a representative of every national organization of women or largely of women, which wants to cooperate.

The National Safety Council has not the slightest desire to set up paper committees. We all have too much to do to serve on any committee that won't get anywhere, but it is my feeling at least that there would be a definite advantage in setting up a committee of that sort for a little better coordination of these efforts and to work with our headquarters' staff.

May I ask, Madam Chairman, for an expression of opinion from this meeting as to whether such a recommendation should be made to the National Safety Council?

MRS. D. EDWIN MILLER (Pittsburgh, Pa.): May I say that the safety movement, like every other great movement, is of greater value when there is consolidation of effort. We know that solidarity always means success. We have tried an experiment in the Safety Council of western Pennsylvania recently. We have sent out letters to the chairmen of all clubs of western Pennsylvania, the Children's Service Bureaus, the mothers' clubs, the International Institute of Pittsburgh, which takes into consideration our Americanization groups.

Our office, through our manager, Mr. Clarkson, has just sent letters stating that all these organizations and clubs that would like to come in under a Home Safety Division will be very welcome and we will be happy to organize that division very widely. There will be a bit of expense connected with it and a committee working on dues or membership have put it this way: Any club wishing to have literature, speakers, monthly information concerning the number of accidents of all kinds, might come in with a membership of ten cents per member.

The Consumers' League of Western Pennsylvania, one of our big organizations interested in industrial work, is coming in at ten cents per member. We believe that is a fine way in which to have the home safety work get spread about.

I am for a National Committee on this work and personally I prefer "Home Safety Division" rather than "Women's Division."

I don't know whether you are ready for a motion that I should like to make, but to get it before the house for discussion, Madam Chairman, I move that this assembly here today go on record as favoring a national division of home safety work.

DR. R. M. LITTLE (State Department of Education, Albany, N. Y.): I wish to second the motion, or the thought of the motion, but I think that it perhaps needs to be restated, slightly differently; namely, that this meeting of today would recommend to the Executive Committee of the National Safety Council the creation of a Home Safety Section of the Council.

MRS. MILLER: May I make my motion to include Dr. Little's suggestion? I am very glad to accept the suggestion made by him.

DR. STEWART: I second the motion.

CHAIRMAN BETHELL: It is moved and seconded that we recommend to the Executive Committee of the Council that they form such a group. Is there any discussion?

DR. LITTLE: It seems to me as I have listened to the reports from the ladies so active in this work that there are certainly sixty other communities in America where there are local safety councils that would furnish equal representation and if the Executive Committee would think it wise, that next year wherever the Council meets, there might be a very, very large gathering. The few general remarks I made at the beginning rest on the deep conviction that we are not

going forward in the general work of this section with as great rapidity as needed until the women are thoroughly interested and active in their respective communities and that won't be unless we have a National Section with officers and a program and a convention and put pep and power into it.

(The question was called for. The motion was put to a vote, and was carried.)

CHAIRMAN BETHELL: It seems to be unanimously carried.

I think we have nothing more before us this morning. I only want to say that those 60 other communities to which Dr. Little referred I think would have great difficulty in producing such speakers as we have had with us this morning. We will part to meet and prove that, I hope, next year.
