SUBJECT: GOLIATH PROGRAM

To: Official Members of the Lead Industries Association, Inc.

The first press coverage of our Goliath program announcement reception is beginning to appear, as per enclosed photo copy. We expect excellent pick-up from the trade press as publication dates are reached.

Enclosed for your file is a folio on the complete press kit.

We will keep you closely informed as to the progress of the Goliath campaign, and welcome your comments at any time.

Sincerely,

CAB:lp

ELECTRIC WORK VEHICLES

AN ANSWER TO THE NATION'S COMMERCIAL TRANSPORT NEEDS

BATTERY-POWERED ELECTRIC WORK VEHICLES: REBIRTH OF A TRANSPORTATION CONCEPT

We are witnessing the rebirth of the battery-powered, short-range, low-cost, ruggedized, and flexible computer, capable of being used in a wide range of applications. The new products are due to be introduced in the next 12 to 18 months, and they are due to be deployed in the next 12 to 24 months. As changes in computing paradigms and economies take place, we will see:

Good (AHE), a 6,000-lb. "quarter-ton" pickup weighs 6,275 lb. and gets 24 mpg, a rate that has been surpassed by the Truck Industries Association (TIA) to demonstrate the many advantages of battery-powered short-haul delivery vehicles. In the first U.S. production line electric, since the late 1970's. There are current orders for more than 450 of this type vehicle, and this is considered the beginning of new technology in design and performance.

Early attempts to build a polycyclic aromatic hydrocarbon were made by Fred M. Randall in Boston in 1860 and by William B. Smith of New Haven, in 1864. By 1904, about one third of the vehicles in operation in New York City and Boston were electric.

For the treatment of 1951-1952, the first period, the mean value of the treatment was 1.4, the mean of the control group of the 1949-1950 data was 1.0. Comparing the results of 1951-1952 with the mean of the first period, the results of the second period are 0.4 per cent above zero.

Most of the companies, who continued to use the electric delivery vehicles, were gradually forced to shift to internal combustion engine delivery vans and trucks, because they could not obtain spare parts. Nevertheless, some electric delivery vehicles were still in operation in the late 1940s.

Batronic Battery-Powered Vehicle

BODY ---- Mounted on 94-1/2" wheelbase chassis. Loadspace dimensions: 71" long x 69-1/2" wide x 63-3/8" high. Overall dimensions: 145" long, 78" wide, 92" high. 160 cu. ft.

STANDARD EQUIPMENT -- High strength Multalloy floor, rear end, body sides, roof and windshield assembly. All parts are multi-stage chemically cleaned, treated and coated with zinc-chromate primer before assembly. Second primer coat applied after assembly.

Joints are sealed with non-hardening sealer to eliminate wetal to metal contact.

Roof consisting of two piece panels with crown.

A heater and defroster, with fuel tank, is provided.

Unit is equipped to meet Federal Safety Standards in effect at time of manufacture to include lighting requirements, two speed electric windshield wipers, windshield washers, safety plate glass windshield, mirrors and horn.

REAR DOOR ---- Aluminum, with lock, 46-1/2" opening single door with continuous type hinge.

CAB DOORS --- Sliding type, left and right sides, with sliding sash windows.

DRIVERS SEAT - Pedestal type with fore and aft slide, and height adjustment.

MIRRORS ----- Two, exterior.

DOVE LIGHT --- In driver's area.

WINDOWS ----- Rear door and one each side of body.

FINISH ----- Exterior and interior, Gray Zinc-Chromate Semi-Gloss.

[illegible][illegible]

... 1 to 1 and 1.96 to 1 ratio.

MINIVAN
Batronic Battery-Powered Vehicle

CHASSIS SPECIFICATIONS

AXLE ----- Front - 2,900 lbs. capacity. Tread width 60.88".
----- Rear - 3,300 lbs. capacity, semi-floating, Hypoid Gears, ratio 3.07 to 1. Tread width 63.5".

BRAKES ----- Service--Dual braking type master cylinder.
Front - 11" x 2" - 90.24 sq. in. effective area
Rear - 11" x 2" - 90.24 sq. in. effective area
Parking--Cable actuated with Orscheln lever on rear wheels.

BUMPERS ----- Straight channel type, front and rear.

CONTROLLER ----- G. E. Reactance type, solid state, SCR, D.C. chopper type with by-pass contactors, fused protection for control circuits. Field weakening smooth acceleration switching and automatic current limiting.

MOTOR ----- G. E. Series wound D.C. traction with thermal protection. External shunt, open self-ventilated, 112 volt, Class F insulation. Maximum RPM 6,000.

FRAME ----- High strength truck type. Pressed steel, 2" flange width. Section Modulus 1.82".

INSTRUMENTS ----- Speedometer including odometer. Battery charge indicator.

SHOCK ABSORBERS - Front and rear, telescopic, double acting.

SPRINGS, FRONT -- 2-1/2" wide x 37-3/8", 6 leaf, 545 lb./in. rate.
REAR --- 2-1/2" wide x 37-3/8", 6 leaf, 545 lb./in. rate.

STEERING ----- 24 to 1 ratio.

TIRES ----- Four 6.70x15, C load range.

TRANSMISSION ---- Two speed, Helical gears. 1 to 1 and 1.96 to 1 ratio. Constant engagement.

WHEELS ----- Four, stamped disc, five stud.

BATTERIES-POWER - Set of two lead-acid type. Rating 112 volt. Variable capacity engineered to vehicle requirement. Quick change feature.

ACCESSORY - 12 volt DC--charged continuously from main batteries.

PATENT NO. 3708028 JANUARY 1973

In the interest of constant product improvement, Batronic Truck Corp. reserves the right to change specifications, add, alter or delete components without notice or incurring obligations.

BOYERTOWN AUTO BODY WORKS

MAXIMUM GRADEABILITY	5% grade - low range 27 MPH 20% grade - low range 10 MPH 5% grade - high range 29 MPH 20% grade - high range 10 MPH 31.1% grade - low range 5 MPH
PARKING BRAKE	Capable of holding the vehicle in either direction on a 30% slope.
DYNAMIC BRAKING	Capable of holding the vehicle to 30 MPH on a 10% grade for a minimum of 1/2 mile.
DUAL MASTER CYLINDER FUNCTION	Front brakes only operable. Stopping distance from 20 MPH was less than 31 feet. Rear brakes only operable, stopping distance from 20 MPH was less than 38 feet.
PANIC STOPS	Vehicle was stopped within a 10 foot wide lane. From 20 MPH, in less than 17 feet. From 30 MPH, in less than 41 ft.
STEERING	Safe, positive steering operation. Steering wheel torque at the hub is 14 lb. - ft. maximum when the vehicle is <u>stationary</u> on a flat smooth concrete surface. No tendency to under or over steer in operation.
TURNING DIAMETER	Wall to Wall - Less than 39 1/2 feet in either direction.
AUXILIARY 12 VOLT BATTERY	Capable of producing 25 amperes for a minimum of 2 hours at a 12 volt nominal voltage.
AUDIBLE NOISE	Noise level in cab - measured on "A" scale. Maximum at 44 MPH in high range - 76 dB. Maximum at 32 MPH in low range - 77 dB.
GROUND CLEARANCE	Minimum ground clearance 7 1/4" at spring U-bolts. No part of vehicle drags or contacts road when driven over a crest with a vertical radius of 13 feet or through a depression with a vertical radius of 22 feet or more.
BODY	Fully enclosed, ventilated, undercoated, adequate visibility. Side door openings 26" wide by 67 1/4" high.
INGRESS AND EGRESS	Adequate ingress and egress at both driver and passenger door. Rear door opening is 53 1/4" high by 46 3/4" wide. All doors operate freely without obstructing ingress or egress and are provided with positive latching mechanisms. All doors can be locked.
BELGIAN BLOCK TEST	Vehicle covered a 10 mile Belgian block type course at speeds of 15 to 20 MPH with no failures of any kind.

Numerous other tests have been conducted covering water tightness, bumper deflection, performance at 80% discharged batteries, energy economy test etc. and all results are available.

ENERGY MARKETING

Electrics get key Post Office tests

Results to date indicate that electric vehicles can handle the mail
One California town moves to fleet testing as Postal Service
funds testing programs in other sections of the country

The more than 100,000 US Postal Service mail-delivery trucks powered by internal-combustion engines may eventually be replaced by fleets of electrics, at a rate of 5,000 vehicles per year. That's what could happen if tests now being conducted in California, Pennsylvania, and Massachusetts prove that lead-acid-battery-powered vehicles can deliver the mails more quietly, efficiently, and with far less energy consumption than internal-combustion vehicles.

One Postal Service official estimates that the initial vehicle-replacement program would begin with about 3,300 electric vehicles per year, and then, as production facilities expand and providing the electric vehicles continue proving themselves—the replacement

rate could increase to about 5,000 per year.

As an indication of the Postal Service's serious interest in evaluating the electric-postal-delivery-van concept, it is funding tests of such vehicles in Cupertino, near San Jose, in northern California (E.W. Dec. 15, 1972, p. 73); in Santa Ana, near Los Angeles, in southern California; in Allentown and Bethlehem, Pennsylvania; and in Lowell, Massachusetts.

The tests are already under way at Cupertino, Santa Ana, and Allentown, and they are slated to begin shortly at Bethlehem and Lowell. The five-city project is designed to test various types of vehicles under various conditions, and to determine the ability of manufacturers to produce electric-powered vehicles that will meet the Postal Service's needs. It is expected that, in time,

a standard Postal Service electric mail truck will be developed from data gained in these tests.

Allentown test

As part of the tests in Allentown, mail-carrier Frank Wetherhold is piloting a new, all-electric, lead-acid-bat-

Vehicles under test by Postal Service include Battrans Truck vehicle at Allentown and Bethlehem, Pa. (top left); the Otis Electric Delivery Vehicle (formerly Westroaster) at Santa Ana, Calif. (bottom left); the Electric Vehicles, Inc. Harbort Electric Vehicle Co. model at Cupertino, Calif. (top right); and the Electromotion Inc. vehicle at Lowell, Mass. (bottom right).

power of the vehicle. The vehicle is a 1972 Chevrolet. As the internal combustion engine (ICE) vehicle it replaces, the electric truck is "easy to handle and drive." He adds that the vehicle is smooth operating, and the absence of a hot engine results in a much easier cab.

Allentown's Postal Service supervisor, Richard Littlell, says the significant factor, in addition to its being pollution free, is the fact that the battery-powered carrier costs less to operate. About 15 kWh are needed to power one electric car for a 10 to 12 mile route. A mounted carrier route in Allentown averages about 30 miles a day, which is three times the amount of range and well within the capabilities of the electric vehicle.

The electric vehicle being tested at Allentown is manufactured by the Electric Vehicle Corp., Bakersfield, Pa., the nation's leading producer of electric vehicles. Batteries alone are producing 100 on the road electric vehicles as part of a multimillion dollar nationwide testing program funded by 35 electric utilities under the sponsorship of the Electric Vehicle Council.

The Lead Industries Association reports that the vehicle batteries are supplied for the Allentown test is powered by a 60-amp lead acid battery and has a top speed of 15 mph. Plus, it is for test purposes only.

At Allentown, carriers operate the vehicle and are asked to note its performance at the end of the initial test period.

A part of the test program states that "battery-powered vehicles are considered for the tested at Allentown. Allentown and its vehicle will be tested against both ICE and EV."

Cupertino test

In Cupertino, plans are being made to replace all mail delivery vehicles with a two-year test of electric vehicles for intra-city mail delivery. Three electric vehicles, powered by lead acid batteries, are slated to replace the stan-

dard ICE-powered vehicles that currently operate in the city's post office delivery fleet.

A combination U.S.-British vehicle will be used for Cupertino's "Electric Mail" project. Harbort Electric Vehicle Co., Manchester, England, built the vehicle's electric propulsion system, and the vehicle was completed and assembled by San Francisco-based Electric Vehicles Inc.

Cupertino Postmaster Alvin R. Carter says the trucks are smog free, and cost only about one-tenth as much as the conventional type to operate. The electric cars operate for at least two days without recharging the batteries, he says. When a recharge is necessary, the batteries are simply connected into an industrial type charger. The trucks are powered by two 100-amp lead acid batteries and have a top speed of 40 mph and a top range of 100 miles. However, they will travel at a maximum of 25 mph in city streets and at 40 mph on highways.

The almost silent vehicle produces only a light hum as they accelerate, and since they draw power only when in motion, pollution from an idling engine is eliminated, and only the power needed to operate the vehicle is used thus saving critical petroleum products.

The test vehicle has now been in operation at Cupertino for a little over two weeks and has been utilized on the mail routes in the city. The Post Office vehicle, a 1972 Chevrolet, has a range of 10 to 15 miles with 100 to 150 kWh.

During the test, daily mileage, power consumption, the number of stops, and several minutes of city driving have been recorded (see Table I). In order to give this data some sort of perspective, a standard vehicle was selected at random and powered by a four-cylinder engine, and comparative data were recorded. The overall results of the test were, ICE comparison proved that four mail delivery vans powered by batteries could be operated at the cost of operating one ICE vehicle.

As to the vehicles by Cupertino postal carriers who operate them, has

been a problem. The vehicle is a 1972 Chevrolet. As the internal combustion engine (ICE) vehicle it replaces, the electric truck is "easy to handle and drive." He adds that the vehicle is smooth operating, and the absence of a hot engine results in a much easier cab.

Allentown's Postal Service supervisor, Richard Littlell, says the significant factor, in addition to its being pollution free, is the fact that the battery-powered carrier costs less to operate. About 15 kWh are needed to power one electric car for a 10 to 12 mile route. A mounted carrier route in Allentown averages about 30 miles a day, which is three times the amount of range and well within the capabilities of the electric vehicle.

Other tests

At Allentown, plans are being made to replace all mail delivery vehicles with a two-year test of electric vehicles for intra-city mail delivery. Three electric vehicles, powered by lead acid batteries, are slated to replace the stan-

dard ICE-powered vehicles that currently operate in the city's post office delivery fleet.

A combination U.S.-British vehicle will be used for Cupertino's "Electric Mail" project. Harbort Electric Vehicle Co., Manchester, England, built the vehicle's electric propulsion system, and the vehicle was completed and assembled by San Francisco-based Electric Vehicles Inc.

LEAD INDUSTRIES ASSOCIATION TO DEMONSTRATE ADVANTAGES
 OF ELECTRIC DELIVERY VEHICLES

NEW YORK, N. Y. - Jan. 16, 1974 -- A battery-powered vehicle that is the first production model of a modern, multi-stop electrically propelled delivery van to be made in America, was introduced by the Lead Industries Association (LIA) here this morning during ceremonies at the Plaza Hotel.

The van, which has been named GOLIATH by LIA to commemorate the fact that its electrical power is supplied by lead acid batteries, will be used for an extensive, multi-city program to demonstrate the effectiveness of battery-powered delivery vans for a wide variety of multiple stop, short-range services.

GOLIATH was produced by Batttronik Truck Corporation, Boyertown, Pa., one of four electric vehicle manufacturers producing lead acid battery-powered vans being tested for mail pick-up and delivery by the U. S. Postal Service in five cities. The first of these tests, which began more than two years ago, have proven so successful that the U. S. Postal Service has announced an order for 300 of the battery-powered vehicles. Mr. Donn Crane, Director of Fleet Management, U. S. Postal Service, and principal speaker for the GOLIATH introduction, says that, providing the 300 vehicles now on order and those currently undergoing additional tests continue to prove themselves, "Our next purchase could be sizable indeed ... perhaps 1,000 this year and as many as 5,000 in 1975." He also added that the U. S. Postal Service alone represents a potential market for 93,000 additional electric vehicles.

Lead Industries Association, Inc. 292 Madison Avenue, New York, N.Y. 10017

LIA/47

- 2 -

In speaking of LIA's involvement in the GoLIATH project, Philip E. Robinson, Executive Vice President of the Association, said, "Our goal is to further demonstrate the economic, environmental and energy conservation advantages of lead acid battery-powered vans for a wide variety of uses. Lead acid battery-powered vehicles are more economical to operate than vehicles powered by other sources; they use no energy while standing or waiting at traffic signals, and they significantly reduce noise levels in city streets." Mr. Robinson added that such vehicles also have the advantage of being recharged during off-peak or nighttime hours when electric energy demand is at its lowest.

The GoLIATH program is being supervised by Mr. Connel A. Baker, a nationally recognized authority on the operation of electric industrial vehicles, who has been with LIA since 1963. He reports that the lead acid battery-powered vehicle will first be used for pay telephone coin pick-up service by New York Bell Telephone beginning in late January. The vehicle will then be used for a variety of pick-up and delivery services in the New York metropolitan area by the Singer Company.

After demonstration programs are completed in the New York metropolitan area, plans are to engage the GoLIATH vehicle in extensive programs in the Chicago area. The electric van will then be demonstrated at trade shows and used for various short-haul transportation projects in Canada as well as major cities in the South and Eastern U. S.

GoLIATH is the first of a series of production-line electric work vehicles. Battelion Truck Corporation is producing for use in a nationwide battery vehicle demonstration program. Sponsored by the Electric Vehicle Council and 55 electric utility companies, the project will involve more than 100 battery-

LIA/47

- 3 -

powered delivery vans. Until the U. S. Postal Service announced the order for 350 of the electric vans late last year, the electric vehicle purchase by the utility companies was the biggest such order in modern times. The utilities will use the electric delivery vans for the same purposes as their conventionally powered vehicles --- for meter reading, to transport maintenance and repair crews, and to carry personnel and cargo --- while learning what effect their extensive use can be expected to have on off-peak power requirements.

REMARKS BY PHILIP E. ROBINSON AT
 GOLIATH CEREMONY JAN. 16, 1974, PLAZA HOTEL, N.Y.C.

GOLIATH, the battery-powered electric delivery truck we are unveiling today, may become as famous as the Model "T" that first rolled out of Henry Ford's plant in Dearborn, Mich., on July 23, 1903. That event marked the beginning of the assembly line produced automobile which had such a remarkable effect on the American life style and economy for nearly 75 years. So, too, could GOLIATH mark the beginning of a new era in the world's economy and life style.

Developed for multi-stop, short-range pick up and delivery service, GOLIATH represents the rebirth of the mass-production electric vehicle industry in this country. We believe that energy conservation offered by these vehicles will help the U. S. achieve its goal of becoming self-sufficient in energy.

To give you an idea of just how significant a role the electric vehicle industry will play in the future American economy, the results of a National Power Survey conducted by the Federal Power Commission last year estimated that 38 million electric road vehicles will be in service by 1990.

It would, of course, be absurd to suggest that thousands of electric vehicles powered by lead acid batteries will appear on the roads immediately. We expect the electric vehicle will find initial acceptance and application as a light van for a wide variety of tasks in fleet-type operations, such as the pick up and delivery of mail. Other fleet-type use of electrician will likely develop in the utility industry, where thousands of van-type vehicles are used to install, maintain and service equipment. In addition, vans such as GOLIATH are used for floral, dry cleaning, laundry, bakery and dairy deliveries. These are some of the services GOLIATH will be demonstrating in major U. S. and Canadian

Lead Industries Association, Inc. 292 Madison Avenue, New York, N.Y. 10017

LIA/54

- 2 -

cities this year as part of our program to illustrate the specific services electrica can perform.

Proof that electrica can perform some of the same short-haul, multiple stop, pick up and delivery tasks now performed by conventional vehicles is demonstrated by the U. S. Postal Service, now in the process of building its own fleet of electrica for mail and parcel delivery service. Its fleet of electrica was ordered upon completion of the first of a series of multi-city demonstration programs, and providing the remaining programs also prove successful, it is expected that a large part of the postal delivery fleet of the future will be electrica. Mr. Donn Crane, Director Fleet Management Services, U. S. Postal Services, will discuss this subject in detail later this morning.

Besides these efforts by the U. S. Postal Service, the electric utility industry has purchased more than 100 units to learn what impact electric vehicle fleet operations will have regarding electricity requirements for battery recharging. The utilities also will determine which of the various tasks now performed by conventional internal combustion vehicles can be accomplished more economically with electrica. In addition, prototype electrica similar to those produced for the U. S. Postal Service's test and demonstration program are also being used to develop operating performance data for a variety of other jobs. These include personnel transportation and pick up and delivery of bakery products. Impressive electric vehicle developments have also been taking place in England and in Europe. For example, in England, thousands of electrica are already in special operations, such as the delivery of food and dairy products.

By now, most of you are probably asking two questions concerning the electric vehicle market: (1) Where is the electric energy coming from to recharge the lead acid batteries? (2) Where is the additional lead coming from that will be necessary to produce the additional lead acid batteries required by the millions

LIA/54

- 3 -

when electrics are mass produced?

To answer the last question first, there already exists a huge lead acid battery market. For example, batteries for starting, lighting and ignition -- or SLI -- continued to show substantial growth last year, reaching a record total of 53 million units. The single most outstanding factor concerning the record production of batteries in 1972 is the fact that they were primarily produced from recycled lead, most of which was obtained from scrapped batteries. For example, more than 610,000 short tons of lead were recycled in 1972, a 2.2% increase over 1971. Scrap batteries accounted for 63% of that. It is therefore obvious that the continued recycling of lead, when added to the domestic mine production that currently stands at well over 600,000 tons, will assure a continued supply of lead for batteries as the need arises.

Answering the question concerning the availability of electricity to recharge batteries, the first point to be stressed is the fact that most battery recharging is done during nighttime, off-peak hours. Also of importance is the fact that even with only one-half of the projected 1990 market of 38 million electric vehicles, the annual consumption of electric energy for recharging batteries would be about 63 million megawatt hours. This figure represents only about 1% of the total electric energy production projected for 1990.

And now, a brief rundown on GoLIath: The 145-in.-long, 78-in.-wide, 92-in.-high van can carry a half-ton payload and it is the first of more than 100 electric work vehicles being produced as part of a demonstration program sponsored by the Electric Vehicle Council. The van was produced by Batronic Truck Corp., Boyertown, Pa., and it is very similar to the type of vehicle being used by the U. S. Postal Service for mail delivery. The remaining electrics have been purchased by 55 electric utilities around the country for such tasks as meter reading, and transporting maintenance and repair specialists.

LIA/54

- 4 -

These electrics also will carry personnel and parcels while careful records will be kept of the amount of electric energy they require. In this manner, the utilities will be able to determine future energy requirements for electrics. The GoLIath-type vehicles are powered with 112-volt lead acid batteries and they have a maximum range of 68 mi. at 20 mph and a minimum range of 20 mi. at 50 mph.

NEWS RELEASE

Wednesday, January 16, 1974

REPORT ON U. S. POSTAL SERVICE
EXPERIENCE WITH ELECTRIC VEHICLES

By Donn P. Crane
Director, Office of Fleet Management
U. S. Postal Service
Washington, D.C.

Thank you, Mr. Chairman, honored guests, ladies and gentlemen. It is a real pleasure to speak with you this afternoon on the occasion of the unveiling of the rebirth of an old transportation idea in a new production line model. Our nation owes its greatness in large measure to our transportation system - our very great mobility. Now, as you all know, we are in the midst of a grave emergency - one that demands new ideas and new engineering if we are to retain that mobility and that greatness. You people of the Lead Industries Association will be, I am convinced, in the forefront in the development of those new ideas and engineering.

Let me tell you at the outset that I am not an electrical engineer. I have only a brushing acquaintance with electric vehicles. But I am a vehicle operations man with over twenty five years in the automotive business. First in the private sector - both in the dealerships and with the manufacturers; and then, with the Postal Service for nineteen years. First in its Washington region, and then, in the headquarters office where I am now in charge of Postal vehicles for our delivery department. The Office of Fleet Management, which I head, is responsible for the policies governing vehicle maintenance, vehicle operations and our Postal operated transport services.

continued.....

At introduction of GoLIATH, the first production model of a modern, multi-stop electric delivery van to be manufactured in the U.S. Plaza Hotel, New York City, January 16, 1974.

Lead Industries Association, Inc. 292 Madison Avenue, New York, N.Y. 10017

- 2 -

This embraces a Postally-owned fleet of over 103,000 vehicles of all sizes from 1/4 ton delivery trucks to tractor-trailer rigs. Additionally, we operate some 39,000 cars and trucks under lease, and about 12,000 carriers use their own cars in transportation to the route. Most of our vehicles are used for delivery or collection activities and more than 93,000, or about 70%, of our letter delivery routes are on wheels, or as we call it, motorized.

To maintain our fleet of vehicles which we own, we operate 310 garages described as vehicle maintenance facilities and we employ approximately 5,200 maintenance and operations people. Additionally, we perform heavy trucking operations in the 120 largest cities of the United States, and for this we use some 6,200 truck and tractor-trailer operators. It is the responsibility of my office to develop our purchase requirements, but, more importantly, to determine what kind of trucks we will buy.

Over the years the Postal service has been an active innovator in the vehicle business due, in the main, to the interest and efforts of our automotive engineering group, which is a part of our research and engineering department. With the cooperation of this engineering group, we have led the field in the areas of vehicle vision factors, early use of automatic transmissions in delivery trucks (1954 and 1955); and, in the area of power plants, we have been testing stratified charge engines for over three years. We have tested diesel engines in half ton vehicles and compressed natural gas in a number of trucks of various sizes. We have, of course, often looked at electric vehicles over the years.

continued.....

- 3 -

Our first electrics were used in 1904 and since then we have continued to look toward the electric as a possible solution to many of our problems. In 1959, 1960 and 1961, we purchased a number of electric vehicles - both three and four wheel. Most of these were tested in Florida and, unfortunately, they were not successful for two reasons. They were too costly, both to buy and to operate; and they were too slow, with a top speed of only fifteen miles an hour. In 1962, we bought some larger vehicles (one ton capacity), which we tested in parcel delivery in midtown Manhattan. Again, high cost of operation, including early battery failure, caused the discontinuance of of the tests after almost two years service.

But since 1965 there has been a changed climate in the postal service. At about that time an internationally-known consultant proved to us the great service advantages and cost benefits to be received from motorizing our many foot routes. The country's tremendous move to suburban living, at the same time that our public transportation systems were shrinking, made it essential that we put our carriers on wheels. It has been estimated that about 72 percent of our letter delivery routes should be on wheels for greatest efficiency. We're close to that figure now, but there is still a little way to go and these new routes have common characteristics. Most are what we call "park and loop" routes with short mileages and only a few stops per day. The carrier parks his truck and delivers his letters and parcels on foot for a few blocks, circling back to the truck to go on to the next stop. So we have a set of well-defined operating parameters with almost no variance from day to day.

continued.....

- 4 -

In 1963, pollution was a nasty word that happened in Los Angeles; but it was not long before the grave danger of air pollution became evident from coast to coast. By 1969 we, in the Postal Service, knew we must take steps beyond those contemplated by the industry. For many years we had been requiring exhaust emission controls before there were national standards, but that was not enough. In 1969 we began a project in our western region testing new electric vehicles in the little town of Cupertino, California, down below San Francisco. Two of the vehicles manufactured by the Harbilt Electric Trucks and Vehicles in England proved to be outstanding in terms of flexibility on the route and, more importantly, in durability. Over almost two years, our records indicate a downtime of only eight hours. The results at Cupertino were so promising that we are leasing 30 additional vehicles for Cupertino so that the entire office will be operating in electric vehicles. Delivery is scheduled for shortly after February 1st, and we are looking forward to their receipt.

Additionally, our research group has purchased three test vehicles: an Otis vehicle manufactured at Stockton, California; a Battronic vehicle of 1/2 ton capacity manufactured at Boyertown, Pennsylvania; and an Electromotion truck of 1/4 ton capacity built for us at Bedford, Massachusetts. All three of these vehicles have been used by the Postal Service on regular letter delivery routes and all of them show very great promise.

Research testing though can take years. I'm afraid we may not have this much time; and so, with the obvious capacity of the electric to do our job in our own well circumscribed routes, we decided that the time was ripe for purchase of 350 electric trucks. These will be built to a

continued.....

- 5 -

specification that recognizes that as yet the electric is not a universal vehicle, not yet substitutable for our large delivery fleet; but is well suited to a large number of our park and loop routes.

For many months we, in the Postal Service, have been working to reduce our use of fuel and have some very interesting projects under way on that score right now - you may have read of our emulsified fuel tests. However, with the Arab embargo on oil, our electric procurement takes on a new urgency and, as a consequence, we shall probably accelerate our planning.

What is the future for electrics in the Postal Service? Well, right now we estimate that we have about 30,000 routes meeting the parameters which fall within the present electric capability. Should these 350 electric trucks prove themselves, the next purchase could be sizable indeed - perhaps 1,000 next year and as many as 5,000 in 1975.

The future is yours to grasp. You, who are the producers and engineers of the electric vehicle industry. To meet our needs, full scale production capability is required. Right now our 1/4 ton trucks are coming off the line at the rate of 1,000 a month. That's what we have to have just to stay even with our fleet. Our replacements will probably exceed 15,000 units a year by 1975 and, of course, we are looking for improvements in the lead acid battery. If you people in the lead industries can develop better batteries - batteries that will give us longer life, more speed, more miles, more stops and great gradeability - there is the rest of those 93,000 routes to shoot for.

continued.....

- 6 -

Ladies and gentlemen, I can't really convey to you how excited I am over this potential, because I firmly believe that now we are on the verge of a real breakthrough in the urban car. With a versatile non-polluting, non-gasoline drinking urban car, our nation's mobility will be assured. We, in the Postal Service, will be doing our best to reach that point. The main task is up to you.

####
