Monsanto PCB study of 300 employees finds no cancer cases. A study of Monsanto's Medical and Environmental Health Dept of over 300 former and current employees at its polychlorinated biphenyls plant in New Jersey has found no incidence of either malignant melanoma or pancreatic cancer. These findings contradict a Mobil Oil study of 72 employees at its Paulsbro, NJ, plant who were exposed to PCBs. The Mobil study revealed two cases of malignant melanoma, a frequently fatal form of skin cancer among a group of 31 employees heavily exposed to PCBs, and one case among a group of 41 employees exposed less intensely. In addition there were two cases of pancreatic cancer in the total group.
